Note: The wsmapping tool accepts the `-action/-a` flag to specify the action to take on individual classes. Unless you are running wsmapping on all of your persistent types at once, or dropping a mapping, you must use the default **add** action or the **build** action. Otherwise, you might inadvertently drop schema components that are used by classes that you are not currently running the tool against.

- **-schemaFile/-sf** <true/t | false/f>: This option can be used to write the planned schema to an XML document rather than modify the database.

The XML document can then be modified, manipulated and committed to the database with the schema tool.

- **-sqlFile/-sql** <stdout | output file>: This option can be used to write the planned schema modifications to an SQL script rather than modify the database.
Combine this parameter with a **schemaAction** of build to generate a script that recreates the schema for the current mappings, even if the schema exists.
 - **-dropTables/-dt** <true/t | false/f>: When this option is set to true, schema drops tables that appear to be unused during **retain** and **refresh** actions.
The default is true.
 - **-dropSequences/-dsq** <true/t | false/f>: If this option is set to true, schema drops sequences that are unused during **retain** and **refresh** actions.
The default is true.
 - **-openjpatables/-ot** <true/t | false/f>: When reflecting the schema, this parameter determines whether to reflect on tables and sequences with names that start with OPENJPA_.
Certain OpenJPA components use these tables and sequences, such as the table schema factory. When using other actions, the openjpaTables parameter controls whether these tables can be dropped or not. The default setting is false.
 - **-ignoreErrors/-i** <true/t | false/f>: If set to false, an exception is occurs if the tool encounters database errors.
The default is set to false.
 - **-schemas/-s** <schema list>: Denotes a list of schema and table names the OpenJPA should access when running the wsschema tool.
This is the equivalent to setting the openjpa.jdbc.Schemas property to run once. This parameter corresponds to the **-schemas/-s** parameter in the wsschema tool. This option is ignored if **-readSchema/-rs** is not set to true.
 - **-readSchema/-rs** <true/t | false/f>: Set this option to true to read the entire existing schema when the mapping tool runs.
Reading the existing schema ensures that OpenJPA does not generate any mappings that use the table, index, primary key or foreign key names that conflict with existing names.
- Note:** Depending on the particular JDBC driver, selecting the **-readSchema/-rs** function can slow down the process for large schemas.
- **-primaryKeys/-pk** <true/t | false/f>: This flag determines if the primary keys can be manipulated on existing tables.
The default is true.
 - **-foreignKeys/-fk** <true/t | false/f>: This flag determines if foreign keys can be manipulated on existing tables.
The default is true. This means that to add a new foreign key to a class that has already been mapped, you must explicitly set this parameter flag to true.
 - **-indexes/-ix** <true/t | false/f>: This flag determines if indexes can be manipulated on existing tables.
The default is true. This means that to add new indexes to a class that has already been mapped, you must explicitly set this parameter flag to true.
 - **-sequences/-sq** <true/t | false/f>: This flag determines if sequences can be manipulated.
The default is true.
 - **-meta/-m** <true/t | false/f>: This flag determines whether a mapping applies to metadata rather than, or in addition to, standard mappings.
 - The wsmapping tool accepts the **-action/-a** flag to specify the action to take on each class. Multiple actions can be composed in a list, separated by commas. The available actions are:
 - **buildSchema**: This is the default action. The **buildSchema** action makes the database schema match your existing mappings. If the provided mappings conflict with the class definitions, OpenJPA fails with an informative exception.
 - **validate**: Ensure that the mappings for the given classes are valid and that they match the schema of the database. No mappings of tables are changed as a result of this action. An exception occurs if any mappings are invalid.

Each additional argument to the wsmapping tool must be one of the following:

- The full name of a persistent class.
- The .java name for a persistent class.
- The .class file of a persistent class.

If you do not supply any arguments to the wsmapping tool, it runs on the classes in the persistent classes list.

Usage

Before running the wsmapping tool, you must configure the data source information, including the URL, user, and password. It is required that the wsenhancer tool is run before the wsmapping tool to insert bytecode into the entity classes. Also, the compiled class files for your entities should be on the class path. Assume that entity class files can be found in target/classes, for example:

```
export CLASSPATH=${CLASSPATH}:target/classes
```

```
wsmapping ...
```

To create tables, run the wsmapping command from the \${profile_root}/bin directory. When completed, the database tables are created or updated. Messages and errors are logged to the administrative console as specified by log settings.

wsmapping.sh . . . On Windows :

Tip: By specifying the buildSchema parameter to the openjpa.jdbc.SynchronizeMappings property, the mapping tool provides the default mapping that matches with the database schema automatically. You are not required to run this mapping tool if the default mapping satisfies the necessary database schema.

Examples

To create the database tables needed for the Magazine.java file:

```
${profile_root}/bin/wsmapping Magazine.java
```

To drop the tables for Magazine.java:

```
C:\> %profile_root%/bin/wsmapping -sa dropDB Magazine.java
```

To validate the mappings for all classes on the class path:

```
C:\> %profile_root%/bin/wsmapping -a validate
```

Additional information

See the mapping information in the Apache OpenJPA User Guide for more information and examples.

wsreversemapping command

The wsreversemapping tool generates persistent class definitions and metadata from a database schema.

Syntax

Before running the command, you must have a copy of the persistence.xml file on the class path, or specify it as a properties file in the -p [path_to_persistence.xml] argument. Issue the command from the bin subdirectory of the profile_root directory.

The command syntax is as follows:

```
wsreversemapping [parameters][arguments]
```

Parameters

The wsreversemapping tool accepts the standard set of command-line arguments defined by the configuration framework along with the following:

- **-schemas/-s** <schema and table names>: A list of schema and table names, separated by commas, to run the wsreversemapping tool on if no XML schema file is supplied.

Each element of the list must follow the naming conventions for the openjpa.jdbc.Schemas property. If this parameter flag is omitted, it defaults to the value of the **Schemas** property. If the **Schemas** property is not defined, then all schemas are reverse mapped.

- **-package/-p** <package name>: The package name of the generated classes.

If no package name is given, the generated code does not contain package declarations.

- **-directory/-d** <output directory>: All generated code and metadata is written to the directory at this path.

If the path does not match the package of a class, the package structure is created beneath this directory. This parameter defaults to the current directory.

- **-useSchemaName/-sn** <true/t | false/f>: Set this parameter flag to true to include the schema and the table name in the name of each generated class.

This method can be useful when dealing with multiple schemas that have tables with identical names.

- **-useForeignKeyName/-fkn** <true/t | false/f>: Set this parameter flag to true if you want the field names for relations to be based on the database foreign key name.

By default, relation field names are derived from the name of the related class.

- **-nullableAsObject/-no** <true/t | false/f>: By default, all non-foreign key columns are mapped to primitives.

Set this parameter flag to true to generate primitive wrapper fields instead for columns that support null values.

- **-blobAsObject/-bo** <true/t | false/f>: By default, all binary columns are mapped to the byte[] fields.

Set this parameter flag to true to map them to Object fields instead.

Attention: When mapped this way, the column is presumed to contain a serialized Java object.

- **-primaryKeyOnJoin/pkj** <true/t | false/f>: The standard reverse mapping tool behavior is to map all tables with primary keys to persistent classes.

If your schema has primary keys on many join tables as well, set this flag to true to avoid creating classes for those tables.

- **-inverseRelations/-ir** <true/t | false/f>: Set this parameter flag to false to prevent the creation of inverse one-to-many or one-to-one relations for every many-to-one or one-to-one relation detected.

- **-useDatastoreIdentity/-ds** <true/t | false/f>: Set to true to use data store identity for tables that have single numeric primary key columns.

Typically, the tool uses application identity for all generated classes.

- **-useBuiltinIdentityClass/-bic** <true/t | false/f>: Set this parameter flag to false to prevent the wsreversemapping tool from using built-in application identity classes when possible.

This forces the tool to create custom application identity classes even when there is only one primary key column.

- **-innerIdentityClasses/-inn** <true/t | false/f>: Set this parameter flag to true to have any generated application identity classed be created as static inner classes within the persistent classes.

The default setting is false.

- **-identityClassSuffix/-is** <suffix>: Suffix to append to the class names to form application identity class names, or for inner identity classes, the inner class name.

The default suffix is Id.

- **-typeMap/-typ** <type mapping>: A string that specifies the default Java classes to generate for each SQL type that is seen in the schema.

The format is SQLTYPE1=JavaClass1, SQLTYPE2=JavaClass2. The SQL type name first looks for a customization that is based on SQLTYPE(SIZE,PRECISION), then SQLTYPE(SIZE), and then SQLTYPE. If a column with type CHAR is found, it first looks for the CHAR(50,0) type name specification, then it looks for the CHAR(50), and finally for the CHAR. For example, to generate a char

array for every char column whose size is exactly 50 characters, and to generate a short for every type name of INTEGER, you might specify, CHAR(50)=char[],INTEGER=short.

Attention: Various databases report different type names differently, one database type might not work for another database. Enable TRACE level logging on the metadata channel to track which type names JPA for WebSphere Application Server is examining.

- **-customizerClass/-cc** *<class name>*: The full class name of an org.apache.openjpa.jdbc.meta.ReverseCustomizer customization plug-in.

If you do not specify a reverse customizer of your own, the system defaults to a PropertiesReverseCustomizer. This customizer supports specifying simple customization options in the properties file given with the -customizerProperties flag.

- **-customizerProperties/-cp** *<properties file or resource>*: The path or resource name of a properties file to pass to the reverse customizer on initialization.
- **-customizer/-c** *<property name>* *<property value>*: The given property name is matched with the corresponding Java bean property in the specified reverse customizer, and set to the given value.

Usage

The wsreversemapping tool is used to perform reverse (bottom-up) mappings of database tables to entity source files. This is useful if developers want to generate Java files from a database for use in other JPA applications. To run this tool:

- You must have database tables and your database connection configured.
- Run the wsreversemapping tool from the command line in the \$ {profile_root}/bin directory.
- The tool generates .java files for every class, along with an XML descriptor file, orm.xml.

The generated Java files from the wsreversemapping tool might require some editing before they can be used in an application. Also, generated files do not contain annotations. Annotations can be added manually. Messages and errors are logged to the administrative console as specified by the configuration.

Examples

Generate entities based on the information saved in the schema.xml file. Schema.xml was created by running the schema tool. The Java files are created in the **src** directory and use the package com.xyz:

```
${profile_root}/bin/wsreversemapping -pkg com.xyz -d ./src schema.xml
```

Generate entities based on information in a DB2 database. Entities are created in the **src** directory, and use the package com.reversemapped:

```
C:\> %profile_root%/bin/wsreversemapping -sa dropDB Magazine.javapkg com.reversemapped -d src  
-connectionDriverName=com.ibm.db2.jcc.DB2Driver -connectionURL=jdbc:db2:localhost:50000/TEST  
-connectionUser=db2User -connectionPassword=db2Password
```

Additional information

For more information, read the mapping section in the Apache OpenJPA User Guide.

wsschema command

The schema tool can be used to view the database schema in XML form or match an XML schema to an existing database.

The wsschema tool can reflect on the current database schema, optionally translating it into an XML representation for further manipulation. The schema tool can take an XML schema definition, calculate the differences between the XML and the existing database schema, and apply the necessary changes to make the databases correspond to the XML schema. The XML format used by the schema tool is abstract from the differences in SQL dialects used by different vendors. The tool also automatically adapts its SQL to meet foreign dependencies, thus the schema tool is useful as a general way to manipulate the schemas.

Syntax

The command syntax is as follows:

```
wsschema [parameters] [arguments]
```

Issue the command from the `bin` subdirectory of the `profile_root` directory.

Parameters

The `wsschema` tool accepts the standard set of command-line arguments defined by the configuration framework along with the following:

- **-ignoreErrors/-i** <true/t | false/f>: If set to `false`, an exception occurs if the tool encounters any database errors.

The default is set to `false`.

- **-file/-f** <stdout | output file>: Use this option to write a SQL script for the planned schema modifications, rather than committing them to the database.

When used with the `export` or `reflect` actions, the named file is used to write the exported schema XML. If the file names a resource in the class path, data is written to that resource. Use `stdout` to write to standard output. The default setting is `stdout`.

- **-openjpatables/-ot** <true/t | false/f>: When reflecting the schema, this parameter determines whether to reflect on tables and sequences whose names start with `OPENJPA_`.

Certain OpenJPA components can use such tables and sequences, like the table schema factory. When using other actions, `openjpaTables` controls if these tables can be dropped. The default setting is `false`.

- **-dropTables/-dt** <true/t | false/f>: When this option is set to `true`, schema drops tables that are unused during `retain` and `refresh` actions.

The default is `true`.

- **-dropSequences/-dsq** <true/t | false/f>: If this option is set to `true`, schema drops sequences that are unused during `retain` and `refresh` actions.

The default is `true`.

- **-sequences/-sq** <true/t | false/f>: This flag determines if sequences can be manipulated.

The default is `true`.

- **-indexes/-ix** <true/t | false/f>: This flag determines if indexes can be manipulated on existing tables.

The default is `true`.

- **-primaryKeys/-pk** <true/t | false/f>: This flag determines if primary keys can be manipulated on existing tables.

The default is `true`.

- **-foreignKeys/-fk** <true/t | false/f>: This flag determines if foreign keys can be manipulated on existing tables.

The default is `true`.

- **-record/-r** <true/t | false/f>: This flag permits or prevents writing schema changes made by the schema tool to the current schema factory.

Select `true` to permit writing schema changes or `false` to prevent writing schema changes. The default is set to `true`.

- **-schemas/-s** <schema list>: Denotes a list of schema and table names the OpenJPA should access when running the schema tool.

This is the equivalent to setting the `openjpa.jdbc.Schemas` property to run one time.

Important: The schema tool accepts the **-action/-a** flag. Multiple actions can be composed in a list, separated by commas. The available actions are:

- **add**: This is the default action if no other actions are specified. It updated the schema with the given XML documents by adding tables, columns, indexes, or other components. This action never drops any schema components.

- **retain**: This action keeps all schema components in the given XML definition but drops the rest from the database. This action never adds any schema components.
 - **drop**: Drops all schema components in the schema XML. This action drops tables only if they would have 0 columns after dropping all columns listed in the XML.
 - **refresh**: This action is the equivalent of the **retain** and the **add** functions.
 - **build**: Generates SQL to build a schema matching the one in the supplied XML file. Unlike the **add** action, this option does not take into account the fact that part of the schema defined in the XML file may already exist in the database. This action is typically used with the **-file/-f** parameter flag to write a SQL script. This script can be used later to recreate the schema in the XML.
 - **reflect**: Generates an XML representation of the current database schema.
 - **createDB**: This action generates SQL to recreate the current database. This action is typically used with the **-file/-f** parameter flag to write a SQL script that can be used to recreate the current schema on a new database.
 - **dropDB**: Generates SQL to drop the current database. Like the **createDB** action, this can be used with the **-file/-f** parameter flag to script a database drop rather than manually perform it.
 - **import**: Imports the given XML schema definition into the current schema factory.
- Note:** This action does nothing if the schema factory does not store a record of the schema.
- **export**: Exports the current schema factory stored schema definition to an XML file.
- Note:** This can produce an empty file if the schema factory does not store a record of the schema.
- **deleteTableContents**: This action implements SQL to delete all rows from all tables that OpenJPA finds.

Usage

The wsschema tool is used to obtain an XML file that describes the schema of your database. To generate an XML schema file:

- You must have database tables and your database connection configured.
- Run the wsschema tool from the command line in the \$ {profile_root}/bin directory.
- The tool generates an XML file that describes the database schema.

Messages and errors are logged to the administrative console as specified by the configuration.

Examples

Add the necessary schema components to the database to match the given XML document without dropping any data:

```
$ wsschema targetSchema.xml
```

Repeat the same action as the previous example, this time not changing the database but instead writing any planned changes to a SQL script:

```
wsschema -f script.sql targetSchema.xml
```

Write an SQL script that recreates the current database:

```
$ wsschema -a createDB -f script.sql
```

Refresh the schema and delete all the contents of all the tables that OpenJPA knows about:

```
$ wsschema -a refresh,deleteTableContents
```

Drop the current database:

```
$ wsschema -a dropDB
```

Write an XML representation of the current schema to the file *schema.xml*:

```
$ wsschema -a reflect -f schema.xml
```

Additional information

For more information read the JDBC information in the Apache OpenJPA documentation.

wsdbgen command

The command supports utilization of the pureQuery feature in Java Persistence API (JPA) applications.

This command has been renamed wsdbgen for Feature Pack for OSGi Applications and JPA 2.0 and later releases. The command is used in the same way as the wsdb2gen command. The command, wsdb2gen, which implies for DB2 only, works only for DB2 database in WebSphere Application Server V7.0. In this release, the command can be used for DB2, Informix and Oracle databases. Because of that, a synonym, wsdbgen command, is introduced.

The JPA commands (.bat on Windows or .sh on UNIX) are run from the *profile_root/bin* directory, rather than from the *app_server_root/bin* directory to make sure that you have the latest version of the commands for your release.

Syntax

The command syntax is as follows:

```
wsdbgen [parameters]
```

Before running the command, your *persistence.xml* file must be in the META-INF directory and the META-INF directory must be in the class path.

Parameters

- **-help**: This parameter displays the help information.
- **-pu**: The name of the persistence unit defined in *persistence.xml* file.
- **-collection**: The collection-id which is assigned to package names. The default is NULLID.
- **-url**: The URL of the target database.

This is used to validate the generated SQL. A URL must be specified either in the *persistence.xml* file or as a command option. If both are specified, the URL that is specified in the command option is used.

- **-user**: The user ID.
- **-pw**: The corresponding password to connect to target database.
If this parameter is not specified, the value found in the *persistence.xml* file is used.
- **-package**: If this parameter is specified, the **-package** parameter takes the string value package name and a single database package with the specified name is generated. If the **-package** parameter is not specified, then one package is generated for each entity class. The entity name is used as package name if the **-package** option is not specified. The name length limit is the database limit -1, for example: 128 - 1 = 127.

Usage

The *persistence.xml* file must be included in the application Java archive (JAR) file and is also used as input in the DB2 bind to create the DB2 package. The command requires a connection to a database to validate generated SQL. The database does not have to be the same as the run time database, but it should be at the same version and release level.

Ensure that the following JAR files are on the class path:

- pdq.jar
- pdqmgmt.jar
- db2jcc.jar
- db2jcc_licence_cu.jar

If the database URL specifies a DB2 for z/OS database, then the following JAR file must also be on the class path: db2jcc_licence_cisuz.jar

Attention: Read more about the DB2 JAR level compliance for IBM Optim PureQuery Runtime at the IBM Support website: System requirements for IBM Optim PureQuery Runtime for Linux, UNIX, and Windows.

Attention: You can review information about pureQuery StaticBinder in the Data Studio Information Center by reading the topic, "The pureQuery StaticBinder utility."

Examples

DB2

```
wsdbgen -pu payroll -collection prod1 -url jdbc:db2://myhostname:50000/proddb -user producer -pw secret
```

Informix

```
wsdbgen -pu payroll -collection prod1 -url jdbc:ids://myhostname:9089/proddb -user producer -pw secret
```

ANT task WsJpaDBGenTask

The ANT task WsJpaDBGenTask provides an alternative to the wsdbgen command.

The WsJpaDBGenTask ANT task utility supports utilizing the pureQuery feature in Java Persistence API (JPA) 2.0 and later applications that do not use DB2 databases. Instead of using the wsdbgen from the command line, you can use the example code in your ANT build XML file to use the WsJpaDBGenTask in your build process.

Both the PDQ runtime Java archive (JAR) files, pdq.jar and pdqmgmt.jar, must be specified using the ANT -lib option.

Attention: Read more about the DB2 JAR level compliance for pureQuery at the IBM Support website: System requirements for IBM Optim pureQuery Run time for Linux, UNIX, and Windows.

Example

The following example is run in the Windows environment with the ANT command:

```
C:\jpa\ant jar -noclasspath -lib c:/was8/dev/JavaEE/j2ee.jar
-lib ${app_server_root}/runtimes/com.ibm.ws.jpa.thinclient_8.0.0.jar
-lib c:/sqllib/java/db2jcc.jar
-lib c:/sqllib/java/db2jcc_license_cu.jar
-lib c:/sqllib/java/pdq.jar
-lib c:/sqllib/java/pdqmgmt.jar
```

When calling the ANT command, the JAR files for pureQuery, JPA, and the JDBC driver must be on the library list.

```
<?xml version="1.0"?>
<project name="sample" default="jar">
<taskdef name="enhancer" classname="org.apache.openjpa.ant.PCEnhancerTask" />
<taskdef name="wsdbgen" classname="com.ibm.websphere.persistence.pdq.ant.WsJpaDB2GenTask" />
<target name="clean" description="remove intermediate files">
<delete dir="classes"/>
<delete dir="enhanced" />
```

```

<delete>
<fileset dir="." includes="META-INF/*.pdqxml" />
<fileset dir="." includes="sample.jar" />
</delete>
</target>

<target name="compile"
description="compile the Java source code to class files">
<mkdir dir="classes"/>
<javac srcdir="." destdir="classes">
<classpath>
<pathelement location="c:/was8/dev/JavaEE/j2ee.jar">
<pathelement location="c:/was8/runtimes/com.ibm.ws.jpa.thinclient_8.0.0.jar" />
</classpath>
</javac>
</target>

<target name="enhance" depends="compile" >
<mkdir dir="enhanced" />
<enhancer directory="./enhanced" >
<config propertiesFile="META-INF/persistence.xml" />
<classpath>
<pathelement location="." />
<pathelement location="classes" />
</classpath>
</enhancer>
</target>

<target name="wsdbgen" depends="enhance" >
<wsdb2gen pu="MyAntTest" url="jdbc:db2://localhost:50000/demodb" user="user1" pw="secret" >
<classpath>
<pathelement location="." />
<pathelement location="enhanced" />
</classpath>
</wsdb2gen>
</target>

<target name="jar" depends="wsdbgen"
description="create a Jar file for the application">
<jar destfile="sample.jar">
<fileset dir="classes" includes="**/*.class"/>
<fileset dir="." includes="META-INF/*.xml" />
</jar>
</target>
</project>

```

SQL statement batching for JPA applications

SQL statement batching can improve the performance of your application server.

About this task

Attention: Support for SQL statement batching is no longer a WebSphere Application Server for JPA extension. You can find information regarding statement batching in the Apache OpenJPA documentation.

By default, statement batching is enabled for DB2 and Oracle databases. To enable SQL statement batching and to set the batch limit for JPA applications, you must configure the `persistence.xml` file. The following steps review how to enable and disable statement batching, and set the batch limit:

Procedure

1. Define the `UpdateManager` property in the `persistence.xml` file. For example:

```
<property name="openjpa.jdbc.UpdateManager"
value="com.ibm.ws.persistence.jdbc.kernel.OperationOrderUpdateManager(batchLimit=100)"/>
```

Note: The example shows that the SQL statement batch limit is set to 100.

Remember: If you are using a DB2 or an Oracle database, by default the SQL statement batching is enabled and set to `batchLimit=100`. However, if you are using DB2 or Oracle, you are not required to specify this property in the `persistence.xml` file.

2. If you must disable SQL statement batching, set the `batchLimit` value to 0 or remove the property. However, if you are using a DB2 or an Oracle database, you must specify the `DBDictionary` property, database, and set the `defaultBatchLimit` to 0. For example:

```
<property name="openjpa.jdbc.DBDictionary" value="db2(defaultBatchLimit=0)"/>
```

Results

You have now updated the `persistence.xml` file to enable or disable statement batching and set the batch limit.

Database generated version ID with JPA

Java Persistence API (JPA) for WebSphere Application Server has extended OpenJPA to work with database generated version IDs. These generated version fields, timestamp, or token, can be used to efficiently detect changes to a given row.

Trigger based version ID generation is supported for all databases that WebSphere Application Server supports. Support is based on two Version Strategies in JPA for WebSphere Application Server.

- `@VersionStrategy("com.ibm.websphere.persistence.RowChangeTimestampStrategy")`, if the entity version field type is Timestamp, and
- `@VersionStrategy("com.ibm.websphere.persistence.RowChangeVersionStrategy")`, if the entity version field type is Long

Database generated version ID example

In this example, the Entity class is defined with the new Version Strategy annotation. The Entity has a surrogate version column.

```
@Entity(name="Item")
@VersionColumn(name="versionField")
@VersionStrategy("com.ibm.websphere.persistence.RowChangeTimestampStrategy")
public class Item implements Serializable
{
    @Id
    private int id2;

    private String name;

    private double price;

    @OneToOne
    private Owner master;
}
```

The create table statement is as follows:

```
CREATE TABLE ITEM
(ID2 INT NOT NULL,
NAME VARCHAR(50) ,
PRICE DOUBLE,
```

```
OWNER_ID INT,
        VERSIONFIELD GENERATED ALWAYS FOR EACH ROW ON
        UPDATE AS ROW CHANGE TIMESTAMP
PRIMARYKEY(ID2));
```

During any updates to Item, insert or update, the VersionColumn value is updated in the database. After the update, the value for VersionColumn is retrieved from the database and updated in the in-memory object. Thereby the objects in the data cache reflect the correct version value. Here the Entity is using the @VersionColumn, which produces a Surrogate Version ID rather than defining an explicit field in the entity.

The Entity could also use @Version annotation to define an explicit version field. The explicit version field could be of type Long or Timestamp corresponding to the @VersionStrategy. During any updates to Item, insert or update, the Version value is updated in the database. After the update, the value for Version is retrieved from the database and updated in the in memory object. Thereby the objects in the data cache reflect the right version value.

This is an example where the Entity has a version field defined, and the type Timestamp matches the RowChangeTimestampStrategy in the @VersionStrategy. If the version field type is using type long, then the RowChangeVersionStrategy should be annotated to match:

```
@Entity(name="Item")
@VersionStrategy("com.ibm.websphere.persistence.RowChangeTimestampStrategy")
public class Item implements Serializable

{
    @Id
    private int id2;

    private String name;

    private double price;

    @Version
    private Timestamp versionField;

    @OneToOne
    private Owner master;
}
```

Note: Be aware of the following conditions when you use RowChangeVersionStrategy:

- For z/OS DB2 V9 and Linux, UNIX, and Windows DB2 V9.5, the generated database column must be of type timestamp, but both the RowChangeTimestampStrategy and the RowChangeVersionStrategy are supported. Microsoft SQL Server only supports a non-timestamp generated version ID that goes with the RowChangeVersionStrategy . To use the RowChangeTimestampStrategy, you must use a trigger on a timestamp field in the database. For other databases, you can use triggers to simulate database version generation and use either strategy.
- For z/OS DB2 V9, install the PTF for APAR PK67706, and ensure that you have installed the required level of IBM Optim PureQuery Runtime (1.3.100 or later) and JCC drivers (3.52.95 or later).

Mapping persistent properties to XML columns for JPA

If your database supports Extensible Markup Language (XML) column types, you can use mapping tools to manage XML objects. You have the choice of mapping XML columns to a Java string or a Java byte array field.

About this task

Attention: Support for mapping persistent properties to XML columns is no longer a WebSphere Application Server for JPA extension. You can find information regarding XML mapping in the Apache OpenJPA documentation.

JPA for the application server supports the management of XML objects by using a third-party solution for mapping management. These mapping techniques make using the XML objects as strings or byte arrays difficult.

DB2, Oracle, and SQLServer databases support XML column types, XPath queries, and indices over these columns.

Persistent properties to XML mapping

An embedded class with XML column support must use XML marshaling to write the data to the XML column and unmarshaling to retrieve the data from the XML column. The path expressions and predicates over the embedded class are converted to XML predicates, XPATH expressions, or XQuery expressions and are written to the database.

WebSphere Application Server supports JPA applications to use a third-party tool for XML mapping. This is done through the extension points for custom field mappings. The third-party mapping tool uses the extension points by providing a custom value handler for the persistent fields that are mapped to the XML columns. In OpenJPA, this value handler is named `org.apache.openjpa.xmlmapping.XmlValueHandler` and this handler requires the `@Strategy` annotation on the Java field that is mapped to the XML column.

Procedure

1. Annotate the entity property using the XML value handler strategy. The mapping of persistent properties to XML columns requires the `@Strategy` and the `@Persistent` annotation.

```
@Persistent
@Strategy("org.apache.openjpa.xmlmapping.XmlValueHandler")
```

The XML value handler for the persistent property is set to `org.apache.openjpa.xmlmapping.XmlValueHandler`.

2. Change the default for fetch type if it is necessary. For example:

```
@Persistence(fetch=FetchType.LAZY)
```

The fetch type is now LAZY. If a value for the fetch type is not entered, the default is set to EAGER.

3. Annotate your embedded classes with the binding annotations for Java API for XML Binding (JAXB). These bindings can be created from an XML schema by using the Java Architecture for XML Binding Compiler (XJC).
4. Make sure that the class that maps to the root of the XML document is annotated with `@XmlRootElement`, in addition to the other annotations.
5. Compile your Java sources.
6. Run the enhancer tool on the entities. Refer to the topic on the entity enhancer tool for more information.

Example

For example, `shipAddress`, a property of `Order` Entity, is mapped to XML column `shipaddr`:

```
@Entity
public class Order {
    @Id
    @GeneratedValue(strategy=GenerationType.IDENTITY)
    int oid;
```

```

@Persistent
@Strategy("org.apache.openjpa.xmlmapping.XmlValueHandler")
    @Column(name="shipaddr")
    Address shipAddress;
...

```

The OpenJPA mapping tool generates a SHIPADDR column with XML type in the table definition for ORDER table.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root

The default installation root directory for the Application Client for IBM WebSphere Application Server is the /QIBM/ProdData/WebSphere/AppClient/V8/client directory.

app_client_user_data_root

The default Application Client for IBM WebSphere Application Server user data root is the /QIBM/UserData/WebSphere/AppClient/V8/client directory.

app_client_profile_root

The default Application Client for IBM WebSphere Application Server profile root is the /QIBM/UserData/WebSphere/AppClient/V8/client/profiles/*profile_name* directory.

app_server_root

The default installation root directory for WebSphere Application Server - Express is the /QIBM/ProdData/WebSphere/AppServer/V8/Express directory.

java_home

Table 88. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32-bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit
64-bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit

plugins_profile_root

The default Web Server Plug-ins profile root is the /QIBM/UserData/WebSphere/Plugins/V8/webserver/profiles/*profile_name* directory.

plugins_root

The default installation root directory for Web Server Plug-ins is the /QIBM/ProdData/WebSphere/Plugins/V8/webserver directory.

plugins_user_data_root

The default Web Server Plug-ins user data root is the /QIBM/UserData/WebSphere/Plugins/V8/webserver directory.

product_library

product_lib

This is the product library for the installed product. The product library for each Version 8.0 installation on the system contains the program and service program objects (similar to .exe, .dll,

.so objects) for the installed product. The product library name is QWAS8x (where x is A, B, C, and so on). The product library for the first WebSphere Application Server Version 8.0 product installed on the system is QWAS8A. The *app_server_root/properties/product.properties* file contains the value for the product library of the installation, *was.install.library*, and is located under the *app_server_root* directory.

profile_root

The default directory for a profile named *profile_name* for WebSphere Application Server - Express is the */QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/profile_name* directory.

shared_product_library

The shared product library, which contains all of the objects shared by all installations on the system, is QWAS8. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root

The default user data directory for WebSphere Application Server - Express is the */QIBM/UserData/WebSphere/AppServer/V8/Express* directory.

The profiles and profileRegistry subdirectories are created under this directory when you install the product.

web_server_root

The default web server path is */www/web_server_name*.

Assembling applications that use the Java Persistence API

Assembling a JPA application in a Java EE environment

You have developed and configured your applications to work with the Java Persistence API (JPA). Now you need to package the JPA applications for your environment.

About this task

Procedure

Package the application. There are several packaging options for an application that uses JPA in a Java EE environment. Choose the packaging option that best suits the JPA usage and configuration within the modules of your application. These are some of the most common packaging options. For a definitive list of packaging options, see the Java Persistence API specification.

Note: IBM Optim PureQuery Runtime, add the *persistence_unit_name.pdqxml* file to the JPA application JAR file. The files are located in same META-INF directory where the *persistence.xml* file is located. These persistence files were created during the development task. See the topic, Developing JPA applications for a Java EE environment for more information.

- For a standalone Enterprise JavaBeans (EJB) module or a stand-alone application client module, package the EJB and application client modules in a standard Java archive (JAR) file. Ensure that you package the application with these conditions:
 - The JAR file must contain your EJB class files or the Java class files for the application client.
 - The META-INF directory of the archive must include your *persistence.xml* file.
 - If your application uses mapping files, *orm.xml*, or a custom mapping file, the JAR file must also contain those files. If the location of the *orm.xml* file is not specified in the persistence unit, the default location is the META-INF directory of the JAR file.
 - The Criteria Metamodel class files that are generated by the Annotation Processor when you developed your application needs to be included in the JAR file in the same location as the entity class files.

- For a stand-alone web module, package the application in a standard web application archive (WAR) file. Ensure that you package the application with these conditions:
 - The Criteria Metamodel class files that are generated by the Annotation Processor while developing your application needs to be included in the WAR file in the same location as the entity class files.
 - The WAR file must contain your web application class files. The web application class files must be included in the WEB-INF/classes directory or in a JAR file that is located in the WEB-INF/lib directory of the WAR file.
 - The persistence.xml file must be included in the WEB-INF/classes/META-INF directory or in the META-INF directory of a JAR file that is included in your WEB-INF/lib directory of your WAR file.
 - If your application uses mapping files, orm.xml, or a custom mapping file, the WAR file must also contain those files. Mapping files can reside in the WEB-INF/classes directory or in a JAR file that is contained within the WEB-INF/lib directory of the WAR file. Use the <mapping-file> element of the persistence.xml file to specify the location of mapping files. For example:

```
<mapping-file>META-INF/JPAorm.xml</mapping-file>
```
- For enterprise application that contains one or more modules, package the application in a standard Enterprise application archive (EAR) file. An enterprise application can contain one or more EJB module, web module, or application client module. Ensure that you package the application with these conditions:
 - If multiple modules use the same persistence unit, you can create a persistence archive and package the persistence archive within the EAR file.
 - Include your entity classes, associated Criteria Metamodel classes, any necessary supporting classes, the persistence.xml file, and additional mapping files in the persistence archive file. Follow the packaging rules for EJB and application client modules for the location of your persistence.xml file and mapping files.
 - Each module that uses the persistence archive must have a class path entry in its META-INF/MANIFEST.MF file. Here is an example manifest file:

```
Manifest-Version: 1.0
Class-Path: MyJPAEntities.jar
```
 - If your modules use separate persistence units and share entity classes, you can package the entity classes in a persistence archive and specify different persistence.xml file and mapping files for each module. If the modules do not share entity classes or a persistence configuration, package each module as a standalone EJB module, a stand-alone application client module, or a standalone web application archive and then package them in the EAR file.

What to do next

For more information about the commands, classes or other OpenJPA information, refer to the Apache OpenJPA User Guide.

Assembling JPA applications for a Java SE environment

You have developed and configured your applications to work with the Java Persistence API (JPA). Now you must package the JPA applications for your environment.

About this task

For this task, you must specify the `com.ibm.ws.jpa.thinclient_8.0.0.jar` stand-alone Java archive (JAR) file in your class path. This stand-alone JAR file is available from the client and server installation images. The location of this file on the client installation image is `${app_client_root}/runtimes/com.ibm.ws.jpa.thinclient_8.0.0.jar`. The location of this file on the server installation image is `${app_server_root}/runtimes/com.ibm.ws.jpa.thinclient_8.0.0.jar`.

Procedure

1. Package the application.

Note: Package the persistence units in separate JAR files to make them more accessible and reusable. If you package the persistence units this way, they can be tested outside the container both with and without the occurrence of database persistence. The persistence units can be included in stand-alone applications or they can be packaged into EAR files as persistence archive files. If you package the persistence unit into a persistence archive file, all of the application components must be able to access the persistence archive. The application that uses the persistence units must declare a dependency on the persistence archive using the MANIFEST.MF Class-Path: declaration.

The Criteria Metamodel class files that are generated by the Annotation Processor when you developed your JPA application, must be included in the JAR file in the same location as the entity class files.

Note: If you are using IBM Optim PureQuery Run time, add the *persistence_unit_name*.pdqxml files to the JPA application JAR file. The files are located in same META-INF directory where your persistence.xml file is located. These persistence files were created during the development task, Developing JPA applications for a Java SE environment.

To package the application use the following command:

```
jar -cvf {jar_Name} {entity_Path}
```

where *{jar_Name}* represents the name of the JAR file to create, and *{entityPath}* represents the root location where the entities reside, which is where you compiled them. Make sure that your *{entity_Path}* also contains the META-INF/persistence.xml file.

2. When you run your stand-alone application, specify the JAR files in your class path when starting your application. The JPA runtime starts the stand-alone JAR file, com.ibm.ws.jpa.thinclient_8.0.0.jar. For example, use the following Java call to run the com.xyz.Main stand-alone application:

```
java -cp /your/directory/{jar_Name}  
-javaagent:{app_client_root}/runtimes/com.ibm.ws.jpa.thinclient_8.0.0.jarcom.xyz.Main
```

What to do next

For more information about any of the commands, classes or other OpenJPA information, refer to the Apache OpenJPA User Guide.

Using JPA access intent

Java Persistence API (JPA) access intent specifies the isolation level and lock level used when reading data from a data source. Access intent controls the Java Database Connectivity (JDBC) isolation level and whether read, update, or exclusive locks are acquired when retrieving data.

About this task

For a JPA persistence provider on the application server, the application can specify isolation and ReadLockMode based on a TaskName. The TaskName provides a better control over applying these characteristics. The application defines a set of entity types and corresponding access intent for each TaskName defined in a persistence unit.

Restriction:

- Access intent is available for application in the Java EE server environment
- Access intent is applicable to non-query entity manager interface methods. Query uses query hint interface to set its isolation and read lock values.
- Access intent is only available for DB2 databases.
- Access intent is in effect only when pessimistic lock manager is used. Add the following to the persistence unit property list. <property name="openjpa.LockManager" value="pessimistic"/>

Table 89. Access intent Properties and Descriptions. The following table compares the Enterprise JavaBeans (EJB) 2.x entity bean access intent with the JPA access intent properties:

WebSphere EJB 2.x entity bean access intent	JPA access intent	Description
optimistic	isolation: Read Committed	Data is read but no lock is held. Version ID is used on update to ensure data integrity. Other transactions can read and update data.
	lockManager: Optimistic	
	query Hint: ReadLockMode: READ	
pessimistic read	isolation: Repeatable Read	Data is read with shared locks. Other transactions attempting to update data are blocked.
	lockManager: Optimistic	
	query Hint: ReadLockMode: READ	
pessimistic update	isolation: Repeatable Read	Data is retrieved with update or exclusive lock. Other writes are blocked until commit. This access intent can be used to serialize update access to data when there are multiple writers.
	lockManager: Pessimistic	
	query Hint: ReadLockMode: WRITE	
pessimistic exclusive	isolation: Serializable	Data is retrieved with update or exclusive lock. Other writes are blocked until commit. This access intent can be used to serialize update access to data when there are multiple writers.
	lockManager: Pessimistic	
	query Hint: ReadLockMode:WRITE	

A TaskName is set on a transaction context by one of the following:

- TaskName is automatically set in the EJB container when a transaction begins using WebSphere local transaction (EJB unspecified transaction), JTA global transaction in a Container-Managed Transaction (CMT) or user-initiated global transaction in a Bean-Managed Transaction (BMT).
- TaskName is manually set in an application using the TaskNameAccessor API provided for JPA.

Using task names supports the specification of access intent on a request scope rather than specifying it in the persistence.xml file, which has an application scope across all entities. Often a query is contained in a method or component which is used in many different transaction contexts. Some of these contexts might require repeatable-read and update lock intent but other contexts do not.

Isolation level and read locks can be specified on:

- An application scope in the persistence.xml file. These isolation levels and read lock types are properties specified in the persistence.xml file. They apply to all entities that are defined in the persistence unit.
- A transaction scope in the task name. Transaction scoped hints override application scope values.
- Query instance with a query hint. Query hint can be used to override isolation and ReadLockMode for a particular query instance. A query hint overrides isolation level and read locks specified at the application or transaction scope.

Procedure

1. “Setting a TaskName using TaskNameAccessor API” on page 736 This task explains how to use the TaskNameAccessor API to set JPA TaskName at run time.
2. “Specifying TaskName in a JPA persistence unit” on page 737 This task explains how to specify a TaskName in JPA persistence unit .

What to do next

For more information about Access intent, see the topic, Access intent service.

Setting a TaskName using TaskNameAccessor API

Using the TaskNameAccessor API to set Java Persistence API (JPA) TaskName at runtime.

About this task

In the Enterprise JavaBeans (EJB) container, a task name is automatically set by default upon a transaction begins. This action is performed when a component or business method is invoked in a CMT session bean or when an application invoke the `sessionContext.getTransaction().begin()` in a BMT session bean. This TaskName consists of a concatenation of the fully package qualified session bean type, a dot character and the method name. For example: `com.acme.MyCmtSessionBean.methodABC`.

If using JPA in the context of the web container, an application must use the TaskNameAccessor API to set the TaskName in the current thread of execution.

Note: Once a TaskName is set on a transaction context, application must not set the TaskName again in the same transaction. This will avoid problems with on the JDBC connection for different database access.

This example contains the TaskNameAccessor API definition

```
package com.ibm.websphere.persistence;

public abstract class TaskNameAccessor {

    /**
     * Returns the current task name attached in the current thread context.
     * @return current task name or null if none is found.
     */
    public static String getTaskName ();

    /**
     * Add a user-defined JPA access intent task name to the current thread
     * context.
     *
     * @param taskName
     * @return false if an existing task has already attached in the current
     *         thread or Transaction Synchronization Registry (TSR) is not
     *         available (i.e. in JSE environment).
     */
    public static boolean setTaskName(String taskName);
}

```

This code example shows how to set a TaskName using TaskNameAccessor.

```
package my.company;

@Remote
class Ejb1 {
    // assumer no tx from the caller
    @TransactionAttribute(Requires)
    public void caller_Method1() {

        // an implicit new transaction begins
        // TaskName "my.company.Ejb1.caller_Method1" set on TSR

       .ejb1.callee_Method?();
    }

    @TransactionAttribute(RequiredNew)
    public void callee_Method2() {

        // an implicit new transaction begins i.e. TxRequiredNew.
        // TaskName "my.company.Ejb1.callee_Method2" set on TSR
    }
}

```

```

}

@TransactionalAttribute(Requires)
public void callee_Method3() {

    // In caller's transaction, hence TaskName remains
    //     "my.company.Ejb1.caller_Method1"
}

@TransactionalAttribute(NotSupported)
public void callee_LocalTx () {

    // Unspecified transaction, a new local transaction implicitly started.
    // TaskName "my.company.Ejb1.callee_LocalTx" set on TSR
}
}

```

Attention: In the above example, an application must be aware of transaction boundary will be subtly changed if Ejb1 uses local interface (@Local). For example, when caller_Method1() calls callee_Method3 or callee_LocalTx, this will be treated as a Java method call. No EJB transaction semantics are honored.

What to do next

Once you have completed this step, continue on with the topic Specify TaskName in a JPA persistence unit.

Specifying TaskName in a JPA persistence unit

Specifying a TaskName in Java Persistence API (JPA) persistence unit

About this task

A TaskName is defined in the persistence.xml file using the wsjpa.AccessIntent property name in a persistence unit. The property value is a list of TaskNames, entity types and access intent definitions. The following example shows the contents of the wsjpa.AccessIntent property name in a persistence unit.

```

<property name = "wsjpa.AccessIntent"
  value = "Tasks=' <taskName> { <entityName> ( <isolationLockValue> ) } ' "/>

```

	<pre> A A A +-----+ , -----+ +-----+ , -----+ +-----+ , -----+ </pre>
Tasks	::= <task> [',' <task>]*
<task>	::= <taskName> '{' <entity> [',' <entity>]* '}'
<entity>	::= <entityName> '(' <isolationLockValues> ')'
<taskName>	::= <fully_qualified_identifier>
<entityName>	::= <fully_qualified_identifier>
<fully_qualified_identifier>	::= <identifier> ['.' <identifier>]*
<identifier>	::= <idStartCharacter> [<idCharacter>]*
<idStartCharacter>	::= Character.isJavaIdentifierStart '?' '*'
<idCharacter>	::= Character.isJavaIdentifierPart '?' '*'
<isolationLockValues>	::= <isolationLockValue> [',' <isolationLockValue>]
<isolationLockValue>	::= <isolation> <readLock>

```

<isolation>                ::= "isolation" '=' <isolationValue>
<readLock>                  ::= "readlock" '=' <readlockValue>
<isolationValue>           ::= "read-uncommitted"|"read-committed"|"repeatable-read"|"serializable"
<readlockValue>           ::= "read" | "write"

```

Before setting the TaskName in a persistence unit, keep the following in mind:

- White spaces are ignored between tokens.
- Only <isolation> and <readLock> contents are not case sensitive.
- <TaskName> is in the form of a fully package qualified method name, such as com.acme.bean.MyBean.increment, or an arbitrary user-defined task name, such as MyProfile.
- <entityName> is in the form of a fully package qualified class name such as com.acme.bean.Entity1.
- The wild card characters '?' or '*' can be used in <TaskName> and <entityName>. "?" matches any single character and "*" matches zero or more sequence characters.
- Only hintNames isolation and readLock are allowed on a task definition and the order is not significant
- If readLock has the value write, then isolation must be repeatable-read or serializable
- If readLock has the value read, it has no effect if the isolation is read-uncommitted.

The following code example shows how to specify a TaskName in JPA persistence unit.

```
package my.company;
```

```

@Remote
class Ejb1 {
    // assumer no tx from the caller
    @TransactionAttribute(Requires)
    public void caller_Method1() {

        // an implicit new transaction begins
        // TaskName "my.company.Ejb1.caller_Method1" set on TSR

       .ejb1.callee_Method?();
    }

    @TransactionAttribute(RequiredNew)
    public void callee_Method2() {

        // an implicit new transaction begins i.e. TxRequiredNew.
        // TaskName "my.company.Ejb1.callee_Method2" set on TSR
    }

    @TransactionAttribute(Requires)
    public void callee_Method3() {

        // In caller's transaction, hence TaskName remains
        // "my.company.Ejb1.caller_Method1"
    }

    @TransactionAttribute(NotSupported)
    public void callee_LocalTx () {

        // Unspecified transaction, a new local transaction implicitly started.
        // TaskName "my.company.Ejb1.callee_LocalTx" set on TSR
    }
}

```

Since a wild card can be used to specify TaskName and entity type, multiple specification matches may occur at runtime. The order defined in the wsjpa.AccessIntent property will be used to search for task names and entity types.

```
<properties>
  <property name="wsjpa.AccessIntent" value="Tasks="
    *.Task1 { *.Employee1 ( isolation=read-uncommitted
      ),
      *.Employee? ( isolation=repeatable-read, readlock=write ),
    },
    *
    { *.Employee3 ( isolation=serializable, readlock=write ) },
  "" />
</properties>
```

Associating persistence providers and data sources

Java Persistence API (JPA) applications specify the underlying data source that is used by the persistence provider to access the database.

About this task

The application server provides three methods for defining the data sources in the persistence.xml file.

Procedure

- Explicitly specify the Java Naming and Directory Interface (JNDI) name in the persistence.xml file, and the application directly references the data source. Switching to another data source requires an update to the persistence.xml file.

JPA has two transactional patterns for accessing a data source:

- The Java Transaction API (JTA) resource pattern depends on global transactions. The JTA resource pattern is typically used within the scope of an Enterprise JavaBeans (EJB) session facade. This supports the session bean to control transaction and security contexts while JPA handles the persistence mappings. In this case, the application does not use the EntityManager interface but relies on the EntityManager enlisted with the global transaction when it is accessed.
- The non-JTA resource pattern is used when dealing with a single resource in the absence of global transactions. The non-JTA resource pattern is typically used within the scope of a web application or an application client. The application controls the transaction with the data source with the EntityManager interface.

Within the application server, the use of the <non-jta-data-source> element requires a special configuration for a non-transactional data source. Data sources that are configured for the application server do not function as a <non-jta-data-source>, because all data sources that are configured by the application server are automatically enlisted with the current transactional context. To prevent this automatic enlistment, add an additional data source custom property nonTransactionalDataSource=true:

1. Select **Resources > JDBC > Data sources**
2. Select the name of the data source that you want to configure.
3. Select **WebSphere Application Server data source properties** from the **Additional Properties** heading.
4. Select **Non-transactional data source**.
5. Click **OK**.

Note: The JPA specification assumes that connections are obtained with an isolation level that does not hold long-term locks in the database, such as READ_COMMITTED. This might not match the WebSphere Application Server default isolation level, which is REPEATABLE_READ for most databases. You can find the level that is used for your database by reading the topic, Requirements for setting isolation level.

If the default for your database is not `READ_COMMITTED`, you can change the default by adding an additional data source custom property `webSphereDefaultIsolationLevel`.

Table 90. Isolation level values. This table shows valid isolation level values.

Value	Isolation Level
1	READ_UNCOMMITTED
2	READ_COMMITTED (JPA default)
4	REPEATABLE_READ (WebSphere Application Server default)
8	SERIALIZABLE

If the isolation level is set to a value that holds long-term read locks, configure the JPA provider to use Pessimistic Locking instead of the default Optimistic Locking. For the JPA provider included with WebSphere Application Server, you can do this by adding the following properties to `persistence.xml` file:

```
<property name="openjpa.Optimistic"="false"/>
<property name="openjpa.LockManager"="pessimistic"/>
```

The JPA specification mandates that the data sources that are defined in `<jta-data-source>` and `<non-jta-data-source>` elements of a persistence unit register in the JNDI name space. For example, the `persistence.xml` file should contain an entry like the following:

```
<jta-data-source>jdbc/DataSourceJNDI</jta-data-source>
```

- The JPA for WebSphere Application Server solution extends the JNDI data-source implementation to allow you to reference data sources in the component name space. In the EJB or web module deployment descriptor file, this is the `<resource-ref>` element. You can prefix the data source with `java:comp/env/` so the application indirectly references the data source by using the local JNDI name. In this association, the application does not require updates, you change `<resource-ref>` to use another data source. See the following example:

```
<jta-data-source>java:comp/env/jdbc/DataSourceJNDI</jta-data-source>
```

Note: The JPA specification does not require implementations to include data sources referenced in local JNDI names, so this method of reference might not be portable to other implementations of JPA.

- You can declare `openjpa.Connection*` properties in the persistence unit as follows:

```
<property name="openjpa.ConnectionDriverName" value="org.apache.derby.jdbc.EmbeddedDriver" />
<property name="openjpa.ConnectionURL" value="jdbc:derby:target/database/jpa-test-database;create=true"/>
```

OR

You can use alternative standard JPA properties that are equivalent to the OpenJPA properties, such as:

Table 91. Standard JPA 2.0 property equivalents. Standard JPA 2.0 properties and the OpenJPA equivalents.

Standard JPA 2.0	OpenJPA Equivalent
<code>javax.persistence.jdbc.driver</code>	<code>openjpa.ConnectionDriverName</code>
<code>javax.persistence.jdbc.url</code>	<code>openjpa.ConnectionURL</code>

What to do next

For information about configuring data sources, see the topic on creating and configuring a data source.

For information about data sources and JPA, see the section on persistence in the Apache OpenJPA User Guide.

Chapter 13. Developing Internationalization service

This page provides a starting point for finding information about globalization and the internationalization service, a WebSphere extension for improving developer productivity.

With the internationalization service, you can automatically recognize the time zone and location information of the calling client so that your application can act appropriately. The technology enables you to deliver each user, around the world, the right date and time information, the appropriate currencies and languages, and the correct date and decimal formats.

This documentation also includes information about internationalizing interface strings using the localizable-text application programming interface.

Task overview: Globalizing applications

An application that can present information to users according to regional cultural conventions is said to be *globalized*: The application can be configured to interact with users from different localities in culturally appropriate ways. In a globalized application, a user in one region sees error messages, output, and interface elements in the requested language. Date and time formats, as well as currencies, are presented appropriately for users in the specified region. A user in another region sees output in the conventional language or format for that region. Globalization consists of two phases: *internationalization* (enabling an application component for multicultural support) and *localization* (translating and implementing a specific regional convention). This product supports globalization through the use of its localizable-text API and internationalization service.

Procedure

- Make sure the server runtime environment is properly configured.
For more information about supported locales and character encodings, see “Working with locales and character encodings” on page 743.
- Implement message catalogs in your application by using the localizable-text API.
This product supports the maintenance and deployment of centralized message catalogs for the output of properly formatted, language-specific (*localized*) interface strings.
For more information about the localizable-text API, see “Task overview: Internationalizing interface strings (localizable-text API)” on page 745.
- Implement more extensive locale support by using the internationalization service.
With the internationalization service, you can manage the distribution of the internationalization information, or *internationalization context*, that is necessary to support globalized Java Platform, Enterprise Edition (Java EE) application components. Supported application components also include web service client environments and web service-enabled enterprise beans.
For more information about the internationalization service, see “Task overview: Internationalizing application components (internationalization service)” on page 757.

Globalization

An application that can present information to users according to regional cultural conventions is said to be *globalized*: The application can be configured to interact with users from different localities in culturally appropriate ways. In a globalized application, a user in one region sees error messages, output, and interface elements in the requested language. Date and time formats, as well as currencies, are presented appropriately for users in the specified region. A user in another region sees output in the conventional language or format for that region. Globalization consists of two phases: *internationalization* (enabling an application component for multicultural support) and *localization* (translating and implementing a specific regional convention).

Historically, the creation of globalized applications has been restricted to large corporations writing complex systems. However, given the rise in distributed computing and in the use of the World Wide Web, application developers are pressured to globalize a much wider variety of applications. This trend requires making globalization techniques much more accessible to application developers.

Internationalization of an application is driven by two variables, the time zone and the locale. The *time zone* indicates how to compute the local time as an offset from a standard time like Greenwich Mean Time. The *locale* is a collection of information about language, currency, and the conventions for presenting information like dates. A time zone can cover many locales, and a single locale can span time zones. With both time zone and locale, the date, time, currency, and language for users in a specific region can be determined.

By convention, a given locale is specified with a pair of codes (for language and region) that are governed by different standards. The ISO-639 standard governs the language code; the ISO-3166 standard governs the regional code. In notation, the two codes are typically joined by an underscore (_) character, for example, en_US for English in the United States. In Java code, locales are set and retrieved by means of the `java.util.Locale` class.

A first step: Localization of interface strings

In an application that is not globalized, the user interface is unalterably written into the application code. Internationalizing a user interface adds a layer of abstraction into the design of an application. The additional layer of abstraction enables you to localize the application for each locale that must be supported by the application.

In a localized application, the locale determines the message catalog from which the application retrieves message strings. Instead of printing an error message, the application represents the error message with some language-neutral information; in the simplest case, each error condition corresponds to a key. To print a usable error message, the application looks up the key in a *message catalog*. Each message catalog is a list of keys with associated strings. Different message catalogs provide strings for the different languages that are supported. The application looks up the key in the appropriate catalog, retrieves the corresponding error message in the requested language, and prints the string for the user.

Localization of text can be used for far more than translating error messages. For example, by using keys to represent each element in a graphical user interface (GUI) and by providing the appropriate message catalogs, the GUI (buttons, menus, and so on) can support multiple languages. Extending support to additional languages requires that you provide message catalogs for those languages; in many cases, the application needs no further modification.

The localizable-text package is a set of Java classes and interfaces that can be used to localize the strings in distributed applications easily. Language-specific string catalogs can be stored centrally so that they can be maintained efficiently.

Globalization challenges in distributed applications

With the advent of Internet-based business computational models, applications increasingly consist of clients and servers that operate in different geographical regions. These differences introduce the following challenges to the task of designing a solid client-server infrastructure:

Clients and servers can run on computers that have different endian architectures or code sets

Clients and servers can reside in computers that have different endian architectures: A client can reside in a little-endian CPU, while the server code runs in a big-endian one. A client might want to call a business method on a server running in a code set different from that of the client.

A client-server infrastructure must define precise endian and code-set tracking and conversion rules. The Java platform has nearly eliminated these problems in a unique way by relying on its

Java virtual machine (JVM), which encodes all of the string data in UCS-2 format and externalizes everything in big-endian format. The JVM uses a set of platform-specific programs for interfacing with the native platform. These programs perform any necessary code set conversions between UCS-2 and the native code set of a platform.

Clients and servers can run on computers with different locale settings

Client and server processes can use different locale settings. For example, a Spanish client might call a business method upon an object that resides on an American English server. Some business methods are locale-sensitive in nature; for example, given a business method that returns a sorted list of strings, the Spanish client expects that list to be sorted according to the Spanish collating sequence, not in the English collating sequence of the server. Because data retrieval and sorting procedures run on the server, the locale of the client must be available to perform a legitimate sort.

A similar consideration applies in instances where the server has to return strings containing date, time, currency, exception messages, and so on, that are formatted according to the cultural expectations of the client.

Clients and servers can reside in different time zones

Client and server processes can run in different time zones. To date, all internationalization literature and resources concentrate mainly on code set and locale-related issues. They have generally ignored the time zone issue, even though business methods can be sensitive to time zone as well as to locale.

For example, suppose that a vendor makes the claim that orders received before 2:00 PM are processed by 5:00 PM the same day. The times given, of course, are in the time zone of the server that is processing the order. It is important to know the time zone of the client to give customers in other time zones the correct times for same-day processing.

Other time zone-sensitive operations include time stamping messages logged to a server, and accessing file or database resources. The concept of Daylight Savings Time further complicates the time zone issue.

Java Platform, Enterprise Edition (Java EE) provides support for application components that run on computers with differing endian architecture and code sets. It does not provide dedicated support for application components that run on computers with different locales or time zones.

The conventional method for solving locale and time zone mismatches across remote application components is to pass one or more extra parameters on all business methods needed to convey the client-side locale or time zone to the server. Although simple, this technique has the following limitations when used in Enterprise JavaBeans (EJB) applications:

- It is intrusive because it requires that one or more parameters be added to all bean methods in the call chain to locale-sensitive or time zone-sensitive methods.
- It is inherently error-prone.
- It is impracticable within applications that do not support modification, such as legacy applications.

The internationalization service addresses the challenges posed by locale and time zone mismatch without incurring the limitations of conventional techniques. The service systematically manages the distribution of internationalization contexts across the various components of EJB applications, including client applications, enterprise beans, and servlets. For more information, see “Task overview: Internationalizing application components (internationalization service)” on page 757.

Working with locales and character encodings

Internationalization support for this product relies on that provided by the Java Platform, Standard Edition (JSE). Support varies by platform.

Procedure

- Verify that the operating system on which the application server is installed supports the locales and encodings that you plan to use.

Java internationalization support might use underlying services of the operating system. For example, if user IDs for your server are expected to contain non-English characters, make sure that the operating system is configured to process those characters.

- Plan for encoding changes as necessary.

Consider differences in encoding support among operating system subcomponents. Although this product and the Java platform are based on Unicode encoding, it is not always possible to run applications in a purely Unicode environment.

- Set the `console.encoding` property as necessary.

Results

If your application produces an `UnsupportedEncodingException` exception, check your operating system documentation to determine if the target operating system supports the required encoding and adjust the runtime environment as needed. Use the `converter.properties` file as appropriate to map an unsupported character set to a supported character set. A typical `converter.properties` file appears below:

```
Shift_JIS=Cp943C
EUC-JP=Cp33722C
EUC-JP=Cp33722C
EUC-KR=Cp970
EUC-TW=Cp964
Big5=Co950
GB2312=Cp1386
ISO-2022-KR=ISO2022KR
```

The `converter.properties` file implements a method for specifying a content type header field that browsers would understand (such as, `SHIFT_JIS`) and a writer that can output characters correctly (such as, `Cp943c`).

Language versions offered by this product

This product is offered in several languages, as enabled by the operating platform on which the product is installed.

WebSphere Application Server offers translations for the following languages.

- Brazilian Portuguese
- Chinese (Simplified)
- Chinese (Traditional)
- Czech
- English
- French
- German
- Hungarian
- Italian
- Japanese
- Korean
- Polish
- Romanian
- Russian
- Spanish

Task overview: Internationalizing interface strings (localizable-text API)

This topic summarizes the steps involved in implementing message catalogs through the localizable-text API.

About this task

This product supports the maintenance and deployment of centralized message catalogs for the output of properly formatted, language-specific (*localized*) interface strings.

Procedure

1. Identify localizable text in your application.
2. Create the message catalogs that are necessary for the locales to be supported by your application.
3. In your application code, compose the language-specific strings for output.
4. Using an assembly tool, assemble your application code as one or more application components.
5. Prepare the localizable-text package for deployment with your localized application. In this step, you create a deployment Java archive (JAR) file.

6. Assemble the application modules and the deployment JAR file into a Java Platform, Enterprise Edition (Java EE) application.
7. Deploy and manage the application.

Results

Your application is deployed with localized text.

Identifying localizable text

The first step in localizing strings in an application component is identifying the best candidates for translation.

Procedure

1. Determine which elements of the application need translating. Good candidates for localization include the following:
 - Graphical user interfaces: window titles, menus and menu items, buttons, on-screen instructions
 - Prompts in command-line interfaces
 - Application output: messages and logs
2. Assign a unique key to each element for use in message catalogs for the application. The key provides a language-neutral link between the application and language-specific strings in the message catalogs. Establishing a naming convention for keys before creating the catalogs can make writing code with these keys much more intuitive for interface programmers.

Example

Suppose you are localizing the GUI for a banking system, and the first window contains a pull-down list to use for selecting a type of account.

The labels for the list and the account types in the list are good choices for localization. Three elements require keys: the list and two items in the list.

What to do next

Create message catalogs for the language-specific strings.

Creating message catalogs

Perform this task to begin the localization of strings in an application component.

Before you begin

Identify strings that need to be localized.

About this task

You can create a catalog as either a `java.util.ResourceBundle` subclass or a Java properties file. The properties-file approach is more common, because properties files can be prepared by people without programming experience and swapped without modifying the application code.

Procedure

1. For each string that is identified for localization, add a line to the message catalog that lists the string key and value in the current language. In a properties file, each line has the following structure:
key = string associated with the key
2. Save the catalog, giving it a locale-specific name. To enable resolution to a specific properties file, the Java API specifies naming conventions for the properties files in a resource bundle as *bundleName_localeID.properties*. Give the set of message catalogs a collective name, for example, *BankingResources*. For information about locale IDs that are recognized by the Java APIs, see "Resources for learning."

Example

The following English catalog (*BankingResources_en.properties*) supports the labels for the list and its two list items:

```
accountString = Accounts
savingsString = Savings
checkingString = Checking
```

Do not create compound strings by concatenation (for example, combining the values of *savingsString* and *accountString* to form *Savings Accounts* in English). Success depends upon the grammar of the original language (in this case, English) and is not likely to extend to other languages.

The corresponding German catalog (*BankingResources_de.properties*) supports the labels as follows:

```
accountString = Konten
savingsString = Sparkonto
checkingString = Girokonto
```

What to do next

Write code to compose the language-specific strings.

Composing language-specific strings

Perform this task to complete the localization of strings in an application component.

Before you begin

Create message catalogs for the language-specific strings.

Procedure

1. In application code, create a *LocalizableTextFormatter* instance, passing in required localization values.
2. Set other localization values as needed for more complex situations.
3. Generate a properly formatted, language-specific string.

What to do next

When the application is finished, deploy your application. For more information, see "Preparing the localizable-text package for deployment" on page 755.

Localization API support

The *com.ibm.websphere.i18n.localizabletext* package contains classes and interfaces for localizing text.

This package makes extensive use of the internationalization features of the standard Java APIs from Sun Microsystems, including the following classes:

- *java.util.Locale*

- `java.util.TimeZone`
- `java.util.ResourceBundle`
- `java.text.MessageFormat`

For more information about the standard Java APIs, see “Globalization: Resources for learning” on page 745.

The `localizable-text` package wraps the Java support and extends it for efficient and simple use in a distributed environment. The primary class used by application programmers is `LocalizableTextFormatter`. Instances of this class are usually created in server programs, but client programs can also create them. `Formatter` instances are created for specific resource-bundle names and keys. Client programs that receive a `LocalizableTextFormatter` instance call its `format` method. This method uses the locale of the client application to retrieve the appropriate resource bundle and compose a locale-specific message based on the key.

For example, suppose that a distributed application supports both French and English locales; the server is using an English locale and the client, a French locale. The server creates two resource bundles, one each for English and French. When the client makes a request that triggers a message, the server creates a `LocalizableTextFormatter` instance that contains the name of the resource bundle and the key for the message and passes the instance back to the client.

When the client receives the `LocalizableTextFormatter` instance, it calls the `format` method of the object. By using the locale and name of the resource bundle, the `format` method determines the name of the resource bundle that supports the French locale and retrieves the message that corresponds to the key from the French resource bundle. Formatting of the message is transparent to the client.

In this simple example, the resource bundles reside centrally with the server. They do not have to exist with the client. Part of what the `localizable-text` package provides is the infrastructure to support centralized catalogs. This implementation uses an enterprise bean (a stateless session bean provided with the `localizable-text` package) to access the message catalogs. When the client calls the `format` method on the `LocalizableTextFormatter` instance, the following events occur:

1. The client application sets the time-zone and locale values in the `LocalizableTextFormatter` instance, either by passing them explicitly or through default values.
2. A `LocalizableTextFormatterEJBFinder` call is made to retrieve a reference to the formatter bean.
3. Information from the `LocalizableTextFormatter` instance, including the time zone and locale of the client, is sent to the formatting bean.
4. The formatting bean uses the name of the resource bundle, the message key, the time zone, and the locale to compose a language-specific message.
5. The formatter bean returns the formatted message to the client.
6. The formatted message is inserted into the `LocalizableTextFormatter` instance and returned by the `format` method.

A call to the `format` method requires at most one remote call, to contact the formatter bean. As an alternative, the `LocalizableTextFormatter` instance can cache formatted messages, eliminating the remote call for subsequent uses. In addition, you can set a fallback string so that the application can return a readable string even if it cannot access the appropriate message catalog.

The resource bundles can be stored locally. The `localizable-text` package provides a static variable that indicates whether the bundles are stored locally (`LocalizableConfiguration.LOCAL`) or remotely (`LocalizableConfiguration.REMOTE`). However, the setting of this variable applies to all applications running within the same Java virtual machine.

LocalizableTextFormatter class

The `LocalizableTextFormatter` class, found in the `com.ibm.websphere.i18n.localizabletext` package, is the primary programming interface for using the `localizable-text` package. Instances of this class contain the information needed to create language-specific strings from keys and resource bundles.

The `LocalizableTextFormatter` class extends the `java.lang.Object` class and implements the following interfaces:

- `java.io.Serializable`
- `com.ibm.websphere.i18n.localizabletext.LocalizableText`
- `com.ibm.websphere.i18n.localizabletext.LocalizableTextL`
- `com.ibm.websphere.i18n.localizabletext.LocalizableTextTZ`
- `com.ibm.websphere.i18n.localizabletext.LocalizableTextLTZ`

Creation and initialization of class instances

The `LocalizableTextFormatter` class supports the following constructors:

- `LocalizableTextFormatter()`
- `LocalizableTextFormatter(String resourceBundleName, String patternKey, String appName)`
- `LocalizableTextFormatter(String resourceBundleName, String patternKey, String appName, Object[] args)`

The `LocalizableTextFormatter` instance must have certain values, such as a resource-bundle name, a key, and the name of the formatting application. If you do not pass these values in by using the second constructor listed previously, you can set them separately by making the following calls:

- `setResourceBundleName(String resourceBundleName)`
- `setPatternKey(String patternKey)`
- `setApplicationName(String appName)`

You can use a fourth method, `setArguments(Object[] args)`, to set optional localization values after construction. See “Processing of application-specific values” on page 750 at the end of this topic. For a usage example, see “Composing complex strings” on page 752.

API for formatting text

The formatting methods in the `LocalizableTextFormatter` class generate a string from a set of message keys and resource bundles, based on some combination of locale and time-zone values. Each method corresponds to one of the four `localizable-text` interfaces implemented. The following list indicates the interface in which each formatting method is defined:

- `LocalizableText.format()`
- `LocalizableTextL.format(java.util.Locale locale)`
- `LocalizableTextTZ.format(java.util.TimeZone timeZone)`
- `LocalizableTextLTZ.format(java.util.Locale locale, java.util.TimeZone timeZone)`

The `format` method with no arguments uses the locale and time-zone values set as defaults for the Java virtual machine. All four methods issue `LocalizableException` objects as needed.

Location of message catalogs and the appName value

Applications written with the `localizable-text` package can access message catalogs locally or remotely. In a distributed environment, the use of remote, centrally located message catalogs is appropriate. All clients can use the same catalogs, and maintenance of the catalogs is simplified. Local formatting is useful in test situations and appropriate under some circumstances. To support either local or remote formatting, a `LocalizableTextFormatter` instance must indicate the name of the formatting application.

For example, when an application formats a message by using remote catalogs, the message is actually formatted by an enterprise bean on the server. Although the `localizable-text` package contains the code to

automate the lookup of the formatter bean and to issue a call to it, the application needs to know the name of the formatter bean. Several methods in the `LocalizableTextFormatter` class use a value described as *appName*, which refers to the name of the formatting application. It is not necessarily the name of the application in which the value is set.

Caching of messages

`LocalizableTextFormatter` instances can optionally cache formatted messages so that they do not require reformatting when needed again. By default, caching is not enabled, but you can use a `LocalizableTextFormatter.setCacheSetting(true)` call to enable caching. When caching is enabled and the `format` method is called, the method determines whether the message is already formatted. If so, the cached message is returned. If the message is not found in the cache, the message is formatted and returned to the caller, and a copy of the message is cached for future use.

If caching is disabled after messages are cached, those messages remain in the cache until the cache is cleared by a call to the `LocalizableTextFormatter.clearCache` method. You can clear the cache at any time; the cache is automatically cleared when any of the following methods is called:

- `setResourceBundleName(String resourceBundleName)`
- `setPatternKey(String patternKey)`
- `setApplicationName(String appName)`
- `setArguments(Object[] args)`

API for providing fallback information

Under some circumstances, it can be impossible to format a message. The `localizable-text` package implements a fallback strategy, making it possible to get some information even if a message cannot be formatted correctly into the requested language. The `LocalizableTextFormatter` instance can optionally store fallback values for a message string, the time zone, and the locale. These values can be ignored unless the `LocalizableTextFormatter` instance issues an exception. To set fallback values, call the following methods as appropriate:

- `setFallbackString(String message)`
- `setFallbackLocale(Locale locale)`
- `setFallbackTimeZone(TimeZone timeZone)`

For a usage example, see “Generating localized text” on page 754.

Processing of application-specific values

The `localizable-text` package provides native support for localization based on time zone and locale, but you can construct messages on the basis of other values as well. If you need to consider variables other than locale and time zone in formatting localized text, write your own formatter class.

Your formatter class can extend the `LocalizableTextFormatter` class or independently implement some or all of the same `localizable-text` interfaces. As a minimum, your class must implement the `java.io.Serializable` interface and at least one of the `localizable-text` interfaces and its corresponding `format` method. If your class implements more than one `localizable-text` interface and `format` method, the order of evaluation of the interfaces is as follows:

1. `LocalizableTextLTZ`
2. `LocalizableTextL`
3. `LocalizableTextTZ`
4. `LocalizableText`

As an example, the `localizable-text` package provides a class that reports the time and date (`LocalizableTextDateTimeArgument`). In that class, date and time formatting is localized in accordance with three values: locale, time zone, and style.

Creating a formatter instance

Perform this task to set localization values for strings in an application component.

About this task

Server programs typically create `LocalizableTextFormatter` instances that are sent to clients as the result of some operation; clients format the objects at the appropriate time. Less typically, client programs create `LocalizableTextFormatter` objects locally.

Procedure

1. If needed for your application, write your own formatter class. For more information about implementation, see “`LocalizableTextFormatter` class” on page 749.
2. In application code, call the appropriate constructor for the formatter class and set required localization values. Some localization values, such as resource bundle name, key and formatting application, must be set, either through a constructor or soon after construction. Other localization values can be set only as needed. For more information about the API, see the related reference.

Example

The following code creates a `LocalizableTextFormatter` instance by using the default constructor and then sets the required localization values:

```
import com.ibm.websphere.i18n.localizabletext.LocalizableException;
import com.ibm.websphere.i18n.localizabletext.LocalizableTextFormatter;
import java.util.Locale;

public void drawAccountNumberGUI(String accountType) {
    ...
    LocalizableTextFormatter ltf = new LocalizableTextFormatter();
    ltf.setPatternKey("accountNumber");
    ltf.setResourceBundleName("BankingSample.BankingResources");
    ltf.setApplicationName("BankingSample");
    ...
}
```

The line of code in boldface exploits default behavior of the Java platform. By default, the Java platform looks first for a subclass of `java.util.ResourceBundle` called `BankingResources`. When none is found, the Java platform looks for a valid properties file of the same name. In this continuing example, a properties file is found.

The application that is requesting a localized message can specify the locale and time zone for message formatting, or the application can use the default values set for the Java virtual machine.

For example, a GUI can enable users to select the language in which to display the interface. A default value must be set initially so that the GUI can be created properly when the application first starts, but users can then change the locale for the GUI to suit their needs. The following code shows how to change the locale used by an application based on the selection of a menu item:

```
import java.awt.event.ActionListener;
import java.awt.event.ActionEvent;
...
import java.util.Locale;

public void actionPerformed(ActionEvent event) {
    String action = event.getActionCommand();
    ...
    if (action.equals("en_us")) {
        applicationLocale = new Locale("en", "US");
        ...
    }
    if (action.equals("de_de")) {
```

```

        applicationLocale = new Locale("de", "DE");
        ...
    }
    if (action.equals("fr_fr")) {
        applicationLocale = new Locale("fr", "FR");
        ...
    }
    ...
}

```

For more information, see "Generating localized text."

What to do next

Set optional localization values.

Setting optional localization values

In addition to setting localization values that are required by the `LocalizableTextFormatter` interface, you can set a number of optional values in application code, either through the constructor or by calling any of several methods for that purpose.

About this task

With optional values, you can do the following actions:

- Compose complex strings from variable substrings
- Customize the formatting of strings, considering variables other than time zone and locale

Procedure

1. In application code, add the optional values into an array of type `Object`.

```
Object[] arg = {new String(getAccountNumber())};
```

2. Pass the array into a `LocalizableTextFormatter` instance. You can pass the array through the appropriate constructor or call the `setArguments(Object[])` method. For a usage example, see "Composing complex strings."

Because the array is passed by value rather than by reference, any updates to the array variable after this point are not reflected in the `LocalizableTextFormatter` instance unless it is reset by calling the `setArguments(Object[])` method.

What to do next

Write code to generate the localized text.

Composing complex strings:

Perform this task to insert variable substrings into a localized string.

Before you begin

Identify strings that need to be localized.

About this task

The localized-text package supports the substitution of variable substrings into a localized string that is retrieved from the message catalog by key.

Procedure

1. In the message catalog, specify the location of the substitution in the string to be retrieved. Variable components are designated by braces (for example, {0}).
2. In application code, create a `LocalizableTextFormatter` instance, passing in an array that contains the variable value. If the variable substring must be localized, you can create a nested `LocalizableTextFormatter` instance and pass the instance in instead of a value.
3. Generate a localized string. When a `format` method is called on a formatter instance, the formatter takes each element of the array passed in the previous step and substitutes it for the placeholder with the matching index in the string that is retrieved from the message catalog. For example, the value at index 0 in the array replaces the {0} variable in the retrieved string.

Example

The following line from an English message catalog shows a string with a single substitution:

```
successfulTransaction = The operation on account {0} was successful.
```

The same key in message catalogs for other languages has a translation of this string with the variable at the appropriate location for each language.

The following code shows the creation of a single-element argument array and the creation and use of a `LocalizableTextFormatter` instance:

```
public void updateAccount(String transactionType) {  
    ...  
    Object[] arg = {new String(this.accountNumber)};  
    ...  
    LocalizableTextFormatter successLTF =  
        new LocalizableTextFormatter ("BankingResources",  
                                     "successfulTransaction",  
                                     "BankingSample",  
                                     arg);  
    ...  
    successLTF.format(this.applicationLocale);  
    ...  
}
```

Nesting formatter instances for localized substrings:

The ability to substitute variable substrings into the strings retrieved from message catalogs adds a level of flexibility to the `localizable-text` package, but this capability is of limited use unless the variable value can be localized. You can localize this value by nesting `LocalizableTextFormatter` instances.

Before you begin

Identify strings that need to be localized.

Procedure

1. In the message catalog, add entries that correspond to potential values for the variable substring.
2. In application code, create a `LocalizableTextFormatter` instance for the variable substring, setting required localization values.
3. Create a `LocalizableTextFormatter` instance for the primary string, passing in an array that contains the formatter instance for the variable substring.

Example

The following line from an English message catalog shows a string entry with two substitutions and entries to support the localizable variable at index 0 (the second variable in the string, the account number, does not need to be localized):

```
successfulTransaction = The {0} operation on account {1} was successful.  
depositOpString = deposit  
withdrawOpString = withdrawal
```

The following code shows the creation of the nested formatter instance and its insertion (with the account number variable) into the primary formatter instance:

```
public void updateAccount(String transactionType) {  
    ...  
    // Successful deposit  
    LocalizableTextFormatter opLTF =  
        new LocalizableTextFormatter("BankingResources",  
                                     "depositOpString",  
                                     "BankingSample");  
    Object[] args = {opLTF, new String(this.accountNumber)};  
    ...  
    LocalizableTextFormatter successLTF =  
        new LocalizableTextFormatter ("BankingResources",  
                                     "successfulTransaction",  
                                     "BankingSample",  
                                     args);  
    ...  
    successLTF.format(this.applicationLocale);  
    ...  
}
```

Generating localized text

Perform this task to specify the runtime formatting of localized text in an application component.

Before you begin

Create a formatter instance and set the localization values as needed.

Procedure

1. If needed, customize the formatting behavior.
2. In application code, call the appropriate format method.

Example

You can provide fallback behavior for use if the appropriate message catalog is not available at formatting time.

The following code generates a localized string. If the formatting fails, the application retrieves and uses a fallback string instead of the localized string:

```
import com.ibm.websphere.i18n.localizabletext.LocalizableException;  
import com.ibm.websphere.i18n.localizabletext.LocalizableTextFormatter;  
import java.util.Locale;  
  
public void drawAccountNumberGUI(String accountType){  
    ...  
    LocalizableTextFormatter ltf = new LocalizableTextFormatter();  
    ...  
    ltf.setFallbackString("Enter account number: ");  
    try {  
        msg = new Label(ltf.format(this.applicationLocale), Label.CENTER);  
    }  
}
```

```

    catch (LocalizableException le) {
        msg = new Label(ltf.getFallbackString(), Label.CENTER);
    }
    ...
}

```

What to do next

When the application is finished, deploy your application. For more information, see “Preparing the localizable-text package for deployment.”

Customizing the behavior of a formatting method:

Perform this task to change the runtime formatting of localized strings in an application component.

About this task

You can customize formatting behavior by passing your own formatter classes into a `LocalizableTextFormatter` instance through an array of optional values. This action enables you to consider variables other than locale and time zone when formatting localized text.

Procedure

1. Write your own formatter class. For more information about implementation, see “`LocalizableTextFormatter` class.”
2. In application code, create an instance of your formatter class as appropriate and pass it with any other optional localization values into an instance of `LocalizableTextFormatter`. When the `LocalizableTextFormatter` instance reads the instance that has been passed in, it attempts to call the `format()` method on the passed-in instance. The string returned is then processed with any other elements in the array.

Example

The `localizable-text` package provides an example of a user-defined class, called `LocalizableTextDateTimeArgument`. This class enables date and time information to be selectively formatted according to the style values defined in the `java.text.DateFormat` interface as well as the constants that are defined within the `LocalizableTextDateTimeArgument` class.

Preparing the localizable-text package for deployment

The `LocalizableTextEJBDeploy` tool is used to create a deployment Java Archive (JAR) file for the localizable text service. You must deploy the enterprise bean in each enterprise application that requires support for localized text.

Before you begin

Write code to compose the language-specific strings.

Procedure

1. Make sure that the `LocalizableTextEJBDeploy` tool is included in the class path.

transition: In versions 6.0.x and earlier, the `LocalizableTextEJBDeploy` tool used to reside in the file `app_server_root/lib/lttext.jar`. It now resides in the file `app_server_root/plugins/com.ibm.ws.runtime_1.0.0.jar`.

2. Set up a working directory for the `LocalizableTextEJBDeploy` tool to use. You need to pass this location to the tool through a command-line interface.

3. Run the LocalizableTextEJBDeploy tool. You might be asked if you want to regenerate deployment code for the LocalizableText bean. Do not redeploy the bean; if you do, an incorrect Java Naming and Directory Interface (JNDI) name will be generated.

To deploy the bean on multiple hosts and servers, run the tool for each host and server combination. This action generates a unique JNDI name for each deployment. After the tool is run, a deployment JAR file is located in the working directory that you specified.

What to do next

Using an assembly tool, assemble the deployment JAR file in an enterprise application with other application components.

As part of preparing for deployment, perform the following:

- Add the resource bundles for your application to the Enterprise Archive (EAR) file as files.
- Add the location of the EAR file to the server class path for the server so that the resource bundles can be located on the virtual host and server.

The same deployment JAR file can be included in several enterprise applications.

LocalizableTextEJBDeploy command

This topic describes the command-line syntax for the LocalizableTextEJBDeploy tool.

transition: In versions 6.0.x and earlier, the LocalizableTextEJBDeploy tool used to reside in the file `app_server_root/lib/ltext.jar`. It now resides in the file `app_server_root/plugins/com.ibm.ws.runtime_1.0.0.jar`.

```
LocalizableTextEJBDeploy
-a applicationName
-h virtualHostName
-i installationDirectory
-s serverName
-w workingDirectory
```

Parameters

The required parameters, which can be specified in any order, follow:

applicationName

The name of the formatting session bean. This name is used in LocalizableTextFormatter instances to specify where the actual formatting occurs. If the name cannot be resolved at run time, the format method issues an exception.

virtualHostName

The name of the virtual host on which the formatting session bean is deployed. This value is case-sensitive on all operating platforms.

installationDirectory

The location at which the application server product is installed.

serverName

The name of the application server. If this argument is not specified, the default server name for the product is used.

workingDirectory

A location for the tool to use temporarily.

Task overview: Internationalizing application components (internationalization service)

This topic summarizes the steps involved in using the internationalization service.

About this task

With the internationalization service, you can manage the distribution of the internationalization information, or *internationalization context*, that is necessary to support globalized Java Platform, Enterprise Edition (Java EE) application components. Supported application components also include web service client environments and web service-enabled enterprise beans.

Procedure

1. Use the internationalization context API within application components to obtain or manage internationalization context.

Servlet and enterprise bean business methods can use internationalization context to perform locale- and time zone-sensitive localizations. Enterprise JavaBeans (EJB) client applications, and server components that are configured to manage internationalization context must use the internationalization context API to set the context elements scoped to their invocations.

You use the internationalization context API within Web service-enabled Java EE client programs and stateless session beans in the same manner that you would use conventional Java EE application components, with one exception. Internationalization context propagated over Web service requests contains a time zone ID, whereas conventional Remote Method Invocation/ Internet Inter-ORB Protocol (RMI/IIOP) requests propagate complete time zone information, including the raw offset, Daylight Savings Time information, and so on.

2. Assemble internationalized applications.

The internationalization type specifies the internationalization policy that applies to a servlet or an enterprise bean and, in particular, indicates whether the application component or its hosting Java EE container manages internationalization context. Container internationalization attributes can be specified for container-managed servlet and enterprise bean business methods. These attributes tailor a policy by indicating which context the container scopes to an invocation. Configuring internationalization policies declaratively prescribes, by means of the application deployment descriptor, the distribution and management of context throughout an application.

As you edit the deployment descriptor for assembly, you can also set the internationalization type and configure any container internationalization attributes for the servlets and enterprise beans in your application.

You configure internationalization type and container internationalization attributes for Web service-enabled stateless session beans in the same manner as you do for conventional beans.

3. Manage the internationalization service.

Use the administrative console to enable the service on all application servers.

By default, the service is enabled within Java EE client environments but is disabled on application servers. You must enable the service on all application servers hosting your servlets and enterprise beans to use internationalization context.

4. Troubleshoot the internationalization service as needed.

Use the administrative console to enable the trace service to log internationalization service messages when debugging your applications.

The trace strings for the internationalization service follow; use both:

```
com.ibm.ws.i18n.context.*=all=enabled:com.ibm.websphere.i18n.context.*=all=enabled
```

Internationalization service

In a distributed client-server environment, application processes can run on different machines, configured for different locales, corresponding to different cultural conventions; they can also be located across geographical boundaries. The internationalization service can help manage your application in a globally distributed environment.

For an understanding of how differences in locale impact application development, read “Globalization” on page 741.

Java Platform, Enterprise Edition (Java EE) provides support for application components that run on computers with differing endian architecture and code sets. It does not provide dedicated support for application components that run on computers with different locales or time zones.

The internationalization service addresses the challenges posed by locale and time zone mismatch without incurring the limitations of conventional techniques. The service systematically manages the distribution of internationalization contexts across the various components of EJB applications, including client applications, enterprise beans, and servlets.

The service works by associating an internationalization context with every service request within an application. When a client-side component calls a business method, the internationalization service interposes by obtaining the internationalization context associated with the current client-side process and by attaching that context to the outgoing request. On the server side, the internationalization service again interposes by detaching the context from the incoming request and associating it with the server-side process on which the business method will run, effectively scoping the context to the business method. For HTTP requests, the caller context is constructed from the HTTP attributes and default values. The service propagates internationalization context on subsequent business method invocations in the same manner, which distributes the context of the originating request over the entire chain of business method invocations.

This basic operation of scoping and propagation is defined precisely by *internationalization context management policies*. Internationalization policies specify whether an application component or its hosting Java EE container are to manage internationalization context. For container-managed components, the policy indicates which internationalization context the container scopes to invocations on that component. Server components configured to manage internationalization context, as well as EJB clients, must use the internationalization context API to manage the internationalization context elements scoped to their invocations.

Every application component has a default policy, which can be overridden and tailored for servlets and enterprise beans at assembly time.

At run time, application components can use the internationalization context API to get any element of the internationalization contexts scoped to an invocation. To programmatically access context elements, application components first resolve an internationalization context API reference, then call the appropriate API method to access the various context elements, such as the caller locale or the invocation time zone. These elements can be used in calls to Java SDK internationalization API methods; for example, to perform localizations such as formatting messages, configuring dates, or comparing strings.

Assembling internationalized applications

Perform this task to configure application components for deployment with the internationalization service.

About this task

Use an assembly tool to configure internationalization in the deployment descriptors for servlets and enterprise beans.

Procedure

1. Set the **internationalization type**.

All servlets and enterprise beans have an internationalization type setting that specifies whether internationalization context is managed by the application component or by its hosting Java Platform, Enterprise Edition (Java EE) container during invocations of their respective life cycle and business methods. The internationalization type can be configured for all server application components except entity beans, which are container-managed only.

By default, all server components use container-managed internationalization (CMI). The default setting suffices in most cases; when it does not, modify the internationalization type setting by completing the steps that are described in one of the following topics:

- “Setting the internationalization type for servlets”
- “Setting the internationalization type for enterprise beans” on page 761

2. Set the **container internationalization attribute**.

You can associate CMI servlets, and business methods of CMI enterprise beans, with a container internationalization attribute. That attribute specifies which of three internationalization contexts (**Caller**, **Server**, or **Specified**) the container is to scope to an invocation. When running as specified, the container internationalization attribute also specifies the custom internationalization context elements.

Named container internationalization attributes can be associated with sets of servlets or with sets of Enterprise JavaBeans (EJB) business methods. Initially, CMI servlets and business methods implicitly run as caller and do not associate with a container internationalization attribute. When the implicit behavior or an associated attribute setting is unsuitable, configure an attribute by completing the steps that are described in one of the following topics:

- “Configuring container internationalization for servlets” on page 760
- “Configuring container internationalization for enterprise beans” on page 761

Setting the internationalization type for servlets

This task sets the internationalization type for a servlet within a Web module.

Before you begin

This topic assumes that you have an assembly tool such as Rational Application Developer.

For information about assembly, refer to the documentation for your assembly tool. The steps in this topic refer to Rational Application Developer.

This topic assumes that you have started the assembly tool, configured the assembly tool for work on Java Platform, Enterprise Edition (Java EE) modules, and created or imported a dynamic Web project.

Procedure

1. In the Java EE perspective, open the Web project for which you want to set the internationalization type.

- a. Double-click **Dynamic Web Projects**.
- b. Double-click the name of the Web project to see its contents.
- c. Double-click the deployment descriptor object.

The Web Deployment Descriptor panel is displayed.

2. In the Web Deployment Descriptor panel, click the Servlets tab.

3. Scroll down to **WebSphere Programming Model Extensions** and then **Internationalization**.

4. From the **Servlets and JSPs** list of the Servlets panel, select the servlet for which you want to set the internationalization type.

5. Under **Internationalization**, select a value from the **Internationalization type** list. Valid values are Application or Container.

6. From the menu bar, click **File > Save**.

Results

The internationalization type setting is assigned to the servlet.

What to do next

If you selected container-managed internationalization, you can then set container-managed internationalization attributes for methods within the servlet. For more information, see "Configuring container internationalization for servlets."

Configuring container internationalization for servlets

This task configures container internationalization for a servlet within a Web module.

Before you begin

This topic assumes that you have an assembly tool such as Rational Application Developer.

For information about assembly, refer to the documentation for your assembly tool. The steps in this topic refer to Rational Application Developer.

This topic assumes that you have started the assembly tool, configured the assembly tool for work on Java Platform, Enterprise Edition (Java EE) modules, and created or imported a dynamic Web project.

You must also have set the internationalization type of one or more servlets in a Web project to Container.

About this task

This procedure relates one or more servlets to a container-managed internationalization attribute.

Procedure

1. In the Java EE perspective, open the Web project for which you want to configure container internationalization.
 - a. Double-click **Dynamic Web Projects**.
 - b. Double-click the name of the Web project to see its contents.
 - c. Double-click the deployment descriptor object.
The Web Deployment Descriptor panel is displayed.
2. In the Web Deployment Descriptor panel, click the Servlets tab.
3. Scroll down to **WebSphere Programming Model Extensions** and then **Internationalization**.
4. Following **Container-managed Internationalization Attribute**, set the **Run As** field by selecting Caller, Server, or Specified.
5. If the servlet is to be run as Specified, select an internationalization policy from the **Specified** list or define a new policy.
 - a. To define an internationalization policy, click **New**. The New Specified Initialization wizard is displayed.
 - b. In the **Description** field, give the policy a name.
 - c. If needed, set a time zone ID and add a time zone description. If you do not find the appropriate time zone in the ID list, click **Customize** to define one relative to Greenwich Mean Time (GMT).
 - d. Create at least one locale for the policy. To create a locale, click **Add**; select a language and (optional) geographic region; specify a variant as needed. Add a locale description and click **OK** to finish. The new locale is added to the **Locales** list.
 - e. If more than one locale is defined for the policy, select a locale from the **Locales** list and click **Finish**. Otherwise, just click **Finish**.

6. From the menu bar, click **File > Save**.

Results

Selected servlets are now configured to run under the associated internationalization settings.

Setting the internationalization type for enterprise beans

This task sets the internationalization type for an enterprise bean within an Enterprise JavaBeans (EJB) module.

Before you begin

This topic assumes that you have an assembly tool such as Rational Application Developer.

For information about assembly, refer to the documentation for your assembly tool. The steps in this topic refer to Rational Application Developer.

This topic assumes that you have started the assembly tool, configured the assembly tool for work on Java Platform, Enterprise Edition (Java EE) modules, and created or imported an EJB project.

About this task

Container-managed internationalization (CMI) is the default type; entity beans cannot be set to application-managed internationalization (AMI). Use CMI also for stateless session beans that are enabled for Web services.

Procedure

1. In the Java EE perspective, open the EJB project for which you want to set the internationalization type.
 - a. Double-click **EJB Projects**.
 - b. Double-click the name of the EJB project to see its contents.
 - c. Double-click the deployment descriptor object.

The EJB Deployment Descriptor panel is displayed.

2. In the EJB Deployment Descriptor panel, click the Internationalization tab. Any enterprise beans that are already configured for AMI are displayed in the **Internationalization type** list.
3. To set the internationalization type for any other enterprise beans to AMI, click **Add** following the **Internationalization type** list. The Internationalization Type wizard opens. Only message-driven or session beans can be selected.
4. Select the beans that you want to set and click **Finish** to exit the wizard.
5. From the menu bar, click **File > Save**.

Results

The internationalization type is assigned to the bean.

What to do next

For beans that use container-managed internationalization, you can then set container-managed internationalization attributes. For more information, see "Configuring container internationalization for enterprise beans."

Configuring container internationalization for enterprise beans

This task configures container internationalization for enterprise bean business methods.

Before you begin

This topic assumes that you have an assembly tool such as Rational Application Developer.

For information about assembly, refer to the documentation for your assembly tool. The steps in this topic refer to Rational Application Developer.

This topic assumes that you have started the assembly tool, configured the assembly tool for work on Java Platform, Enterprise Edition (Java EE) modules, and created or imported an EJB project.

You must also have one or more enterprise beans set to container-managed internationalization (CMI) by default.

About this task

This procedure relates one or more business methods to one or more container-managed internationalization (CMI) attributes. Use this procedure also for stateless session beans that are enabled for Web services.

Procedure

1. In the Java EE perspective, open the EJB project for which you want to configure container internationalization.
 - a. Double-click **EJB Projects**.
 - b. Double-click the name of the EJB project to see its contents.
 - c. Double-click the deployment descriptor object.

The EJB Deployment Descriptor panel is displayed.

2. In the EJB Deployment Descriptor panel, click the Internationalization tab. Any business methods that are already configured are displayed in the **Internationalization attributes** list.
3. To configure a CMI business method, click **Add** following the **Internationalization attributes** list. The Internationalization Attributes wizard opens.
4. Set the **Run As** field by selecting **Caller**, **Server**, or **Specified**. Add a meaningful description. As a group, the CMI attribute settings comprise an internationalization policy.
 - The description appears as *Internationalization description (runAsSetting)* in the **Internationalization attributes** list when you are finished.
 - If you do not provide a description, the policy name appears as *Internationalization (runAsSetting)*.

If the bean is to be run as **Specified**, complete the following steps to specify the context elements that the container scopes to bean method invocations.

- a. Set a time zone ID and add a time zone description as needed. If you do not find the appropriate time zone in the ID list, click **Custom** to define one relative to Greenwich Mean Time (GMT).
 - b. Set a locale. Select a language and (optional) geographic region; specify a variant as needed. Add a locale description as needed and click **OK** to finish.
5. Click **Next**.
 6. Select the beans for which you want to configure method-level internationalization attributes and click **Next**.
 7. Select the methods that you want to configure and click **Next**. A check box is displayed next to each method name that you select.
 - Click **Apply to All** to place a check box next to the displayed bean name.
 - Click **Select Beans** to select more beans with CMI.
 8. Click **Finish** to exit the wizard.
 9. From the menu bar, click **File > Save**.

Results

The bean methods are now configured to run under the associated internationalization settings.

Using the internationalization context API

Enterprise JavaBeans (EJB) client applications, servlets, and enterprise beans can programmatically obtain and manage internationalization context using the internationalization context API. For Web service client applications, you use the API to obtain and manage internationalization context in the same manner as for EJB clients.

Before you begin

The `java.util` and `com.ibm.websphere.i18n.context` packages contain all of the classes necessary to use the internationalization service within an EJB application.

Procedure

1. Gain access to the internationalization context API.

Resolve internationalization context API references once over the life cycle of an application component, within the initialization method of that component (for example, within the `init` method of servlets, or within the `SetXxxContext` method of enterprise beans). For Web service client programs, resolve a reference to the internationalization context API during initialization. For stateless session beans enabled for Web services, resolve the reference in the `setSessionContext` method.

2. Access caller locales and time zones.

Every remote invocation of an application component has an associated caller internationalization context associated with the thread that is running that invocation. A caller context is propagated by the internationalization service and middleware to the target of a request, such as an Enterprise JavaBeans (EJB) business method or servlet service method. This task also applies to Web service client programs.

3. Access invocation locales and time zones.

Every remote invocation of a servlet service or Enterprise JavaBeans (EJB) business method has an invocation internationalization context associated with the thread that is running that invocation. Invocation context is the internationalization context under which servlet and business method implementations run; it is propagated on subsequent invocations by the internationalization service and middleware. This task also applies to Web service client programs.

Results

The resulting components are said to use *application-managed internationalization* (AMI). For more information about AMI, see “Internationalization context: Management policies” on page 778.

Example

Each supported application component uses the internationalization context API differently. Code examples are provided that illustrate how to use the API within each component type. Differences in API usage, as well as other coding tips, are noted in comments that precede the relevant statement blocks.

- Managing internationalization context in an EJB client program
- Managing internationalization context in a servlet
- Managing internationalization context in a session bean
- Representing internationalization context in a SOAP header

Managing internationalization context in an EJB client program: The following code example illustrates how to use the internationalization context API within a contained EJB client program or Web service client program.

```

//-----
// Basic Example: J2EE EJB client.
//-----
package examples.basic;

//-----
// INTERNATIONALIZATION SERVICE: Imports.
//-----
import com.ibm.websphere.i18n.context.UserInternationalization;
import com.ibm.websphere.i18n.context.Internationalization;
import com.ibm.websphere.i18n.context.InvocationInternationalization;

import javax.naming.InitialContext;
import javax.naming.Context;
import javax.naming.NamingException;
import java.util.Locale;
import java.util.SimpleTimeZone;

public class EjbClient {

    public static void main(String args[]) {

        //-----
        // INTERNATIONALIZATION SERVICE: API references.
        //-----
        UserInternationalization userI18n = null;
        Internationalization callerI18n = null;
        InvocationInternationalization invocationI18n = null;

        //-----
        // INTERNATIONALIZATION SERVICE: JNDI name.
        //-----
        final String UserI18NUrl =
            "java:comp/websphere/UserInternationalization";

        //-----
        // INTERNATIONALIZATION SERVICE: Resolve the API.
        //-----
        try {
            Context initialContext = new InitialContext();
            userI18n = (UserInternationalization)initialContext.lookup(
                UserI18NUrl);
            callerI18n = userI18n.getCallerInternationalization();
            invI18n = userI18n.getInvocationInternationalization ();
        } catch (NamingException ne) {
            log("Error: Cannot resolve UserInternationalization: Exception: " + ne);
        } catch (IllegalStateException ise) {
            log("Error: UserInternationalization is not available: " + ise);
        }
        ...

        //-----
        // INTERNATIONALIZATION SERVICE: Set invocation context.
        //
        // Under Application-managed Internationalization (AMI), contained EJB
        // client programs may set invocation context elements. The following
        // statements associate the supplied invocation locale and time zone
        // with the current thread. Subsequent remote bean method calls will
        // propagate these context elements.
        //-----
        try {
            invocationI18n.setLocale(new Locale("fr", "FR", ""));
            invocationI18n.setTimeZone("ECT");
        } catch (IllegalStateException ise) {
            log("An anomaly occurred accessing Invocation context: " + ise );
        }
        ...
    }
}

```

```

//-----
// INTERNATIONALIZATION SERVICE: Get locale and time zone.
//
// Under AMI, contained EJB client programs can get caller and
// invocation context elements associated with the current thread.
// The next four statements return the invocation locale and time zone
// associated above, and the caller locale and time zone associated
// internally by the service. Getting a caller context element within
// a contained client results in the default element of the JVM.
//-----
Locale invocationLocale = null;
SimpleTimeZone invocationTimeZone = null;
Locale callerLocale = null;
SimpleTimeZone callerTimeZone = null;
try {
    invocationLocale = invocationI18n.getLocale();
    invocationTimeZone =
        (SimpleTimeZone)invocationI18n.getTimeZone();
    callerLocale = callerI18n.getLocale();
    callerTimeZone = (SimpleTimeZone)callerI18n.getTimeZone();
} catch (IllegalStateException ise) {
    log("An anomaly occurred accessing I18n context: " + ise );
}

...
} // main

...
void log(String s) {
    System.out.println ((s == null) ? "null" : s);
}
} // EjbClient

```

Managing internationalization context in a servlet: The following code example illustrates how to use the internationalization context API within a servlet. Note comments in the init and doPost methods.

```

...
//-----
// INTERNATIONALIZATION SERVICE: Imports.
//-----
import com.ibm.websphere.i18n.context.UserInternationalization;
import com.ibm.websphere.i18n.context.Internationalization;
import com.ibm.websphere.i18n.context.InvocationInternationalization;

import javax.naming.InitialContext;
import javax.naming.Context;
import javax.naming.NamingException;
import java.util.Locale;

public class J2eeServlet extends HttpServlet {

    ...
    //-----
    // INTERNATIONALIZATION SERVICE: API references.
    //-----
    protected UserInternationalization userI18n = null;
    protected Internationalization i18n = null;
    protected InvocationInternationalization invI18n = null;

    //-----
    // INTERNATIONALIZATION SERVICE: JNDI name.
    //-----
    public static final String UserI18NUrl =
        "java:comp/websphere/UserInternationalization";

    protected Locale callerLocale = null;

```

```

protected Locale invocationLocale = null;

/**
 * Initialize this servlet.
 * Resolve references to the JNDI initial context and the
 * internationalization context API.
 */
public void init() throws ServletException {

    //-----
    // INTERNATIONALIZATION SERVICE: Resolve API.
    //
    // Under Container-managed Internationalization (CMI), servlets have
    // read-only access to invocation context elements. Attempts to set these
    // elements result in an IllegalStateException.
    //
    // Suggestion: cache all internationalization context API references
    // once, during initialization, and use them throughout the servlet
    // lifecycle.
    //-----
    try {
        Context initialContext = new InitialContext();

Gaining access to the internationalization context API

Perform this task to access the internationalization service by resolving a reference to the internationalization context API.

About this task

Resolve internationalization context API references once over the life cycle of an application component, within the initialization method of that component (for example, within the `init` method of servlets, or within the `SetXxxContext` method of enterprise beans). For Web service client programs, resolve a reference to the internationalization context API during initialization. For stateless session beans enabled for Web services, resolve the reference in the `setSessionContext` method.

Procedure

1. Resolve a reference to the `UserInternationalization` interface by performing a lookup on the Java Naming and Directory Interface (JNDI) name `java:comp/websphere/UserInternationalization`. For example:

```
//-----
// Internationalization context imports.
//-----
import com.ibm.websphere.i18n.context.*;
import javax.naming.*;
...

public class MyApplication {
    ...

    //-----
    // Resolve a reference to the UserInternationalization interface.
    //-----
    InitialContext initCtx = null;
    UserInternationalization userI18n = null;
    final String UserI18nUrl = "java:comp/websphere/UserInternationalization";
    try {
        initCtx = new InitialContext();
        userI18n = (UserInternationalization)initCtx.lookup(UserI18nUrl);
    }
    catch (NamingException ne) {
        // UserInternationalization URL is unavailable.
    }
}
```

If the `UserInternationalization` object is unavailable because of an anomaly or a restriction, the JNDI lookup invocation issues a `javax.naming.NameNotFoundException` exception that contains the `java.lang.IllegalStateException` instance.

2. Use the `UserInternationalization` reference to create references to the `CallerInternationalization` or `InvocationInternationalization` objects, which provide access to elements of the `Caller` or `Invocation` internationalization contexts, respectively. The `CallerInternationalization` reference can be bound to the `Internationalization` interface only; the `InvocationInternationalization` reference can be bound to either the `Internationalization` or the `InvocationInternationalization` interfaces, depending on whether the application requires read-only or read-write access to the invocation context. For example:

```
...
//-----
// Resolve references to the Internationalization and
// InvocationInternationalization interfaces.
//-----
Internationalization callerI18n = null;
InvocationInternationalization invocationI18n = null;
```

```

try {
    callerI18n = userI18n.getCallerInternationalization();
    invocationI18n = userI18n.getInvocationInternationalization();
}
catch (IllegalStateException ise) {
    // An Internationalization interface(s) is unavailable.
}

```

Accessing caller locales and time zones

Perform this task to access elements of the caller internationalization context.

Before you begin

An application component must first resolve a reference to the `CallerInternationalization` object and then bind it to the `Internationalization` interface.

About this task

Every remote invocation of an application component has an associated caller internationalization context associated with the thread that is running that invocation. A caller context is propagated by the internationalization service and middleware to the target of a request, such as an Enterprise JavaBeans (EJB) business method or servlet service method. This task also applies to Web service client programs.

Procedure

1. Obtain the desired caller context elements.

```

java.util.Locale [] myLocales = null;
try {
    myLocales = callerI18n.getLocales();
}
catch (IllegalStateException ise) {
    // The Caller context is unavailable;
    // is the service started and enabled?
}
...

```

The `Internationalization` interface contains the following methods to get caller internationalization context elements:

- **Locale [] getLocales()** Returns the list of caller locales that are associated with the current thread.
- **Locale getLocale()** Returns the first in the list of caller locales that are associated with the current thread.
- **TimeZone getTimeZone()** Returns the `SimpleTimeZone` caller that is associated with the current thread.

The `Internationalization` interface supports read-only access to internationalization context within application components. Methods of the `Internationalization` interface are available to all EJB application components and are used in the same manner for each, but the method semantics vary according to the component type. For instance, when obtaining the caller locale within an EJB client application, the interface returns the default locale of the host Java virtual machine (JVM); in contrast, when obtaining caller context within a servlet service method (for example, `doPost` or `doGet` methods), the interface returns the first locale (accept-language) propagated within the corresponding HTML request. See `Internationalization context` for a discussion of how the service propagates internationalization context throughout an application.

2. Use the caller context elements to localize computations under a locale or time zone of the calling process.

```

DateFormat df = DateFormat.getDateInstance(myLocale);
String localizedDate = df.getDateInstance().format(aDateInstance);
...

```

Accessing invocation locales and time zones

Perform this task to access elements of the invocation internationalization context.

Before you begin

An application component must first resolve a reference to the `InvocationInternationalization` object and then bind it to the `InvocationInternationalization` interface of the internationalization context API.

About this task

Every remote invocation of a servlet service or Enterprise JavaBeans (EJB) business method has an invocation internationalization context associated with the thread that is running that invocation. Invocation context is the internationalization context under which servlet and business method implementations run; it is propagated on subsequent invocations by the internationalization service and middleware. This task also applies to Web service client programs.

Procedure

1. Obtain the desired invocation context elements.

```
java.util.Locale myLocale;
try {
    myLocale = invocationI18n.getLocale();
}
catch (IllegalStateException ise) {
    // The invocation context is unavailable;
    // is the service started and enabled?
}
...
```

The `InvocationInternationalization` interface contains the following methods to both get and set invocation internationalization context elements:

- **Locale [] getLocales()**. Returns the list of invocation locales that is associated with the current thread.
- **Locale getLocale()**. Returns the first in the list of invocation locales that is associated with the current thread.
- **TimeZone getTimeZone()**. Returns the `SimpleTimeZone` invocation that is associated with the current thread.
- **setLocales(Locale [])**. Sets the list of invocation locales that are associated with the current thread to the supplied list.
- **setLocale(Locale)**. Sets the list of invocation locales that are associated with the current thread to a list that contains the supplied locale.
- **setTimeZone(TimeZone)**. Sets the invocation time zone that is associated with the current thread to the supplied `SimpleTimeZone`.
- **setTimeZone(String)**. Sets the invocation time zone that is associated with the current thread to a `SimpleTimeZone` that has the supplied ID.

The `InvocationInternationalization` interface supports read and write access to invocation internationalization context within application components. However, according to internationalization context management policies, only components configured to manage internationalization context (application-managed internationalization, or AMI, components) have write access to invocation internationalization context elements. Calls to set invocation context elements within container-managed internationalization (CMI) application components result in a `java.lang.IllegalStateException` exception. Any differences in how application components can use `InvocationInternationalization` methods are explained in `Internationalization context`.

2. Use the invocation context elements to localize a computation under a locale or time zone of the calling process.

```
DateFormat df = DateFormat.getDateInstance(myLocale);
String localizedDate = df.getDateInstance().format(aDateInstance);
...
```

Example

In the following code example, locale (en,GB) and simple time zone (GMT) transparently propagate on the call to the myBusinessMethod method. Server-side application components, such as myEjb, can use the InvocationInternationalization interface to obtain these context elements.

```
...
//-----
// Set the invocation context under which the business method or
// servlet will run and propagate on subsequent remote business
// method invocations.
//-----
try {
    invocationI18n.setLocale(new Locale("en", "GB"));
    invocationI18n.setTimeZone(SimpleTimeZone.getTimeZone("GMT"));
}
catch (IllegalStateException ise) {
    // Is the component CMI; is the service started and enabled?
}
myEjb.myBusinessMethod();
```

Within CMI application components, the Internationalization and InvocationInternationalization interfaces are semantically equivalent. You can use either of these interfaces to obtain the context associated with the thread on which that component is running. For instance, both interfaces can be used to obtain the list of locales propagated to the servlet doPost service method.

Internationalization context API: Programming reference

Application components programmatically manage internationalization context through the UserInternationalization, Internationalization, and InvocationInternationalization interfaces in the com.ibm.websphere.i18n.context package.

The following code example introduces the internationalization context API:

```
public interface UserInternationalization {
    public Internationalization getCallerInternationalization();
    public InvocationInternationalization
        getInvocationInternationalization();
}

public interface Internationalization {
    public java.util.Locale[] getLocales();
    public java.util.Locale getLocale();
    public java.util.TimeZone getTimeZone();
}

public interface InvocationInternationalization
    extends Internationalization {
    public void setLocales(java.util.Locale[] locales);
    public void setLocale(java.util.Locale jmLocale);
    public void setTimeZone(java.util.TimeZone timeZone);
    public void setTimeZone(String timeZoneId);
}
```

UserInternationalization interface

The UserInternationalization interface provides factory methods for obtaining references to the CallerInternationalization and InvocationInternationalization context objects. Use these references to access elements of the caller and invocation contexts correlated to the current thread.

Methods of the UserInternationalization interface:

Internationalization getCallerInternationalization()

Returns a reference implementing the Internationalization interface that supports access to

elements of the caller internationalization context correlated to the current thread. If the service is disabled, this method issues an `IllegalStateException` exception.

InvocationInternationalization getInvocationInternationalization()

Returns a reference implementing the `InvocationInternationalization` interface. If the service is disabled, this method issues an `IllegalStateException` exception.

Internationalization interface

The `Internationalization` interface declares methods that provide read-only access to internationalization context. Given a caller or invocation internationalization context object created with the `UserInternationalization` interface, bind the object to the `Internationalization` interface to get elements of that context type. Observe that caller internationalization context can be accessed only through this interface.

Methods of the `Internationalization` interface:

Locale[] getLocales()

Returns the chain of locales within the internationalization context (object) that is bound to the interface, provided the chain is not null; otherwise this method returns a chain of length(1) containing the default locale of the Java virtual machine (JVM).

Locale getLocale()

Returns the first in the chain of locales within the internationalization context (object) that is bound to the interface, provided the chain is not null; otherwise this method returns the default locale of the JVM.

TimeZone getTimeZone()

Returns the caller time zone (that is, the `SimpleTimeZone` instance) that is associated with the current thread, provided the time zone is non-null; otherwise this method returns the process time zone.

InvocationInternationalization interface

The `InvocationInternationalization` interface declares methods that provide read and write access to `InvocationInternationalization` context. Given an invocation internationalization context object created with the `UserInternationalization` interface, bind the object to the `InvocationInternationalization` interface to get and set elements of the invocation context.

According to the container-managed internationalization (CMI) policy, all set methods, `setXxx()`, issue an `IllegalStateException` exception when called within a CMI servlet or enterprise bean.

Methods of the `InvocationInternationalization` interface:

void setLocales(java.util.Locale[] locales)

Sets the chain of locales to the supplied chain, *locales*, within the invocation internationalization context. The supplied chain can be null or have length(≥ 0). When the supplied chain is null or has length(0), the service sets the chain of invocation locales to an array of length(1) containing the default locale of the JVM. Null entries can exist within the supplied locale list, for which the service substitutes the default locale of the JVM on remote invocations.

void setLocale(java.util.Locale locale)

Sets the chain of locales within the invocation internationalization context to an array of length(1) containing the supplied locale, *locale*. The supplied locale can be null, in which case the service instead sets the chain to an array of length(1) containing the default locale of the JVM.

void setTimeZone(java.util.TimeZone timeZone)

Sets the time zone within the invocation internationalization context to the supplied time zone, *timeZone*. If the supplied time zone is not an exact instance of `java.util.SimpleTimeZone` or is null, the service sets the invocation time zone to the default time zone of the JVM instead.

void setTimeZone(String timeZoneId)

Sets the time zone within the invocation internationalization context to the `java.util.SimpleTimeZone` having the supplied ID, *timeZoneId*. If the supplied time zone ID is null or

invalid (that is, the ID is not displayed in the list of IDs returned by the `java.util.TimeZone.getAvailableIds` method) the service sets the invocation time zone to the simple time zone having an ID of GMT, an offset of 00:00, and otherwise invalid fields.

Internationalization context:

An *internationalization context* is a distributable collection of internationalization information containing an ordered list, or chain, of locales and a single time zone, where the locales and time zone are instances of the `java.util.Locale` and `java.util.TimeZone` Java SDK types, respectively. A locale chain is ordered according to the user's preference.

The internationalization service manages and makes available two varieties of internationalization context: the *caller context*, which represents the caller's localization environment, and the *invocation context*, which represents the localization environment under which a business method runs. Server application components use elements of the caller and invocation internationalization contexts to appropriately tailor locale-sensitive and time zone-sensitive computations.

The internationalization service does not support time zone types other than the `java.util.SimpleTimeZone` type that is found in the Java SDK. Unsupported time zone types silently map to the default time zone of the JVM when supplied to internationalization context API methods. For a complete description of the `java.util.Locale`, `java.util.TimeZone` and `java.util.SimpleTimeZone` types, refer the Java SDK API documentation.

Caller context

Caller internationalization context contains the locale chain and time zone received on incoming EJB business method and servlet service method invocations; it is the internationalization context propagated from the calling process. Use caller context elements within server application components to localize computations to the calling component. Caller context is read-only and can be accessed by all application components by using the Internationalization interface of the internationalization context API.

Caller context is computed in the following manner: On an EJB business method or servlet service method invocation, the internationalization service extracts the internationalization context from the incoming request and scopes this context to the method as the caller context. For any missing or null context element, the service inserts the corresponding default element of the JVM (for example, `java.util.Locale.getDefault()` or `java.util.TimeZone.getDefault()`.) The service performs a similar insertion whenever missing or null Caller context elements are encountered on invocations of stateless session beans that are enabled for Web services.

Formally, caller context is the invocation context of the calling business method or application component.

Invocation context

Invocation internationalization context contains the locale chain and time zone under which EJB business methods and servlet service methods run. It is managed by either the hosting container or the application component, depending on the applicable internationalization policy. On outgoing business method requests, it is the context that propagates to the target process. Use invocation context elements to localize computations under the specified settings of the current application component.

Invocation context is computed in the following manner: On an incoming business method or servlet service method invocation, the internationalization service queries the associated context management policy. If the policy is container-managed internationalization (CMI), the container scopes the context designated by the policy to the invocation; otherwise the policy is application-managed internationalization (AMI), and the container scopes an empty context to the invocation that can be altered by the method implementation.

Application components can access invocation context elements through both the Internationalization and InvocationInternationalization interfaces of the internationalization context API. Invocation context elements can be set (overwritten) under the application-managed internationalization policy only.

On an outgoing business method request, the service obtains the currently scoped invocation context and attaches it to the request. This outgoing exported context becomes the caller context of the target invocation. When supplying invocation context elements, either for export on outgoing requests or through the API, the internationalization service always provides the most recent element set using the API; the service also supplies the corresponding default element of the JVM for any null invocation context element.

Because the internationalization context that is propagated over Web services (SOAP) requests contains a time zone ID rather than the entire state of a `java.lang.SimpleTimeZone` object, time zone information might be lost when a Web service-enabled client program or session bean becomes involved in remote business computation.

Internationalization context: Propagation and scope:

The scope of internationalization context is implicit. Every Enterprise JavaBeans (EJB) client application, servlet service method, and EJB business method call has two internationalization contexts under which it runs.

For each application component call, the container enters the caller context and the call context, as indicated by the pertinent internationalization policy, into scope before the container delegates to the actual implementation. When the implementation returns, the service removes these contexts from scope. The internationalization service supplies no programmatic mechanism for components to explicitly manage the scope of internationalization context.

The service scopes internationalization context differently with respect to application component type:

- “EJB client programs (contained)”
- “Servlets” on page 777
- “Enterprise beans” on page 777
- “Web service client programs (contained)” on page 777
- “Stateless session beans that are enabled for Web services” on page 778

Internationalization context observes by-value semantics over remote method requests. Changes to internationalization context elements that are scoped to a call do not affect the corresponding elements of the internationalization context that is scoped to the remote calling process. Also, modifications to context elements obtained using the internationalization context API do not affect the corresponding elements that are scoped to the invocation.

EJB client programs (contained)

Before it calls the main method of a client program, the Java EE client container introduces into scope invocation and caller internationalization some contexts that contain null elements. These contexts remain in scope throughout the life of the program. EJB client programs are the base in a chain of remote business method invocations and, technically, do not have a logical caller context. Accessing a caller context element yields the corresponding default element of the client JVM. On outgoing EJB business method requests, the internationalization service propagates the invocation context to the target process. Any unset (null) invocation context elements are replaced with the default of the JVM when exported by the internationalization context API or by outgoing requests.

Tip:

To propagate values other than the JVM defaults to remote business methods, EJB client programs, as well as AMI servlets or enterprise beans, must set (override) elements of the invocation context. To learn how to set invocation context elements, see “Accessing invocation locales and time zones” on page 771.

Servlets

On every servlet service method (doGet or doPost) invocation, the Java EE Web container introduces caller and invocation internationalization contexts into scope before delegating to the service method implementation. The caller context contains the accept-languages propagated in the HTTP servlet request, typically from a Web browser. The invocation context contains whichever context is indicated by the container internationalization attribute of the internationalization policy that is associated with the servlet. Any unset (null) invocation context elements are replaced with the default of the server JVM when exported by the internationalization context API or by outgoing requests. The caller and invocation contexts remain effective until immediately after the implementation returns, at which time the container removes them from scope.

Enterprise beans

On every EJB business method invocation, the Java EE EJB container introduces caller and invocation internationalization contexts into scope before delegating to the business method implementation. The caller context contains the internationalization context elements imported from the incoming IIOP request; if the incoming request lacks a particular internationalization context element, the container scopes a null element. The invocation context contains whichever context is indicated by the container internationalization attribute of the internationalization policy that is associated with the business method.

On outgoing EJB business method requests, the service propagates the invocation context to the target process. Any unset (null) invocation context elements are replaced with the default of the server JVM when exported by the internationalization context API or by outgoing requests. The caller and invocation contexts remain effective until immediately after the implementation returns, when the container removes them from scope.

Consider a simple EJB application with a Java client that calls the remote myBeanMethod bean method. On the client side, the application can use the Internationalization Service API to set invocation context elements. When the client calls myBeanMethod(), the service exports the client invocation context to the outgoing request. On the server side, the service detaches the imported context from the incoming request and scopes it to the method as its caller context; the service also scopes the invocation context to the method as indicated by the associated internationalization context management policy. The EJB container then calls the myBeanMethod method, which can use the internationalization context API to access elements of either the caller or invocation contexts. When the myBeanMethod method returns, the EJB container removes these contexts from scope.

Web service client programs (contained)

Before it calls the main method of a Web service client program, the client container introduces into scope both invocation and caller internationalization contexts that contain null elements. These contexts remain in scope throughout the duration of the program. Web service client programs are the base in a chain of remote business method invocations and, technically, do not have a logical caller context. Accessing a Caller context element yields the corresponding default element of the client virtual machine.

On outgoing Web service requests, the internationalization service transparently creates a SOAP header block that contains the invocation context that is associated with the current thread; the SOAP representation of invocation context is propagated through the request to the target process. Any unset (that is, null) invocation context elements are replaced with the default element of the JVM when exported by the internationalization context API or by outgoing requests. Also, because the header contains only a

time zone ID, the additional state of the time zone object (`java.lang.SimpleTimeZone`) of the invocation context might be lost, because it does not get propagated through the request.

Tip:

To propagate values other than the JVM defaults to remote business methods, Web service client programs, as well as AMI servlets or enterprise beans, must set (override) elements of the invocation context. For more information, see “Accessing invocation locales and time zones” on page 771.

Stateless session beans that are enabled for Web services

On every method invocation of a Web service-enabled bean, the EJB container introduces caller and invocation internationalization contexts into scope before delegating control to the business method implementation. The caller context contains the internationalization context elements that are imported from the SOAP header block of the incoming request. If the incoming request lacks a particular internationalization context element, the container introduces a null element into scope. The invocation context contains whichever context is indicated by the container internationalization attribute of the internationalization policy that is associated with the business method.

On outgoing EJB business method requests, the service propagates the invocation context to the target process. Any unset (that is, null) invocation context elements are replaced with the default element of the server JVM when exported by the internationalization context API or by outgoing requests. The caller and invocation contexts remain effective until immediately after control returns from the business method implementation, at which time the container removes them from scope.

On outgoing Web service requests, the internationalization service transparently creates a SOAP header block that contains the invocation context associated with the current thread. The SOAP representation of the invocation context is propagated through the request to the target process. Any unset (that is, null) invocation context elements are replaced with the default element of the JVM when exported by the internationalization context API or by outgoing requests.

Thread association considerations

The Web and EJB containers scope internationalization contexts to a method by associating the method with the thread that run the method implementation. Similarly, methods of the internationalization context API either associate context with, or obtain context associated with, the thread on which these methods run.

In cases where new threads are spawned within an application component (for instance, a user-generated thread inside the service method of a servlet, or a system-generated event handling thread in an AWT client) the internationalization contexts associated with the parent thread does not automatically transfer to the newly-spawned thread. In such instances, the service exports the default locale and time zone of the JVM on any remote business method request and on any API calls that run on the new thread.

If the default context is inappropriate, the desired invocation context elements must be explicitly associated to the new thread by using the `setXxx` methods of the `InvocationInternationalization` interface. Currently, internationalization context management policies enable invocation context to be set within EJB client programs, as well as within servlets, session beans, and message-driven beans that use application-managed internationalization.

Internationalization context: Management policies:

Internationalization policies prescribe how Java EE application components or their hosting containers manage internationalization context on component invocations. Two internationalization context management policies apply to all component types: Application-managed internationalization (AMI) and Container-managed internationalization (CMI).

These policies are represented in two parts:

- Internationalization type
- Container internationalization attribute

The service defines a default, or implicit, internationalization policy for every application component type. At development time, assemblers can override the default policy for server component types by explicitly configuring their internationalization type, and optional container internationalization attributes. Policies configured during assembly are preserved in the deployment descriptor for the application.

All components have an internationalization type that indicates whether it is AMI or CMI; that is, whether a component is to deploy under the application-managed or the container-managed internationalization policy. Application assemblers can set the internationalization type for servlets, session beans, and message-driven beans. Entity beans are implicitly CMI and EJB clients are implicitly AMI; neither can be configured otherwise.

For CMI servlets and enterprise beans, optional container internationalization attributes can be specified to indicate which invocation internationalization context the container is to scope to service or business methods. A CMI service or business method invocation can run under the context of the caller's process, under the default context of the server JVM, or under a custom context specified in the attribute. Assemblers can specify one container internationalization attribute per disjoint set of CMI servlets within a Web module, or one Attribute per disjoint set of business methods of CMI beans within an EJB module. A container internationalization attribute can be associated with more than one method, but a method cannot be associated with more than one attribute.

When an application server launches an application, the internationalization service collects policy information from the deployment descriptor, then uses this information to construct and associate an internationalization policy to every component invocation. A policy is denoted as:

```
[<Internationalization Type>,<Container Internationalization Attribute>]
```

Several cases exist in which the deployment descriptor seems to lack policy information, for example: EJB client applications have no configurable internationalization policy settings; AMI components do not have container internationalization attributes; and you are not required to specify container internationalization attributes for CMI components. When the service cannot obtain the explicit internationalization type and container attribute settings from a well-formed deployment descriptor, it implicitly inserts the appropriate setting into the policy.

The service observes the following conventions when applying policies to invocations:

- Servlets (service) and EJB business methods lacking all internationalization policy information in the deployment descriptor implicitly run under policy [CMI,RunAsCaller].
- CMI servlets and business methods lacking a container internationalization attribute in the deployment descriptor implicitly run under policy [CMI,RunAsCaller].
- AMI servlets and business methods always lack container internationalization attributes in the deployment descriptor, but implicitly run under the logical policy [AMI,RunAsServer].
- EJB clients always lack internationalization policy information in the deployment descriptor. By definition, EJB clients are implicitly AMI types and run under the invocation context of the JVM; they run under the logical policy [AMI,RunAsServer].

For conditions other than these cited examples, such as a malformed deployment descriptor, refer to Internationalization service errors.

Internationalization policies for EJB clients and HTTP clients cannot be configured; HTTP clients do, however, run under the language priority settings of the hosting Web browser. These settings are configurable under the options dialog of most Web browsers. Refer to your Web browser documentation for details.

Internationalization type:

Every server application component has an *internationalization type* setting that indicates whether the invocation internationalization context is managed by the component or by the hosting Java EE container.

Server application components can be deployed to use one of two types of internationalization context management:

- Application-managed internationalization (AMI)
- Container-managed internationalization (CMI)

A server component can be deployed as AMI or CMI, but not both; CMI is the default. The setting applies to the entire component on every invocation. Entity beans use CMI only. Enterprise JavaBeans (EJB) client applications do not have an internationalization type setting; they implicitly use AMI.

Application-managed internationalization

Under the AMI deployment policy, component developers assume complete control over the invocation internationalization context. AMI components can use the internationalization context API to programmatically set invocation context elements.

AMI components are expected to manage invocation context. Invocations of AMI components implicitly run under the default locale and time zone of the hosting JVM. Invocation context elements not set using the API default to the corresponding elements of the JVM when accessed through the API or when exported on business methods. To export context elements other than the JVM defaults, AMI servlets, AMI enterprise beans, and EJB client applications must set (overwrite) invocation elements using the internationalization context API. Moreover, the container logically suspends the caller context that is imported on the AMI servlet lifecycle method and AMI EJB business method invocations. To continue propagating the context of the calling process, AMI servlets and enterprise beans must use the API to transfer caller context elements to the invocation context.

Specify AMI for server components that have internationalization context management requirements that are not supported by container-managed internationalization (CMI).

Container-managed internationalization

CMI is the preferred internationalization context management policy for server application components; it is also the default policy. Under CMI, the internationalization service collaborates with the Web and EJB containers to set the invocation internationalization context for servlets and enterprise beans. The service sets invocation context according to the container internationalization attribute of the policy that is associated with a servlet (service method) or an EJB business method.

A CMI policy has a container internationalization attribute that indicates which internationalization context the container is to scope to an invocation. For details, see Container internationalization attributes. By default, invocations of CMI components run under the caller's internationalization context; or rather, they adhere to the implicit policy `[CMI,RunasCaller]` whenever the servlet or business is not associated with an attribute in the deployment descriptor. For complete details, see Internationalization context: Management policies.

Methods within CMI components can obtain elements of the invocation context using the internationalization context API, but cannot set them. Any attempt to set invocation context elements within CMI components results in a `java.lang.IllegalStateException` exception.

Specify container-managed internationalization for server application components that require standard internationalization context management. Then specify the container internationalization attributes for CMI servlets and for business methods of CMI enterprise beans that you do not want to run under the caller's internationalization context.

Container internationalization attributes:

The internationalization policy of every CMI servlet and EJB business method has a *container internationalization attribute* that specifies which internationalization context the container is to scope to its invocation.

The container internationalization attribute has three main fields:

- Run as
- Locales
- Time zone ID

As a convenience, you can create named container internationalization attributes and associate them to the following subsets:

- CMI servlets within a Web module
- Business methods of CMI enterprise beans within an Enterprise JavaBeans (EJB) module
- Business methods of Web service-enabled session beans. In the following descriptions, the term *supported enterprise bean* refers to both CMI enterprise beans and Web service-enabled session beans.

Run-as field

The **Run-as** field specifies one of three types of invocation context that a container can scope to a method. For servlet service and EJB business methods, the container constructs the invocation internationalization context according to the **Run as** field setting and associates this context to the current thread before delegating to the method implementation.

By default, invocations of servlet service methods and EJB business methods implicitly run as caller (`RunAsCaller`) unless the **Run as** field of a policy attribute specifies otherwise. EJB client applications and AMI server components always run as server (`RunAsServer`).

You can specify the following invocation context types with the **Run as** field are:

Caller The container calls the method under the internationalization context of the calling process. For any missing context element, the container supplies the corresponding default context element of the Java virtual machine (JVM). Select run as caller when you want the invocation to run under the invocation context of the calling process.

Server

The container calls the method under the default locale and time zone of the JVM. Select run as server when you want the invocation to run under the invocation context of the JVM.

Specified

The container calls the method under the internationalization context specified in the attribute. Select run as specified when you want the invocation to run under the custom invocation context that is specified in the policy; then provide the custom context elements by completing the Locales and Time zone ID fields.

Remember: Java Message Service (JMS) messages do not contain internationalization context. Although container-managed message-driven beans can be configured to run as caller, the container associates the default elements of the server process when calling the `onMessage` method of any message-driven bean that is configured as `[CMI, RunAsCaller]`. You can also configure the **Run as** field for Web service business methods.

Locales field

The **Locales** field specifies an ordered list of locales that the container scopes to an invocation. A locale represents a specific geographical, cultural, or political region and contains three fields:

- **Language code.** Ideally, language code is one of the lower-case, two-character codes that are defined by the ISO 639 standard; however, language code is not restricted to ISO codes and is not a required field. A valid locale must specify a language code if it does not specify a country code.

- **Country code.** Ideally, country code is one of the upper-case, two-character codes that are defined by the ISO 3166 standard; however, country code is not restricted to ISO codes and is not a required field. A valid locale must specify a country code if it does not specify a language code.
- **Variant.** Variant is a vendor-specific code. Variant is not a required field and serves only to supplement the language and country code fields according to application- or platform-specific requirements.

A valid locale must specify at least a language code or a country code; the variant is always optional. The first locale of the list is returned when accessing invocation context using the `getLocale` method of the internationalization context API.

Time zone ID field

The **Time zone ID** field specifies an abbreviated identifier for a time zone that the container scopes to an invocation. You can also configure the **Time zone ID** field for Web service business methods.

A time zone represents a temporal offset and computes daylight savings information. A valid ID indicates any time zone supported by the `java.util.TimeZone` type. Specifically, a valid ID is any of the IDs that appear in the list of time zone IDs returned by method `java.util.TimeZone.getAvailableIds()`, or a custom ID having the form `GMT[+|-]hh[[:]mm]`; for example, `America/Los_Angeles`, `GMT-08:00` are valid time zone IDs.

Administering the internationalization service

To use internationalization context in an Enterprise JavaBeans (EJB) application, the internationalization service must be enabled in the runtime environments for all server-side components (servlets and enterprise beans, including session beans enabled for Web service usage) as well as all client-side components (EJB client applications and Web service clients).

About this task

If you do not require the internationalization service, do not enable it. Leaving the service disabled prevents any possible performance degradation incurred by the implicit distribution of internationalization resources.

The internationalization service cannot be enabled for HTTP clients, because support for internationalization in that case is provided by the browser, not by the application server.

Procedure

- Enable or disable the internationalization service for servlets and enterprise beans. By default, the service is disabled for server-side components within the application server. You enable the service by using either the administrative console or the `wsadmin` tool.
- Enable or disable the internationalization service for EJB clients. By default, the service is disabled within the client container. You enable the service by using the `launchClient` tool.

Enabling the internationalization service for servlets and enterprise beans

Perform this task to enable the internationalization service in the application server runtime environment.

About this task

Any servlet or enterprise bean can use internationalization context if the internationalization service is enabled within the hosting application server instance.

Procedure

1. Start the administrative console.
2. Click **Servers > Application servers > *server_name* > Container services > Internationalization service**.

3. Enable the internationalization service.
 - a. If not already selected, select the **Enable service at server startup** check box.
 - b. Click **OK**.

Results

When you select the **Enable service at server startup** setting, the application server automatically initializes and starts the internationalization service whenever the server starts. If you change this setting, be sure to restart the application server for the new setting to take effect.

To disable the service, clear the **Enable service at server startup** check box. In this case, the internationalization service is initialized but not started when the application server starts.

Example

Alternatively, the internationalization service can be enabled from the command line by using the wsadmin tool. Start the wsadmin tool and enter the following commands:

```
set x [$AdminConfig list I18NService]
$AdminConfig modify $x { { enable true } }
$AdminConfig save
exit
```

What to do next

If you enable or disable the internationalization service, be sure to stop and then restart the application server for the new setting to take effect.

Enabling the internationalization service for EJB clients

By default, the internationalization service is disabled for use within Enterprise JavaBeans (EJB) and Web-service enabled client applications. You must enable the service for client applications as well as for all server instances in the runtime environment.

Procedure

Enable the service.

When calling the launchClient tool, include the argument `-CCDI18NService.enable=true` or `-CCDI18NService.enable=yes`.

Internationalization service settings

Use this page to enable or disable the internationalization service. The internationalization service manages the implicit propagation and scoping of locale and time zone information, called *internationalization context*, within application components. When the service is enabled, application components can use the internationalization context API to programmatically manage locale and time zone information. In turn, components can use that locale and time zone information with the Java Platform, Standard Edition (JSE) Internationalization API to perform localizations. If internationalization support is not required on the server, disabling the service can improve performance.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > server_name**. Then, under Container Settings, click **Container Services > Internationalization Service**.

Enable service at server startup:

Specifies whether the server attempts to start the internationalization service.

Default

Cleared

Range

Valid values are Selected or Cleared

More information about valid values follows:

Selected

When the application server starts, it attempts to start the internationalization service automatically.

Cleared

The server does not try to start the internationalization service.

To enable the internationalization service for applications on this server, the system administrator must select this property and then restart the server.

Internationalization service errors

Certain conditions might cause the internationalization service not to start, to issue `java.lang.IllegalStateException` exceptions while an application is running, or to exercise default behaviors.

The `java.lang.IllegalStateException` exception indicates one of the following things:

- An application component attempted an operation that is not supported by the internationalization programming model.

The `IllegalStateException` exception is issued whenever a server application component whose internationalization type is set to container-managed internationalization (CMI) attempts to set invocation context. This behavior is a violation of the CMI policy, under which servlets and enterprise beans cannot modify their invocation internationalization context.

- An anomaly occurred that disabled the service.

For instance, if the internationalization service is not properly initialized, the Java Naming and Directory Interface (JNDI) lookup on the `UserInternationalization` URL attribute issues a `javax.naming.NameNotFoundException` exception that contains an `IllegalStateException` instance.

The following conditions can occur while your internationalized application is running. These conditions might cause the internationalization service not to start, to issue `IllegalStateException` exceptions, or to exercise default behaviors:

- “The service is disabled ”
- “The service is not started” on page 785
- “Invalid context element” on page 786
- “Missing context element” on page 786
- “Invalid policy” on page 786
- “Missing policy” on page 786

If you encounter unexpected or exceptional behavior, the problem is likely related to one of these conditions. You need to examine the trace log to investigate these conditions, which requires that you configure the diagnostic trace service to generate messages about internationalization service function.

The trace strings for the internationalization service follow; use both:

```
com.ibm.ws.i18n.context.*=all=enabled;com.ibm.websphere.i18n.context.*=all=enabled
```

The service is disabled

The internationalization service is not initialized when the startup setting is cleared. The service generates a message that indicates whether it is enabled or disabled. Applications cannot access the internationalization API when the service is disabled. If an application attempts a JNDI lookup to obtain the `UserInternationalization` reference, the lookup fails with a `NamingException` exception, indicating that the reference cannot be found. In addition, the service does not scope (propagate) internationalization context on incoming (outgoing) business method calls.

The service is not started

The internationalization service is operational whenever it is in the STARTED state. For example, if an application attempts to access internationalization context and the service is not started, the API issues an `IllegalStateException` exception. In addition, the service does not provide runtime support for servlets and enterprise beans.

As an application server progresses through its life cycle, it initializes, starts, stops, and terminates (destroys) the internationalization service. If an anomaly occurs during initialization, the service does not start. After the service is started, its state can change to BLOCKED in the event that a serious error occurs. The service generates a message for every state change.

If a trace message indicates that the service is not STARTED, examine previous messages to determine the problem. For instance, the internationalization service does not start if the activity service is unavailable and a message is displayed to that effect during initialization of the internationalization service.

During startup, the following messages indicate potential configuration or runtime problems:

No ORB support

The service cannot obtain an instance of the object request broker (ORB). This condition is a fatal error. Examine the `SystemErr.log` and `SystemOut.log` files for information.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log`, `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

No TCM support

The service cannot obtain an instance of its thread context manager (TCM). This condition is a fatal error. Examine the `SystemErr.log` and `SystemOut.log` files for information.

No IIOP (activity service) support

The service cannot register with the activity service. This condition is a fatal error. The internationalization service cannot propagate or receive context on Internet Inter-ORB Protocol (IIOP) requests without activity service support. Examine the `SystemErr.log` and `SystemOut.log` files for information.

No AsynchBeans support

The service cannot register into the asynchronous beans environment. This warning indicates that the asynchronous beans environment cannot support internationalization context.

No EJB container support

The service cannot register with the Enterprise JavaBeans (EJB) container. This warning indicates that the internationalization service cannot support enterprise beans. Without EJB container support, internationalization contexts do not scope properly to EJB business methods. Review the trace log for any EJB container-related error conditions.

No Web container support

The service cannot register with the Web container. This warning indicates that the internationalization service cannot support servlets and JavaServer Page (JSP) files. Without Web container support, internationalization contexts do not scope properly to servlet service methods. Review the trace log for any Web container-related error conditions.

No Metadata support

The service cannot register with the metadata service. This warning indicates that the internationalization service cannot process the internationalization policies within application deployment descriptors. Without metadata support, the service associates the default internationalization context management policy, `[CMI, RunAsCaller]`, to every servlet lifecycle method and enterprise bean business method invocation. Review the trace log for any metadata service-related error conditions.

No JNDI (Naming service) support

The service cannot bind the `UserInternationalization` object into the namespace. This condition is a fatal error. Application components are unable to access internationalization context API references, and are therefore unable to access internationalization context elements. Review the trace log for any Naming (JNDI) service-related error conditions.

No API support

The service cannot obtain an instance of an internationalization context API object. This condition is a fatal error. Application components are unable to access internationalization context API references, and are therefore unable to access internationalization context elements.

Invalid context element

The service detected an invalid internationalization context element. For example, the internationalization service does not support `TimeZone` instances of a type other than `java.util.SimpleTimeZone`. If the service encounters an unusable element, it logs a message and substitutes the corresponding default element of the JVM.

Missing context element

The service detected a missing internationalization context element. Incoming requests (for example, from application servers that do not support the internationalization service) lack internationalization context. When the service attempts to access a caller internationalization context element (which does not exist in this case), the service logs a message and substitutes the corresponding default element of the Java virtual machine (JVM).

Whenever possible, enable the internationalization service within all clients and hosting application servers that comprise an internationalized enterprise application. Read more information about Administering the internationalization service in the *Administering applications and their environment* PDF book.

Invalid policy

The internationalization service detected a malformed internationalization policy in the application deployment descriptor. The service replaces the malformed attribute with the appropriate default. For instance, if the internationalization type for an entity bean is set to `Application` during the run of a servlet or EJB business method call, the service logs the inconsistency and enforces the `Container` setting instead.

Also, AMI application components do have an implicit container internationalization attribute. By default they run as server. The service silently enforces the implicit policy, `[AMI, RunAsServer]`, and logs messages to this effect.

Invalid container internationalization attributes are likely to occur when specifying the `Locales` and `Time zone ID` fields. When encountering invalid locales and time zone IDs within attributes, the service replaces each value with the corresponding default element of the JVM. Be sure to follow the guidelines provided in the *Developing and deploying applications* PDF book.

Missing policy

The service detected a missing internationalization policy. The service replaces the missing policy with the appropriate default. For instance, if the internationalization type is missing for a servlet or enterprise bean, the service sets the attribute to `Container`.

Container internationalization attributes are not mandatory for CMI application components. In the event that a CMI servlet or EJB business method lacks a container internationalization attribute, the service silently enforces the implicit policy `[CMI, RunAsCaller]`.

When an application lacks internationalization policies in its deployment descriptor, or metadata support is unavailable, the service logs a message and applies the policy [CMI, RunAsCaller] on every servlet service method and EJB business method invocation.

Read the information in the *Developing and deploying applications* PDF book:

- Assembling internationalized applications
- Container internationalization attributes
- Internationalization type

Chapter 14. Developing Mail, URLs, and other Java EE resources

This page provides a starting point for finding information about resources that are used by applications that are deployed on a Java Enterprise Edition (Java EE)-compliant application server. They include:

- JavaMail support for applications to send Internet mail
- URLs, for describing logical locations
- Resource environment entries, for mapping logical names to physical names
- Java DataBase Connectivity (JDBC) resources and other technology for data access (discussed elsewhere)
- Java Message Service (JMS) resources and other messaging system support (discussed elsewhere)

Developing applications that use the JavaMail API

Debugging mail sessions

When you debug a mail application, you can use the mail debugging feature. The mail component generates debugging information, on a per session basis, that can be used for problem determination or tuning.

About this task

Enabling the debug mode triggers the mail component of the application server to print the following data to the standard output stream:

- interactions with the mail servers
- properties of the mail session

This output stream is redirected to the `SystemOut.log` file for the specific application server.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log`, `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

Procedure

1. Open the administrative console.
2. Click **Resources > Mail > Mail sessions > mail session**.
3. Click **Enable debug mode**. Debugging is enabled for that session only.
4. Click **Apply** or **OK**.

Example

The following example shows sample mail debugging output:

```
ResourceMgrIm I   WSVR0049I: Binding Test as mail/test

This output illustrates a connection failure to a Simple Mail Transfer Protocol (SMTP) server because a fictitious name, `smtp.coldmail.com`, is specified as the server name.

The following list provides tips on reading the previous sample of debugger output:

- The lines headed by `DEBUG` are printed by the mail provider at run time, while the two lines headed by `***` are printed by the application server at run time.
- In the second paragraph of code, the first few lines state that some configuration files are skipped. The mail component attempts to load a number of configuration files from different locations at run time. All those files are not required. If a required file cannot be accessed, however, the mail component creates an exception. In this sample, there is no exception and the third-line announces that default providers are loaded.
- The next few lines, headed by either `Providers Listed by Class Name` or `Providers Listed by Protocols`, show the protocol providers that are loaded. The six providers that are listed are the default protocol providers that come under the built-in mail provider for the application server. If you install special service providers, and these providers are used in the current mail session, those providers are listed here with the default providers.
- The two lines headed by `***` and the few lines below them are printed by the application server to show the configuration properties of the current mail session. Although these properties are listed by their internal name rather than the name you establish in the administrative console, you can easily recognize the relationships between them. For example, the `mail.store.protocol` property corresponds to the **Protocol** property in the **Incoming Mail Properties** section of the console panel for mail session configuration. Review the listed properties and values to verify that they correspond.
- The few lines above the exception stack show the mail activities when sending a message. First, the JavaMail API recognizes that the transport protocol is set to SMTP and that the `com.sun.mail.smtp.SMTPTransport` provider exists. Next, the output log displays the `useEhlo` and `useAuth` parameters, which are used by SMTP. Finally, the log shows the SMTP provider trying to connect to the `smtp.coldmail.com` mail server.
- The output log show the exception stack next. This data indicates that the specified mail server either does not exist or is not functioning.

JavaMail API

The JavaMail APIs provide a framework that is platform and protocol independent for building mail client applications that are based on Java. The JavaMail APIs are generic for sending and reading mail. They require service providers, known in the application server as protocol providers, to interact with mail servers that run on pertaining protocols. For example, Simple Mail Transfer Protocol (SMTP) is a popular transport protocol for sending mail. Mail applications can connect to an SMTP server and send mail through it by using this SMTP protocol provider.

The application server supports the JavaMail API, Version 1.4. In the application server, the JavaMail API is supported in all web application components, namely:

- servlets
- JavaServer Pages (JSP) files
- enterprise beans
- application clients

In addition to service providers, the JavaMail API requires the JavaBeans Activation Framework (JAF) to handle mail content that is not plain text, including Multipurpose Internet Mail Extensions (MIME), URL pages, and file attachments.

The JavaMail APIs, the JAF, the service providers, and the protocols are shipped as part of the application server. The API and related specifications are repackaged from materials that are licensed to Sun Microsystems.

Note: If you are using Java 5 to run your code, you will need the JAF 1.1 package. For Java 6 and later, the JAF package is part of the run time environment.

Chapter 15. Developing Messaging resources

This page provides a starting point for finding information about the use of asynchronous messaging resources for enterprise applications with WebSphere Application Server.

WebSphere Application Server supports asynchronous messaging based on the Java Message Service (JMS) and the Java EE Connector Architecture (JCA) specifications, which provide a common way for Java programs (clients and Java EE applications) to create, send, receive, and read asynchronous requests, as messages.

JMS support enables applications to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics). Some messaging providers also allow WebSphere Application Server applications to use JMS support to exchange messages asynchronously with non-JMS applications; for example, WebSphere Application Server applications often need to exchange messages with WebSphere MQ applications. Applications can explicitly poll for messages from JMS destinations, or they can use message-driven beans to automatically retrieve messages from JMS destinations without explicitly polling for messages.

WebSphere Application Server supports the following messaging providers:

- The WebSphere Application Server default messaging provider (which uses service integration as the provider).
- The WebSphere MQ messaging provider (which uses your WebSphere MQ system as the provider).
- Third-party messaging providers that implement either a JCA Version 1.5 resource adapter or the ASF component of the JMS Version 1.0.2 specification.

Programming to use asynchronous messaging

You can build enterprise applications that use Java Message Service (JMS) APIs directly to provide asynchronous messaging services. You can also use message-driven beans as asynchronous message consumers. If you are writing messaging programs that interoperate between WebSphere Application Server and WebSphere MQ, there are some environmental differences that you need to take into account.

About this task

Enterprise applications can use JMS APIs directly to explicitly poll for messages on a JMS destination, then retrieve messages for processing by business logic beans (enterprise beans).

Message-driven beans can also be used as asynchronous message consumers. When a message arrives at the destination, the EJB container invokes the message-driven bean automatically without an application having to explicitly poll the destination.

Procedure

- “Programming to use JMS and messaging directly” on page 794.
Your enterprise applications can use Java Message Service (JMS) programming interfaces directly to provide messaging services, and methods that implement business logic.
If you choose not to use JNDI to obtain configuration information for your messaging provider, for example for connection factories or destinations, you can instead use an API provided by your messaging provider to specify that configuration information programmatically.
- Chapter 17, “Programming for interoperation with WebSphere MQ,” on page 817
There are some differences between the WebSphere Application Server environment and the WebSphere MQ environment. If you are writing messaging programs that interoperate between these two environments, you should be aware of these differences and take them into account when designing, coding and deploying your programs.

- “Programming to use message-driven beans” on page 626.
Applications can use message-driven beans as asynchronous message consumers. You deploy a message-driven bean as a message listener for a destination. When a message arrives at the destination, the EJB container invokes the message-driven bean automatically without an application having to explicitly poll the destination.

Asynchronous beans - WebSphere Trader sample application

The Asynchronous beans - WebSphere Trader sample application illustrates how to implement a streaming stock ticker server and client using asynchronous beans and Java Platform, Enterprise Edition (Java EE) services such as:

- Servlets
- Java Message Service (JMS)
- Session enterprise beans
- Container-managed persistence (CMP) 2.0 enterprise beans
- Message-driven beans (MDB)

This sample uses several parts to maximize the utilization of a server:

- Work - Runs Java EE context-aware code on a thread.
- Alarm - Runs Java EE context-aware code at a given time interval.
- EventSource - A method of broadcasting events to registered listeners.
- SubsystemMonitor - A thread that monitors the status of any asynchronous system and uses an EventSource method to inform registered listeners of the system status.
- WorkManager - Thread configuration and Java EE context policies that are used by various asynchronous beans parts.
- AsynchScope - A collection of alarms, subsystem monitors and other asynchronous scopes that support relationships. This collection uses a single WorkManager thread and is also an event source.
- Startup Bean - A specialized, stateful session enterprise bean that supports bootstrapping asynchronous work when the application starts.

This sample is available from the Samples section of the information center.

Programming to use JMS and messaging directly

Your enterprise applications can use Java Message Service (JMS) programming interfaces directly to provide messaging services, and methods that implement business logic.

About this task

WebSphere Application Server supports asynchronous messaging as a method of communication based on JMS programming interfaces. Using JMS, enterprise applications can exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics). An enterprise application can explicitly poll for messages on a destination.

If you choose not to use JNDI to obtain configuration information for your messaging provider, for example for connection factories or destinations, you can instead use an API provided by your messaging provider to specify that configuration information programmatically.

If you want to transmit messages between JMS applications and traditional WebSphere MQ applications, you must consider how the JMS message structure is mapped onto a WebSphere MQ message . This includes scenarios where you want to use WebSphere MQ to manipulate messages transmitted between two JMS applications; for example, by using WebSphere MQ as a message broker.

By default, JMS messages held on WebSphere MQ queues use an MQRFH2 header to hold some of the JMS message header information. Many traditional WebSphere MQ applications cannot process messages with these headers, and require their own characteristic headers, for example the MQWIH for WebSphere MQ Workflow applications. For more information about how the JMS message structure is mapped onto a WebSphere MQ message, see the section *Mapping JMS messages* in the WebSphere MQ information center.

Example

This following example shows how to programmatically configure a resource for the default messaging provider.

In this example, a JMS connection to a service integration bus is created by using the API in the `com.ibm.websphere.sib` package. This is an alternative to using JNDI to look up administratively configured connection factories. After the connection is established, the sample program reads lines of input from the console and sends them as JMS text messages to the specified destination.

This example can be run as a thin client application, or as a stand-alone client application.

    }
}
}
}

```

Designing an enterprise application to use JMS

There are many things to consider when designing an enterprise application to use the JMS APIs directly for asynchronous messaging.

Procedure

- For messaging operations, you should write application programs that use only references to the interfaces defined in Sun's `javax.jms` package.

JMS defines a generic view of messaging that maps onto the underlying transport. An enterprise application that uses JMS makes use of the following interfaces that are defined in Sun's `javax.jms` package:

Connection

Provides access to the underlying transport, and is used to create Sessions.

Session

Provides a context for producing and consuming messages, including the methods used to create `MessageProducers` and `MessageConsumers`.

MessageProducer

Used to send messages.

MessageConsumer

Used to receive messages.

The generic JMS interfaces are subclassed into the following more specific versions for point-to-point and publish/subscribe behavior.

Table 92. The point-to-point and publish/subscribe versions of JMS common interfaces. The first column of this table lists the JMS common interfaces, the second column lists the corresponding point-to-point interfaces, and the third column lists the corresponding publish/subscribe interfaces.

JMS common interfaces	Point-to-point interfaces	Publish/subscribe interfaces
ConnectionFactory	QueueConnectionFactory	TopicConnectionFactory
Connection	QueueConnection	TopicConnection
Destination	Queue	Topic
Session	QueueSession,	TopicSession,
MessageProducer	QueueSender	TopicPublisher
MessageConsumer	QueueReceiver, QueueBrowser	TopicSubscriber

For more information about using these JMS interfaces, see the Java Message Service Documentation and the *Using Java* section of the WebSphere MQ information center.

The section “Java Message Service (JMS) Requirements” of the J2EE specification gives a list of methods that must not be called in web and EJB containers:

```

javax.jms.Session method setMessageListener
javax.jms.Session method getMessageListener
javax.jms.Session method run
javax.jms.QueueConnection method createConnectionConsumer
javax.jms.TopicConnection method createConnectionConsumer
javax.jms.TopicConnection method createDurableConnectionConsumer
javax.jms.MessageConsumer method getMessageListener
javax.jms.MessageConsumer method setMessageListener
javax.jms.Connection setExceptionListener
javax.jms.Connection stop
javax.jms.Connection setClientID
    
```

This method restriction is enforced in WebSphere Application Server by throwing a `javax.jms.IllegalStateException` exception.

- Applications refer to JMS resources that are predefined, as administered objects, to WebSphere Application Server.

Details of JMS resources that are used by enterprise applications are defined to WebSphere Application Server and bound into the JNDI namespace by the WebSphere administrative support. An enterprise application can retrieve these objects from the JNDI namespace and use them without needing to know anything about their implementation. This enables the underlying messaging architecture defined by the JMS resources to be changed without requiring changes to the enterprise application.

Table 93. JMS resources for point-to-point and publish/subscribe messaging. The left hand column of this table lists the JMS resources for point-to-point messaging, and the right hand column lists the JMS resources for publish/subscribe.

Point-to-point	Publish/subscribe
ConnectionFactory (or QueueConnectionFactory) Queue	ConnectionFactory (or TopicConnectionFactory) Topic

A connection factory is used to create connections from the JMS provider to the messaging system, and encapsulates the configuration parameters needed to create connections.

- To improve performance, the application server pools connections and sessions with the JMS provider. You have to configure the connection and session pool properties appropriately for your applications, otherwise you might not get the connection and session behavior that you want.
- Applications must not cache JMS connections, sessions, producers or consumers. WebSphere Application Server closes these objects when a bean or servlet completes, and so any attempt to use a cached object will fail with a `javax.jms.IllegalStateException` exception.

To improve performance, applications can cache JMS objects that have been looked up from JNDI. For example, an EJB or servlet needs to look up a JMS ConnectionFactory only once, but it must call the

createConnection method on each instantiation. Because of the effect of pooling on connections and sessions with the JMS provider, there should be no performance impact.

- A non-durable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created.
- Using durable subscriptions with the default messaging provider. A durable subscription on a JMS topic enables a subscriber to receive a copy of all messages published to that topic, even after periods of time when the subscriber is not connected to the server. Therefore, subscriber applications can operate disconnected from the server for long periods of time, and then reconnect to the server and process messages that were published during their absence. If an application creates a durable subscription, it is added to the runtime list that administrators can display and act on through the administrative console.

Each durable subscription is given a unique identifier, *clientID##subName* where:

clientID

The client identifier used to associate a connection and its objects with the messages maintained for applications (as clients of the JMS provider). You should use a naming convention that helps you identify the applications, in case you have to relate durable subscriptions to the associated applications for runtime administration.

subName

The subscription name used to uniquely identify a durable subscription within a given client identifier.

For durable subscriptions created by message-driven beans, these values are set on the JMS activation specification. For other durable subscriptions, the client identifier is set on the JMS connection factory, and the subscription name is set by the application on the createDurableSubscriber operation.

To create a durable subscription to a topic, an application uses the createDurableSubscriber operation defined in the JMS API:

```
public TopicSubscriber createDurableSubscriber(Topic topic,
                                             java.lang.String subName,
                                             java.lang.String messageSelector,
                                             boolean noLocal)
    throws JMSException
```

topic The name of the JMS topic to subscribe to. This is the name of an object supporting the javax.jms.Topic interfaces, such as found by looking up a suitable JNDI entry.

subName

The name used to identify this subscription.

messageSelector

Only messages with properties matching the message selector expression are delivered to consumers. A value of null or an empty string indicates that all messages should be delivered.

noLocal

If set to true, this parameter prevents the delivery of messages published on the same connection as the durable subscriber.

Applications can use a two argument form of the createDurableSubscriber operation that takes only topic and subName parameters. This alternative call directly invokes the four argument version shown above, but sets messageSelector to null (so all messages are delivered) and sets noLocal to false (so messages published on the connection are delivered). For example, to create a durable subscription to the topic called myTopic, with the subscription name of mySubscription:

```
session.createDurableSubscriber(myTopic, "mySubscription");
```

If the createDurableSubscription operation fails, it throws a JMS exception that provides a message and linked exception to give more detail about the cause of the problem.

To delete a durable subscription, an application uses the unsubscribe operation defined in the JMS API. In normal operation there can be at most one active (connected) subscriber for a durable subscription at a time. However, the subscriber application can be running in a cloned application server, for failover

and load balancing purposes. In this case the “one active subscriber” restriction is lifted to provide a shared durable subscription that can have multiple simultaneous consumers.

For more information about application use of durable subscriptions, see the section “Using Durable Subscriptions” in the JMS specification.

- Decide what message selectors are needed. You can use the JMS message selector mechanism to select a subset of the messages on a queue so that this subset is returned by a receive call. The selector can refer to fields in the JMS message header and fields in the message properties.
- Acting on messages received. When a message is received, you can act on it as needed by the business logic of the application. Some general JMS actions are to check that the message is of the correct type and extract the content of the message. To extract the content from the body of the message, cast from the generic Message class (which is the declared return type of the receive methods) to the more specific subclass, such as TextMessage. It is good practice always to test the message class before casting, so that unexpected errors can be handled gracefully.

In this example, the instanceof operator is used to check that the message received is of the TextMessage type. The message content is then extracted by casting to the TextMessage subclass.

```
if ( inMessage instanceof TextMessage )
```

```
...
```

```
String replyString = ((TextMessage) inMessage).getText();
```

- JMS applications using the default messaging provider can access, without any restrictions, the content of messages that have been received from WebSphere Application Server Version 5 embedded messaging or WebSphere MQ.
- JMS applications can access the full set of JMS_IBM* properties. These properties are of value to JMS applications that use resources provided by the default messaging provider, the V5 default messaging provider, or the WebSphere MQ provider.
For messages handled by WebSphere MQ, the JMS_IBM* properties are mapped to equivalent WebSphere MQ Message Descriptor (MQMD) fields. For more information about the JMS_IBM* properties and MQMD fields, see the *Using Java* section of the WebSphere MQ information center.
- JMS applications can use report messages as a form of managed request/response processing, to give remote feedback to producers on the outcome of their send operations and the fate of their messages. JMS applications can request a full range of report options using **JMS_IBM_Report_Xxxx** message properties. For more information about using JMS report messages, see “JMS report messages” on page 801.
- JMS applications can use the **JMS_IBM_Report_Discard_Msg** property to control how a request message is disposed of if it cannot be delivered to the destination queue.

MQRO_Dead_Letter_Queue

This is the default. The request message should be written to the dead letter queue.

MQRO_Discard

The request message should be discarded. This is usually used in conjunction with MQRO_Exception_With_Full_Data to return an undeliverable request message to its sender.

- Using a listener to receive messages asynchronously. In a client, not in a servlet or enterprise bean, an alternative to making calls to QueueReceiver.receive() is to register a method that is called automatically when a suitable message is available; for example:

```
...
MyClass listener =new MyClass();
queueReceiver.setMessageListener(listener);
//application continues with other application-specific behavior.
...
```

When a message is available, it is retrieved by the onMessage() method on the listener object.

```
import javax.jms.*;
public class MyClass implements MessageListener
{
    public void onMessage(Message message)
```

```

{
System.out.println("message is "+message);
//application specific processing here
...
}
}

```

For asynchronous message delivery, the application code cannot catch exceptions raised by failures to receive messages. This is because the application code does not make explicit calls to receive() methods. To cope with this situation, you can register an ExceptionListener, which is an instance of a class that implements the onException() method. When an error occurs, this method is called with the **JMSException** passed as its only parameter.

For more details about using listeners to receive messages asynchronously, see the Java Message Service Documentation.

Note: An alternative to developing your own JMS listener class, you can use a message-driven bean, as described in Programming with message-driven beans.

- If you want to use authentication with WebSphere MQ or the Version 5 Embedded Messaging support, you cannot have user IDs longer than 12 characters. For example, the default Windows NT user ID, **administrator**, is not valid for use with WebSphere internal messaging, because it contains 13 characters.
- The following points, as defined in the EJB specification, apply to the use of flags on createxxxSession calls:
 - The transacted flag passed on createxxxSession is ignored inside a global transaction and all work is performed as part of the transaction. Outside of a transaction the transacted flag is used and, if set to true, the application should use session.commit() and session.rollback() to control the completion of the work. In an EJB2.0 module, if the transacted flag is set to true and outside of an XA transaction, then the session is involved in the WebSphere local transaction and the unresolved action attribute of the method applies to the JMS work if it is not committed or rolled back by the application.
 - Clients cannot use Message.acknowledge() to acknowledge messages. If a value of CLIENT_ACKNOWLEDGE is passed on the createxxxSession call, then messages are automatically acknowledged by the application server and Message.acknowledge() is not used.
- If you want your application to use WebSphere MQ as an external JMS provider, then send messages within a container-managed transaction.

When you use WebSphere MQ as an external JMS provider, messages sent within a user-managed transaction can arrive before the transaction commits. This occurs only when you use WebSphere MQ as an external JMS provider, and you send messages to a WebSphere MQ queue within a user-managed transaction. The message arrives on the destination queue before the transaction commits.

The cause of this problem is that the WebSphere MQ resource manager has not been enlisted in the user-managed transaction.

The solution is to use a container-managed transaction.

JMS report messages:

JMS applications can use report messages as a form of managed request/response processing, to give remote feedback to producers on the outcome of their send operations and the fate of their messages.

JMS applications can request the following types of report message by setting appropriate JMS_IBM_Report_Xxxx message properties and options. The options have the same general syntax and meaning:

MQRO_report-type

A report message of the indicated type is generated that contains the MQMD of the original message. It does not contain any message body data.

MQRO_report-type_WITH_DATA

A report message of the indicated type is generated that contains the MQMD, any MQ headers, and 100 bytes of body data.

MQRO_report-type_WITH_FULL_DATA

A report message of the indicated type is generated that contains all data from the original message.

Use the following prefix with each option: com.ibm.websphere.sib.api.jms.

For example, to request a Confirm on delivery (COD) report message with full data, the JMS application must set JMS_IBM_Report_COD to the value com.ibm.websphere.sib.api.jms.MQRO_COD_WITH_FULL_DATA.

Type of report message	Description	JMS_IBM_Report_Xxxx message property and options
Exception	Send a report message if the request message cannot be put to the target queue. The exception report messages are generated when a message has been rerouted to an exception destination.	JMS_IBM_Report_Exception <ul style="list-style-type: none"> • MQRO_EXCEPTION • MQRO_EXCEPTION_WITH_DATA • MQRO_EXCEPTION_WITH_FULL_DATA
Discard	Discard the original request message rather than sending it to an exception destination. You can use this option with the JMS_IBM_Report_Exception property set to MQRO_EXCEPTION_WITH_FULL_DATA to return an undeliverable request message to its sender.	JMS_IBM_Report_Discard_Msg <ul style="list-style-type: none"> • TRUE • FALSE
Expiration	Send a report message if the request message passes its expiry time.	JMS_IBM_Report_Expiration <ul style="list-style-type: none"> • MQRO_EXPIRATION • MQRO_EXPIRATION_WITH_DATA • MQRO_EXPIRATION_WITH_FULL_DATA
Confirm on arrival (COA)	<p>Send a report message when the request message has been put to the target queue.</p> <p>For publish/subscribe messaging, the COA report message is generated only on the producers messaging engine. Therefore, such reports are relevant only to local subscriptions.</p> <p>For point-to-point messaging, COA messages are generated when the message arrives at the final destination. For partitioned queues, the report message is generated only when the put operation has committed and a final destination has therefore been selected. Any With_Data or With_Full_Data report options specified are ignored; the COA report message deals only with message headers.</p> <p>If a forward-routing path is used, the COA message are generated when the message arrives at the final destination in the path.</p>	JMS_IBM_Report_COA <ul style="list-style-type: none"> • MQRO_COA • MQRO_COA_WITH_DATA • MQRO_COA_WITH_FULL_DATA

Type of report message	Description	JMS_IBM_Report_Xxxx message property and options
Confirm on delivery (COD)	<p>Send a report message when the request message has been removed from the queue or topic space by a message consumer.</p> <p>For publish/subscribe messaging, the COD message is generated when all subscribers have received the request message. Therefore, there is one COD message generated for every COA. When a message is consumed by a subscriber, the reference count of the message on the topic space is reduced. When the reference count reaches zero, the message is removed from the topic space then a COD report message is generated.</p> <p>For point-to-point messaging, the COD message is generated after the message has been successfully received by a consuming application. Any With_Data or With_Full_Data report options specified are ignored; the COD report message deals only with message headers.</p>	<p>JMS_IBM_Report_COD</p> <ul style="list-style-type: none"> • MQRO_COD • MQRO_COD_WITH_DATA • MQRO_COD_WITH_FULL_DATA
Positive action notification (PAN)	Ask the consumer application to send a report message when it has successfully processed the request message.	<p>JMS_IBM_Report_PAN</p> <ul style="list-style-type: none"> • TRUE • FALSE
Negative action notification (NAN)	Ask the consumer application to send a report message if it has not successfully processed the request message.	<p>JMS_IBM_Report_NAN</p> <ul style="list-style-type: none"> • TRUE • FALSE

The requesting application can control other aspects of the report message as follows:

- How the message Id is generated for the report message and any reply message:

MQRO_New_Msg_Id

This the default. A new message Id is generated for the report message.

MQRO_Pass_Msg_Id

The message Id of the report message is set to the message Id of the request message.

- How the correlation Id of the report or reply message is to be set.

MQRO_Copy_Msg_Id_To_Correl_Id

This the default. the correlation Id of the report message is set to the message Id of the request message.

MQRO_Pass_Correl_Id

The correlation Id of the report message is set to the correlation Id of the request message.

For more information about report messages and the associated properties and options, see the *Report messages* section of the WebSphere MQ information center.

Developing an enterprise application to use JMS

Use this task to develop an enterprise application to use the JMS API directly for asynchronous messaging.

About this task

This topic gives an overview of the steps needed to develop an enterprise application (servlet or enterprise bean) to use the JMS API directly for asynchronous messaging.

This topic only describes the JMS-related case; it does not describe general enterprise application programming, which you should already be familiar with. For detailed information about these steps, and for examples of developing an enterprise application to use JMS, see the [Java Message Service Documentation](#)

Details of JMS resources that are used by enterprise applications are defined to WebSphere Application Server and bound into the JNDI namespace by the WebSphere Application Server administrative support.

To use JMS, complete the following general steps:

Procedure

1. Import JMS packages. An enterprise application that uses JMS starts with a number of import statements for JMS, which should include at least the following statements:

```
import javax.jms.*;           //JMS interfaces
import javax.naming.*;       //Used for JNDI lookup of administered objects
```

2. Get an initial context:

```
try {
    ctx = new InitialContext(env);
    ...
}
```

3. Retrieve administered objects from the JNDI namespace. The `InitialContext.lookup()` method is used to retrieve administered objects (a JMS connection factory and JMS destinations). The following example shows how to receive a message from a queue:

```
qcf = (QueueConnectionFactory)ctx.lookup( qcfName );
...
inQueue = (Queue)ctx.lookup( qnameIn );
...
```

An alternative, but less manageable, approach to obtaining administratively-defined JMS destination objects by JNDI lookup is to use the `Session.createQueue(String)` method or `Session.createTopic(String)` method. For example:

```
Queue q = mySession.createQueue("Q1");
```

creates a JMS Queue instance that can be used to reference the existing destination Q1.

In its simplest form, the parameter to these create methods is the name of an existing destination. For more complex situations, applications can use a URI-based format, which allows an arbitrary number of name value pairs to be supplied to set various properties of the JMS destination object.

4. Create a connection to the messaging service provider. The connection provides access to the underlying transport, and is used to create sessions. The `createQueueConnection()` method on the factory object is used to create the connection.

```
connection = qcf.createQueueConnection();
```

The JMS specification defines that connections should be created in the stopped state. Until the connection starts, `MessageConsumers` that are associated with the connection cannot receive any messages. To start the connection, issue the following command:

```
connection.start();
```

5. Create a session, for sending or receiving messages. The session provides a context for producing and consuming messages, including the methods used to create `MessageProducers` and `MessageConsumers`. The `createQueueSession` method is used on the connection to obtain a session. The method takes two parameters:
 - A boolean that determines whether the session is transacted.
 - A parameter that determines the acknowledge mode.

```

boolean transacted = false;
session = connection.createQueueSession( transacted,
                                         Session.AUTO_ACKNOWLEDGE);

```

In this example, the session is not transacted, and it should automatically acknowledge received messages. With these settings, a message is backed out only after a system error or if the application terminates unexpectedly.

The following points, as defined in the EJB specification, apply to these flags:

- The transacted flag passed on createQueueSession is ignored inside a global transaction and all work is performed as part of the transaction. Outside of a transaction the transacted flag is used and, if set to true, the application should use session.commit() and session.rollback() to control the completion of the work. In an EJB2.0 module, if the transacted flag is set to true and outside of an XA transaction, then the session is involved in the WebSphere local transaction and the unresolved action attribute of the method applies to the JMS work if it is not committed or rolled back by the application.
- Clients cannot use Message.acknowledge() to acknowledge messages. If a value of CLIENT_ACKNOWLEDGE is passed on the createQueueSession call, then messages are automatically acknowledged by the application server and Message.acknowledge() is not used.

6. Send a message.

- a. Create MessageProducers to create messages. For point-to-point messaging the MessageProducer is a QueueSender that is created by passing an output queue object (retrieved earlier) into the createSender method on the session. A QueueSender is usually created for a specific queue, so that all messages sent by that sender are sent to the same destination.

```
QueueSender queueSender = session.createSender(inQueue);
```

- b. Create the message. Use the session to create an empty message and add the data passed. JMS provides several message types, each of which embodies some knowledge of its content. To avoid referencing the vendor-specific class names for the message types, methods are provided on the Session object for message creation.

In this example, a text message is created from the outString property:

```
TextMessage outMessage = session.createTextMessage(outString);
```

- c. Send the message.

To send the message, the message is passed to the send method on the QueueSender:

```
queueSender.send(outMessage);
```

7. Receive replies.

- a. Create a correlation ID to link the message sent with any replies. In this example, the client receives reply messages that are related to the message that it has sent, by using a provider-specific message ID in a JMSCorrelationID.

```
messageID = outMessage.getJMSMessageID();
```

The correlation ID is then used in a message selector, to select only messages that have that ID:

```
String selector = "JMSCorrelationID = '"+messageID+"'";
```

- b. Create a MessageReceiver to receive messages. For point-to-point the MessageReceiver is a QueueReceiver that is created by passing an input queue object (retrieved earlier) and the message selector into the createReceiver method on the session.

```
QueueReceiver queueReceiver = session.createReceiver(outQueue, selector);
```

- c. Retrieve the reply message. To retrieve a reply message, the receive method on the QueueReceiver is used:

```
Message inMessage = queueReceiver.receive(2000);
```

The parameter in the receive call is a timeout in milliseconds. This parameter defines how long the method should wait if there is no message available immediately. If you omit this parameter, the call blocks indefinitely. If you do not want any delay, use the receiveNoWait() method. In this example, the receive call returns when the message arrives, or after 2000ms, whichever is sooner.

- d. Act on the message received. When a message is received, you can act on it as needed by the business logic of the client. Some general JMS actions are to check that the message is of the correct type and extract the content of the message. To extract the content from the body of the message, it is necessary to cast from the generic Message class (which is the declared return type of the receive methods) to the more specific subclass, such as TextMessage. It is good practice always to test the message class before casting, so that unexpected errors can be handled gracefully.

In this example, the instanceof operator is used to check that the message received is of the TextMessage type. The message content is then extracted by casting to the TextMessage subclass.

```
if ( inMessage instanceof TextMessage )
```

```
...
```

```
String replyString = ((TextMessage) inMessage).getText();
```

8. Closing down. If the application needs to create many short-lived JMS objects at the Session level or lower, it is important to close all the JMS resources used. To do this, you call the close() method on the various classes (QueueConnection, QueueSession, QueueSender, and QueueReceiver) when the resources are no longer required.

```
queueReceiver.close();
```

```
...
```

```
queueSender.close();
```

```
...
```

```
session.close();  
session = null;
```

```
...
```

```
connection.close();  
connection = null;
```

9. Publishing and subscribing to messages. To use JMS Publish/Subscribe support instead of point-to-point messaging, the general actions are the same; for example, to create a session and connection. The exceptions are that topic resources are used instead of queue resources (such as TopicPublisher instead of QueueSender), as shown in the following example to publish a message:

```
// Creating a TopicPublisher  
TopicPublisher pub = session.createPublisher(topic);  
...  
pub.publish(outMessage);  
...  
// Closing TopicPublisher  
pub.close();
```

10. Handling errors Any JMS runtime errors are reported by exceptions. The majority of methods in JMS throw JMSEExceptions to indicate errors. It is good programming practice to catch these exceptions and display them on a suitable output.

Unlike normal Java exceptions, a JMSEException can contain another exception embedded in it. The implementation of JMSEException does not include the embedded exception in the output of its toString() method. Therefore, you must check explicitly for an embedded exception and print it out, as shown in the following example:

```
catch (JMSEException je)  
{  
    System.out.println("JMS failed with "+je);  
    Exception le = je.getLinkedException();  
    if (le != null)  
    {  
        System.out.println("linked exception "+le);  
    }  
}
```

What to do next

After you have packaged your application, you can next deploy the application into WebSphere Application Server, as described in Chapter 16, “Deploying an enterprise application to use JMS,” on page 815.

Developing a JMS client

Use this task to develop a JMS client application to use messages to communicate with enterprise applications.

About this task

This topic gives an overview of the steps needed to develop a JMS client application. This topic only describes the JMS-related case; it does not describe general client programming, which you should already be familiar with. For detailed information about these steps, and for examples of developing JMS clients, see the Java Message Service Documentation and the *Using Java* section of the WebSphere MQ information center.

A JMS client assumes that the JMS resources (such as a queue connection factory and queue destination) already exist. A client application can obtain suitable JMS resources either by JNDI lookup or programmatically without using JNDI.

For information about the Thin Client for JMS with WebSphere Application Server, which is an embeddable technology that provides JMS V1.1 connections to a WebSphere Application Server default messaging provider messaging engine, see [../ae/tjj_jmsthcli.dita](#).

For more information about developing client applications and configuring JMS resources for them, see [Developing J2EE application client code and related tasks](#).

To use JMS, a typical JMS client program completes the following general steps. This example is based on the use of JNDI lookups to obtain JMS resources.

Procedure

1. Import JMS packages. An enterprise application that uses JMS starts with a number of import statements for JMS; for example:

```
import javax.naming.Context;
import javax.naming.InitialContext;
import javax.rmi.PortableRemoteObject;
import javax.jms.*;
```

2. Get an initial context.

```
try {
    ctx = new InitialContext(env);
    ...
}
```

3. Define the parameters that the client is to use; for example, to identify the queue connection factory and to assemble a message to be sent.

```
public class JMSppSampleClient
{
    public static void main(String[] args)
        throws JMSEException, Exception
    {
        String messageID           = null;
        String outString           = null;
        String qcfName             = "java:comp/env/jms/ConnectionFactory";
        String qnameIn             = "java:comp/env/jms/Q1";
        String qnameOut            = "java:comp/env/jms/Q2";
        boolean verbose            = false;
```

```

QueueSession      session    = null;
QueueConnection   connection = null;
Context           ctx         = null;

QueueConnectionFactory qcf      = null;
Queue             inQueue     = null;
Queue             outQueue    = null;

```

...

4. Retrieve administered objects from the JNDI namespace. The `InitialContext.lookup()` method is used to retrieve administered objects (a queue connection factory and the queue destinations):

```
qcf = (QueueConnectionFactory)ctx.lookup( qcfName );
```

...

```
inQueue = (Queue)ctx.lookup( qnameIn );
outQueue = (Queue)ctx.lookup( qnameOut );
```

...

5. Create a connection to the messaging service provider. The connection provides access to the underlying transport, and is used to create sessions. The `createQueueConnection()` method on the factory object is used to create the connection.

```
connection = qcf.createQueueConnection();
```

The JMS specification defines that connections should be created in the stopped state. Until the connection starts, `MessageConsumers` that are associated with the connection cannot receive any messages. To start the connection, issue the following command:

```
connection.start();
```

6. Create a session, for sending and receiving messages. The session provides a context for producing and consuming messages, including the methods used to create `MessageProducers` and `MessageConsumers`. The `createQueueSession` method is used on the connection to obtain a session. The method takes two parameters:

- A boolean that determines whether the session is transacted.
- A parameter that determines the acknowledge mode.

```
boolean transacted = false;
session = connection.createQueueSession( transacted,
                                         Session.AUTO_ACKNOWLEDGE);
```

In this example, the session is not transacted, and it should automatically acknowledge received messages. With these settings, a message is backed out only after a system error or if the client application terminates unexpectedly.

7. Send the message.

- a. Create `MessageProducers` to create messages. For point-to-point the `MessageProducer` is a `QueueSender` that is created by passing an output queue object (retrieved earlier) into the `createSender` method on the session. A `QueueSender` is usually created for a specific queue, so that all messages sent by that sender are sent to the same destination.

```
QueueSender queueSender = session.createSender(inQueue);
```

- b. Create the message. Use the session to create an empty message and add the data passed.

JMS provides several message types, each of which embodies some knowledge of its content. To avoid referencing the vendor-specific class names for the message types, methods are provided on the `Session` object for message creation.

In this example, a text message is created from the `outString` property, which could be provided as an input parameter on invocation of the client program or constructed in some other way:

```
TextMessage outMessage = session.createTextMessage(outString);
```

- c. Send the message.

To send the message, the message is passed to the `send` method on the `QueueSender`:

```
queueSender.send(outMessage);
```

8. Receive replies.

- a. Create a correlation ID to link the message sent with any replies. In this example, the client receives reply messages that are related to the message that it has sent, by using a provider-specific message ID in a `JMSCorrelationID`.

```
messageID = outMessage.getJMSMessageID();
```

The correlation ID is then used in a message selector, to select only messages that have that ID:

```
String selector = "JMSCorrelationID = '"+messageID+"'";
```

- b. Create a `MessageReceiver` to receive messages. For point-to-point the `MessageReceiver` is a `QueueReceiver` that is created by passing an input queue object (retrieved earlier) and the message selector into the `createReceiver` method on the session.

```
QueueReceiver queueReceiver = session.createReceiver(outQueue, selector);
```

- c. Retrieve the reply message. To retrieve a reply message, the `receive` method on the `QueueReceiver` is used:

```
Message inMessage = queueReceiver.receive(2000);
```

The parameter in the `receive` call is a timeout in milliseconds. This parameter defines how long the method should wait if there is no message available immediately. If you omit this parameter, the call blocks indefinitely. If you do not want any delay, use the `receiveNoWait()` method. In this example, the `receive` call returns when the message arrives, or after 2000ms, whichever is sooner.

- d. Act on the message received. When a message is received, you can act on it as needed by the business logic of the client. Some general JMS actions are to check that the message is of the correct type and extract the content of the message. To extract the content from the body of the message, cast from the generic `Message` class (which is the declared return type of the `receive` methods) to the more specific subclass, such as `TextMessage`. It is good practice always to test the message class before casting, so that unexpected errors can be handled gracefully.

In this example, the `instanceof` operator is used to check that the message received is of the `TextMessage` type. The message content is then extracted by casting to the `TextMessage` subclass.

```
if ( inMessage instanceof TextMessage )
```

```
...
```

```
String replyString = ((TextMessage) inMessage).getText();
```

9. Closing down. If the application needs to create many short-lived JMS objects at the `Session` level or lower, it is important to close all the JMS resources used. To do this, you call the `close()` method on the various classes (`QueueConnection`, `QueueSession`, `QueueSender`, and `QueueReceiver`) when the resources are no longer required.

```
queueReceiver.close();
```

```
...
```

```
queueSender.close();
```

```
...
```

```
session.close();  
session = null;
```

```
...
```

```
connection.close();  
connection = null;
```

10. Publishing and subscribing messages. To use `publish/subscribe` support instead of point-to-point messaging, the general client actions are the same; for example, to create a session and connection. The exceptions are that topic resources are used instead of queue resources (such as `TopicPublisher` instead of `QueueSender`), as shown in the following example to publish a message:

```
// Creating a TopicPublisher
```

```
TopicPublisher pub = session.createPublisher(topic);
```

```
...
```

```
pub.publish(outMessage);
```

```
...
```

```
// Closing TopicPublisher  
pub.close();
```

11. Handling errors Any JMS runtime errors are reported by exceptions. The majority of methods in JMS throw `JMSEExceptions` to indicate errors. It is good programming practice to catch these exceptions and display them on a suitable output.

Unlike normal Java exceptions, a `JMSEException` can contain another exception embedded in it. The implementation of `JMSEException` does not include the embedded exception in the output of its `toString()` method. Therefore, you must check explicitly for an embedded exception and print it out, as shown in the following example:

```
catch (JMSEException je)
{
    System.out.println("JMS failed with "+je);
    Exception le = je.getLinkedException();
    if (le != null)
    {
        System.out.println("linked exception "+le);
    }
}
```

What to do next

For information about running a client against a specific remote server: “Running a Java EE client application with `launchClient`” on page 301.

JMS interfaces

WebSphere Application Server supports applications that use JMS 1.1 domain-independent interfaces (referred to as “common interfaces” in the JMS specification) and JMS 1.0.2 domain-specific interfaces.

With JMS 1.1, the preferred approach for implementing applications is to use common interfaces because they provide a simpler programming model than domain-specific interfaces. Also, applications can create both queues and topics in the same session and coordinate their use in the same transaction. Common interfaces are parents of domain-specific interfaces.

Note: Domain-specific interfaces (provided for JMS 1.0.2 in WebSphere Application Server Version 5) are supported only to provide compatibility for applications that have already been implemented to use those interfaces.

Table 94. The point-to-point and publish/subscribe versions of JMS common interfaces. The first column of the table lists the JMS common interfaces. The second column lists the point-to-point versions of the JMS common interfaces. The third column lists the publish/subscribe versions of the JMS common interfaces.

JMS common interfaces	Point-to-point interfaces	Publish/subscribe interfaces
ConnectionFactory	QueueConnectionFactory	TopicConnectionFactory
Connection	QueueConnection	TopicConnection
Destination	Queue	Topic
Session	QueueSession	TopicSession,
MessageProducer	QueueSender	TopicPublisher
MessageConsumer	QueueReceiver, QueueBrowser	TopicSubscriber

For more information about JMS interfaces, see the JMS documentation at <http://java.sun.com/products/jms/docs.html>.

Example: Programmatically configuring a resource for the default messaging provider

In this example, a JMS connection to a service integration bus is created by using the API in the `com.ibm.websphere.sib` package. This is an alternative to using JNDI to look up administratively configured

connection factories. After the connection is established, the example reads lines of input from the console and sends them as JMS text messages to the specified destination.

This example can be run as a thin client application, or as a stand-alone client application.

    // Setter methods could be called here to configure the queue
    dest = queue;
}

// Create a unified JMS connection factory
JmsConnectionFactory connFact = jmsFact.createConnectionFactory();

// Configure the connection factory
connFact.setBusName(busName);
connFact.setProviderEndpoints(providerEndpoints);
connFact.setTargetTransportChain(targetTransportChain);

// Create the connection
Connection conn = connFact.createConnection();

Session session = null;
MessageProducer producer = null;
try {

    // Create a session
    session = conn.createSession(false, // Not transactional
                                 Session.AUTO_ACKNOWLEDGE);

    // Create a message producer
    producer = session.createProducer(dest);

    // Loop reading lines of text from the console to send
    System.out.println("Ready to send to " + dest + " on bus " + busName);
    BufferedReader lineInput = new BufferedReader(new InputStreamReader(System.in));
    String line = lineInput.readLine();
    while (line != null && line.length() > 0) {

        // Create a text message containing the line
        TextMessage message = session.createTextMessage();
        message.setText(line);

        // Send the message
        producer.send(message,
                      Message.DEFAULT_DELIVERY_MODE,
                      Message.DEFAULT_PRIORITY,
                      Message.DEFAULT_TIME_TO_LIVE);

        // Read the next line
        line = lineInput.readLine();
    }
}
// Finally block to ensure we close our JMS objects
finally {

    // Close the message producer
    try {
        if (producer != null) producer.close();
    }
    catch (JMSException e) {
        System.err.println("Failed to close message producer: " + e);
    }

    // Close the session
    try {
        if (session != null) session.close();
    }
}

```

```
    catch (JMSEException e) {
        System.err.println("Failed to close session: " + e);
    }

    // Close the connection
    try {
        conn.close();
    }
    catch (JMSEException e) {
        System.err.println("Failed to close connection: " + e);
    }
}
}
```

Chapter 16. Deploying an enterprise application to use JMS

You can deploy an enterprise application to use JMS.

About this task

This task description assumes that you have an .EAR file, which contains an application enterprise bean with code for JMS, that can be deployed in WebSphere Application Server.

To deploy an enterprise application to use JMS, complete the following steps:

Procedure

1. Configure the deployment attributes for the application, as described in Assembling applications.
2. Use the WebSphere Application Server administrative console to install the application.
This stage is a standard WebSphere Application Server task, as described in Installing applications.

Chapter 17. Programming for interoperation with WebSphere MQ

There are some differences between the WebSphere Application Server environment and the WebSphere MQ environment. If you are writing messaging programs that interoperate between these two environments, you should be aware of these differences and take them into account when designing, coding and deploying your programs.

Procedure

1. Learn more about the environment differences and other relevant concepts in How messages are passed between service integration and a WebSphere MQ network.
2. Read about designing programs that interoperate with WebSphere MQ in “Designing an application for interoperation with WebSphere MQ.”

Designing an application for interoperation with WebSphere MQ

To design an application to interoperate with queue managers in a WebSphere MQ network you need to first consider the differences between the two environments, then design your JMS client based on the Java EE pattern, then identify any name-handling incompatibilities between the service integration bus and WebSphere MQ environments, then define the topic mappings.

Before you begin

Identify the WebSphere MQ queues with which your applications will interoperate. The exact names and locations can be left to the installation.

Procedure

1. Familiarize yourself with important reference information for the two interoperating environments, WebSphere MQ and the service integration bus.

There are three types of reference material:

- For mapping that is unique to service integration bus messaging, see “Mapping additional MQRFH2 header fields in service integration” on page 832.
 - For mapping between WebSphere Application Server service integration bus messaging and WebSphere MQ, see How service integration converts messages to and from WebSphere MQ format and “Mapping additional MQRFH2 header fields in service integration” on page 832.
 - For the differences between the WebSphere MQ functions and the service integration bus, see “WebSphere MQ functions not supported by service integration” on page 835.
2. Design your JMS client based on the typical Java EE pattern:
 - a. Use JNDI to find a ConnectionFactory object.
 - b. Use JNDI to find one or more Destination objects.
 - c. Use the connection factory to create a JMS Connection object.
 - d. Use the JMS connection to create one or more JMS Session objects.
 - e. Use a JMS session and the destinations to create the MessageProducer and MessageConsumer objects.
 - f. Start delivery of messages by starting the JMS connection.

At this point a client has the basic JMS setup needed to produce and consume messages.

3. Identify any name-handling incompatibilities between the service integration bus and WebSphere MQ environments. If necessary, identify alias requirements, so that the WebSphere MQ application can handle service integration bus destination names of greater than 48 characters. For more information, see How to address bus destinations and WebSphere MQ queues.

4. Identify any reply destinations that are used by your application and check them for name-handling incompatibilities. For more information, see “Mapping destinations to and from WebSphere MQ queues, topics, and destinations” on page 826.
5. If your application publishes messages that you want to be forwarded to WebSphere MQ brokers, work with your administrator to define appropriate topic mappings on a publish/subscribe broker profile. You must also define topic mappings for any permanent reply topics. See Reply-to topics for request-reply messaging through a WebSphere MQ link and Request-reply messaging through a WebSphere MQ link for more information.

Mapping the message body to and from WebSphere MQ format

The WebSphere MQ message header (MQRFH2) and descriptor (MQMD) can contain information about the format of the WebSphere MQ message body. Service integration uses information contained in the MQRFH2 and MQMD when converting a message from WebSphere MQ format, and puts information into the MQRFH2 and MQMD when converting a message to WebSphere MQ format.

Exchanging messages between JMS programs through service integration and WebSphere MQ

Usually, you do not have to be aware of conversion between message formats to exchange JMS messages between service integration and WebSphere MQ, because service integration performs the appropriate conversion automatically, including character and numeric encoding. However, you might have to learn about message conversion if your JMS applications do not behave as expected, or if your service integration configuration includes JMS programs or mediations that process messages to or from non-JMS WebSphere MQ programs.

If your service integration applications exchange MapMessage objects with WebSphere MQ applications, you might have to specify a non-default map message encoding format.

WebSphere MQ message payload: format indications

The WebSphere MQ format message contains the following two indications of the payload format:

MQRFH2 <mcd> folder, Msd field

This field can contain information about the payload format. This is the “JMS format” information.

- When service integration converts a message to WebSphere MQ format, it automatically sets the appropriate value for the JMS message class.
- When service integration converts a message from WebSphere MQ format, it uses the value in this field (if there is an MQRFH2 that contains the field) to set the JMS message class.

JMS message class	MQRFH2 <mcd> folder, Msd field (“JMS format”)
TextMessage	jms_text
BytesMessage	jms_bytes
StreamMessage	jms_stream
MapMessage	jms_map
ObjectMessage	jms_object
Message	jms_none

If the “JMS format” information is not available, for example if there is no MQRFH2, service integration sets the JMS message class based on the “MQ format” (see below).

For more information about the MQRFH2 <mcd> folder, see the WebSphere MQ Using Java documentation.

MQRFH2 (or MQMD) format field

The MQRFH2 (or the MQMD if there is no MQRFH2) format field contains information about the payload format. This is the “MQ format” information. Typically it contains MQFMT_STRING, which indicates that the payload is character data (and can be translated to a different codepage by WebSphere MQ), or MQFMT_NONE, which indicates that the payload is not character data. These values are suitable for most JMS messages, and when service integration converts a message to WebSphere MQ format it automatically sets this field to one of the following values:

JMS message class	MQRFH2 (or MQMD) format field (“MQ format”)
TextMessage	MQFMT_STRING
BytesMessage	MQFMT_NONE
StreamMessage	MQFMT_STRING
MapMessage	MQFMT_STRING
ObjectMessage	MQFMT_NONE
Message	MQFMT_NONE

If your application constructs messages for a WebSphere MQ application that requires a different format value, you can override the value from the previous table by setting the `JMS_IBM_Format` property to the required value. A particular example is when the WebSphere MQ application requires an additional header (for example, the MQCIH header for a CICS bridge application). Your application constructs a `BytesMessage` object that contains the header followed by any other message data, then replaces the default “MQ format” (MQFMT_NONE) by setting the `JMS_IBM_Format` property to the appropriate value for the header (for example, MQFMT_CICS for an MQCIH header).

When service integration converts a message from WebSphere MQ format, it sets the `JMS_IBM_Format` property to the value in the “MQ format” field. If the “JMS format” is not available, for example if there is no MQRFH2, service integration sets the JMS message class to `TextMessage` if the “MQ format” is MQFMT_STRING and to `BytesMessage` otherwise.

For more information about the MQRFH2 (or MQMD) format field, see the WebSphere MQ Application Programming Reference.

WebSphere MQ message payload: character and numeric encoding

In addition to the format field, the MQRFH2 (or the MQMD if there is no MQRFH2) contains fields that identify the character encoding and numeric encoding for the message payload.

When service integration converts a message to WebSphere MQ format, it automatically selects default values (UTF-8 character encoding and big-endian numeric encoding) that are suitable for most JMS messages. If your application constructs messages for a WebSphere MQ application that requires a different character or numeric encoding, you can override the character encoding value by setting the `JMS_IBM_Character_Set` property to the required coded character set ID (CCSID), or the `JMS_IBM_Encoding` property to the required numeric format, or both. For information about the values you can use for `JMS_IBM_Character_Set` and `JMS_IBM_Encoding`, see the documentation in the WebSphere MQ library.

When the JMS message has a body that is encoded as character data in WebSphere MQ (`TextMessage`, `StreamMessage`, or `MapMessage`), setting `JMS_IBM_Character_Set` causes service integration to convert the text to that coded character set in the WebSphere MQ message body.

When the JMS message has a body that is not character data (`BytesMessage` or `ObjectMessage`), setting `JMS_IBM_Character_Set` does not cause service integration to convert the bytes; it indicates to WebSphere MQ that any character data in the message body is already encoded using the specified

coded character set. If the value of the **JMS_IBM_Format** is a format that WebSphere MQ recognises, it can convert that character data to the coded character set that the receiving application requires.

When service integration converts a message from WebSphere MQ format, it sets the **JMS_IBM_Character_Set** and **JMS_IBM_Encoding** properties from the fields in the MQRFH2 (or the MQMD if there is no MQRFH2). If the JMS message is a `TextMessage`, `StreamMessage`, `MapMessage`, or `ObjectMessage`, your application makes no use of the values of the **JMS_IBM_Character_Set** and **JMS_IBM_Encoding** properties. If the JMS message is a `BytesMessage`, then the body of the JMS message is binary data. In this case, your application must be aware of the values of the **JMS_IBM_Character_Set** and **JMS_IBM_Encoding** properties, because they indicate the encoding of any character data or numeric data that is embedded within the binary data of the message.

Mapping the message header fields and properties to and from WebSphere MQ format

When service integration converts a message to WebSphere MQ format, it sets fields in the MQMD and the MQRFH2 based on the service integration message header fields and properties; these include JMS message header fields and properties applicable to the message. When service integration converts a message from WebSphere MQ format, it sets the service integration message header fields and properties from the MQMD and the MQRFH2 in the WebSphere MQ message.

Exchanging messages between JMS programs through service integration and WebSphere MQ

Usually, you do not have to be aware of conversion between message formats to exchange JMS messages between service integration and WebSphere MQ, because service integration performs the appropriate conversion automatically, including character and numeric encoding. However, you might have to learn about message conversion if your JMS applications do not behave as expected, or if your service integration configuration includes JMS programs or mediations that process messages to or from non-JMS WebSphere MQ programs.

If your service integration applications exchange `MapMessage` objects with WebSphere MQ applications, you might have to specify a non-default map message encoding format.

WebSphere MQ message properties: the MQMD and the MQRFH2

WebSphere MQ messages contain message properties in the message descriptor (MQMD) and in the rules and formatting header 2 (MQRFH2). The WebSphere MQ message always includes an MQMD, but the MQRFH2 is optional because some WebSphere MQ applications cannot process messages that contain an MQRFH2. To simplify interoperation, you can configure service integration to omit the MQRFH2 from messages for applications that cannot process the MQRFH2. When service integration omits the MQRFH2, it discards the corresponding service integration header fields and properties.

Note: A small amount of the MQRFH2 information is also stored in MQMD fields. However, these MQMD fields are not exact equivalents, tend to be less specific, and cannot be relied upon to provide an adequate substitute for the MQRFH2 information. Therefore if the receiving application can accept an MQRFH2 header, you should always provide one.

Similarly, service integration might receive messages from WebSphere MQ applications that generate messages with no MQRFH2. When service integration receives a message with no MQRFH2, it creates a “best guess” service integration header, by getting as much information as it can from the MQMD, and using default values for the other fields.

For detailed information about the contents of the message descriptor and the message headers, see the WebSphere MQ Application Programming Reference. For details of WebSphere MQ JMS support,

including details of how WebSphere MQ stores JMS message properties and header fields in the MQMD and the MQRFH2, see WebSphere MQ Using Java.

WebSphere MQ message properties: JMS header fields

The following table shows how service integration maps JMS header fields to and from MQMD and MQRFH2 fields when converting messages to and from WebSphere MQ format.

The table shows the MQRFH2 field as *folder.field*, where *folder* is the name of the MQRFH2 folder that contains the field, and *field* is the name of the field within the MQRFH2 folder.

For several JMS header fields, there is both an MQMD field and an MQRFH2 field. When service integration is converting messages to WebSphere MQ format, it sets both the MQMD and the MQRFH2 fields. When service integration is converting messages from WebSphere MQ format, it sets the JMS header field from the MQRFH2 field if it is available, otherwise from the MQMD field.

Table 95. JMS, MQMD and MQRFH2 header fields. The first column of this table lists the JMS header fields, and the second column shows the MQMD fields that relate to the JMS header fields in the first column. The third column shows the MQRFH2 fields that relate to the JMS header fields in the first column. The fourth column provides links, where required, to the footnotes that appear after the table.

JMS header field	MQMD field	MQRFH2 field	Notes
JMSCorrelationID	CorrelId	jms.Cid	See Note 1.
JMSDeliveryMode	Persistence	jms.Dlv	See Note 15.
JMSDestination		jms.Dst	See Note 16.
JMSExpiration	Expiry	jms.Exp	
JMSMessageID	MsgId		
JMSPriority	Priority		See Note 2.
JMSRedelivered	BackoutCount		See Note 3.
JMSReplyTo	ReplyToQ and ReplyToQMgr	jms.Rto	See Note 16.
JMSTimestamp	PutDate and PutTime	jms.Tms	
JMSType		mcd.Type	

Note 1: The MQMD **CorrelId** field can hold a standard WebSphere MQ Correlation ID of 48 hexadecimal digits (24 bytes). The **JMSCorrelationID** can be a byte[] value, a string value containing hexadecimal characters and prefixed with "ID:", or an arbitrary string value not beginning "ID:". The first two of these represent a standard WebSphere MQ Correlation ID and map directly to or from the MQMD **CorrelId** field (truncated or padded with zeros as applicable); they do not use the MQRFH2 **jms.Cid** field. The third (arbitrary string) uses the MQRFH2 **jms.Cid** field; the first 24 bytes of the string, in UTF-8 format, are written into the MQMD **CorrelId**.

Note 2: WebSphere MQ stores the **JMSPriority** value in the MQRFH2 **jms.Pri** field but does not use any value already in that field. Service integration does not check or set the MQRFH2 **jms.Pri** field.

Note 3: Service integration sets the **JMSRedelivered** indicator for a message it receives from WebSphere MQ based on the **BackoutCount** field of the MQMD; a non-zero **BackoutCount** value indicates that a previous receive for the message was rolled back.

WebSphere MQ message properties: JMS defined properties

The following table shows how service integration maps JMS defined properties to and from MQMD and MQRFH2 fields when converting messages to and from WebSphere MQ format.

The table shows the MQRFH2 field as *folder.field*, where *folder* is the name of the MQRFH2 folder that contains the field, and *field* is the name of the field within the MQRFH2 folder.

For several JMS-defined properties, there is both an MQMD field and an MQRFH2 field. When service integration is converting messages to WebSphere MQ format, it sets both the MQMD and the MQRFH2 fields. When service integration is converting messages from WebSphere MQ format, it sets the JMS defined property from the MQRFH2 field if it is available, otherwise from the MQMD field.

Table 96. JMS properties with MQMD and MQRFH2 fields. The first column of this table lists the JMS defined properties, and the second column shows the MQMD fields that relate to the JMS defined properties in the first column. The third column shows the MQRFH2 fields that relate to the JMS defined properties in the first column. The fourth column provides links, where required, to the footnotes that appear after the table.

JMS defined property	MQMD field	MQRFH2 field	Notes
JMSXAppID	PutAppName		
JMSXDeliveryCount	BackoutCount		
JMSXGroupID	GroupID	jms.Gid	See Notes 4 and 5.
JMSXGroupSeq	MsgSeqNumber	jms.Seq	
JMSXUserID	UserIdentifier		

Note 4: The MQMD **GroupID** field can hold a standard WebSphere MQ **GroupID** of 48 hexadecimal digits (24 bytes). The **JMSXGroupID** is a string value containing hexadecimal characters and prefixed with "ID:" or an arbitrary string value not beginning "ID:". The first of these represents a standard WebSphere MQ **GroupID** and maps directly to or from the MQMD **GroupID** field (truncated or padded with zeros as applicable). The second (arbitrary string) uses the MQRFH2 **jms.Gid** field; the first 24 bytes of the string, in UTF-8 format, are written into the MQMD **GroupID**.

Note 5: When service integration is converting messages to WebSphere MQ format, if the **JMSXGroupID** has been set then service integration also sets the **MQMF_MSG_IN_GROUP** flag in the **MsgFlags** field of the MQMD. Note that when sending group messages, the sending JMS application must ensure that the **MQMF_LAST_MSG_IN_GROUP** flag is set as required (see "WebSphere MQ message properties: JMS provider-specific properties").

WebSphere MQ message properties: JMS provider-specific properties

The following table shows how service integration maps JMS provider-specific properties to and from MQMD and MQRFH2 fields when converting messages to and from WebSphere MQ format. Typically you use these properties to satisfy special requirements in the receiving application, so you should consult the developer or administrator of the receiving application for details of the required property values.

Table 97. JSM provider-specific properties with MQMD and MQRFH2 fields. The first column of this table lists the JMS provider-specific properties, and the second column shows the MQMD fields that relate to the JMS provider-specific properties in the first column. The third column shows the MQRFH2 fields that relate to the JMS provider-specific properties in the first column. The fourth column provides links, where required, to the footnotes that appear after the table.

JMS provider-specific property	MQMD field	MQRFH2 field	Notes
JMS_IBM_ArmCorrelator		mnext.Arm	See Note 6.
JMS_IBM_Character_Set	CodedCharacterSetId	CodedCharacterSetId	See Note 7.
JMS_IBM_Encoding	Encoding	Encoding	See Note 7.
JMS_IBM_Feedback	Feedback		
JMS_IBM_Format	Format	Format	See Note 7.
JMS_IBM_Last_Msg_In_Group	MQMF_LAST_MSG_IN_GROUP		See Note 8.
JMS_IBM_MQMD_CorrelId	CorrelId		See Notes 9 and 10.

Table 97. JMS provider-specific properties with MQMD and MQRFH2 fields (continued). The first column of this table lists the JMS provider-specific properties, and the second column shows the MQMD fields that relate to the JMS provider-specific properties in the first column. The third column shows the MQRFH2 fields that relate to the JMS provider-specific properties in the first column. The fourth column provides links, where required, to the footnotes that appear after the table.

JMS provider-specific property	MQMD field	MQRFH2 field	Notes
JMS_IBM_MQMD_MsgId	MsgId		See Notes 9 and 11.
JMS_IBM_MQMD_Persistence	Persistence		See Notes 9, 12, and 15.
JMS_IBM_MQMD_ReplyToQ	ReplyToQ		See Notes 9, 13, and 16.
JMS_IBM_MQMD_ReplyToQMgr	ReplyToQMgr		See Notes 9, 13, and 16.
JMS_IBM_MsgType	MsgType		
JMS_IBM_PutDate	PutDate		
JMS_IBM_PutTime	PutTime		
JMS_IBM_Report_*	Report		See Note 14.
JMS_IBM_RMCorrelator		mqext.Wrm	
JMS_TOG_ARM_Correlator		mqext.Arm	See Note 6.

Note 6: You should use the name **JMS_TOG_ARM_Correlator** for the ARM correlator. The name **JMS_IBM_ArmCorrelator** is available for compatibility with some existing JMS programs.

Note 7: The **JMS_IBM_Character_Set**, **JMS_IBM_Encoding**, and **JMS_IBM_Format** properties contain information about the WebSphere MQ message payload; that is, the part of the WebSphere MQ message that follows the MQRFH2 (if there is one) or the whole WebSphere MQ message, excluding the MQMD, if there is no MQRFH2. For more information about these properties and how to use them, see “Mapping the message body to and from WebSphere MQ format” on page 818.

Note 8: **MQMF_LAST_MSG_IN_GROUP** is one of the flags in the **MsgFlags** field of the MQMD.

Note 9: The **JMS_IBM_MQMD_CorrelId**, **JMS_IBM_MQMD_MsgId**, **JMS_IBM_MQMD_Persistence**, **JMS_IBM_MQMD_ReplyToQ**, and **JMS_IBM_MQMD_ReplyToQMgr** properties allow JMS applications to override the service integration default processing of WebSphere MQ MQMD fields. When service integration converts messages to WebSphere MQ format, service integration sets the corresponding MQMD field for each of these properties if, and only if, that property has been explicitly set by the application (using `setObjectProperty()` or `setNonNullProperty()`).

Service integration sets each of these properties from the corresponding MQMD field when it converts a message from WebSphere MQ format.

Note 10: The **JMS_IBM_MQMD_CorrelId** property overrides the default processing of the **JMSCorrelationID** property. When service integration converts messages to WebSphere MQ format, service integration sets the MQMD **CorrelId** field to the value (`byte[]`) if explicitly set of the **JMS_IBM_MQMD_CorrelId** property, regardless of the value (if any) of the **JMSCorrelationID** property. Setting the **JMS_IBM_MQMD_CorrelId** property does not affect the value of the MQRFH2 **jms.Cid** field.

When service integration converts messages from WebSphere MQ format, service integration sets the **JMS_IBM_MQMD_CorrelId** property to the value (`byte[]`) of the **MQMD CorrelId** field, regardless of the value (if any) of the MQRFH2 **jms.Cid** field.

Note 11: The **JMS_IBM_MQMD_MsgId** property overrides the JMS default processing of the **JMSMessageID** property. When service integration converts messages to WebSphere MQ format, service integration checks whether the **JMS_IBM_MQMD_MsgId** property has been

explicitly set. If so, service integration sets the MQMD **MsgId** field to this value (byte[]) , and replaces the unique value of the **JMSMessageID** that JMS allocates to the message.

When service integration converts messages from WebSphere MQ format, service integration sets the **JMS_IBM_MQMD_MsgId** property to the value (byte[]) of the MQMD **MsgId** field.

Note 12: The **JMS_IBM_MQMD_Persistence** property overrides the default processing of the **JMSDeliveryMode** property. When service integration converts messages to WebSphere MQ format, service integration sets the MQMD **Persistence** field to the value (integer) if explicitly set of the **JMS_IBM_MQMD_Persistence** property, regardless of the value (if any) of the **JMSDeliveryMode** property. Setting the **JMS_IBM_MQMD_Persistence** property does not affect the value of the MQRFH2 **jms.Div** field.

When service integration converts messages from WebSphere MQ format, service integration sets the **JMS_IBM_MQMD_Persistence** property to the value (integer) of the MQMD **Persistence** field, regardless of the value (if any) of the MQRFH2 **jms.Div** field.

Note 13: The **JMS_IBM_MQMD_ReplyToQ** and **JMS_IBM_MQMD_ReplyToQMgr** properties override the default processing of the **JMSReplyTo** property. When service integration converts messages to WebSphere MQ format, service integration sets the MQMD **ReplyToQ** field to the value (string) if explicitly set of the **JMS_IBM_MQMD_ReplyToQ** property and the MQMD **ReplyToQMgr** field to the value (string) if explicitly set of the **JMS_IBM_MQMD_ReplyToQMgr** property, regardless of the value (if any) of the **JMSReplyTo** property. Setting the **JMS_IBM_MQMD_ReplyToQ** or **JMS_IBM_MQMD_ReplyToQMgr** field does not affect the value of the MQRFH2 **jms.Rto** field.

When service integration converts messages from WebSphere MQ format, service integration sets the **JMS_IBM_MQMD_ReplyToQ** and **JMS_IBM_MQMD_ReplyToQMgr** property to the values (string) of the MQMD **ReplyToQ** and **ReplyToQMgr** fields, regardless of the value (if any) of the MQRFH2 **jms.Rto** field.

Note 14: For a list of the **JMS_IBM_Report_*** properties, see “Mapping MQMD Report fields to JMS provider-specific properties” on page 829.

Note 15: For more information see “Mapping the JMS delivery option and message reliability to and from the WebSphere MQ persistence value.”

Note 16: For more information see “Mapping destinations to and from WebSphere MQ queues, topics, and destinations” on page 826.

Mapping the JMS delivery option and message reliability to and from the WebSphere MQ persistence value

When converting messages between WebSphere MQ format and service integration format, service integration processes the message header fields and properties relating to message delivery mode, reliability, and persistence.

Quality of service indications in the WebSphere MQ format message

The WebSphere MQ format message contains the following indications of the quality of service:

MQMD persistence

This property is present in all WebSphere MQ format messages. The property specifies the quality of service that WebSphere MQ provides for the message as follows:

MQMD persistence	Quality of service
MQPER_PERSISTENT	Persistent quality of service. WebSphere MQ assures once and once only delivery of the message.
MQPER_NOT_PERSISTENT	Nonpersistent quality of service. WebSphere MQ can discard the message in exceptional circumstances.
MQPER_PERSISTENCE_AS_Q_DEF	WebSphere MQ sets the quality of service (persistent or nonpersistent) to the value configured for the destination queue.

For more information about the WebSphere MQ persistent and nonpersistent qualities of service, see the WebSphere MQ documentation .

MQRFH2 jms.Dlv (JMSDeliveryMode)

This property is present in WebSphere MQ format JMS messages that include the MQRFH2 header. The property contains the **JMSDeliveryMode** that was set when the application issued send for the message.

Quality of service indications when service integration converts a message to WebSphere MQ format

Message reliability levels - JMS delivery mode and service integration quality of service describes how service integration sets the message reliability. Briefly: JMS applications send messages with a JMS delivery mode (persistent or nonpersistent), then service integration uses JMS connection factory settings to map the JMS delivery mode to a service integration message reliability setting, and finally additional settings on bus destinations (including foreign destinations and alias destinations) can override this message reliability. When service integration converts the message to WebSphere MQ format, it sets the **MQMD persistence** indicator as follows:

Service integration message reliability	MQMD persistence
Reliable persistent	Persistent
Assured persistent	Persistent
Reliable nonpersistent	Nonpersistent
Express nonpersistent	Nonpersistent
Best effort nonpersistent	Nonpersistent

The sending application can optionally override this by setting the **JMS_IBM_MQMD_Persistence** message property in the message.

Quality of service indications when service integration converts a message from WebSphere MQ format

When service integration receives a message from WebSphere MQ, it uses the **MQMD persistence** value of the message together with the corresponding service integration reliability value that you configure in the WebSphere MQ link receiver or the WebSphere MQ server queue point to determine the reliability of the service integration message.

Mapping destinations to and from WebSphere MQ queues, topics, and destinations

Service integration messages and WebSphere MQ messages both contain header fields and properties. Some of these header fields and properties contain destinations or destination properties that provide information about send-to and reply-to destinations, and about destinations in the bus forward and reverse routing paths. Because service integration and WebSphere MQ have different definitions for destinations, mappings are used to process the destinations and destination properties when messages are converted between service integration format and WebSphere MQ format.

Destinations and destination properties in the WebSphere MQ format message

The WebSphere MQ format message contains the following information related to destinations:

MQXQH RemoteQName

MQXQH RemoteQMgrName

These fields are present in the MQXQH (the WebSphere MQ Transmission-queue header). The MQXQH is attached to messages only while they travel between WebSphere MQ queue managers, or between WebSphere MQ queue managers and service integration buses across a WebSphere MQ link. Sending and receiving applications cannot access these fields.

The **RemoteQName** field contains the name of the send-to queue (WebSphere MQ) or send-to destination (service integration). The **RemoteQMgrName** field identifies the queue manager or queue-sharing group (WebSphere MQ) or service integration bus (service integration) where the send-to queue or destination is located. Usually, the **RemoteQMgrName** field contains the name of the remote queue manager, queue-sharing group, or service integration bus, but it can contain a WebSphere MQ queue manager alias or a service integration virtual queue manager name. Note that these fields are not used for topics.

The **RemoteQName** and **RemoteQMgrName** values can be up to a maximum length of 48 characters, and must conform to WebSphere MQ naming restrictions.

MQRFH2 **jms.Dst** (JMSDestination)

This field is present in WebSphere MQ format JMS messages that include the MQRFH2 header.

The **jms.Dst** field contains a serialized representation (a WebSphere MQ URI) of the send-to JMS destination that was set when the application issued send for the message. Refer to the WebSphere MQ library for more information about the WebSphere MQ URI format for JMS destinations.

When service integration sends a message that has a forward-routing path to WebSphere MQ, it adds an **ibmRoutingPath** attribute to this URI. The **ibmRoutingPath** value identifies the forward routing path from the service integration message. WebSphere MQ does not use the forward routing path, but the send-to destination might be in a remote service integration bus that can use the forward routing path.

MQMD ReplyToQ

MQMD ReplyToQMgr

These fields are present in all WebSphere MQ format messages.

If the sending application specifies a reply-to queue, the **ReplyToQ** field contains the name of the reply-to queue (WebSphere MQ) or reply-to destination (service integration), and the **ReplyToQMgr** field identifies the queue manager or queue-sharing group (WebSphere MQ) or service integration bus (service integration) where that queue is located. Usually, the **ReplyToQMgr** field contains the name of the queue manager, queue-sharing group, or service integration bus, but it can contain a WebSphere MQ queue manager alias or a service integration virtual queue manager name. If the sending application specifies a reply-to topic, or if it does not specify a reply-to destination, these fields contain null values.

The **ReplyToQ** and **ReplyToQMgr** values can be up to a maximum length of 48 characters, and must conform to WebSphere MQ naming restrictions.

MQRFH2 jms.Rto (JMSReplyTo)

This field is present in WebSphere MQ format JMS messages that include the MQRFH2 header and that specify a reply-to destination. WebSphere MQ JMS applications usually use this message attribute as the destination for reply messages, but other (non-JMS) WebSphere MQ applications usually do not use it; they use the MQMD reply-to fields instead.

The **jms.Rto** field contains a serialized representation (a WebSphere MQ URI) of the reply-to JMS destination that is set by the sending JMS application. Refer to the WebSphere MQ library for more information about the WebSphere MQ URI format for JMS destinations.

When service integration sends a message that has a reverse-routing path to WebSphere MQ, service integration adds an **ibmRoutingPath** attribute to this URI. The **ibmRoutingPath** value identifies the reverse-routing path from the service integration message. When the receiving JMS application sends a reply, WebSphere MQ includes the routing path information from the reply-to URI in the send-to URI of the reply message so that service integration can use it for routing the reply message.

Note:

- When the sending application specifies a reply-to queue for a message, that queue is usually located in the bus, queue manager, or queue-sharing group to which the sending application connects. This allows the sending application to receive the reply message from the reply-to queue. Service integration applications that send messages to or through WebSphere MQ should not specify a reply-to queue in a different bus, queue manager, or queue-sharing group.
- It is important to understand that it is the receiving application which uses the reply-to destination in a message. The bus, queue manager, or queue-sharing group to which the receiving application connects must be configured with the information that allows routing to the reply-to destination.

Destination conversion when service integration converts a message to WebSphere MQ format

When service integration converts a message to WebSphere MQ format, it puts the following destination information into the WebSphere MQ format message:

MQXQH RemoteQName

MQXQH RemoteQMgrName

These fields apply only when service integration is sending the message across a WebSphere MQ link, and only when the destination is a queue.

Service integration sets these fields based on the resolved send-to destination for the message; that is, if the send-to destination is an alias, service integration uses the target bus and target identifier. Processing is then as follows:

- If the send-to destination is in an indirectly-connected bus, it stores the destination name (identifier) as the **RemoteQName** and the bus name as the **RemoteQMgrName**.
- If the send-to destination is in the directly-connected bus and the destination name (identifier) is in the form *queue@queueManager*, it stores the queue name (*queue*) as the **RemoteQName** and the queue manager name (*queueManager*) as the **RemoteQMgrName**.
- If the send-to destination is in the directly-connected bus and the destination name (identifier) is not in the form *queue@queueManager*, it stores the destination name as the **RemoteQName** and the bus name as the **RemoteQMgrName**.

If the send-to destination is in an indirectly-attached service integration bus and its destination name does not comply with WebSphere MQ naming restrictions, you must define an alias destination with a compliant name; the sending application must use the compliant (alias) name. In this case, you must define the alias destination in the remote (indirectly-attached) bus, not the local bus.

If the send-to destination is in an indirectly-attached service integration bus and its bus name does not comply with WebSphere MQ naming restrictions, there must be a virtual queue manager name for the indirectly-attached bus. In this case, the local bus must define the indirectly-attached bus with its virtual queue manager name, not its bus name.

For more information about mapping service integration bus names that do not comply with WebSphere MQ naming restrictions, see *How to address bus destinations and WebSphere MQ queues*.

MQRFH2 `jms.Dst` (JMSDestination)

If the WebSphere MQ format message includes the MQRFH2 header, service integration serializes the **JMSDestination** header field into a WebSphere MQ URI and stores it in the **JMSDestination** field in the WebSphere MQ message. If the message has a forward-routing path, service integration includes that in the URI as the **ibmRoutingPath** attribute.

MQMD `ReplyToQ`

MQMD `ReplyToQMgr`

The sending JMS application can set these fields directly by using the provider-specific JMS message properties **JMS_IBM_MQMD_ReplyToQ** and **JMS_IBM_MQMD_ReplyToQMgr**. If the sending application does not do this, service integration sets the properties if (and only if) the message has a reply-to destination and that destination is a queue.

Service integration sets these fields based on the unresolved reply-to destination for the message; that is, if the reply-to destination is an alias, service integration uses the alias bus and identifier, not the target bus and identifier. Service integration applications should not provide reply-to destinations that are foreign destinations or have names that include the @ character. Provided applications do not do this, processing is as follows:

- The reply-to destination name (identifier) is stored in the **ReplyToQ** field and the reply-to destination bus name (that is, the local bus name) in the **ReplyToQMgr** field.
- If the virtual queue manager name is different from the local bus name, the virtual queue manager name is stored in the **ReplyToQMgr** field instead of the local bus name.

If the real name of the reply-to destination does not comply with WebSphere MQ naming restrictions (including if the name includes the @ character), you must define an alias destination with a compliant name and the sending application must use the compliant (alias) name. In this case, you must define the alias destination in the local bus, not in the remote (indirectly-attached) bus.

MQRFH2 `jms.Rto` (JMSReplyTo)

If the message has a reply-to destination and the WebSphere MQ format message includes the MQRFH2 header, service integration constructs a WebSphere MQ URI to represent that reply-to destination, and stores the URI in the **JMSReplyTo** property in the WebSphere MQ message. If the reply-to destination is a queue, the URI includes the reply-to destination bus name (the local bus) or the virtual queue manager name (if that is different). If the message has a reverse-routing path, service integration includes that path in the URI in the **ibmRoutingPath** attribute.

Destination conversion when service integration converts a message from WebSphere MQ format

When service integration converts a message from WebSphere MQ format, it uses the following destination information from the WebSphere MQ format message:

MQXQH `RemoteQName`

MQXQH `RemoteQMgrName`

These fields are applicable only when service integration is receiving the message across a WebSphere MQ link, and only when the destination is a queue.

Service integration interprets the **RemoteQName** field as the destination identifier (always a queue) for the message, and the **RemoteQMGrName** field as the name of the destination bus for the message. If the **RemoteQMGrName** field contains the virtual queue manager name of the local bus, service integration interprets it as the name of the local bus. Service integration then uses the resulting bus and destination identifier combination (which can be an alias destination in the local bus) to deliver the message in the usual way. For the case where the destination bus is a foreign bus, this includes forwarding the message to that foreign bus.

MQRFH2 jms.Dst (JMSDestination)

If this field is available, service integration uses it to create the **JMSDestination** header field for the message. If the URI includes the **ibmRoutingPath** attribute, service integration uses that to create the forward-routing path for the message.

If this property is not available (for example, if the WebSphere MQ message has no MQRFH2 header), service integration can create a **JMSDestination** header field from the service integration destination where the message is delivered.

MQMD ReplyToQ

MQMD ReplyToQMGr

If these fields contain non-null values, service integration uses them to construct the first element of the reverse-routing path for the service integration message, as follows:

- If **ReplyToQMGr** is the local bus name or virtual queue manager name, service integration sets the bus to the local bus and the destination name (identifier) to **ReplyToQ**.
- If **ReplyToQMGr** is a foreign bus defined in the local bus, service integration sets the bus to **ReplyToQMGr** and the destination name (identifier) to **ReplyToQ**.
- If **ReplyToQMGr** is not the local bus name, virtual queue manager name, or a foreign bus defined in the local bus, service integration sets the bus to the directly-attached WebSphere MQ bus and the destination name (identifier) to *queue@queueManager* where *queue* is **ReplyToQ** and *queueManager* is **ReplyToQMGr**.

MQRFH2 jms.Rto (JMSReplyTo)

If this field is available, service integration uses it with the MQMD **ReplyToQ** and **ReplyToQMGr** fields to construct the reverse-routing path and **JMSReplyTo** header field for the service integration message. It constructs the reverse-routing path from the first element (which it constructs from the MQMD **ReplyToQ** and **ReplyToQMGr** fields) and any remaining elements that it obtains from the **ibmRoutingPath** attribute (if there is one) of the **JMSReplyTo** URI in the WebSphere MQ message. It constructs the **JMSReplyTo** header field from the first element of the reverse-routing path together with the destination attributes of the **JMSReplyTo** URI in the WebSphere MQ message.

Mapping MQMD Report fields to JMS provider-specific properties

JMS applications can use report messages as a form of managed request/response processing, to give remote feedback to producers on the outcome of their send operations and the fate of their messages. A JMS application can request different types of report message by setting JMS_IBM_Report_Xxxx message properties and options.

JMS applications can request the following types of report message by setting the appropriate JMS_IBM_Report_Xxxx message properties and options. The options have the same general syntax and meaning:

MQRO_report-type

A report message of the indicated type is generated that contains the WebSphere MQ message descriptor (MQMD) of the original message. It does not contain any message body data.

MQRO_report-type_WITH_DATA

A report message of the indicated type is generated that contains the MQMD, any MQ headers, and 100 bytes of body data.

MQRO_report-type_WITH_FULL_DATA

A report message of the indicated type is generated that contains all data from the original message.

Use the following prefix with each option: com.ibm.websphere.sib.api.jms.

For example, to request a Confirm on delivery (COD) report message with full data, the JMS application must set JMS_IBM_Report_COD to the value com.ibm.websphere.sib.api.jms.MQRO_COD_WITH_FULL_DATA.

For each type of report message, the following table shows the JMS_IBM_Report_Xxxx message property that a JMS application can set, and the MQMD Report field options that map to the property.

Type of report message	Description	JMS_IBM_Report_Xxxx message property and options
Exception	Send a report message if the request message cannot be put to the target queue. The exception report messages are generated when a message has been rerouted to an exception destination.	JMS_IBM_Report_Exception <ul style="list-style-type: none">• MQRO_EXCEPTION• MQRO_EXCEPTION_WITH_DATA• MQRO_EXCEPTION_WITH_FULL_DATA
Discard	Discard the original request message rather than sending it to an exception destination. You can use this option with the JMS_IBM_Report_Exception property set to MQRO_EXCEPTION_WITH_FULL_DATA to return an undeliverable request message to its sender.	JMS_IBM_Report_Discard_Msg <ul style="list-style-type: none">• TRUE• FALSE
Expiration	Send a report message if the request message passes its expiry time.	JMS_IBM_Report_Expiration <ul style="list-style-type: none">• MQRO_EXPIRATION• MQRO_EXPIRATION_WITH_DATA• MQRO_EXPIRATION_WITH_FULL_DATA
Confirm on arrival (COA)	<p>Send a report message when the request message has been put to the target queue.</p> <p>For publish/subscribe messaging, the COA report message is generated only on the producers messaging engine. Therefore, such reports are relevant only to local subscriptions.</p> <p>For point-to-point messaging, COA messages are generated when the message arrives at the final destination. For partitioned queues, the report message is generated only when the put operation has committed and a final destination has therefore been selected. Any With_Data or With_Full_Data report options specified are ignored; the COA report message deals only with message headers.</p> <p>If a forward-routing path is used, the COA message are generated when the message arrives at the final destination in the path.</p>	JMS_IBM_Report_COA <ul style="list-style-type: none">• MQRO_COA• MQRO_COA_WITH_DATA• MQRO_COA_WITH_FULL_DATA

Type of report message	Description	JMS_IBM_Report_Xxxx message property and options
Confirm on delivery (COD)	<p>Send a report message when the request message has been removed from the queue or topic space by a message consumer.</p> <p>For publish/subscribe messaging, the COD message is generated when all subscribers have received the request message. Therefore, there is one COD message generated for every COA. When a message is consumed by a subscriber, the reference count of the message on the topic space is reduced. When the reference count reaches zero, the message is removed from the topic space then a COD report message is generated.</p> <p>For point-to-point messaging, the COD message is generated after the message has been successfully received by a consuming application. Any With_Data or With_Full_Data report options specified are ignored; the COD report message deals only with message headers.</p>	<p>JMS_IBM_Report_COD</p> <ul style="list-style-type: none"> • MQRO_COD • MQRO_COD_WITH_DATA • MQRO_COD_WITH_FULL_DATA
Positive action notification (PAN)	Ask the consumer application to send a report message when it has successfully processed the request message.	<p>JMS_IBM_Report_PAN</p> <ul style="list-style-type: none"> • TRUE • FALSE
Negative action notification (NAN)	Ask the consumer application to send a report message if it has not successfully processed the request message.	<p>JMS_IBM_Report_NAN</p> <ul style="list-style-type: none"> • TRUE • FALSE

The requesting application can control other aspects of the report message as follows:

- How the message Id is generated for the report message and any reply message:

MQRO_New_Msg_Id

This the default. A new message Id is generated for the report message.

MQRO_Pass_Msg_Id

The message Id of the report message is set to the message Id of the request message.

- How the correlation Id of the report or reply message is to be set.

MQRO_Copy_Msg_Id_To_Correl_Id

This the default. the correlation Id of the report message is set to the message Id of the request message.

MQRO_Pass_Correl_Id

The correlation Id of the report message is set to the correlation Id of the request message.

For more information about report messages and the associated properties and options refer to the *Using Java* section of the WebSphere MQ information center, available from the WebSphere MQ library.

Mapping additional MQRFH2 header fields in service integration

In the WebSphere MQ message header (MQRFH2), there are additional fields that are specific to the service integration bus and that allow for functions that are not used in WebSphere MQ. When WebSphere MQ transports a message from one service integration bus to another service integration bus, these fields convey information that can be used by service integration applications but is not required by WebSphere MQ.

The additional fields are inserted in the MQRFH2 header of application messages, in the <sib> and <jms> folders. These fields do not appear as JMS message fields or properties.

When a message is sent to WebSphere MQ, a <sib> folder is included in the MQRFH2 header of the message if both of the following are true:

- The WebSphere MQ queue point attributes of the service integration destination are configured to use MQRFH2 headers.
- The fields that correspond to the <sib> folder content are set in the service integration message.

MQRFH2 header and field (<jms> folder)	SIBusMessage field or property
Frp (appended to Dst field)	Forward routing path header field
Rrp (appended to Rto field)	Reverse routing path header field

MQRFH2 header and field (<sib> folder)	SIBusMessage field or property
RTopic	Reply topic
RPri	Reply priority
RPer	Reply persistence
RTTL	Reply time to live
JsApiUserId	Application user ID (JMSXUserId) for the service integration application
JsDst	JMS destination
JsFmt	Message format
JsSysMsgId	System message identifier

Mapping the JMS Destination property between service integration and WebSphere MQ

The properties of service integration destinations differ from those used by WebSphere MQ queues, and they cannot be mapped exactly. When service integration uses WebSphere MQ to transport a message, it is useful to keep both representations of the JMS destination property in the message. To address this, when a message leaves service integration and enters WebSphere MQ, an additional **RFH2** property is introduced into the RFH2 header to store the service integration destination property.

The service integration destination property is serialized, formatted as a hexadecimal string, then stored using the **JsDst** property of the service integration RFH2 folder, the <sib> folder. WebSphere MQ applications do not make use of this folder, but if the message is to be retrieved by another service integration application, it can use the information.

For example, a service integration destination SIQ1 is localized on a WebSphere MQ queue MQQ1, residing on queue manager QM1. The following actions occur when a service integration application sends a message to SIQ1:

- A serialized representation of PMQ1 is placed in the <sib> folder of the RFH2 header, using the **JsDst** property.

- The message is stored on MQQ1.
- The string “queue://QM1/MQQ1” is also placed in the <jms> folder of the RFH2 header, using the **Dst** property.

This follows the convention used by the WebSphere MQ messaging provider to encode JMS destinations. If the message is retrieved by a service integration application, the JMS destination can be recovered from the _{ib} folder of the RFH2 header. If the message is retrieved by a WebSphere MQ application, the JMS destination can be recovered from the contents of the <jms> folder of the RFH2 header.

Note: If a WebSphere MQ server bus member is configured so that it does not use RFH2 headers, the JMS destination is not preserved when the message enters WebSphere MQ. In this situation, a service integration application can still retrieve the JMS message, but any attempt to examine the JMS destination property causes a JMS exception.

How to process WebSphere MQ message headers

WebSphere MQ messages can optionally include additional headers, or alternative headers, to the MQRFH2 header, which contains JMS properties. WebSphere Application Server application programs can use the `com.ibm.mq.headers` classes to access headers in messages from WebSphere MQ and to construct headers in messages to WebSphere MQ.

WebSphere MQ message headers

WebSphere MQ messages always include a message descriptor (MQMD). They can also include headers that contain additional information about the messages; for example, messages to or from JMS applications usually include an MQRFH2 header that contains message properties. WebSphere MQ defines the format and usage of some headers (for example, MQRFH2) and also allows users and third-party software providers to define their own custom headers.

Typically it is not necessary for application programs to process WebSphere MQ message headers. Most WebSphere MQ applications either do not use headers at all, or only use the MQRFH2 header, and the service integration and WebSphere MQ messaging providers automatically process the MQRFH2 header when you are communicating with these applications. However, if you are communicating with a WebSphere MQ application that uses or creates additional or different headers, then your WebSphere Application Server application can use the `com.ibm.mq.headers` classes to create the headers in messages it sends, and process them in messages it receives.

In the WebSphere MQ message, the headers (if there are headers) are at the start of the message, before the message payload. Each header contains fields that describe the following header, or the payload if there are no more headers; the MQMD contains the fields that describe the first header, or the payload if there are no headers. The MQMD and the MQRFH2 header do not normally appear in a JMS message. When the messaging provider converts a WebSphere MQ message into a JMS message, it uses information from the MQMD and MQRFH2 header to set JMS header fields and properties. Similarly, when the messaging provider converts a JMS message into a WebSphere MQ message, it uses the JMS header fields and properties to construct the MQMD and MQRFH2 header.

The JMS provider handles other headers in WebSphere MQ messages by converting the WebSphere MQ message to or from a JMS `BytesMessage`; the headers appear at the start of the message body, followed by the WebSphere MQ message payload (if any). The **JMS_IBM_Format** property of the JMS message indicates the format of the data in the message body (in this case, first header) and the **JMS_IBM_Encoding** and **JMS_IBM_Character_Set** properties indicate its encoding and CCSID.

Processing WebSphere MQ message headers in a JMS BytesMessage

The `com.ibm.mq.headers` package contains classes and interfaces that you can use to parse and manipulate WebSphere MQ headers in the body of a JMS `BytesMessage`. The `MQHeader` interface

provides general-purpose methods for accessing header fields and for reading and writing message content. Each header type has its own class that implements the MQHeader interface and adds getter and setter methods for individual fields. For example, the MQCIH class represents the MQCIH (CICS Bridge) header type. The header classes perform any necessary data conversion automatically, and can read or write data in any specified numeric encoding or character set (CCSID).

Two helper classes, MQHeaderIterator and MQHeaderList, assist with reading and decoding (parsing) the header content in messages:

- MQHeaderIterator works like a java.util.Iterator. For as long as there are more headers in the message, the next() method returns true, and the nextHeader() or next() method returns the next header object.
- MQHeaderList works like a java.util.List. Like MQHeaderIterator, it parses header content, but it also allows you to search for particular headers, add new headers, remove existing headers, update header fields, and then write the header content back to a message. Alternatively, you can create an empty MQHeaderList, then populate it with header instances and write it to a message once or repeatedly.

Every header class implements the MQHeader interface, which provides the methods int read (java.io.DataInput message, int encoding, int characterSet) and int write (java.io.DataOutput message, int encoding, int characterSet). The java.io.DataInputStream and java.io.DataOutputStream classes implement DataInput and DataOutput respectively. You can obtain DataInput and DataOutput objects from byte arrays carried in JMS messages, as in the following example, which processes a single MQCIH header:

```
import java.io.*;
import javax.jms.*;
import com.ibm.mq.headers.*;
...
BytesMessage bytesMessage = (BytesMessage) msg; // Message received from JMS consumer
byte[] bytes = new byte [(int) bytesMessage.getBodyLength ()];
bytesMessage.readBytes (bytes);
DataInput in = new DataInputStream (new ByteArrayInputStream (bytes));
MQCIH cih = new MQCIH (in,
    bytesMessage.getIntProperty("JMS_IBM_Encoding"),
    819);
```

Alternatively, you can use the MQHeaderIterator class to process a sequence of headers, replacing the line starting MQCIH cih = new MQCIH with:

```
MQHeaderIterator it = new MQHeaderIterator (in,
    bytesMessage.getStringProperty("JMS_IBM_Format"),
    bytesMessage.getIntProperty("JMS_IBM_Encoding"),
    819);
while (it.hasNext()) {
    MQHeader item = (MQHeader) it.next();
    ...
}
```

This example creates a single header (an MQCIH type header) and adds it into a BytesMessage:

```
import java.io.*;
import javax.jms.*;
import com.ibm.mq.constants.CMQC;
import com.ibm.mq.headers.*;
...
MQCIH header = new MQCIH();
ByteArrayOutputStream out = new ByteArrayOutputStream ();

header.write (new DataOutputStream (out), CMQC.MQENC_NATIVE, 819);
byte[] bytes = out.toByteArray ();
BytesMessage newMsg = origSes.createBytesMessage();
newMsg.writeBytes(bytes);
```

This example uses the MQHeaderList class to add two headers into a BytesMessage:

```

import java.io.*;
import javax.jms.*;
import com.ibm.mq.constants.CMQC;
import com.ibm.mq.headers.*;
...
byte[] outheaders = null;
byte[] outbody = ...
try {
    MQHeaderList it = new MQHeaderList ();
    MQHeader header1 = ... // Could be any header type
    MQHeader header2 = ... // Could be any header type
    ByteArrayOutputStream out = new ByteArrayOutputStream ();
    DataOutput dout = new DataOutputStream(out);
    it.add(header1);
    it.add(header2);
    it.write(dout);
    outheaders = out.toByteArray();
} catch (Exception e) {
    System.out.println("error generating MQ message headers : " + e);
}
BytesMessage newMsg = origSes.createBytesMessage();
newMsg.writeBytes(outheaders);
newMsg.writeBytes(bytes);

newMsg.setStringProperty("JMS_IBM_Format", "MQCICS");
newMsg.setIntProperty("JMS_IBM_Encoding", CMQC.MQENC_NATIVE);
newMsg.setIntProperty("JMS_IBM_Character_Set", 819);

```

Always use the correct values for the encoding and characterSet arguments. When you read headers, specify the encoding and CCSID with which the byte content was originally written. When writing headers, specify the encoding and CCSID that you want to produce. The data conversion is performed automatically by the header classes.

More information about the com.ibm.mq.headers classes

The com.ibm.mq.headers package is part of the WebSphere MQ Resource Adapter, which is installed automatically in WebSphere Application Server. This package comprises a set of classes and interfaces that allow the Java programmer to work with WebSphere MQ Message Headers. These include the MQHeaderIterator and MQHeaderList classes mentioned in this topic, and classes for some commonly used WebSphere MQ Message Headers, including:

- MQCIH – CICS bridge header
- MQIIH – IMS™ information header
- MQSAPH – SAP header

You can also define classes representing your own headers.

WebSphere MQ functions not supported by service integration

There are various functions available in a WebSphere MQ network that are not available on a service integration bus.

The following list helps you identify those functions but it is given as guidance rather than a complete definition. Functions not supported include:

1. Native MQ client (this includes client applications that make use of the base MQ classes for Java) attach.
2. Message segmentation.
3. Message grouping.
4. The MQMD Offset. Original length, MsgFlags, MsgSeqNumber, and GroupId fields are not supported because Message grouping and message segmentation are not supported.

5. Distribution lists.
6. Reference messages.
7. Triggering.
8. Alternate user authority.
9. Pass/set identity context.
10. In a program, setting the attributes of a queue (that is, the equivalent function of MQSET).
11. Confirmation of arrival/delivery.
12. Cluster sender/receiver channels (and cluster workload exits), because a messaging engine cannot participate in a WebSphere MQ cluster.
13. Server and requestor channels.
14. API crossing exits.
15. Data conversion exits.
16. Channel exits.
17. The equivalent to the MCAUSER and PUTAUTH fields of a channel.
18. Networks based on NetBIOS, SPX or SNA.
19. Message based command server.
20. PCF (Programmable Canonical Form messages).
21. Model queues. Service integration does not allow you to define model queues of a given name. Service integration technology supports only one model queue called the SYSTEM.DEFAULT.MODEL.QUEUE.
22. Dynamic queue name prefix length. Service integration suffixes all dynamic queue names with “_Q” and a unique id. This restricts the name specified in the dynamic queue name field of the Object Descriptor to up to 12 chars. If this name is greater than 12 characters, then it is truncated to 12 characters. In service integration, it is not possible to create a dynamic queue with the full name specified in the dynamic queue name field of the Object Descriptor.
23. Mark skip backout option.
24. Signal option on a get request.
25. Version 3 get message options structures.
26. All queue properties (the properties of a service integration destination do not map, one for one, to the properties of a WebSphere MQ local queue, for example).
27. Poisoned messages. Service integration bus local destination definitions have a maximum failed deliveries count (that is, the equivalent to the WebSphere MQ BackoutThreshold value) but there is no equivalent of the WebSphere MQ backout requeue queue name. In service integration technology, poisoned messages are instead backed out to an exception destination. Additionally, in service integration technology, when the number of times an application backs out a poisoned message is equal to the maximum failed deliveries count, the message is automatically backed out to an ExceptionDestination. If there is more than one message in the current unit of recovery, only the poisoned message is backed out to the ExceptionDestination. The remainder of the messages in the unit of recovery are backed out to the destination from which they were read.
28. A strict limitation of 48 bytes on the name of a queue. Service integration bus destination names can be greater than 48 bytes in length. If a destination name is to be returned to a WebSphere MQ JMS application, then it is important to use 48 byte destination lengths. Though, in some cases, it might be feasible to define an alias destination with a name length of up to 48 bytes to map to a local destination with a name of length greater than 48 bytes.

Chapter 18. Programming to use message-driven beans

Applications can use message-driven beans as asynchronous message consumers. You deploy a message-driven bean as a message listener for a destination. When a message arrives at the destination, the EJB container invokes the message-driven bean automatically without an application having to explicitly poll the destination.

About this task

You can use a tool such as Rational Application Developer to develop applications that use message-driven beans. You can use the WebSphere Application Server runtime tools, such as the administrative console, to deploy and administer applications that use message-driven beans.

For more information about implementing enterprise applications that use message-driven beans, see the following topics:

Procedure

- Develop message-driven beans.
- Design an enterprise application to use message-driven beans.
- Develop an enterprise application to use message-driven beans.
- Deploy an enterprise application to use message-driven beans with JCA 1.5-compliant resources.
- Deploy an enterprise application to use message-driven beans with listener ports.

Developing message-driven beans

You can develop a bean implementation class for a message-driven bean as introduced by the Enterprise JavaBeans specification. A message-driven bean (MDB) is a message consumer that implements business logic and runs on the server.

Before you begin

Determine the messaging model you want for your application regarding use of topics, queues, producers and consumers, publish or subscribe, and so on. You can refer to the message-driven bean component contract that is described in the Enterprise JavaBeans™ specification.

About this task

A message-driven bean (MDB) is a consumer of messages from a Java Message Service (JMS) provider. An MDB is invoked on arrival of a message at the destination or endpoint that the MDB services. MDB instances are anonymous, and therefore, all instances are equivalent when not actively servicing a client message. The container controls the life cycle of bean instances, which hold no state that is visible to a client.

The following example is a basic message-driven bean:

```
@MessageDriven(activationConfig={
    @ActivationConfigProperty(propertyName="destination", propertyValue="myDestination"),
    @ActivationConfigProperty(propertyName="destinationType", propertyValue="javax.jms.Queue")
})
public class MsgBean implements javax.jms.MessageListener {

    public void onMessage(javax.jms.Message msg) {

        String receivedMsg = ((TextMessage) msg).getText();
        System.out.println("Received message: " + receivedMsg);
    }
}
```

```
}
}
```

As with other enterprise bean types, you can also declare metadata for message-driven beans in the deployment descriptor rather than using annotations, for example:

```
<?xml version="1.0" encoding="UTF-8"?>

<ejb-jar id="EJBJar_1060639024453" version="3.0"
  xmlns="http://java.sun.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/.ejb-jar_3_0.xsd"
  metadata-complete="false">
<enterprise-beans>

  <message-driven>

    <ejb-name>MsgBean</ejb-name>
    <ejb-class>com.acme.ejb.MsgBean</ejb-class>
    <activation-config>
      <activation-config-property>
        <activation-config-property-name>destination</activation-config-property-name>
        <activation-config-property-value>myDestination</activation-config-property-value>
      </activation-config-property>
      <activation-config-property>
        <activation-config-property-name>destinationType</activation-config-property-name>
        <activation-config-property-value>javax.jms.Queue</activation-config-property-value>
      </activation-config-property>
    </activation-config>

  </message-driven>

</enterprise-beans>
</ejb-jar>
```

Procedure

- Code the business logic of the message-driven bean, which must implement the appropriate message listener interface defined by the messaging type; for example, `javax.jms.MessageListener`. The business logic is invoked when the message listener method of the MDB is called to service a message; for example, `MessageListener.onMessage()`. If the MDB implements more than one interface, denote the message listener interface by coding the `messageListenerInterface` attribute of the `MessageDriven` annotation, or by coding the `<messaging-type>` element of the message-driven deployment descriptor element. You do not have to specify which is the message listener interface, as long as there is only one interface other than `java.io.Serializable`, `java.io.Externalizable`, or any of the `javax.ejb` package interfaces.
- You can optionally define message destination references on any type of enterprise bean. A message destination reference is a logical name by which an enterprise bean can refer to a message destination. The `Resource` annotation is used to inject a message destination reference, for example:

```
@Resource (name="jms/Outlet", type=javax.jms.Queue) Queue salesOutlet;
```

Alternatively, you can use the `<message-destination-ref>` element in the deployment descriptor to specify the message destination reference; for example:

```
<message-destination-ref>
  <message-destination-ref-name>jms/Outlet</message-destination-ref-name>
  <message-destination-type>javax.jms.Queue</message-destination-type>
  <injection-target>
    <injection-target-class>com.acme.ejb.MsgBean</injection-target-class>
    <injection-target-name>salesOutlet</injection-target-name>
  </injection-target>
</message-destination-ref>
```

The `message-destination-ref` element is similar to the `resource-env-ref` element, but also has subelements, `message-destination-usage` with possible values `Produces`, `Consumes` or

ProducesConsumes, and message-destination-link. You can use the message-destination-link element to tie two or more message-destination-ref references in the deployment descriptor together, which allows the deployer to bind the destination for several enterprise beans all at once, to the same destination. The message-destination-link value must match the message-destination-name value in the message-destination element; for example:

```
<ejb-jar>

  <enterprise-beans>

    <session>
      <ejb-name>OutletBean</display-name>
      ...
      <message-destination-ref>
        <message-destination-ref-name>jms/target</message-destination-ref-name>
        <message-destination-type>javax.jms.Queue</message-destination-type>
        <message-destination-usage>Produces</message-destination-usage>
        <message-destination-link>destination</message-destination-link>
      </message-destination-ref>
      ...
    </session>

    <session>
      <ejb-name>InletBean</display-name>
      ...
      <message-destination-ref>
        <message-destination-ref-name>jms/source</message-destination-ref-name>
        <message-destination-type>javax.jms.Queue</message-destination-type>
        <message-destination-usage>Consumes</message-destination-usage>
        <message-destination-link>destination</message-destination-link>
      </message-destination-ref>
      ...
    </session>

    <message-driven>
      <ejb-name>InletBean</display-name>
      ...

      <ejb-name>MsgBean</ejb-name>
      <ejb-class>com.acme.MsgBean</ejb-class>
      <messaging-type>javax.jms.MessageListener</messaging-type>
      <message-destination-type>javax.jms.Queue</message-destination-type>
      <message-destination-link>destination</message-destination-link>

      ...
    </message-driven>
  </enterprise-beans>
  ...
  <assembly-descriptor>
    ...
    <message-destination>
      <message-destination-name>destination</message-destination-name>
    </message-destination>
    ...
  </assembly-descriptor>
</ejb-jar>
```

The message-destination-link element can refer to a destination that is defined in a different Java archive (JAR) file within the same application, as with an ejb-link element. For example, to link to the destination, ProduceQueue, defined in the grocery.jar file, enter the following line in the deployment descriptor:

```
<message-destination-link>grocery.jar#ProduceQueue</message-destination-link>
```

- As with any enterprise bean, you can package a message-driven bean in a JAR file, or in a web application archive (WAR) file.

Results

You developed a simple message-driven bean, along with some deployment and packaging options.

What to do next

Read related information about designing an enterprise application that uses message-driven beans.

Designing an enterprise application to use message-driven beans

To help you design your enterprise application, consider a generic enterprise application that uses one message-driven bean to retrieve messages from a JMS queue destination, and passes the messages on to another enterprise bean that implements the business logic.

About this task

To design an enterprise application to use message-driven beans, complete the following steps:

Procedure

1. Identify the message listener interface for the message type that the message-driven bean is to handle. The message-driven bean class must implement this message listener interface. For example, an EJB message-driven bean class used for JMS messaging must implement the `javax.jms.MessageListener` interface.
2. Identify the resources that the application is to use. This helps to identify the properties of resources that must be used within the application and configured as application deployment descriptors or within WebSphere Application Server.

Table 98. JMS resource types and examples of their properties. The left hand column of this table lists the JMS resource types, and the right hand column shows examples of the properties of each of the JMS resource types shown in the left hand column.

JMS resource type	Properties (for example)
JMS connection factory	Name: SamplePtoPQueueConnectionFactory JNDI Name: Sample/JMS/QCF
JMS destination	Name: Q1 JNDI Name: Sample/JMS/Q1
J2C activation specification properties	Name: MyMDBsActivationSpec JNDI Name: eis/MyMDBsActivationSpec Destination JNDI Name: MyQueue Destination type: javax.jms.Queue
Message-driven bean (deployment properties)	Name: JMSppSampleMDBBean Transaction type: Container Message selector: JMSType='car' Acknowledge mode: Dups OK Acknowledge Destination type: javax.jms.Queue ActivationSpec JNDI name: MyMDBsActivationSpec
Business logic bean	Name: MyLogicBean

Ensure that you use consistent values where needed; for example, the JNDI name for the J2C activation specification must be the same in both the activation specification and the Message-driven bean deployment attributes.

3. Separate out the business logic. You should develop a message-driven bean to delegate the business processing of incoming messages to another enterprise bean. This provides clear separation of message handling and business processing. This also enables the business processing to be invoked by either the arrival of incoming messages or, for example, from a WebSphere J2EE client.
4. Decide whether to configure security. Messages arriving at a destination being processed by a listener have no client credentials associated with them; the messages are anonymous. Security depends on

the role specified by the RunAs Identity for the message-driven bean as an EJB component. For more information about EJB security, see EJB component security.

5. Understand how best effort nonpersistent messages are handled by the default messaging provider.

If you have a non-transactional message-driven bean, the system either deletes the message when the message-driven bean starts, or when the message-driven bean completes. If the message-driven bean generates an exception, and therefore does not complete, the system takes one of the following actions:

- If the system is configured to delete the message when the message-driven bean completes, then the message is despatched to a new instance of the message-driven bean, so the message has another opportunity to be processed.
- If the system is configured to delete the message when the message-driven bean starts, then the message is lost.

The message is deleted when the message-driven bean starts if the quality of service is set to Best effort nonpersistent. For all other qualities of service, the message is deleted when the message-driven bean completes.

Developing an enterprise application to use message-driven beans

Applications can use message-driven beans as asynchronous message consumers. You deploy a message-driven bean as a message listener for a destination. The message-driven bean is invoked by an activation specification or a JMS listener when a message arrives on the input destination that is being monitored.

About this task

You develop an enterprise application to use a message-driven bean as with any other enterprise bean, except that a message-driven bean does not have a home interface or a remote interface.

You should develop your message-driven bean to delegate the business processing of incoming messages to another enterprise bean, which provides clear separation of message handling and business processing. This separation also means that the business processing can be invoked either by the arrival of incoming messages or, for example, by a WebSphere J2EE client. Responses can be handled by another enterprise bean acting as a sender bean, or they can be handled in the message-driven bean.

EJB 2.0 message-driven beans support only Java Message Service (JMS) messaging. EJB 2.1 and EJB 3 message-driven beans can support other messaging types in addition to JMS. All message-driven beans must implement the `MessageDrivenBean` interface. For JMS messaging, a message-driven bean must also implement the message listener interface `javax.jms.MessageListener`. Other Java EE Connector Architecture (JCA)-compliant resource adapters might provide their own message listener interfaces that must be implemented.

You can use the New Enterprise Bean wizard of Rational Application Developer to create an enterprise bean with a bean type of Message-driven bean. The wizard creates appropriate methods for the type of bean.

By convention, the message-driven bean class is named *nameBean*, where *name* is the name you assign to the message-driven bean; for example:

```
public class MyJMSppMDBBean implements MessageDrivenBean, javax.jms.MessageListener
```

A message-driven bean can be registered with the EJB timer service for time-based event notifications if it also implements the `javax.ejb.TimerObject` interface, and invokes the timer callback method by the following call: `void ejbTimeout(Timer)`. At the scheduled time, the container then calls the message-driven bean `ejbTimeout` method.

The message-driven bean class must define and implement the following methods:

- `onMessage(message)`, which must meet the following requirements:
 - The method must have a single argument of type `javax.jms.Message`.
 - The `throws` clause must not define any application exceptions.
 - If the message-driven bean is configured to use bean-managed transactions, it must call the `javax.transaction.UserTransaction` interface to scope the transactions. Because these calls occur inside the `onMessage()` method, the transaction scope does not include the initial message receipt. For more information, see the topic about message-driven beans transaction support.

To handle the message within the `onMessage()` method (for example, to pass the message on to another enterprise bean), you use standard JMS. This is known as bean-managed messaging.

If you are using a JCA-compliant resource adapter with a different message listener interface, another method besides the `onMessage()` method might be needed. For information about the message listener interface needed, see the documentation that was provided with your JCA-compliant resource adapter.

- `ejbCreate()`

You must define and implement an `ejbCreate` method for each way in which you want a new instance of an enterprise bean to be created.

- `ejbRemove()`

This method is invoked by the container when a client invokes the `remove` method inherited by the enterprise bean home interface from the `javax.ejb.EJBHome` interface. This method must contain any code that you want to execute before an enterprise bean instance is removed from the container (and the associated data is removed from the data source).

- `ejbTimeout(Timer)`

This method is needed only to support notifications from the timer service, and contains the business logic that handles time events received.

Procedure

1. Create the Enterprise Application project.
2. Create the message-driven bean class. You can use the New Enterprise Bean wizard of Rational(r) Application Developer to create the enterprise bean with a bean type of Message-driven bean. For an example of how to create the message-driven bean class, see the Example section of this topic. For more information, see *Creating message-driven beans* in the Rational Application Developer information center. The result of this step is a message-driven bean that can be assembled into an EAR file for deployment.
3. Optional: Use the EJB deployment descriptor editor to review and, if needed, change the deployment attributes. You can use the EJB deployment descriptor editor to review deployment attributes that you specified on the EJB creation wizard (such as **Transaction type** and **Message selector**) and other default deployment attributes.

If needed, you can override the values of these attributes later, after the enterprise application has been exported into an EAR file for deployment, as described in “Configuring deployment attributes for a message-driven bean against JCA 1.5-compliant resources” on page 635 and “Configuring deployment attributes for a message-driven bean against a listener port” on page 638.

- a. In the property pane, select the **Bean** tab.
- b. On the main panel, configure the **Transaction type** attribute.

Transaction type

This attribute determines whether the message-driven bean manages its own transactions, or whether the container manages transactions on behalf of the bean.

Bean The message-driven bean manages its own transactions.

Container

The container manages transactions on behalf of the bean.

- c. Under **Activation Configuration**, review the following attributes:

acknowledgeMode

This attribute determines how the session acknowledges any messages it receives.

Auto Acknowledge

The session automatically acknowledges delivery of each message.

Dups OK Acknowledge

The session lazily acknowledges the delivery of messages. This setting is likely to result in the delivery of some duplicate messages if JMS fails, so it should be used only by consumer applications that are tolerant of duplicate messages.

As defined in the EJB specification, clients cannot use the `Message.acknowledge()` method to acknowledge messages. If a value of `CLIENT_ACKNOWLEDGE` is passed on the `createXXXSession` call, then messages are automatically acknowledged by the application server and the `Message.acknowledge()` method is not used.

Note:

The acknowledgement is sent when the message is deleted.

If you have a non-transactional message-driven bean, the system either deletes the message when the message-driven bean starts, or when the message-driven bean completes. If the message-driven bean generates an exception, and therefore does not complete, the system takes one of the following actions:

- If the system is configured to delete the message when the message-driven bean completes, then the message is despatched to a new instance of the message-driven bean, so the message has another opportunity to be processed.
- If the system is configured to delete the message when the message-driven bean starts, then the message is lost.

The message is deleted when the message-driven bean starts if the quality of service is set to Best effort nonpersistent. For all other qualities of service, the message is deleted when the message-driven bean completes.

destinationType

This attribute determines whether the message-driven bean uses a queue or topic destination.

Queue

The message-driven bean uses a queue destination.

Topic The message-driven bean uses a topic destination.

subscriptionDurability

This attribute determines whether a JMS topic subscription is durable or nondurable.

Durable

A subscriber registers a durable subscription with a unique identity that is retained by JMS. Subsequent subscriber objects with the same identity resume the subscription in the state it was left in by the earlier subscriber. If there is no active subscriber for a durable subscription, JMS retains the subscription messages until they are received by the subscription or until they expire.

Nondurable

Nondurable subscriptions last for the lifetime of their subscriber object. This means that a client sees the messages published on a topic only while its subscriber is active. If the subscriber is not active, the client is missing messages published on its topic.

A nondurable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created.

messageSelector

This attribute determines the JMS message selector that is used to select which messages the message-driven bean receives. For example:

```
JMSType='car' AND color='blue' AND weight>2500
```

The selector string can refer to fields in the JMS message header and fields in the message properties. Message selectors cannot reference message body values.

- d. Specify bindings deployment attributes.

Under **WebSphere Bindings**, select the **JCA Adapter** option then specify the bindings deployment attributes:

ActivationSpec JNDI name

This attribute specifies the JNDI name of the activation specification that is used to deploy this message-driven bean. This name must match the name of an activation specification that you define to WebSphere Application Server.

ActivationSpec Authorization Alias

This attribute specifies the name of an authentication alias used for authentication of connections to the JCA resource adapter. An authentication alias specifies the user ID and password that is used to authenticate the creation of a new connection to the JCA resource adapter.

Destination JNDI name

This attribute specifies the JNDI name that the message-driven bean uses to look up the JMS destination in the JNDI namespace.

- e. Optional: Specify **Destination Link** to enable message linking.

Message linking allows the routing of messages to a specific message-driven bean in a deployment. Message linking allows message flow to be orchestrated between components in the same application.

For a message to be consumed and processed by a message-driven bean, the `<message-destination-link>` element must be defined in the deployment descriptor associated with the message-driven bean. The destination identified by the `<message-destination-link>` element corresponds to the logical destination.

When the `<message-destination-ref>` includes a `<message-destination-link>` element, messages are consumed at that destination.

In order to get the message-driven bean to consume messages sent to a destination, you can declare a `<message-destination-link>` element in the deployment descriptor, or alternatively set it in the activation specification.

4. Assemble and package the application for deployment.

Results

The result of this task is an EAR file, containing the message-driven bean, for the enterprise application that can be deployed in WebSphere Application Server.

Example

The following example shows how to create the message-driven bean class. The example code shows how to access the text and the JMS **MessageID**, from a JMS message of type `TextMessage`. In this example, first the `onMessage()` method of a message-driven bean is used to unpack the incoming text message and to extract the text and message identifier; then a private `putMessage` method (defined within the same message bean class) is used to put the message onto another queue:

```
public void onMessage(javax.jms.Message msg)
{
    String text      = null;
    String messageID = null;

    try
    {
        text = ((TextMessage)msg).getText();

        System.out.println("senderBean.onMessage(), msg text2: "+text);
    }
}
```

```

        //
        // store the message id to use as the Correlator value
        //
        messageID = msg.getJMSMessageID();

        // Call a private method to put the message onto another queue
        putMessage(messageID, text);
    }
    catch (Exception err)
    {
        err.printStackTrace();
    }
    return;
}

```

What to do next

After you have developed an enterprise application to use message-driven beans, configure and deploy the application. For example, define activation specifications for the message-driven beans and, optionally, change the deployment descriptor attributes for the application. For more information, see “Deploying an enterprise application to use message-driven beans with JCA 1.5-compliant resources” on page 635 and “Deploying an enterprise application to use message-driven beans with listener ports” on page 637.

Deploying an enterprise application to use message-driven beans with JCA 1.5-compliant resources

Message-driven beans can be configured as listeners on a Java EE Connector Architecture (JCA) 1.5 resource adapter, such as the default messaging provider or the WebSphere MQ messaging provider in WebSphere Application Server.

Before you begin

This task assumes that you have an EAR file that contains an enterprise application, developed as a message-driven bean, that can be deployed in WebSphere Application Server.

Note: You can continue to deploy message-driven beans against a listener port. You might want to do this for compatibility with existing message-driven bean applications. However, listener ports are stabilized, and you should plan to migrate all your message-driven beans to use JCA 1.5-compliant resources.

About this task

You deploy message-driven beans against JCA 1.5-compliant resources, and configure the resources as deployment descriptor attributes and (for EJB 3) as annotations.

Procedure

1. For each message-driven bean in the application, create a J2C activation specification.
2. For each message-driven bean in the application, configure the J2C deployment attributes, as described in “Configuring deployment attributes for a message-driven bean against JCA 1.5-compliant resources” on page 635.
3. Use the WebSphere Application Server administrative console to install the application.

Configuring deployment attributes for a message-driven bean against JCA 1.5-compliant resources

You can configure the message-driven bean deployment attributes for a Java EE Connector Architecture (JCA) 1.5-compliant enterprise application, to override the deployment attributes defined within the application EAR file.

Before you begin

This task assumes that you have an EAR file that contains an enterprise application, developed as a message-driven bean, that can be deployed in WebSphere Application Server.

Note: You can continue to configure message-driven beans against a listener port. You might want to do this for compatibility with existing message-driven bean applications. However, listener ports are stabilized, and you should plan to migrate all your message-driven beans to use JCA 1.5-compliant resources.

About this task

You configure the deployment attributes of a message-driven bean application by using an assembly tool. Detailed steps given in this task are for Rational Application Developer, but other tools have very similar steps.

Procedure

1. Start your assembly tool.
2. Edit the application EAR file. For example, use the Rational Application Developer import wizard to import the EAR file into the assembly tool. To start the import wizard:
 - a. Click **File > Import > EAR file**.
 - b. Click **Next**, then select the EAR file.
 - c. Click **Finish**.
3. Open the deployment attributes for editing. In the Java EE Hierarchy view, right-click the EJB module for the message-driven bean then click **Open With > Deployment Descriptor Editor**. A property dialog notebook for the message-driven bean is displayed in the property pane.
4. Review and, if needed, change the deployment attributes.
 - a. In the property pane, select the **Bean** tab.
 - b. Under **Activation Configuration**, review the attributes.

Note: For EJB 3 message-driven beans, you can instead use an EJB 3 annotation to configure the activation configuration properties. Do not use an EJB 3 annotation to change or replace what is specified in the bean deployment descriptor. If an activation configuration property is specified in both places, the value used is the one that is given in the deployment descriptor.

acknowledgeMode

This attribute determines how the session acknowledges any messages it receives.

Auto Acknowledge

The session automatically acknowledges delivery of each message.

Dups OK Acknowledge

The session lazily acknowledges the delivery of messages. This setting is likely to result in the delivery of some duplicate messages if JMS fails, so it should be used only by consumer applications that are tolerant of duplicate messages.

destinationType

This attribute determines whether the message-driven bean uses a queue or topic destination.

Queue

The message-driven bean uses a queue destination.

Topic The message-driven bean uses a topic destination.

subscriptionDurability

This attribute determines whether a JMS topic subscription is durable or nondurable.

Durable

A subscriber registers a durable subscription with a unique identity that is retained by JMS. Subsequent subscriber objects with the same identity resume the subscription in the state it was left in by the earlier subscriber. If there is no active subscriber for a durable subscription, JMS retains the subscription messages until they are received by the subscription or until they expire.

Nondurable

Nondurable subscriptions last for the lifetime of their subscriber object. This means that a client sees the messages published on a topic only while its subscriber is active. If the subscriber is not active, the client is missing messages published on its topic.

A nondurable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created.

messageSelector

This attribute determines the JMS message selector that is used to select which messages the message-driven bean receives. For example:

```
JMSType='car' AND color='blue' AND weight>2500
```

The selector string can refer to fields in the JMS message header and fields in the message properties. Message selectors cannot reference message body values.

- c. Specify bindings deployment attributes.

Under **WebSphere Bindings**, select the **JCA Adapter** option then specify the bindings deployment attributes:

ActivationSpec JNDI name

This attribute specifies the JNDI name of the activation specification that is used to deploy this message-driven bean. This name must match the name of an activation specification that you define to WebSphere Application Server.

ActivationSpec Authorization Alias

This attribute specifies the name of an authentication alias used for authentication of connections to the JCA resource adapter. An authentication alias specifies the user ID and password that is used to authenticate the creation of a new connection to the JCA resource adapter.

Destination JNDI name

This attribute specifies the JNDI name that the message-driven bean uses to look up the JMS destination in the JNDI namespace.

5. Save your changes to the deployment descriptor:
 - a. Close the deployment descriptor editor.
 - b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.
6. Verify the archive files.
7. From the pop-up menu for the project, click **Deploy** to generate EJB deployment code.
8. Optional: Test your completed module on a WebSphere Application Server installation.

Right-click a module, click **Run on Server**, then follow the instructions in the displayed wizard.

Restriction: **Run on Server** works on the Windows, Linux/Intel, and AIX operating systems only. You cannot deploy remotely to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

Important: Use **Run on Server** for unit testing only. When an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use on production servers.

What to do next

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that will run the application; for example, use the administrative console as described in [Deploying and managing applications](#).

Deploying an enterprise application to use message-driven beans with listener ports

Define the listener ports for your application. For each message-driven bean in the application, configure the deployment attributes to match the listener port definitions. Install the application, specifying the name of the listener port to use for late responses.

Before you begin

Listener ports are stabilized. For more information, read the article on [stabilized features](#). You should only deploy your application against a listener port for compatibility with existing message-driven bean applications. Otherwise, you should deploy your application against JCA 1.5-compliant resources.

If you have existing message-driven beans that use the WebSphere MQ messaging provider (or a compliant third-party JMS provider) with listener ports, and instead you want to use EJB 3 message-driven beans with listener ports, these new beans can continue to use the same messaging provider.

This task assumes that you have an EAR file, which contains an enterprise application developed as a message-driven bean, that can be deployed in WebSphere Application Server.

Procedure

1. Define the listener ports for your application, by using the WebSphere Application Server administrative console as described in [Creating a new listener port](#).
2. For each message-driven bean in the application, configure the deployment attributes to match the listener port definitions, as described in [“Configuring deployment attributes for a message-driven bean against a listener port”](#) on page 638.
3. Install the application, as described in [Installing enterprise application files with the console](#).

When you install the application, you are prompted to specify the name of the listener port that the application is to use for late responses. Select the listener port, then click **OK**.

Configuring deployment attributes for a message-driven bean against a listener port

You can configure the message-driven beans deployment attributes for an enterprise bean, to override the deployment attributes defined within the application EAR file.

Before you begin

Listener ports are stabilized. For more information, read the article on [stabilized features](#). You should only configure your application against a listener port for compatibility with existing message-driven bean applications. Otherwise, you should configure your application against JCA 1.5-compliant resources.

If you have existing message-driven beans that use the WebSphere MQ messaging provider (or a compliant third-party JMS provider) with listener ports, and instead you want to use EJB 3 message-driven beans with listener ports, these new beans can continue to use the same messaging provider.

This task assumes that you have an EAR file that contains an enterprise application, developed as a message-driven bean, that can be deployed in WebSphere Application Server.

About this task

You configure the deployment attributes of a message-driven bean application by using an assembly tool. Detailed steps given in this task are for Rational Application Developer, but other tools have very similar steps.

Procedure

1. Start your assembly tool.
2. Edit the application EAR file. For example, use the Rational Application Developer import wizard to import the EAR file into the assembly tool. To start the import wizard:
 - a. Click **File > Import > EAR file**.
 - b. Click **Next**, then select the EAR file.
 - c. Click **Finish**.
3. Open the deployment attributes for editing. In the Java EE Hierarchy view, right-click the EJB module for the message-driven bean then click **Open With > Deployment Descriptor Editor**. A property dialog notebook for the message-driven bean is displayed in the property pane.
4. Specify general deployment attributes.
 - a. In the property pane, select the **Bean** tab.
 - b. On the main panel, configure the **Transaction type** attribute.

This attribute determines whether the message-driven bean manages its own transactions, or whether the container manages transactions on behalf of the bean.

Bean The message-driven bean manages its own transactions.

Container
The container manages transactions on behalf of the bean.
5. Under **Activation Configuration**, review the following attributes:

Note: For EJB 3 message-driven beans, you can instead use an EJB 3 annotation to configure the activation configuration properties. Do not use an EJB 3 annotation to change or replace what is specified in the bean deployment descriptor. If an activation configuration property is specified in both places, the value used is the one that is given in the deployment descriptor.

acknowledgeMode

This attribute determines how the session acknowledges any messages it receives.

Auto Acknowledge

The session automatically acknowledges delivery of each message.

Dups OK Acknowledge

The session lazily acknowledges the delivery of messages. This setting is likely to result in the delivery of some duplicate messages if JMS fails, so it should be used only by consumer applications that are tolerant of duplicate messages.

destinationType

This attribute determines whether the message-driven bean uses a queue or topic destination.

Queue

The message-driven bean uses a queue destination.

Topic The message-driven bean uses a topic destination.

subscriptionDurability

This attribute determines whether a JMS topic subscription is durable or nondurable.

Durable

A subscriber registers a durable subscription with a unique identity that is retained by JMS. Subsequent subscriber objects with the same identity resume the subscription in

the state it was left in by the earlier subscriber. If there is no active subscriber for a durable subscription, JMS retains the subscription messages until they are received by the subscription or until they expire.

Nondurable

Nondurable subscriptions last for the lifetime of their subscriber object. This means that a client sees the messages published on a topic only while its subscriber is active. If the subscriber is not active, the client is missing messages published on its topic.

A nondurable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created.

messageSelector

This attribute determines the JMS message selector that is used to select which messages the message-driven bean receives. For example:

```
JMSType='car' AND color='blue' AND weight>2500
```

The selector string can refer to fields in the JMS message header and fields in the message properties. Message selectors cannot reference message body values.

6. Specify the bindings deployment attribute.
 - a. Under **WebSphere Bindings**, specify the following attribute:
Listener port name
Type the name of the listener port for this message-driven bean.
7. Save your changes to the deployment descriptor:
 - a. Close the deployment descriptor editor.
 - b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.
8. Verify the archive files.
9. From the pop-up menu for the project, click **Deploy** to generate EJB deployment code.
10. Optional: Test your completed module on a WebSphere Application Server installation.
Right-click a module, click **Run on Server**, then follow the instructions in the displayed wizard.

Restriction: **Run on Server** works on the Windows, Linux/Intel, and AIX operating systems only. You cannot deploy remotely to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

Important: Use **Run on Server** for unit testing only. When an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use on production servers.

What to do next

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that will run the application; for example, use the administrative console as described in Deploying and managing applications.

Chapter 19. Developing Naming and directory

This page provides a starting point for finding information about naming support. Naming includes both server-side and client-side components. The server-side component is a Common Object Request Broker Architecture (CORBA) naming service (CosNaming). The client-side component is a Java Naming and Directory Interface (JNDI) service provider. JNDI is a core component in the Java Platform, Enterprise Edition (Java EE) programming model.

The WebSphere JNDI service provider can be used to interoperate with any CosNaming name server implementation. Yet WebSphere name servers implement an extension to CosNaming, and the JNDI service provider uses those WebSphere extensions to provide greater capability than CosNaming alone. Some added capabilities are binding and looking up of non-CORBA objects.

Java EE applications use the JNDI service provider supported by WebSphere Application Server to obtain references to objects related to server applications, such as enterprise bean (EJB) homes, which have been bound into a CosNaming name space.

Developing applications that use JNDI

References to enterprise bean (EJB) homes and other artifacts such as data sources are bound to the WebSphere Application Server name space. These objects can be obtained through Java Naming and Directory Interface (JNDI). Before you can perform any JNDI operations, you need to get an initial context. You can use the initial context to look up objects bound to the name space.

About this task

The following examples describe how to get an initial context and how to perform lookup operations.

- Getting the default initial context
- Getting an initial context by setting the provider URL property
- Setting the provider URL property to select a different root context as the initial context
- Looking up an EJB home with JNDI

In these examples, the default behavior of features specific to the WebSphere Application Server JNDI Context implementation is used.

The WebSphere Application Server JNDI context implementation includes special features. JNDI caching enhances performance of repeated lookup operations on the same objects. Name syntax options offer a choice of a name syntaxes, one optimized for typical JNDI clients, and one optimized for interoperability with CosNaming applications. Most of the time, the default behavior of these features is the preferred behavior. However, sometimes you should modify the behavior for specific situations.

JNDI caching and name syntax options are associated with a `javax.naming.InitialContext` instance. To select options for these features, set properties that are recognized by the WebSphere Application Server initial context factory. To set JNDI caching or name syntax properties which will be visible to the initial context factory, do the following:

Procedure

1. Optional: Configure JNDI caches

JNDI caching can greatly increase performance of JNDI lookup operations. By default, JNDI caching is enabled. In most situations, this default is the desired behavior. However, in specific situations, use the other JNDI cache options.

Objects are cached locally as they are looked up. Subsequent lookups on cached objects are resolved locally. However, cache contents can become stale. This situation is not usually a problem, since most objects you look up do not change frequently. If you need to look up objects which change relatively frequently, change your JNDI cache options.

JNDI clients can use several properties to control cache behavior.

You can set properties:

- From the command line by entering the actual string value. For example:

```
java -Dcom.ibm.websphere.naming.jndicache.maxentrylife=1440
```

- In a `jndi.properties` file by creating a file named `jndi.properties` as a text file with the desired properties settings. For example:

```
...
com.ibm.websphere.naming.jndicache.cacheobject=none
...
```

If you use this technique, be aware that other instances of the `jndi.properties` file might exist in the classpath, and might contain conflicting property settings. Property settings are determined by the order in which the class loader picks up the `jndi.properties` files. There is no way to control the order that the class loader uses to locate files in the classpath. WebSphere Application Server does not initially contain or create any `jndi.properties` files that set the `com.ibm.websphere.naming.jndicache.cacheobject` property.

- Within a Java program by using the `PROPS.JNDI_CACHE*` Java constants, defined in the `com.ibm.websphere.naming.PROPS` file. The constant definitions follow:

```
public static final String JNDI_CACHE_OBJECT =
    "com.ibm.websphere.naming.jndicache.cacheobject";
public static final String JNDI_CACHE_OBJECT_NONE = "none";
public static final String JNDI_CACHE_OBJECT_POPULATED = "populated";
public static final String JNDI_CACHE_OBJECT_CLEARED = "cleared";
public static final String JNDI_CACHE_OBJECT_DEFAULT =
    JNDI_CACHE_OBJECT_POPULATED;

public static final String JNDI_CACHE_NAME =
    "com.ibm.websphere.naming.jndicache.cachename";
public static final String JNDI_CACHE_NAME_DEFAULT = "providerURL";

public static final String JNDI_CACHE_MAX_LIFE =
    "com.ibm.websphere.naming.jndicache.maxcachelife";
public static final int JNDI_CACHE_MAX_LIFE_DEFAULT = 0;

public static final String JNDI_CACHE_MAX_ENTRY_LIFE =
    "com.ibm.websphere.naming.jndicache.maxentrylife";
public static final int JNDI_CACHE_MAX_ENTRY_LIFE_DEFAULT = 0;
```

To use the previous properties in a Java program, add the property setting to a hashtable and pass it to the `InitialContext` constructor as follows:

```
java.util.Hashtable env = new java.util.Hashtable();
...

// Disable caching
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_NONE); ...
javax.naming.Context initialContext = new javax.naming.InitialContext(env);
```

Following are examples that illustrate how you can use JNDI cache properties to achieve the desired cache behavior. Cache properties take effect when an `InitialContext` object is constructed.

Example: Controlling JNDI cache behavior from a program

```
import java.util.Hashtable;
import javax.naming.InitialContext;
import javax.naming.Context;
import com.ibm.websphere.naming.PROPS;
```

```
/*****
```

```
 Caching discussed in this section pertains to the WebSphere Application Server initial context factory.
 Assume the property, java.naming.factory.initial, is set to
 "com.ibm.websphere.naming.WsnInitialContextFactory" as a java.lang.System property.
```

```
*****/
```

```
Hashtable env;
```

```

Context ctx;

// To clear a cache:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_CLEARED);
ctx = new InitialContext(env);

// To set a cache's maximum cache lifetime to 60 minutes:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_MAX_LIFE, "60");
ctx = new InitialContext(env);

// To turn caching off:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_NONE);
ctx = new InitialContext(env);

// To use caching and no caching:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_POPULATED);
ctx = new InitialContext(env);
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_NONE);
Context noCacheCtx = new InitialContext(env);

Object o;

// Use caching to look up home, since the home should rarely change.
o = ctx.lookup("com/mycom/MyEJBHome");
// Narrow, etc. ...

// Do not use cache if data is volatile.
o = noCacheCtx.lookup("com/mycom/VolatileObject");
// ...

```

Example: Looking up a JavaMail session with JNDI

The following example shows a lookup of a JavaMail resource:

```

// Get the initial context as shown above
...
Session session =
    (Session) initialContext.lookup("java:comp/env/mail/MailSession");

```

2. Optional: Specify the name syntax

INS syntax is designed for JNDI clients that need to interoperate with CORBA applications. This syntax allows a JNDI client to make the proper mapping to and from a CORBA name. INS syntax is very similar to the JNDI syntax with the additional special character, dot (.). Dots are used to delimit the id and kind fields in a name component. A dot is interpreted literally when it is escaped. Only one unescaped dot is allowed in a name component. A name component with a non-empty id field and empty kind field is represented with only the id field value and must not end with an unescaped dot. An empty name component (empty id and empty kind field) is represented with a single unescaped dot. An empty string is not a valid name component representation.

JNDI name syntax is the default syntax and is suitable for typical JNDI clients. This syntax includes the following special characters: forward slash (/) and backslash (\). Components in a name are delimited by a forward slash. The backslash is used as the escape character. A forward slash is interpreted literally if it is escaped, that is, preceded by a backslash. Similarly, a backslash is interpreted literally if it is escaped.

Most WebSphere applications use JNDI to look up EJB objects and do not need to look up objects bound by CORBA applications. Therefore, the default name syntax used for JNDI names is the most convenient. If your application needs to look up objects bound by CORBA applications, you may need to change your name syntax so that all CORBA CosNaming names can be represented.

JNDI clients can set the name syntax by setting a property. The property setting is applied by the initial context factory when you instantiate a new `java.naming.InitialContext` object. Names specified in JNDI operations on the initial context are parsed according to the specified name syntax.

You can set the property:

- From a command line, enter the actual string value. For example:

```
java -Dcom.ibm.websphere.naming.name.syntax=ins
```

- Create a file named `jndi.properties` as a text file with the desired properties settings. For example:

```
...
com.ibm.websphere.naming.name.syntax=ins
...
```

If you use this technique, be aware that other instances of the `jndi.properties` file might exist in the classpath, and might contain conflicting property settings. Property settings are determined by the order in which the class loader picks up the `jndi.properties` files. There is no way to control the order that the class loader uses to locate files in the classpath. WebSphere Application Server does not initially contain or create any `jndi.properties` files that set the `com.ibm.websphere.naming.name.syntax` property.

- Use the `PROPS.NAME_SYNTAX*` Java constants, defined in the `com.ibm.websphere.naming.PROPS` file, in a Java program. The constant definitions follow:

```
public static final String NAME_SYNTAX =
    "com.ibm.websphere.naming.name.syntax";
public static final String NAME_SYNTAX_JNDI = "jndi";
public static final String NAME_SYNTAX_INS = "ins";
```

To use the previous properties in a Java program, add the property setting to a hashtable and pass it to the `InitialContext` constructor as follows:

```
java.util.Hashtable env = new java.util.Hashtable();
...
env.put(PROPS.NAME_SYNTAX, PROPS.NAME_SYNTAX_INS); // Set name syntax to INS
...
javax.naming.Context initialContext = new javax.naming.InitialContext(env);
```

Example: Setting the syntax used to parse name strings

The name syntax property can be passed to the `InitialContext` constructor through its parameter, in the System properties, or in a `jndi.properties` file. The initial context and any contexts looked up from that initial context parse name strings based on the specified syntax.

The following example shows how to set the name syntax to make the initial context parse name strings according to INS syntax.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
import com.ibm.websphere.naming.PROPS; // WebSphere naming constants
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
    "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, "...");
env.put(PROPS.NAME_SYNTAX, PROPS.NAME_SYNTAX_INS);
Context initialContext = new InitialContext(env);
// The following name maps to a CORBA name component as follows:
//   id = "a.name", kind = "in.INS.format"
// The unescaped dot is used as the delimiter.
// Escaped dots are interpreted literally.
java.lang.Object o = initialContext.lookup("a\\.name.in\\.INS\\.format");
...
```

INS name syntax requires that embedded periods (.) in a name such as `in.INS.format` be escaped using a backslash character (\\). In a Java String literal, a backslash character (\\) must be escaped with another backslash character (\\\\).

3. Optional: Disable host name normalization

References to host names, IP addresses, and `localhost` in provider URLs are typically normalized. The format of a normalized host name is the fully-qualified form of the host name. Host name normalization improves system efficiency because it enables the same JNDI cache to be used for a given bootstrap host regardless of the format of the reference in the provider URL. For example, host name normalization enables the same JNDI cache to be used for `myhost`, `myhost.mydomain.com`, and `localhost` references if all of these references refer to the same host.

Because normalized host names are cached, subsequent normalizations execute more quickly. In some network environments, domain name lookup data changes dynamically, causing the cached host name normalization data to become stale. In such environments, you might need to disable hostname normalization. When you disable host normalization, host name and IP addresses are used as is. References to `localhost` typically resolve to the loopback address, 127.0.0.1.

JNDI clients can disable host name normalization by setting a property. The property setting is applied by the initial context factory when you instantiate a new `java.naming.InitialContext` object.

Use one of the following techniques to set this property:

- You can enter the actual string value from a command line. For example:

```
java -Dcom.ibm.websphere.naming.hostname.normalizer=...none...
```

- You can create a file named `jndi.properties` as a text file with the desired properties settings. For example:

```
...
com.ibm.websphere.naming.hostname.normalizer=...none...
...
```

If you use this technique, be aware that other instances of the `jndi.properties` file might exist in the classpath, and might contain conflicting property settings. Property settings are determined by the order in which the class loader picks up the `jndi.properties` files. There is no way to control the order that the class loader uses to locate files in the classpath. WebSphere Application Server does not initially contain or create any `jndi.properties` files that set the `com.ibm.websphere.naming.hostname.normalizer` property.

- You can use the `PROPS.HOSTNAME_NORMALIZER*` Java constants in a Java program. These Java constants are defined in the `com.ibm.websphere.naming.PROPS` file. Following are the constant definitions to specify if you use this technique:

```
public static final String HOSTNAME_NORMALIZER =
    "com.ibm.websphere.naming.hostname.normalizer";
public static final String HOSTNAME_NORMALIZER_NONE = "...none...";
```

To use these definitions in a Java program, add the property setting to a hashtable and pass it to the `InitialContext` constructor:

```
java.util.Hashtable env = new java.util.Hashtable();
...
env.put(PROPS.HOSTNAME_NORMALIZER, PROPS.HOSTNAME_NORMALIZER_NONE);
// Disable hostname normalization
...
javax.naming.Context initialContext =
    new javax.naming.InitialContext(env);
```

Example: Disabling host name normalization

You can pass the host name normalizer property to the `InitialContext` constructor through the `InitialContext` constructor parameter in the system properties file, or in a `jndi.properties` file. The initial context and any future contexts looked up from that initial context use this property setting.

The following example shows how to disable host name normalization.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
import com.ibm.websphere.naming.PROPS; // WebSphere naming constants
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
    "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, "...");
env.put(PROPS.HOSTNAME_NORMALIZER, PROPS.HOSTNAME_NORMALIZER_NONE);
Context initialContext = new InitialContext(env);
java.lang.Object o = initialContext.lookup(...);
...
```

Example: Getting the default initial context

There are various ways for a program to get the default initial context.

The following example gets the default initial context. Note that no provider URL is passed to the `javax.naming.InitialContext` constructor.

```
...
import javax.naming.Context;
import javax.naming.InitialContext;
...
Context initialContext = new InitialContext();
...
```

The default initial context returned depends the runtime environment of the Java Naming and Directory Interface (JNDI) client. Following are the initial contexts returned in the various environments:

Thin client

The initial context is the server root context of the server running on the local host at port 2809.

Pure client

The initial context is the context specified by the `java.naming.provider.url` property passed to `launchClient` command with the `-CCD` command line parameter. The context usually is the server root context of the server at the address specified in the URL, although it is possible to construct a `corbaname` or `corbaloc` URL which resolves to some other context.

If no provider URL is specified, it is the server root context of the server running on the host and port specified by the `-CCproviderURL`, or `-CCBootstrapHost` and `-CCBootstrapPort` command line parameters. The default host is the local host, and the default port is 2809.

Server process

The initial context is the server root context for that process.

Even though no provider URL is explicitly specified in the above example, the `InitialContext` constructor might find a provider URL defined in other places that it searches for property settings.

Users of properties which affect ORB initialization should read the rest of this section for a deeper understanding of exactly how initial contexts are obtained.

Determining which server is used to obtain the initial context

WebSphere Application Server name servers are CORBA CosNaming name servers, and the product provides a CosNaming JNDI plug-in implementation for JNDI clients to perform naming operations on product namespaces. The CosNaming plug-in implementation is selected through a JNDI property that is passed to the `InitialContext` constructor. This property is `java.naming.factory.initial`, and it specifies the initial context factory implementation to use to obtain an initial context. The factory returns a `javax.naming.Context` instance, which is part of its implementation.

The initial context factory, `com.ibm.websphere.naming.WsnInitialContextFactory`, is typically used by applications to perform JNDI operations. The WebSphere Application Server runtime environment is set up to use this initial context factory if one is not specified explicitly by the JNDI client. When the initial context factory is invoked, an *initial context* is obtained. The following paragraphs explain how the initial context factory obtains the initial context in client and server environments.

- **Registration of initial references in server processes**

Every WebSphere Application Server has an ORB used to receive and dispatch invocations on objects running in that server. Services running in the server process can register initial references with the ORB. Each initial reference is registered under a key, which is a string value. An initial reference can be any CORBA object. WebSphere Application Server name servers register several initial contexts as initial references under predefined keys. Each name server initial reference is an instance of the interface `org.omg.CosNaming.NamingContext`.

- **Obtaining initial references in pure client processes**

Pure JNDI clients, that is, JNDI clients which are not running in a WebSphere Application Server process, also have an ORB instance. This client ORB instance can be passed to the `InitialContext`

constructor, but typically the initial context factory creates and initializes the client ORB instance transparently. A client ORB can be initialized with initial references, but the initial references most likely resolve to objects running in some server. The initial context factory does not define any default initial references when it initializes an ORB. If the `resolve_initial_references` method is invoked on the client ORB when no initial references have been configured, the method invocation fails. This condition is typical for pure client processes. To obtain an initial NamingContext reference, the initial context factory must invoke `string_to_object` with an IIOB type CORBA object URL, such as `corbaloc:iiop:myhost:2809`. The URL specifies the address of the server from which to obtain the initial context. The host and port information is extracted from the provider URL passed to the InitialContext constructor.

If no provider URL is defined, the WebSphere Application Server initial context factory uses the default provider URL of `corbaloc:iiop:your.server.name:2809`.

The `string_to_object` ORB method resolves the URL and communicates with the target server ORB to obtain the initial reference.

- **Obtaining initial references in server processes**

If the JNDI client is running in a WebSphere Application Server process, the initial context factory obtains a reference to the server ORB instance if the JNDI client does not provide an ORB instance. Typically, JNDI clients running in server processes use the server ORB instance; that is, they do not pass an ORB instance to the InitialContext constructor. The name server which is running in the server process sets a provider URL as a `java.lang.System` property to serve as the default provider URL for all JNDI clients in the process. This default provider URL is `corbaloc:rir:/NameServiceServerRoot`. This URL resolves to the server root context for that server. (The URL is equivalent to invoking `resolve_initial_references` on the ORB with a key of `NameServiceServerRoot`. The name server registers the server root context as an initial reference under that key.)

- **Understanding the legacy ORB protocol**

Releases previous to WebSphere Application Server Version 5 used a different ORB implementation, which used a legacy protocol in contrast with the Interoperable Name Service (INS) protocol now used. This change has affected the implementation of the initial context factory. **Certain types of pure clients can experience different behavior when getting initial JNDI contexts as compared to previous releases of WebSphere Application Server.** This behavior is discussed in more detail below.

The following ORB properties are used with the legacy ORB protocol for ORB initialization and are now deprecated:

- `com.ibm.CORBA.BootstrapHost`
- `com.ibm.CORBA.BootstrapPort`

The new INS ORB is different in a major respect, in that it exhibits no default behavior if no initial references are defined.

In the legacy ORB, the bootstrap host and port values defaulted to `your.server.name` and 900.

All initial references were obtained from the server running on the bootstrap host and port. So, if the ORB user provided no bootstrap host and port, all initial references are resolved from the server running on the local host at port 900. The INS ORB has no concept of bootstrap host or bootstrap port. All initial references are defined independently. That is, different initial references could resolve to different servers. If `ORB.resolve_initial_references` is invoked with a key such that the ORB is not initialized with an initial reference having that key, the call fails.

In releases previous to Version 5, the initial context factory invoked `resolve_initial_references` on the ORB in the absence of any provider URL. This action succeeded if a name server at the default bootstrap host and port was running. In the current release, with the INS ORB, this would fail. (Actually, the ORB would fall back to the legacy protocol during the deprecation period, but when the legacy protocol is no longer supported, the operation would fail.)

The initial context factory now uses a default provider URL of `corbaloc:iiop:your.server.name:2809`, and invokes `string_to_object` with the provider URL.

This operation preserves the behavior that pure clients in previous releases experienced when they set no ORB bootstrap properties or provider URL. **However, this different initial context factory implementation changes the behavior experienced by certain legacy pure clients, which do not specify a provider URL:**

- Clients which set the ORB bootstrap properties listed above when getting an initial context.
- Clients which supply their own ORB instance to the InitialContext constructor.

There are two ways to circumvent this change of behavior:

- Always specify an IIOp type provider URL. This approach does not depend on the bootstrap host and port properties and continues to work when support for the bootstrap host and port properties is removed. For example, you can express bootstrap host and port property values of myHost and 2809, respectively, as `corbaloc:iiop:myHost:2809`.
- Use an rir type provider URL:
 - Specify `corbaloc:rir:/NameServiceServerRoot` if the ORB is initialized to use a Version 5 server as the bootstrap server.
 - Specify `corbaname:rir:/NameService#domain/legacyRoot` if the ORB is initialized to use a Version 4.0.x server as the bootstrap server.
 - Specify `corbaloc:rir:/NameService` if the ORB is initialized to use a server other than a Version 5 or 4.0.x server as the bootstrap server.

URLs of this type are equivalent to invoking `resolve_initial_references` on the ORB with the specified key. If the bootstrap host and port properties are being used to initialize the ORB, this approach will not work when the bootstrap and host properties are no longer supported.

- **The InitialContext constructor search order for JNDI properties**

If the code snippet shown at the beginning of this section is executed by an application, the bootstrap server depends on the value of the property, `java.naming.provider.url`.

If the property is not set (in server processes the default value is set as a system property), the default host of *your.server.name* and default port of 2809 are used as the address of the server from which to obtain the initial context.

The JNDI specification describes where the InitialContext constructor looks for `java.naming.provider.url` property settings, but briefly, the property is picked up from the following places in the order shown:

InitialContext constructor

This does not apply to the above example because the example uses the empty InitialContext constructor.

System environment

You can add JNDI properties to the system environment as an option on the Java command invocation and by program code. The recommended way to set the provider URL in the system environment is as an option supplied to the Java command invocation. Setting the provider URL in this manner is not temporal, so that getting a default initial context will always yield the same result. It is generally recommended that program code not set the provider URL property in the system environment because as a side-effect, this could adversely affect other, possibly unrelated, code running elsewhere in the same process.

jndi.properties file

There may be many `jndi.properties` files that are within the scope of the class loader in effect. All `jndi.properties` files are used for setting JNDI properties, but the provider URL setting is determined by the first `jndi.properties` file returned by the class loader.

Example: Getting an initial context by setting the provider URL property

In general, Java Naming and Directory Interface (JNDI) clients should assume the correct environment is already configured so there is no need to explicitly set property values and pass them to the InitialContext constructor. However, a JNDI client might need to access a namespace other than the one identified in its environment. In this case, it is necessary to explicitly set the `java.naming.provider.url` (provider URL) property used by the InitialContext constructor. A provider URL contains bootstrap server

information that the initial context factory can use to obtain an initial context. Any property values passed in directly to the `InitialContext` constructor take precedence over settings of those same properties found elsewhere in the environment.

You can use two different provider URL forms with the WebSphere Application Server initial context factory:

- A CORBA object URL
- An IIOP URL

CORBA object URLs are more flexible than IIOP URLs and are the recommended URL format to use. CORBA object URLs are part of the OMG CosNaming Interoperable Naming Specification. A corbaname URL, for example, can include initial context and lookup name information and can be used as a lookup name without the need to explicitly obtain another initial context. The IIOP URLs are the legacy JNDI format, but are still supported by the WebSphere Application Server initial context factory.

The following examples illustrate the use of these URLs.

- “Using a CORBA object URL”
- “Using a CORBA object URL from a non-WebSphere Application Server JNDI implementation”
- “Using an IIOP URL” on page 860

Using a CORBA object URL

This example shows a CORBA object URL.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
        "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, "corbaloc:iiop:myhost.mycompany.com:2809");
Context initialContext = new InitialContext(env);
...
```

Using a CORBA object URL from a non-WebSphere Application Server JNDI implementation

Initial context factories for CosNaming JNDI plug-in implementations other than the WebSphere Application Server initial context factory most likely obtain an initial context using the object key, `NameService`. When you use such a context factory to obtain an initial context from a WebSphere Application Server name server, the initial context is the cell root context. Since system artifacts such as EJB homes associated with a server are bound under the server's server root context, names used in JNDI operations must be qualified. If you want to use relative names, ensure your initial context is the server root context under which the target object is bound. In order to make the server root context the initial context, specify a `corbaloc` provider URL with an object key of `NameServiceServerRoot`.

This example shows a CORBA object type URL from a non-WebSphere Application Server JNDI implementation. This example assumes full CORBA object URL support by the non-WebSphere Application Server JNDI implementation. The object key of `NameServiceServerRoot` is specified so that the initial context will be the specified server's server root context.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
        "com.somecompany.naming.TheirInitialContextFactory");
```

```

env.put(Context.PROVIDER_URL,
        "corbaname:iiop:myhost.mycompany.com:9810/NameServiceServerRoot");
Context initialContext = new InitialContext(env);
...

```

If qualified names are used, you can use the default key of NameService.

Using an IIOP URL

The IIOP type of URL is a legacy format which is not as flexible as CORBA object URLs. However, URLs of this type are still supported. The following example shows an IIOP type URL as the provider URL.

```

...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
        "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, "iiop://myhost.mycompany.com:2809");
Context initialContext = new InitialContext(env);
...

```

Example: Setting the provider URL property to select a different root context as the initial context

Each server contains its own server root context, and, when bootstrapping to a server, the server root is the default initial JNDI context. Most of the time, this default is the desired initial context, since system artifacts such as EJB homes are bound there. However, other root contexts exist, which can contain bindings of interest. It is possible to specify a provider URL to select other root contexts.

Examples for selecting other root contexts follow:

- Initial root contexts with a CORBA object URL
- Initial root contexts with the namespace root property

Selecting the initial root context with a CORBA object URL

There are several object keys registered with the bootstrap server that you can use to select the root context for the initial context. To select a particular root context with a CORBA object URL object key, set the object key to the corresponding value. The default object key is NameService. Using JNDI yields the server root context. A table that lists the different root contexts and their corresponding object key follows:

Root Context	CORBA Object URL Object Key
Server Root	NameServiceServerRoot
Cell Persistent Root	NameServiceCellPersistentRoot
Cell Root	NameServiceCellRoot
Node Root	NameServiceNodeRoot

The following example shows the use of a corbaloc URL with the object key set to select the cell persistent root context as the initial context.

```

...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
        "com.ibm.websphere.naming.WsnInitialContextFactory");

```

```

env.put(Context.PROVIDER_URL,
        "corbaloc:iiop:myhost.mycompany.com:2809/NameServiceCellPersistentRoot");
Context initialContext = new InitialContext(env);
...

```

Selecting the initial root context with the namespace root property

You can also select the initial root context by passing a namespace root property setting to the InitialContext constructor. Generally, the object key setting described above is sufficient. Sometimes a property setting is preferable. For example, you can set the root context property on the Java invocation to make which server root is being used as the initial context transparent to the application. The default server root property setting is defaultroot, which yields the server root context.

Root Context	Namespace Root Property Value
Server Root	bootstrapserverroot
Cell Persistent Root	cellpersistentroot
Cell Root	cellroot
Node Root	bootstrapnoderoot

The initial context factory ignores the namespace root property if the provider URL contains an object key other than NameService.

The following example shows use of the namespace root property to select the cell persistent root context as the initial context. Note that available constants are used instead of hard-coding the property name and value.

```

...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
import com.ibm.websphere.naming.PROPS;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
        "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, "corbaloc:iiop:myhost.mycompany.com:2809");
env.put(PROPS.NAME_SPACE_ROOT, PROPS.NAME_SPACE_ROOT_CELL_PERSISTENT);
Context initialContext = new InitialContext(env);
...

```

Example: Looking up an EJB home or business interface with JNDI

Most applications that use Java Naming and Directory Interface (JNDI) run in a container. Some do not. The name used to look up an object depends on whether or not the application is running in a container. Sometimes it is more convenient for an application to use a corbaname URL as the lookup name. Container-based JNDI clients and thin Java clients can use a corbaname URL.

The following examples show how to perform JNDI lookups from different types of applications.

- “JNDI lookup from an application running in a container”
- “JNDI lookup from an application that does not run in a container” on page 862
- “JNDI lookup with a corbaname URL” on page 864

JNDI lookup from an application running in a container

Applications that run in a container can use java: lookup names. Lookup names of this form provide a level of indirection such that the lookup name used to look up an object is not dependent on the object's name as it is bound in the name server's namespace. The deployment descriptors for the application

provide the mapping from the `java:` name and the name server lookup name. The container sets up the `java:` namespace based on the deployment descriptor information so that the `java:` name is correctly mapped to the corresponding object.

The following example shows a lookup of an EJB 3.0 remote business interface. The actual home lookup name is determined by the interface's `ibm-ejb-jar-bnd.xml` binding file, if present, or by the default name assigned by the EJB container if no binding file is present. For more information, see topics on default bindings for business interfaces and homes and on user-defined bindings for EJB business interfaces and homes.

```
// Get the initial context as shown in a previous example.
...
// Look up the business interface using the JNDI name.
try {
    java.lang.Object ejbBusIntf =
        initialContext.lookup(
            "java:comp/env/com/mycompany/accounting/Account");
    accountIntf =
        (Account)javadoc.rmi.PortableRemoteObject.narrow(ejbBusIntf, Account.class);
}
catch (NamingException e) { // Error getting the business interface
    ...
}
```

The following example shows a lookup of an EJB 1.x or 2.x EJB home. The actual home lookup name is determined by the application's deployment descriptors. The enterprise bean (EJB) resides in an EJB container, which provides an interface between the bean and the application server on which it resides.

```
// Get the initial context as shown in a previous example
...
// Look up the home interface using the JNDI name
try {
    java.lang.Object ejbHome =
        initialContext.lookup(
            "java:comp/env/com/mycompany/accounting/AccountEJB");
    accountHome = (AccountHome)javadoc.rmi.PortableRemoteObject.narrow(
        (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
catch (NamingException e) { // Error getting the home interface
    ...
}
```

JNDI lookup from an application that does not run in a container

Applications that do not run in a container cannot use `java:` lookup names because it is the container which sets the `java:` namespace up for the application. Instead, an application of this type must look the object up directly from the name server. Each application server contains a name server. System artifacts such as EJB homes are bound relative to the server root context in that name server. The various name servers are federated by means of a system namespace structure. The recommended way to look up objects on different servers is to qualify the name so that the name resolves from any initial context in the cell. If a relative name is used, the initial context must be the same server root context as the one under which the object is bound. The form of the qualified name depends on whether the qualified name is a topology-based name or a fixed name. Examples of each form of qualified name follow.

- **Topology-based qualified names**

Topology-based qualified names traverse through the system namespace to the server root context under which the target object is bound. A topology-based qualified name resolves from any initial context in the cell.

Single server

The following example shows a lookup of an EJB business interface that is running in the single server, `MyServer`, configured in the node, `Node1`.

```

// Get the initial context as shown in a previous example.
// Using the form of lookup name below, it does not matter which
// server in the cell is used to obtain the initial context.
...
// Look up the business interface using the JNDI name
try {
    java.lang.Object ejbBusIntf = initialContext.lookup(
        "cell/nodes/Node1/servers/MyServer/com/mycompany/accounting/Account");
    accountIntf =
        (Account)jvax.rmi.PortableRemoteObject.narrow(ejbBusIntf, Account.class);
}
catch (NamingException e) { // Error getting the business interface
    ...
}

```

The following example shows a lookup of an EJB home that is running in the single server, MyServer, configured in the node, Node1.

```

// Get the initial context as shown in a previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
// Look up the home interface using the JNDI name
try {
    java.lang.Object ejbHome = initialContext.lookup(
        "cell/nodes/Node1/servers/MyServer/com/mycompany/accounting/AccountEJB");
    accountHome = (AccountHome)jvax.rmi.PortableRemoteObject.narrow(
        (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
catch (NamingException e) { // Error getting the home interface
    ...
}

```

- **Fixed qualified names**

If the target object has a cell-scoped fixed name defined for it, you can use its qualified form instead of the topology-based qualified name. Even though the topology-based name works, the fixed name does not change with the specific cell topology or with the movement of the target object to a different server.

An example lookup of an EJB business interface with a qualified fixed name follows.

```

// Get the initial context as shown in a previous example.
// Using the form of lookup name below, it does not matter which
// server in the cell is used to obtain the initial context.
...
// Look up the business interface using the JNDI name
try {
    java.lang.Object ejbBusIntf = initialContext.lookup(
        "cell/persistent/com/mycompany/accounting/Account");
    accountIntf =
        (Account)jvax.rmi.PortableRemoteObject.narrow(ejbBusIntf, Account.class);
}
catch (NamingException e) { // Error getting the business interface
    ...
}

```

An example lookup with a qualified fixed name is shown below.

```

// Get the initial context as shown in a previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
// Look up the home interface using the JNDI name
try {
    java.lang.Object ejbHome = initialContext.lookup(
        "cell/persistent/com/mycompany/accounting/AccountEJB");
    accountHome = (AccountHome)jvax.rmi.PortableRemoteObject.narrow(
        (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}

```

```

    }
    catch (NamingException e) { // Error getting the home interface
    ...
    }

```

JNDI lookup with a corbaname URL

A corbaname can be useful at times as a lookup name. If, for example, the target object is not a member of the federated namespace and cannot be located with a qualified name, a corbaname can be a convenient way to look up the object.

A lookup of an EJB business interface with a corbaname URL follows.

```

// Get the initial context as shown in a previous example.
...
// Look up the business interface using a corbaname URL.
try {
    java.lang.Object ejbBusIntf = initialContext.lookup(
        "corbaname:iiop:someHost:2809#com/mycompany/accounting/Account");
    accountIntf =
        (Account)javax.rmi.PortableRemoteObject.narrow(ejbBusIntf, Account.class);
}
catch (NamingException e) { // Error getting the business interface
    ...
}

```

A lookup with a corbaname URL follows.

```

// Get the initial context as shown in a previous example
...
// Look up the home interface using a corbaname URL
try {
    java.lang.Object ejbHome = initialContext.lookup(
        "corbaname:iiop:someHost:2809#com/mycompany/accounting/AccountEJB");
    accountHome = (AccountHome)javax.rmi.PortableRemoteObject.narrow(
        (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
catch (NamingException e) { // Error getting the home interface
    ...
}

```

JNDI interoperability considerations

You must take extra steps to enable your programs to interoperate with non-product JNDI clients and to bind resources from MQSeries to a namespace.

EJB clients running in an environment other than WebSphere Application Server accessing EJB applications running on WebSphere Application Server servers

When an enterprise bean (EJB) application running in WebSphere Application Server is accessed by a non-product EJB client, the JNDI initial context factory is presumed to be a non-product implementation. In this case, the default initial context is the cell root. If the JNDI service provider being used supports CORBA object URLs, the corbaname format can be used to look up the EJB home.

Single server

Following is a URL that has the bootstrap host **myHost**, the port **2809**, and the enterprise bean installed in the server **server1** in node **node1** and bound in that server under the name **myEJB**:

```

initialContext.lookup(
    "corbaname:iiop:myHost:2809#cell/nodes/node1/servers/server1/myEJB");

```

Without CORBA object URL support

If the JNDI initial context factory being used does not support CORBA object URLs, the initial context can be obtained from the server, and the lookup can be performed on the initial context as follows:

```
Hashtable env = new Hashtable();
env.put(CONTEXT.PROVIDER_URL, "iiop://myHost:2809");
Context ic = new InitialContext(env);
Object o = ic.lookup("cell/clusters/myCluster/myEJB");
```

Binding resources from MQSeries 5.2

In releases previous to WebSphere Application Server Version 5.0, the MQSeries jmsadmin tool could be used to bind resources to the namespace. When used with a WebSphere Application Server namespace, the resource is bound within a transient partition in the namespace and does not persist past the life of the server process. Instead of binding the MQSeries resources with the jmsadmin tool, bind them from the administrative console, under **Resources** in the console navigation tree.

JNDI caching

To increase the performance of Java Naming and Directory Interface (JNDI) operations, the product JNDI implementation employs caching to reduce the number of remote calls to the name server for lookup operations. For most cases, use the default cache setting.

When an InitialContext object is instantiated, an association is established between the InitialContext instance and a cache. The initial context and any contexts returned directly or indirectly from a lookup on the initial context are all associated with that same cache instance. By default, the association is based on the provider URL, in particular, the host name and port. The caller can specify the cache name to override this default behavior. A cache instance of a given name is shared by all instances of InitialContext configured to use a cache of that name which were created with the same context class loader in effect. Two enterprise bean (EJB) applications running in the same server will use their own cache instances, if they are using different context class loaders, even if the cache names are the same.

After an association between an InitialContext instance and cache is established, the association does not change. A `javax.naming.Context` object returned from a lookup operation inherits the cache association of the Context object on which the lookup was performed. Changing cache property values with the `Context.addToEnvironment()` or `Context.removeFromEnvironment()` method does not affect cache behavior. You can change properties affecting a given cache instance with each InitialContext instantiation.

A cache is restricted to a process and does not persist past the life of that process. A cached object is returned from lookup operations until either the maximum cache life for the cache is reached, or the maximum entry life for the object's cache entry is reached. After this time, a lookup on the object causes the cache entry for the object to be refreshed. By default, caches and cache entries have unlimited lifetimes.

Usually, cached objects are relatively static entities, and objects becoming stale is not a problem. However, you can set timeout values on cache entries or on a cache so that cache contents are periodically refreshed.

If a bind or rebind operation is executed on an object, the change is not reflected in any caches other than the one associated with the context from which the bind or rebind was issued. This scenario is most likely to happen when multiple processes are involved, since different processes do not share the same cache, and context objects in all threads in a process typically share the same cache instance for a given name service provider.

JNDI cache settings

Various Java Naming and Directory Interface (JNDI) cache property settings follow. Ensure that all property values are string values.

com.ibm.websphere.naming.jndicache.cachename

The name of the cache to associate with an initial context instance can be specified with this property.

It is possible to create multiple InitialContext instances, each operating on the namespace of a different name server. By default, objects from each bootstrap address are cached separately, since they each involve independent namespaces and name collisions could occur if they used the same cache. The provider URL specified when the initial context is created by default serves as the basis for the cache name. With this property, a JNDI client can specify a cache name. Valid options for cache names follow:

Valid options	Resulting cache behavior
providerURL (default)	Use the value for java.naming.provider.url property as the basis for the cache name. Cache names are based on the bootstrap host and port specified in the URL. The bootstrap host is normalized to a fully qualified name, if possible. For example, "corbaname:iiop:server1:2809#some/starting/context" and "corbaloc:iiop://server1" are normalized to the same cache name. If no provider URL is specified, a default cache name is used.
Any string	Use the specified string as the cache name. You can use any arbitrary string with a value other than "providerURL" as a cache name.

com.ibm.websphere.naming.jndicache.cacheobject

Turn caching on or off and clear an existing cache with this property.

By default, when an InitialContext is instantiated, it is associated with an existing cache or, if one does not exist, a new one is created. An existing cache is used with its existing contents. In some circumstances, this behavior is not desirable. For example, when objects that are looked up change frequently, they can become stale in the cache. Other options are available. The following table lists these other options along with the corresponding property value.

Valid values	Resulting cache behavior
populated (default)	Use a cache with the specified name. If the cache already exists, leave existing cache entries in the cache; otherwise, create a new cache.
cleared	Use a cache with the specified name. If the cache already exists, clear all cache entries from the cache; otherwise, create a new cache.
none	Do not cache. If this option is specified, the cache name is irrelevant. Therefore, this option will not disable a cache that is already associated with other InitialContext instances. The InitialContext that is instantiated is not associated with any cache.

com.ibm.websphere.naming.jndicache.maxcachelife

Impose a limit to the age of a cache with this property.

By default, cached objects remain in the cache for the life of the process or until cleared with the com.ibm.websphere.naming.jndicache.cacheobject property set to cleared. This property enables a JNDI client to set the maximum life of a cache. This property differs from the maxentrylife property (below) in that the entire cache is cleared when the cache lifetime is reached. The table below lists the various maxcachelife values and their affect on cache behavior:

Valid values	Resulting cache behavior
0 (default)	Make the cache lifetime unlimited.

Valid values	Resulting cache behavior
Positive integer	Set the maximum lifetime of the entire cache, in minutes, to the specified value. When the maximum lifetime for the cache is reached, the next attempt to read any entry from the cache causes the cache to be cleared

com.ibm.websphere.naming.jndicache.maxentrylife

Impose a limit to the age of individual cache entries with this property.

By default, cached objects remain in the cache for the life of the process or until cleared with the `com.ibm.websphere.naming.jndicache.cacheobject` property set to `cleared`. This property enables a JNDI client to set the maximum lifetime of individual cache entries. This property differs from the `maxcachelife` property in that individual entries are refreshed individually as their maximum lifetime reached. This might avoid any noticeable change in performance that might occur if the whole cache is cleared at once. The table below lists the various `maxentrylife` values and their effect on cache behavior:

Valid values	Resulting cache behavior
0 (default)	Lifetime of cache entries is unlimited.
Positive integer	Set the maximum lifetime of individual cache entries, in minutes, to the specified value. When the maximum lifetime for an entry is reached, the next attempt to read the entry from the cache causes the individual cache entry to refresh.

JNDI to CORBA name mapping considerations

WebSphere Application Server name servers are an implementation of the CORBA CosNaming interface. The product provides a Java Naming and Directory Interface (JNDI) implementation which you can use to access CosNaming name servers through the JNDI interface. Issues can exist when mapping JNDI name strings to and from CORBA names.

Each component in a CORBA name consists of an `id` and `kind` field, but a JNDI name component consists of no such fields. Each component in a JNDI name is atomic. Typical JNDI clients do not need to make a distinction between the `id` and `kind` fields of a name component, or know how JNDI name strings map to CORBA names. JNDI clients of this sort can use the JNDI syntax described below. When a name is parsed according to JNDI syntax, each name component is mapped to the `id` field of the corresponding CORBA name component. The `kind` field always has an empty value. This basic syntax is the least obtrusive to the JNDI client in that it has the fewest special characters. However, you cannot represent with this syntax a CORBA name with a non-empty `kind` field. This restriction can prevent EJB applications from interoperating with CORBA applications.

Some clients, however must interoperate with CORBA applications which use CORBA names with non-empty `kind` fields. These JNDI clients must make a distinction between `id` and `kind` so that JNDI names are correctly mapped to CORBA names, particularly when the CORBA names contain components with non-empty `kind` fields. Such JNDI clients can use the INS name syntax. With its additional special character, you can use INS to represent any CORBA name. Use of this syntax is not recommended unless it is necessary, because this syntax is more restrictive from the JNDI client's perspective in that the JNDI client must be aware that name components with multiple unescaped dots are syntactically invalid. INS name syntax is part of the OMG CosNaming Interoperable Naming Specification.

Developing applications that use CosNaming (CORBA Naming interface)

CORBA clients can perform naming operations on WebSphere Application Server name servers through the CosNaming interface.

About this task

The following examples show how to obtain an ORB instance and an initial context as well as how to look up an EJB home.

Procedure

1. Get an initial context.
2. Perform desired CosNaming operations.

Example: Getting an initial context with CosNaming

In WebSphere Application Server, an initial context is obtained from a bootstrap server. The address for the bootstrap server consists of a host and port. To get an initial context, you must know the host and port for the server that is used as the bootstrap server.

Obtaining an initial context consists of two basic steps:

1. Obtain an ORB reference.
2. Use an ORB reference to get an initial context. Alternatively, use an existing ORB and invoke `string_to_object` with a CORBA object URL with multiple name server addresses to get an initial context.

Obtaining an ORB reference

Pure CosNaming clients, that is clients that are not running in a server process, must create and initialize an ORB instance with which to obtain the initial context. CosNaming clients which run in server processes can obtain a reference to the server ORB with a JNDI lookup. The following examples illustrate how to create and initialize a client ORB and how to obtain a server ORB reference.

Creating a client ORB instance

To create an ORB instance, invoke the static method, `org.omg.CORBA.ORB.init`. The `init` method requires a property set to the name of the ORB class you want to instantiate. An ORB implementation with the class name `com.ibm.CORBA.iiop.ORB` is included with the product. The WebSphere Application Server ORB recognizes additional properties with which you can specify initial references.

The basic steps for creating an ORB are as follows:

1. Create a Properties object.
2. Set the ORB class property to the product's ORB class.
3. Set the initial reference properties.
4. Invoke `ORB.init`, passing in the Properties object.

```
...
import java.util.Properties;
import org.omg.CORBA.ORB;
...
Properties props = new Properties();
props.put("org.omg.CORBA.ORBClass", "com.ibm.ws390.orb.ORB");
props.put("com.ibm.CORBA.ORBInitRef.NameService",
    "corbaloc:iiop:myhost.mycompany.com:2809/NameService");
props.put("com.ibm.CORBA.ORBInitRef.NameServiceServerRoot",
    "corbaloc:iiop:myhost.mycompany.com:2809/NameServiceServerRoot");
ORB _orb = ORB.init((String[])null, props);
...
```

Obtaining a reference to the server ORB

CosNaming clients which run in a server process can obtain a reference to the server ORB with a JNDI lookup on a `java: name`, shown as follows:

```

...
import javax.naming.Context;
import javax.naming.InitialContext;
import org.omg.CORBA.ORB;
...
Context initialContext = new InitialContext();
ORB orb = (ORB) initialContext.lookup("java:comp/ORB");
...

```

Using an ORB reference to get an initial naming reference

There are two basic ways to get an initial CosNaming context. Both ways involve an ORB method invocation. The first way is to invoke the `resolve_initial_references` method on the ORB with an initial reference key. For this call to work, the ORB must be initialized with an initial reference for that key. The other way is to invoke the `string_to_object` method on the ORB, passing in a CORBA object URL with the host and port of the bootstrap server. The following examples illustrate both approaches.

Invoking `resolve_initial_references`

Once an ORB reference is obtained, invoke the `resolve_initial_references` method on the ORB to obtain a reference to the initial context. The following code example invokes `resolve_initial_reference` on an ORB reference.

```

...
import org.omg.CORBA.ORB;
import org.omg.CosNaming.NamingContextExt;
import org.omg.CosNaming.NamingContextExtHelper;
...
// Obtain ORB reference as shown in examples earlier in this section
...
org.omg.CORBA.Object obj = _orb.resolve_initial_references("NameService");
NamingContextExt initCtx = NamingContextExtHelper.narrow(obj);
...

```

Note that the key `NameService` is passed to the `resolve_initial_references` method. Other initial context keys are registered in product servers. For example, `NameServiceServerRoot` can be used to obtain a reference to the server root context in the bootstrap name server. For more information on the initial contexts registered in server ORBs, refer to the topic on initial context support.

Invoking `string_to_object` with a CORBA object URL

You can use an INS-compliant ORB to obtain an initial context even if the ORB is not initialized with any initial references or bootstrap properties, or if those property settings are for a different server than the name server from which you want to obtain the initial context. To obtain an initial context by explicitly specifying the bootstrap name server, invoke the `string_to_object` method on the ORB, passing in a CORBA object URL which contains the bootstrap server host and port.

The code in the example below invokes the `string_to_object` method on an existing ORB reference, passing in a CORBA object URL which identifies the desired initial context.

```

...
import org.omg.CORBA.ORB;
import org.omg.CosNaming.NamingContextExt;
import org.omg.CosNaming.NamingContextExtHelper;
...
// Obtain ORB reference as shown in examples earlier in this section
...
org.omg.CORBA.Object obj =
    orb.string_to_object("corbaloc:iiop:myhost.mycompany.com:2809/NameService");
NamingContextExt initCtx = NamingContextExtHelper.narrow(obj);
...

```

Note that the key `NameService` is used in the `corbaloc` URL. Other initial context keys are registered in product servers. For example, you can use `NameServiceServerRoot` to obtain a reference to the server root context in the bootstrap name server.

Using an existing ORB and invoking `string_to_object` with a CORBA object URL with multiple name server addresses to get an initial context

CORBA object URLs can contain more than one bootstrap server address. Use this feature when attempting to obtain an initial context from a server cluster. You can specify the bootstrap server addresses for all servers in the cluster in the URL. The operation will succeed if at least one of the servers is running, eliminating a single point of failure. There is no guarantee of any particular order in which the address list will be processed. For example, the second bootstrap server address may be used to obtain the initial context even though the first bootstrap server in the list is available. An example of a `corbaloc` URL with multiple addresses follows.

```
...
import org.omg.CORBA.ORB;
import org.omg.CosNaming.NamingContextExt;
import org.omg.CosNaming.NamingContextExtHelper;
...
// Assume orb is an existing ORB instance
org.omg.CORBA.Object obj = orb.string_to_object(
    "corbaloc::myhost1:9810,myhost1:9811,myhost2:9810/NameService");
NamingContextExt initCtx = NamingContextExtHelper.narrow(obj);
...
```

Example: Looking up an EJB home with `CosNaming`

You can look up an EJB home or other CORBA object from a WebSphere Application Server name server through the CORBA `CosNaming` interface.

You can invoke `resolve` or `resolve_str` on the initial context, or you can invoke `string_to_object` on the ORB. You can use a qualified name so that the name resolves regardless of which name server the lookup is executed on, or use an unqualified name that only resolves from the server root context on the name server that actually contains the object binding. (The qualified name traverses the federated system namespace to the specified server root context.)

Qualified and unqualified names

Each application server contains a name server. System artifacts such as EJB homes are bound in that name server. The various name servers are federated by means of a system namespace structure. The recommended way to look up objects on different servers is to use a qualified name.

A qualified name can be a topology-based name, based on the name of the single server and node that contains the object.

You can define fixed qualified names for objects. With qualified names, you can look up objects residing on different servers from the same initial context by traversing the system namespace structure. Alternatively, you can use an unqualified name, but an unqualified name will only resolve using the name server associated with the object's application server.

`CosNaming.resolve` (and `resolve_str`) vs. `ORB.string_to_object`

If you have an initial context from any name server in a WebSphere Application Server cell, you can look up any CORBA object with a qualified name. You do not need additional host and port information for the target object's name server.

Alternatively, you can look up an object by invoking `string_to_object` on the ORB, passing in a `corbaname` URL. Typically, an IOP type URL is specified, so the bootstrap address information required

for an initial context must be contained in the URL. You can use a qualified or unqualified stringified name, but an unqualified name resolves only if the initial context is from the name server in which the object is bound.

The following examples show CosNaming resolve operations using qualified topology-based lookup names and an unqualified lookup name.

CosNaming resolve operation using a qualified name

The topology-based qualified name can be found for an object that is bound in a single server.

Single server

The following example shows the lookup of an EJB home that is running in a single server. The enterprise bean that is being looked up is running in the server, MyServer, on the node, Node1.

```
// Get the initial context as shown in the previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
// Look up the home interface using the name under which the EJB home is bound
org.omg.CORBA.Object ejbHome = initialContext.resolve_str(
    "cell/nodes/Node1/servers/MyServer/mycompany/accounting/AccountEJB");
accountHome =
    (AccountHome)javadoc.rmi.PortableRemoteObject.narrow(ejbHome, AccountHome.class);
```

ORB string_to_object operation using an unqualified stringified name

If the resolve operation is being performed on the name server that contains the object, the system namespace does not need to be traversed, and you can use an unqualified lookup name. Note that this name does not resolve on other name servers. If an unqualified name is provided, the object key must be NameServiceServerRoot so that the correct initial context is selected. If a qualified name is provided, you can use the default key of NameService.

The following example shows a lookup of an EJB home. The enterprise bean that is being looked up is bound on the name server running on the host myHost on port 2809. Note the object key of NameServiceServerRoot.

```
// Assume orb is an existing ORB instance
...
// Look up the home interface using the name under which the EJB home is bound
org.omg.CORBA.Object ejbHome = orb.string_to_object(
    "corbaname:iiop:myHost:2809/NameServiceServerRoot#mycompany/accounting");
accountHome =
    (AccountHome)javadoc.rmi.PortableRemoteObject.narrow(ejbHome, AccountHome.class);
```

Chapter 20. Developing Object pools

This page provides a starting point for finding information about object pools.

Object pools provide an effective means of improving application performance at run time, by supporting the reuse of multiple instances of objects.

Using object pools

An object pool helps an application avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused.

About this task

Object pools are not meant to be used for pooling JDBC connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To use an object pool, the product administrator must define an *object pool manager* using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Note: The Object pool manager service is only supported from within the EJB container or Web container. Looking up and using a configured object pool manager from a Java 2 Platform Enterprise Edition (J2EE) application client container is not supported.

Procedure

1. Start the administrative console.
2. Click **Resources > Object pool managers**.
3. Specify a **Scope** value and click **New**.
4. Specify the required properties for work manager settings.
 - Scope** The scope of the configured resource. This value indicates the location for the configuration file.
 - Name** The name of the object pool manager. This name can be up to 30 ASCII characters long.
 - JNDI Name**
 - The Java Naming and Directory Interface (JNDI) name for the pool manager.
5. [Optional] Specify a **Description** and a **Category** for the object pool manager.

Results

After you have completed these steps, applications can find the object pool manager by doing a JNDI lookup using the specified JNDI name.

Example

The following code illustrates how an application can find an object pool manager object:

```
InitialContext ic = new InitialContext();
ObjectPoolManager opm = (ObjectPoolManager)ic.lookup("java:comp/env/pool");
```

When the application has an ObjectPoolManager, it can cache an object pool for classes of the types it wants to use. The following is an example:

```
ObjectPool arrayListPool = null;
ObjectPool vectorPool = null;
try
```

```

{
    arrayListPool = opm.getPool(ArrayList.class);
    vectorPool = opm.getPool(Vector.class);
}
catch(InstantiationException e)
{
    // problem creating pool
}
catch(IllegalAccessException e)
{
    // problem creating pool
}
}

```

When the application has the pools, the application can use them as in the following example:

```

ArrayList list = null;
try
{
    list = (ArrayList)arrayListPool.getObject();
    list.clear(); // just in case
    for(int i = 0; i < 10; ++i)
    {
        list.add("" + i);
    }
    // do what ever we need with the ArrayList
}
finally
{
    if(list != null) arrayListPool.returnObject(list);
}

```

This example presents the basic pattern for using object pooling. If the application does not return the object, then the only adverse effect is that the object cannot be reused.

Object pool managers

Object pool managers control the reuse of application objects and Developer Kit objects, such as Vectors and HashMaps.

Multiple object pool managers can be created in an Application Server cell. Each object pool manager has a unique cell-wide Java Naming and Directory Interface (JNDI) name. Applications can find a specific object pool manager by doing a JNDI lookup using the specific JNDI name.

The object pool manager and its associated objects implement the following interfaces:

```

public interface ObjectPoolManager
{
    ObjectPool getPool(Class aClass)
        throws InstantiationException, IllegalAccessException;
    ObjectPool createFastPool(Class aClass)
        throws InstantiationException, IllegalAccessException;
}

public interface ObjectPool
{
    Object getObject();
    void returnObject(Object o);
}

```

The getObject() method removes the object from the object pool. If a getObject() call is made and the pool is empty, then an object of the same type is created. A returnObject() call puts the object back into the object pool. If returnObject() is not called, then the object is no longer allocatable from the object pool. If the object is not returned to the object pool, then it can be garbage collected.

Each object pool manager can be used to pool any Java object with the following characteristics:

- The object must be a public class with a public default constructor.
- If the object implements the `java.util.Collection` interface, it must support the optional `clear()` method.

Each pooled object class must have its own object pool. In addition, an application gets an object pool for a specific object using either the `ObjectPoolManager.getPool()` method or the `ObjectPoolManager.createFastPool()` method. The difference between these methods is that the `getPool()` method returns a pool that can be shared across multiple threads. The `createFastPool()` method returns a pool that can only be used by a single thread.

If in a Java virtual machine (JVM), the `getPool()` method is called multiple times for a single class, the same pool is returned. A new pool is returned for each call when the `createFastPool()` method is called. Basically, the `getPool()` method returns a pool that is thread-synchronized.

The pool for use by multiple threads is slightly slower than a fast pool because of the need to handle thread synchronization. However, extreme care must be taken when using a fast pool.

Consider the following interface:

```
public interface PoolableObject
{
    void init();
    void returned();
}
```

If the objects placed in the pool implement this interface and the `ObjectPool.getObject()` method is called, the object that the pool distributes has the `init()` method called on it. When the `ObjectPool.returnObject()` method is called, the `PoolableObject.returned()` method is called on the object before it is returned to the object pool. Using this method objects can be pre-initialized or cleaned up.

It is not always possible for an object to implement `PoolableObject`. For example, an application might want to pool `ArrayList` objects. The `ArrayList` object needs clearing each time the application reuses it. The application might extend the `ArrayList` object and have the `ArrayList` object implement a poolable object. For example, consider the following:

```
public class PooledArrayList extends ArrayList implements PoolableObject
{
    public PooledArrayList()
    {
    }

    public void init() {
    }

    public void returned()
    {
        clear();
    }
}
```

If the application uses this object, in place of a true `ArrayList` object, the `ArrayList` object is cleared automatically when it is returned to the pool.

Clearing an `ArrayList` object simply marks it as empty and the array backing the `ArrayList` object is not freed. Therefore, as the application reuses the `ArrayList`, the backing array expands until it is big enough for all of the application requirements. When this point is reached, the application stops allocating and copying new backing arrays and achieves the best performance.

It might not be possible or desirable to use the previous procedure. An alternative is to implement a custom object pool and register this pool with the object pool manager as the pool to use for classes of

that type. The class is registered by the WebSphere administrator when the object pool manager is defined in the cell. Take care that these classes are packaged in Java Archive (JAR) files available on all of the nodes in the cell where they might be used.

Object pool managers collection

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers**.

To use an object pool, the product administrator must define an object pool manager using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Name

Specifies the name by which the object pool manager is known for administrative purposes.

Data type	String
Range	1 through 30 ASCII characters

JNDI name

Specifies the Java Naming and Directory Interface (JNDI) name for the object pool manager.

Data type	String
------------------	--------

Scope

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Description

Specifies the description of the object pool manager.

Data type	String
------------------	--------

Category

Specifies the category name used to classify or group this object pool manager.

Data type	String
------------------	--------

Object pool managers settings

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers > *objectpoolmanager_name***

To use an object pool, the product administrator must define an object pool manager using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Name:

The name by which the object pool manager is known for administrative purposes.

Data type	String
Range	1 through 30 ASCII characters

JNDI Name:

The Java Naming and Directory Interface (JNDI) name for the object pool manager.

Data type	String
------------------	--------

Description:

A description of the object pool manager.

Data type	String
------------------	--------

Category:

A category name used to classify or to group this object pool manager.

Data type	String
------------------	--------

Custom object pool collection:

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers > *objectpoolmanager_name* > Custom object pools**.

Use custom object pools to insert additional logic around the following mechanisms:

- Constructing an object pool (A list of properties can be set)
- Flushing the object pool
- Getting objects from the pool
- Returning objects from the pool

These features allow for actions such as, clearing the state of an object when returning it to the pool, configuring the state of an object when retrieving it from the pool, or configuring generic pools and sending instructions on how to behave using custom properties.

To use an object pool the product administrator must define an object pool manager using the administrative console. You can create multiple object pool managers in an Application Server cell.

Pool class name:

Specifies the fully qualified class name of the objects that are stored in the custom object pool.

Data type String

Pool implementation class name:

Specifies the fully qualified class name of the implementation class for the custom object pool.

Data type String

Custom object pool settings:

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers > objectpoolmanager_name > Custom object pools > objectpool_name**.

Use custom object pools to insert additional logic around the following mechanisms:

- Constructing an object pool (A list of properties can be set)
- Flushing the object pool
- Getting objects from the pool
- Returning objects from the pool

These features allow for actions such as, clearing the state of an object when returning it to the pool, configuring the state of an object when retrieving it from the pool, or configuring generic pools and sending instructions on how to behave using custom properties.

To use an object pool, the product administrator must define an object pool manager using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Pool Class Name:

The fully qualified class name of the objects that are stored in the object pool.

Data type String

Pool Impl Class Name:

The fully qualified class name of the CustomObjectPool implementation class for this object pool.

Data type String

Object pool service settings

Use this page to enable or disable the object pool service, which manages object pool resources used by the server.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > *server_name* > Container Services > Object pool service.**

Enable service at server startup

Specifies whether the server attempts to start the object pool service.

Default	Cleared
Range	Selected When the application server starts, it attempts to start the object pool service automatically.
	Cleared The server does not try to start the object pool service. If object pool resources are used on this server, then the system administrator must start the object pool service manually or select this property, and then restart the server.

Object pools: Resources for learning

This topic provides links to find relevant supplemental information about object pools.

Use the following links to find relevant supplemental information about object pools. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Furthermore, these links provide guidance on using object pools. Since object pooling is a general topic and the WebSphere Application Server product implementation is only one way to use it, you must understand when object pooling is necessary. These articles help you make that decision.

Programming model and decisions

- Build your own ObjectPool in Java to boost application speed
- Improve the robustness and performance of your ObjectPool
- Recycle broken objects in resource pools

MBeans for object pool managers and object pools

Legacy MBean names for object pool managers and object pools are deprecated. The legacy names are based on the object pool manager name (which is not required to be unique) rather than the object pool manager JNDI name.

About this task

For object pools, the legacy name is also lacking any identifier of the version of the pooled class. Additionally, object pool Performance Monitoring Instrumentation (PMI) statistics are aggregated for object pools with the same legacy object pool MBean name.

For example, if the object pool manager and pooled class are as follows:

```
object pool manager name:      My ObjectPool
object pool manager JNDI name: op/MyObjectPool
pooled class name:            java.util.ArrayList
hash code of java.util.ArrayList.class: 1111eb3f (hexadecimal)
```

the legacy object pool manager MBean name will be:

ObjectPoolManager_My ObjectPool

and the legacy object pool MBean name will be:

ObjectPool_My ObjectPool_java.util.ArrayList

Instead of using the deprecated legacy MBean names, use the MBean names that are based on the JNDI name of the object pool manager.

For the example above, the JNDI name-based object pool manager MBean name is:

ObjectPoolManager_op/MyObjectPool

and the JNDI name-based object pool MBean name is:

ObjectPool_op/MyObjectPool_java.util.ArrayList.class@1111eb3f

Formats for MBean names

Type	Name format
Deprecated legacy object pool manager MBean name:	ObjectPoolManager_[object pool manager name]
JNDI name-based object pool manager MBean name:	ObjectPoolManager_[object pool manager JNDI name]
Deprecated legacy object pool MBean name:	ObjectPool_[object pool manager name]_[pooled class name]
JNDI name-based object pool MBean name:	ObjectPool_[object pool manager JNDI name]_[pooled class name].class@[hexadecimal representation of the hash code of the pooled class' java.lang.Class reference]

In all of the above formats, characters that are not valid for MBean names are replaced with the '.' character.

Chapter 21. Developing Object Request Broker (ORB)

This page provides a starting point for finding information about the Object Request Broker (ORB). The product uses an ORB to manage communication between client applications and server applications as well as among product components. These Java Platform, Enterprise Edition (Java EE) standard services are relevant to the ORB: Remote Method Invocation/Internet Inter-ORB Protocol (RMI/IOP) and Java Interface Definition Language (Java IDL).

The ORB provides a framework for clients to locate objects in the network and call operations on those objects as though the remote objects were located in the same running process as the client, providing location transparency.

Developing Object Request Brokers

Client-side programming tips for the Object Request Broker service

Every Internet InterORB Protocol (IIOP) request and response exchange consists of a client-side ORB and a server-side ORB. It is important that any application that uses IIOP is properly programmed to communicate with the client-side Object Request Broker (ORB).

The following tips should help you ensure that an application that uses IIOP to handle request and response exchanges is properly programmed to communicate with the client-side Object Request Broker (ORB).

Resolution of initial references to services

Client applications can use the `ORBInitRef` and `ORBDefaultInitRef` properties to configure the network location that the ORB service uses to find a service such as naming. When set, these properties are included in the parameters that are used to initialize the ORB, as illustrated in the following example:

```
org.omg.CORBA.ORB.init(java.lang.String[] args,  
                      java.util.Properties props)
```

You can set these properties in client code or by command-line argument. It is possible to specify more than one service location by using multiple `ORBInitRef` property settings (one for each service), but only a single `ORBDefaultInitRef` value can be specified.

For setting in client code, these properties are `com.ibm.CORBA.ORBInitRef.service_name` and `com.ibm.CORBA.ORBDefaultInitRef`, respectively. For example, to specify that the naming service (`NameService`) is located in `sample.server.com` at port 2809, set the `com.ibm.CORBA.ORBInitRef.NameService` property to `corbaloc::sample.server.com:2809/NameService`.

For setting by command-line argument, these properties are `-ORBInitRef` and `-ORBDefaultInitRef`, respectively. To locate the same naming service specified previously, use the following Java command:

After these properties are set for services that the ORB supports, Java Platform, Enterprise Edition (Java EE) applications can call the `resolve_initial_references` function on the ORB, as defined in the CORBA/IIOP specification, to obtain the initial reference to a given service.

Preferred API for obtaining an ORB instance

For Java EE applications, you can use either of the following approaches. However, it is strongly recommended that you use the Java Naming and Directory Interface (JNDI) approach to ensure that the same ORB instance is used throughout the client application; you avoid the unintended inconsistencies that might occur when different ORB instances are used.

JNDI approach: For Java EE applications (including enterprise beans, Java EE clients and servlets), you can obtain an ORB instance by creating a JNDI InitialContext object and looking up the ORB under the `java:comp/ORB` name, as illustrated in the following example:

```
javax.naming.Context ctx = new javax.naming.InitialContext();
org.omg.CORBA.ORB orb =
    (org.omg.CORBA.ORB)javax.rmi.PortableRemoteObject.narrow(ctx.lookup("java:comp/ORB"),
                                                            org.omg.CORBA.ORB.class);
```

The ORB instance obtained using JNDI is a singleton object, shared by all the Java EE components that are running in the same Java virtual machine process.

Note: You must use the JNDI approach if you want to take advantage of WLM functionality and cluster failover within the application. For information on how to obtain an InitialContext from a server cluster, see the example for using a CORBA object URL with multiple name server addresses, which is in the topic on getting an initial context by setting the provider URL property.

CORBA approach: Because thin-client applications do not run in a Java EE container, they cannot use JNDI interfaces to look up the ORB. In this case, you can obtain an ORB instance by using CORBA programming interfaces, as follows:

```
java.util.Properties props = new java.util.Properties();
java.lang.String[] args = new java.lang.String[0];
org.omg.CORBA.ORB orb = org.omg.CORBA.ORB.init(args, props);
```

In contrast to the JNDI approach, the CORBA specification requires that a new ORB instance be created each time the `ORB.init` method is called. If necessary to change the ORB default settings, you can add ORB property settings to the Properties object that is passed in the `ORB.init` method call.

The use of the `com.ibm.ejs.oe.EJSORB.getORBInstance` method, supported in previous releases of this product is deprecated.

API restrictions with sharing an ORB instance among Java EE application components

For performance reasons, it often makes sense to share a single ORB instance among components in a Java EE application. As required by the Java EE Specification, Version 1.3, all web and EJB containers provide an ORB instance in the JNDI namespace as `java:comp/ORB`. Each container can share this instance among application components but is not required to. For proper isolation between application components, application code must comply with the following restrictions:

- Do not call the ORB shutdown or destroy methods
- Do not call `org.omg.CORBA_2_3.ORB` methods `register_value_factory`, or `unregister_value_factory`

In addition, do not share an ORB instance among application components in different Java EE applications.

Required use of `rmic` and `idlj` that ship with the IBM Developer Kit

The Java Runtime Environment (JRE) used by this product includes the **rmic** and **idlj** tools. You use the tools to generate Java language bindings for the CORBA/IIOP protocol.

During product installation, the tools are installed in the `app_server_root/java/ibm_bin` directory. Versions of these tools included with Java development kits in the `$JAVA_HOME/bin` directory other than the IBM Developer Kit installed with this product are incompatible with this product.

When you install this product, the `app_server_root/java/ibm_bin` directory is included in the `$PATH` search order to enable use of the `rmic` and `idlj` scripts provided by IBM. Because the scripts are in the `app_server_root/java/ibm_bin` directory instead of the JRE standard `app_server_root/java/bin` directory, it is unlikely that you can overwrite them when applying maintenance to a JRE not provided by IBM.

In addition to the `rmic` and `idlj` tools, the JRE also includes Interface Definition Language (IDL) files. The files are based on those defined by the Object Management Group (OMG) and can be used by applications that need an IDL definition of selected ORB interfaces. The files are placed in the `app_server_root/java/ibm_lib` directory.

Before using either the `rmic` or `idlj` tool, ensure that the `app_server_root/java/ibm_bin` directory is included in the proper `PATH` variable search order in the environment. If your application uses IDL files in the `app_server_root/java/ibm_lib` directory, also ensure that the directory is included in the `PATH` variable.

Directory conventions

References in product information to `app_server_root`, `profile_root`, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root

The default installation root directory for the Application Client for IBM WebSphere Application Server is the `/QIBM/ProdData/WebSphere/AppClient/V8/client` directory.

app_client_user_data_root

The default Application Client for IBM WebSphere Application Server user data root is the `/QIBM/UserData/WebSphere/AppClient/V8/client` directory.

app_client_profile_root

The default Application Client for IBM WebSphere Application Server profile root is the `/QIBM/UserData/WebSphere/AppClient/V8/client/profiles/profile_name` directory.

app_server_root

The default installation root directory for WebSphere Application Server - Express is the `/QIBM/ProdData/WebSphere/AppServer/V8/Express` directory.

java_home

Table 99. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32-bit IBM Technology for Java	<code>/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit</code>
64-bit IBM Technology for Java	<code>/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit</code>

plugins_profile_root

The default Web Server Plug-ins profile root is the `/QIBM/UserData/WebSphere/Plugins/V8/webserver/profiles/profile_name` directory.

plugins_root

The default installation root directory for Web Server Plug-ins is the `/QIBM/ProdData/WebSphere/Plugins/V8/webserver` directory.

plugins_user_data_root

The default Web Server Plug-ins user data root is the `/QIBM/UserData/WebSphere/Plugins/V8/webserver` directory.

product_library

product_lib

This is the product library for the installed product. The product library for each Version 8.0

installation on the system contains the program and service program objects (similar to .exe, .dll, .so objects) for the installed product. The product library name is QWAS8x (where x is A, B, C, and so on). The product library for the first WebSphere Application Server Version 8.0 product installed on the system is QWAS8A. The *app_server_root/properties/product.properties* file contains the value for the product library of the installation, *was.install.library*, and is located under the *app_server_root* directory.

profile_root

The default directory for a profile named *profile_name* for WebSphere Application Server - Express is the */QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/profile_name* directory.

shared_product_library

The shared product library, which contains all of the objects shared by all installations on the system, is QWAS8. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root

The default user data directory for WebSphere Application Server - Express is the */QIBM/UserData/WebSphere/AppServer/V8/Express* directory.

The *profiles* and *profileRegistry* subdirectories are created under this directory when you install the product.

web_server_root

The default web server path is */www/web_server_name*.

Chapter 22. Developing OSGi applications

You can develop bundles, optionally group them into composite bundles, and add them to an OSGi application or a bundle repository.

Procedure

- Develop and deploy an OSGi application.

As an introduction to developing an OSGi application, you can develop a simple hello-world OSGi application, which consists of two bundles. One bundle defines a hello service, and the other is a client bundle that uses this service to produce the message “OSGi Service: Hello World!”.

- Develop a composite bundle.

A composite bundle groups shared bundles together into aggregates. It provides one or more packages at specific versions to an OSGi application. You can also extend a deployed application by adding one or more composite bundles to the composition unit for the application.

- Convert existing applications to OSGi applications.

You can convert an enterprise application or a Spring application to an OSGi application.

What to do next

You might also want to explore the sample OSGi applications.

Developing and deploying an OSGi application

As an introduction to developing an OSGi application, you can develop a simple hello-world OSGi application, which consists of two bundles. One bundle defines a hello service, and the other is a client bundle that uses this service to produce the message “OSGi Service: Hello World!”.

About this task

An OSGi application is a Java application that uses OSGi technologies. OSGi applications are collections of OSGi bundles (typically bundles that use the Blueprint component model), and can expose or consume a number of services. The OSGi application described in these topics demonstrates the use of the OSGi service registry to share the hello service between the defining bundle and the client bundle. All interactions with the service registry are handled through Blueprint.

OSGi bundles are packaged as Java archive (.jar) files. A single OSGi application is packaged in an enterprise bundle archive (.eba) file, just as an enterprise application is packaged in an enterprise archive (.ear) file. In this example application, the bundles are packaged directly in the .eba file. However the .eba file does not have to contain the bundles; they can be pulled in at run time.

Note: In the following procedure, the first three steps are specific to this example application, and lead you through creating the application artefacts using IBM Rational Application Developer Version 8 or similar tooling. The final step is not specific to this example application, and describes the process of deploying any OSGi application in WebSphere Application Server, using the administrative console or wsadmin commands.

Procedure

1. Create your service bundle.
2. Create your client bundle.
3. Create your OSGi application.
4. Deploy an OSGi application as a business-level application.

What to do next

To help solve any unexpected problems with your deployed applications, you can debug the bundles at run time using the command-line console.

You might also want to explore the sample OSGi applications.

Creating a service bundle

For the simple hello-world OSGi application, the service bundle declares the HelloWorldEBA interface, and exports it as an OSGi service.

About this task

A bundle, the modular unit in the OSGi model, is a JAR file that includes the OSGi application metadata. This metadata is defined in the manifest file of the JAR file, META-INF/MANIFEST.MF.

IBM Rational Application Developer Version 8 provides graphical support for creating and packaging bundles. The sample procedure below uses this tool. You can also use other tools, and the steps are adaptable to other tools.

This sample procedure builds a bundle called `com.ibm.ws.eba.helloWorldService`. This bundle declares the HelloWorldEBA interface, and exports it as an OSGi service. The exported service is used by client bundle `com.ibm.ws.eba.helloWorldClient`, as described in “Creating a client bundle” on page 888.

Note: In this simple example, the interface definition and implementation are co-located in the same bundle. In a more realistic business scenario, you would separate the service interface declaration and service implementation into separate bundles, because the interface declaration is likely to change far less often than the business implementation of the service.

Procedure

1. Create an OSGi bundle project.
 - a. Click **File > New > Project**. The Select a wizard panel is displayed.
 - b. Click **OSGi > OSGi Bundle Project**, then click **Next**. The OSGi Bundle Project panel is displayed.
 - c. Configure the project.
 - For **Project name**, enter `com.ibm.ws.eba.helloWorldService`.
 - Leave the other options as the default values.
 - d. Click **Next**. The Java Configuration panel is displayed. Accept the default values for all the options on this panel.
 - e. Click **Next**. The OSGi bundle settings panel is displayed. Accept the default values for all the options on this panel.
 - f. Click **Finish**.

You have created your OSGi project.

2. Declare and implement the HelloWorld service.
 - a. Create a package called `com.ibm.ws.eba.helloWorld`, that includes an interface called HelloWorldEBA. Code this interface to contain just one method: `hello()`.

Note: In a later step, you create code in a Blueprint XML file that exposes this interface as a service.

 - 1) Under your `com.ibm.ws.eba.helloWorldService` project, right-click the folder `src`, then select **new > package**.
 - 2) Name the new package `com.ibm.ws.eba.helloWorld`.

- 3) Click **Finish**.
- 4) Right-click the new package, then select **new > interface**.
- 5) Name the new interface HelloWorldEBA.
- 6) Click **Finish**.
- 7) Copy and paste the following method to replace the content of the interface file:

```
package com.ibm.ws.eba.helloWorld;
public interface HelloWorldEBA {

    public void hello();
}
```

- 8) Save and close the file.

- b. Create a package called `com.ibm.ws.eba.helloWorld.impl`, that includes an implementation class called `HelloWorldEBAImpl`. Code this class to implement the `hello()` method from the `HelloWorldEBA` interface. This implementation of the class causes “OSGi Service: Hello World!” to be displayed.

- 1) Under your `com.ibm.ws.eba.helloWorldService` project, right-click the folder `src`, then select **new > package**.
- 2) Name the new package `com.ibm.ws.eba.helloWorld.impl`.
- 3) Click **Finish**.
- 4) Right-click the new package, then select **new > class**.
- 5) Name the new interface implementation class `HelloWorldEBAImpl`.
- 6) Click **Finish**.
- 7) Copy and paste the following method to replace the content of the interface implementation class file:

```
package com.ibm.ws.eba.helloWorld.impl;

import com.ibm.ws.eba.helloWorld.HelloWorldEBA;

public class HelloWorldEBAImpl implements HelloWorldEBA {
    @Override
    public void hello() {
        System.out.println("OSGi Service: Hello World!");
    }
}
```

- 8) Save and close the file.

3. Create a Blueprint configuration.

A Blueprint configuration contains the bundle component assembly and configuration information. It also describes how components are registered in the OSGi service registry, or how they look up services from the OSGi service registry. This information is used at run time to instantiate and configure the required components when the bundle is started.

- a. In the project `com.ibm.ws.eba.helloWorldService`, create a Blueprint XML file:

- 1) Click **File > New > Other > OSGi > Blueprint File**.
- 2) Accept the default values for all the options on this panel.
- 3) Click **Finish**.

- b. Update the Blueprint XML file to contain the following Blueprint information:

```
<?xml version="1.0" encoding="UTF-8"?>
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0">
  <bean id="helloEBA" class="com.ibm.ws.eba.helloWorld.impl.HelloWorldEBAImpl"/>
  <service ref="helloEBA" interface="com.ibm.ws.eba.helloWorld.HelloWorldEBA"/>
</blueprint>
```

In the previous code block:

- The bean element defines a Blueprint component to be instantiated. In this example, the bean element causes bean `helloEBA` to be instantiated, by calling the constructor for the `com.ibm.ws.eba.helloWorld.impl.HelloWorldEBAImpl` class.

- The **id** attribute identifies the bean. You must specify this attribute if the bean is referenced from elsewhere in the Blueprint information, for example from the service element.
- The **class** attribute specifies which implementation class of the bean is instantiated.
- The service element defines the registration of a component in the OSGi service registry. In this example, the service element registers the bean with the name `helloEBA` as a service in the OSGi service registry with interface `com.ibm.ws.eba.helloWorld.HelloWorldEBA`, specified by the interface attribute.
 - The **ref** attribute refers to the **id** of the bean to be registered. This **id** is defined in the bean element.
 - The **interface** attribute refers to the interface that the bean class implements.

For more information, see section 121.5 “Bean Manager” and section 121.6 “Service Manager” of the OSGi Service Platform Release 4 Version 4.2 Enterprise Specification.

Note: You might get an exception message (visible in the Problems pane) saying that there is no `bin.include` entry for OSGI-INF in the build properties file. If you see this message, use the **quick-fix** option to add the entry (right-click the problem, then select **quick-fix**).

4. Configure the `com.ibm.ws.eba.helloWorld` package as an exported package.

Edit the bundle manifest to allow other bundles to load classes from the `com.ibm.ws.eba.helloWorld` package. Classes that are in packages not exported in the bundle manifest are private to the defining bundle and cannot be loaded by any other bundle.

 - a. Open the bundle `MANIFEST.MF` file with the manifest editor. This file is in the `BundleContent/META-INF` directory.
 - b. Click the **Runtime** tab.
 - c. In the Exported Packages pane, click **Add**.
 - d. Select the `com.ibm.ws.eba.helloWorld` package from the list, then click **OK**.
 - e. In the Exported Packages pane, click **Properties**.
 - f. In the **Properties** dialog, set the **version** to `1.0.0`, then click **OK**.
 - g. Save the changes in the manifest editor. Click **File > Save**.

Results

You have created a bundle called `com.ibm.ws.eba.helloWorldService`. This bundle contains the business logic and metadata needed to export the `HelloWorldEBA` service.

What to do next

You can now create the client bundle that uses the `HelloWorldEBA` service.

Creating a client bundle

For the simple hello-world OSGi application, the client bundle consumes the `HelloWorldEBA` service, and uses it to produce the message “OSGi Service: Hello World!”.

Before you begin

This task assumes that you have already created the `HelloWorldEBA` service, as described in “Creating a service bundle” on page 886.

About this task

A bundle, the modular unit in the OSGi model, is a JAR file that includes the OSGi application metadata. This metadata is defined in the manifest file of the JAR file, `META-INF/MANIFEST.MF`.

IBM Rational Application Developer Version 8 provides graphical support for creating and packaging bundles. The sample procedure below uses this tool. You can also use other tools, and the steps are adaptable to other tools.

This sample procedure builds a bundle called `com.ibm.ws.eba.helloWorldClient`. This bundle uses the `HelloWorldEBA` service that is exported by the bundle `com.ibm.ws.eba.helloWorldService`, as described in “Creating a service bundle” on page 886.

Procedure

1. Create an OSGi bundle project.
 - a. Click **File > New > Project**. The Select a wizard panel is displayed.
 - b. Click **OSGi > OSGi Bundle Project**, then click **Next**. The OSGi Bundle Project panel is displayed.
 - c. Configure the project.
 - For **Project name**, enter `com.ibm.ws.eba.helloWorldClient`.
 - Leave the other options as the default values.
 - d. Click **Next**. The Java Configuration panel is displayed. Accept the default values for all the options on this panel.
 - e. Click **Next**. The OSGi bundle settings panel is displayed. Accept the default values for all the options on this panel.
 - f. Click **Finish**.

You have created your OSGi project.

2. Make the `HelloWorldEBA` service available to the client bundle.

Edit the client bundle manifest to make classes inside the `com.ibm.ws.eba.helloWorld` package available to the client bundle. The `com.ibm.ws.eba.helloWorld` package is part of the `com.ibm.ws.eba.helloWorldService` bundle.

 - a. Open the bundle `MANIFEST.MF` file with the manifest editor. This file is in the `BundleContent/META-INF` directory.
 - b. Click the **Dependencies** tab.
 - c. In the Imported Packages pane, click **Add**.
 - d. In the Package Selection dialog, enter `com.ibm.ws.eba.helloWorld` then click **OK**. The package is added to the Imported Packages list.
 - e. In the Imported Packages list, select the `com.ibm.ws.eba.helloWorld` package then click **Properties**.
 - f. In the **Properties** dialog, set the **minimum version** to `1.0.0 Inclusive`, and set the **maximum version** to `2.0.0 Exclusive`, then click **OK**. The entry for this package in the Imported Packages list is updated to `com.ibm.ws.eba.helloWorld [1.0.0,2.0.0)`.

Note: This version syntax means “exported packages with versions between 1.0.0 inclusive and 2.0.0 exclusive will match this import”. For more information, see section 3.2.6 “Version Ranges” of the OSGi Service Platform Release 4 Version 4.2 Core Specification.

- g. Save the changes in the manifest editor. Click **File > Save**.
3. Create a class `HelloWorldRefEBA`.
 - a. In the project source folder `src`, create a package called `com.ibm.ws.eba.helloWorld.client`. In the package, create an interface called `HelloWorldRefEBA` with the following contents:

```
package com.ibm.ws.eba.helloWorld.client;

import com.ibm.ws.eba.helloWorld>HelloWorldEBA;

public interface HelloWorldRefEBA {
```

```

    public void refHello();
    public HelloWorldEBA getHelloWorldEBAService(); //property getter
}

```

- b. In the same package, to implement the HelloWorldRefEBA interface, create a class called HelloWorldRefEBAImpl with the following contents:

```

package com.ibm.ws.eba.helloWorld.client;

import com.ibm.ws.eba.helloWorld.HelloWorldEBA;

public class HelloWorldRefEBAImpl implements HelloWorldRefEBA {
    private HelloWorldEBA helloWorldEBAService = null; //a reference to the service

    public void refHello() {
        System.out.println("Client: Start...");
        helloWorldEBAService.hello();
        System.out.println("Client: End...");
    }

    public HelloWorldEBA getHelloWorldEBAService() {
        return helloWorldEBAService;
    }

    public void setHelloWorldEBAService(HelloWorldEBA helloWorldEBAService) {
        this.helloWorldEBAService = helloWorldEBAService;
    }
}

```

In the previous code block:

- The line `HelloWorldEBA helloWorldEBAService = null;` defines the service dependency (the `HelloWorldRefEBAImpl` class depends on a service with a `HelloWorldEBA` interface).
- The line `helloWorldEBAService.hello();` demonstrates that a service has been injected for the `helloWorldEBAService` dependency.

4. Create a Blueprint configuration.

A Blueprint configuration contains the bundle component assembly and configuration information. It also describes how components are registered in the OSGi service registry, or how they look up services from the OSGi service registry. This information is used at run time to instantiate and configure the required components when the bundle is started.

- a. In the project `com.ibm.ws.eba.helloWorldClient`, create a Blueprint XML file:

- 1) Click **File** > **New** > **Other** > **OSGi** > **Blueprint File**.
- 2) (Optional) Specify the file name. This can be any name provided it is an XML file. For example, `helloWorldRef.xml`.
- 3) Leave the other options as the default values.
- 4) Click **Finish**.

- b. Update the Blueprint XML file to contain the following Blueprint information. This Blueprint file specifies the internal wiring of the components.

```

<?xml version="1.0" encoding="UTF-8"?>
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0">
  <bean class="com.ibm.ws.eba.helloWorld.client.HelloWorldRefEBAImpl" init-method="refHello">
    <property name="helloWorldEBAService" ref="helloEBARef"/>
  </bean>
  <reference id="helloEBARef" interface="com.ibm.ws.eba.helloWorld.HelloWorldEBA"/>
</blueprint>

```

In the previous code block:

- The `init-method refHello` is called when the `com.ibm.ws.eba.helloWorld.client.HelloWorldRefEBAImpl` bean is created.
- The property element specifies how a dependency is injected.

- The property `helloWorldEBAService` is set by invoking the property setter `public void setHelloWorldEBAService>HelloWorldEBA helloWorldEBAService`. You can use setter injection for bean properties that are defined in accordance with Java bean conventions.
- The attribute `ref` specifies the Blueprint element ID of the component to be injected. The `ref` attribute must match a top-level element in this file. In this case, it matches the reference element.
- The reference element defines a dependency of this Blueprint module on an OSGi service with interface `com.ibm.ws.eba.helloWorld>HelloWorldRefEBA`. When the Blueprint Container starts this module, it must match the name of the interface attribute with an available service in the OSGi service registry. If this cannot be done, the Blueprint module is not started. In this case, the service is defined in the service element of the Blueprint XML of the service bundle.

For more information, see section 121.5 “Bean Manager” and section 121.7 “Service Reference Managers” of the OSGi Service Platform Release 4 Version 4.2 Enterprise Specification.

Results

You have created a bundle called `com.ibm.ws.eba.helloWorldClient`. This bundle consumes the `HelloWorldEBA` service, and uses it to produce the message “OSGi Service: Hello World!”.

What to do next

You can now create an OSGi application, in which multiple bundles are packaged together.

Creating an OSGi application

For the simple hello-world OSGi application, the bundle that defines the service, and the bundle that uses the service, are packaged together in an OSGi application.

Before you begin

This topic assumes that you have already completed the following tasks:

- “Creating a service bundle” on page 886 `com.ibm.ws.eba.helloWorldService`.
- “Creating a client bundle” on page 888 `com.ibm.ws.eba.helloWorldClient`.

You can create your application as described in this topic, in which case the application manifest file is created for you by the tooling, or you can create your application using Apache Ant.

About this task

OSGi bundles are packaged as Java archive (.jar) files. A single OSGi application is packaged in an enterprise bundle archive (.eba) file, just as an enterprise application is packaged in an enterprise archive (.ear) file. In this example application, the bundles are packaged directly in the .eba file. However the .eba file does not have to contain the bundles; they can be pulled in at run time. For an OSGi application deployed to WebSphere Application Server, a bundle can be located in the .eba file, or in the WebSphere Application Server internal bundle repository, or in an external bundle repository. Every .eba file contains an application manifest (APPLICATION.MF) file, which contains the metadata that defines the application. It lists the bundles that the application uses, and says where each bundle is located.

IBM Rational Application Developer Version 8 provides graphical support for creating and packaging bundles. The sample procedure below uses this tool. You can also use other tools, and the steps are adaptable to other tools.

This sample procedure creates a simple hello-world OSGi application called `com.ibm.ws.eba.helloWorld`, in which the two bundles `com.ibm.ws.eba.helloWorldService` and `com.ibm.ws.eba.helloWorldClient` are packaged together in an .eba file.

When you deploy and start this application, it prints the greeting message “OSGi Service: Hello World!” to the system output log.

Procedure

1. Create an OSGi application project.
 - a. Click **File > New > Project**. The Select a wizard panel is displayed.
 - b. Click **OSGi > OSGi Application Project**, then click **Next**. The OSGi Application Project panel is displayed.
 - c. Configure the project.
 - For **Project name**, enter `com.ibm.ws.eba.helloWorld`.
 - Ensure that **Use default location** is selected.
 - Ensure that **Add project to working sets** is cleared.
 - d. Click **Next**.
 - e. In the Contained Bundles list, select `com.ibm.ws.eba.helloWorldService 1.0.0` and `com.ibm.ws.eba.helloWorldClient 1.0.0`
For more information about these bundles, see “Creating a service bundle” on page 886 and “Creating a client bundle” on page 888.

f. Click **Finish**.

2. Optional: Deploy and test the OSGi application project on a server running inside IBM Rational Application Developer.

If you are using IBM Rational Application Developer Version 8, you can deploy to a local machine without first exporting the OSGi application as an EBA file. This is typically how you would test your application. If you are using another tool, omit this step.

- a. Right-click the project name then select **Run As > Run on Server**. The Run On Server panel is displayed.
- b. Configure the Run On Server panel:
 - 1) For server type, select **IBM > WebSphere Application Server v8.0**.
 - 2) For server host name, enter a valid TCP/IP host name. For example, enter the TCP/IP hostname for your computer or enter `localhost`.
 - 3) For server name, enter the name by which you want to refer to the server within IBM Rational Application Developer.
 - 4) For server runtime environment, select **WebSphere Application Server v8.0**. If this option is not available in the list, complete the following steps:
 - a) Click **Add**.
 - b) Navigate to `app_server_root` for the installation of WebSphere Application Server.
 - c) Click **Finish**.
 - 5) Click **Next**.

The WebSphere Application Server Settings panel is displayed.

- c. Configure the WebSphere Application Server Settings panel:
 - 1) For profile name, select the profile that you use with OSGi Applications.
 - 2) For application server name, verify that the application server name for your profile is displayed. By default, the first application server for a profile is called `server1`.
 - 3) Click **Next**.

The list of configured OSGi application projects is displayed.

- d. Check that your OSGi application project is in the list of configured projects.
- e. Click **Finish**.
- f. Start the OSGi application:

- 1) Click the **Servers** tab. If the tab is not already visible, open it by selecting **Window > Show View > Servers**.
- 2) On the **Servers** tab, right-click your application server then select **Start**.

The server starts, your application is published and started, and the following output is displayed on the **Console** tab:

```
[4/15/10 14:07:33:295 GMT] 00000023 SystemOut 0 Client: Start...
[4/15/10 14:07:33:581 GMT] 00000023 SystemOut 0 OSGi Service: Hello World!
[4/15/10 14:07:33:581 GMT] 00000023 SystemOut 0 Client: End...
```

3. Export the project as an EBA file.
 - a. Right-click the project name, then select **Export > OSGi > OSGi Application EBA**.
 - b. Enter a location for the exported file, then name the file `com.ibm.ws.eba.helloWorld.eba`.
 - c. Click **Finish**.

Results

You have completed the detailed instructions for developing a simple OSGi application. This application consists of two bundles: one bundle defines a hello service, and the other is a client bundle that uses this service to produce the message “OSGi Service: Hello World!”. Your application uses the OSGi service registry to share the hello service between the defining bundle and the client bundle. All interactions with the service registry are handled through Blueprint.

What to do next

You are now ready to deploy and start your OSGi application outside of IBM Rational Application Developer, by completing the following steps:

1. Deploy your OSGi application as a business-level application.
2. Start your business-level application.
3. Check the system output log for the greeting message “OSGi Service: Hello World!”.

You can use the administrative console or wsadmin commands to deploy and start an OSGi application in WebSphere Application Server. For information about how to do this for any OSGi application, see “Deploying an OSGi application as a business-level application” on page 894 and Starting your business-level application. When you check the system output log, you should see the following message:

```
[4/15/10 14:07:33:295 GMT] 00000023 SystemOut 0 Client: Start...
[4/15/10 14:07:33:581 GMT] 00000023 SystemOut 0 OSGi Service: Hello World!
[4/15/10 14:07:33:581 GMT] 00000023 SystemOut 0 Client: End...
```

Creating an OSGi application using Apache Ant

You can use the Apache Ant (Ant) command-line tool to package bundles together into an OSGi application.

Before you begin

This topic assumes that you understand how to use the Ant build tooling, and that you have already created the bundles and the application manifest file that you want to package together as an OSGi application.

For a detailed overview of creating an OSGi application, and instructions on how to do this using IBM Rational Application Developer Version 8 or similar tooling, see “Creating an OSGi application” on page 891.

About this task

The code example in this topic shows the syntax for using the Ant zip task to package a set of bundles and an application manifest (APPLICATION.MF) file into an enterprise bundle archive (.eba) file.

Example

```
<zip destfile="${output.dir}/myExample.eba" basedir="${basedir}">
  <filename name="META-INF/APPLICATION.MF"/>
  <fileset dir="${basedir}">
    <include name="*.jar"/>
  </fileset>
</zip>
```

This example packages the META-INF/APPLICATION.MF file into the EBA file, and also includes all files ending in “.jar” (that is, the bundles).

`${output.dir}` and `${basedir}` refer to the following Ant properties:

- **output.dir** is user-defined, and specifies the output directory for your build.
- **basedir** is predefined, and specifies the directory that contains the Ant `build.xml` file.

What to do next

You can use the administrative console or `wsadmin` commands to deploy and start an OSGi application in WebSphere Application Server. See “Deploying an OSGi application as a business-level application” and Starting your business-level application.

Deploying an OSGi application as a business-level application

Import an OSGi application as an enterprise bundle archive (EBA) asset, then add the asset to a business-level application by creating a composition unit. Optionally, add a composite bundle extension to the composition unit.

Before you begin

This topic assumes that you have already created an enterprise OSGi application packaged as an EBA file, for example as described in “Creating an OSGi application” on page 891. You might also have developed a composite bundle extension, as described in Extending a deployed OSGi application.

As well as specifying the configuration information for the EBA asset through the following procedure, you can also change it later as described in Modifying the configuration of an OSGi composition unit. For example, if you update a bundle in an EBA asset, or replace a composite bundle extension, you might introduce a resource that needs additional configuration, such as a new or changed Blueprint resource reference, or security role mapping.

About this task

To deploy an OSGi application in WebSphere Application Server, you import your OSGi application (EBA file) as an asset and create an empty business-level application. You then add a composition unit to the business-level application. This composition unit consists of the new EBA asset plus configuration information for the context roots, virtual hosts, security role mappings, and web application or Blueprint resource bindings for your OSGi application. The composition unit can also include composite bundle extensions.

Note:

- An EBA file can be imported into only one asset.
- An EBA asset can be added to only one business-level application.

- One or more composite bundle extensions can be added to a composition unit.

A business-level application is scoped to cell scope, therefore only one instance of a given OSGi application can be deployed in a cell.

This topic describes the specific task of deploying an OSGi application and any composite bundle extensions as a business-level application. The more generalized task of creating any business-level application is described in [Creating business-level applications](#).

Each step can be completed using either the administrative console or wsadmin commands. You can also create an empty business-level application or add a composition unit using programming.

Procedure

1. Import the EBA file as an asset.

Note: You can import the asset before or after you create the empty business-level application. An EBA file can be imported into only one asset.

To import the EBA file using the administrative console, navigate to **Applications > New Application > New Asset**. For more information, see [Importing assets](#).

To import the EBA file using the importAsset command, enter (for example) the following command:

```
AdminTask.importAsset(["-storageType", "FULL",
                    "-source", com.ibm.ws.eba.helloWorldService.eba])
```

For more information, see the step “Import assets to your configuration” in topic [Setting up business-level applications using wsadmin scripting](#).

Notes:

- When you import the EBA file as an asset, it is checked for any bundle dependencies. If the OSGi application has dependencies on bundles that are not included in the EBA file, the dependencies are resolved against any configured bundle repositories. Asset registration cannot complete unless all missing dependencies are available from configured bundle repositories.
 - When asset registration completes, if the asset requires bundles to be downloaded from bundle repositories, a warning message is displayed telling you to save your changes to the master configuration after completing the asset import. When you save changes, the missing dependencies are downloaded from the configured bundle repositories.
 - If the asset uses Java 2 security, the security permissions are displayed. This information comes from the META-INF/permissions.perm file for your application. For more information, see [Java 2 security and OSGi Applications](#).
 - Do not add the asset to a business-level application until the bundle download has completed. You can view the download status of the bundles from the administrative console, or by calling the areAllDownloadsComplete () method of the BundleCacheManager MBean. See [Interacting with the OSGi bundle cache](#).
2. Create an empty business-level application.

To create an empty business-level application using the administrative console, navigate to **Applications > New Application > New Business Level Application**. For more information, see the step “Create an empty business-level application” in topic [Creating business-level applications with the console](#).

To create an empty business-level application using the createEmptyBLA command, enter (for example) the following command:

```
AdminTask.createEmptyBLA(['-name "helloWorld"
                        -description "helloWorld OSGi sample"]')
```

For more information, see the step “Create an empty business-level application” in topic [Setting up business-level applications using wsadmin scripting](#).

To create an empty business-level application using programming, see [Creating an empty business-level application using programming](#).

3. Add the EBA asset to the business-level application as a composition unit.

An EBA asset can be added to only one business-level application. An OSGi composition unit consists of an EBA asset, (optionally) one or more composite bundle extensions, and some or all of the following configuration information:

- Mappings from the composition unit to a target application server, web server or cluster.
- Configuration of the application's session manager, context roots or virtual hosts.
- Bindings to any associated web applications or blueprint resource references.
- Mappings from security roles to particular users or groups.

To add the asset to the business-level application as a composition unit, use one of the following methods:

- “Adding an EBA asset to a composition unit using the administrative console.”
- “Adding an EBA asset to a composition unit using wsadmin commands” on page 899.
- Adding a composition unit using programming.

4. Optional: Add a composite bundle as an extension to the composition unit.

After you import the enterprise bundle archive (EBA) file for your OSGi application as an asset, you can update versions of existing bundles but you cannot add extra bundles to the asset. However, after you have added the asset as a composition unit to a business-level application, you can extend the business-level application by adding one or more composite bundles to the composition unit.

5. Save your changes to the master configuration.

If you are using wsadmin commands, enter the following command:

```
AdminConfig.save()
```

What to do next

You are now ready to start your business-level application.

Adding an EBA asset to a composition unit using the administrative console

Use the administrative console to add a composition unit that consists of a previously-imported EBA asset plus configuration information. The configuration information can include HTTP session management, context roots, virtual hosts, security roles, run-as roles, and web application or Blueprint resource reference bindings for your OSGi application.

Before you begin

You can add an EBA asset to a business-level application by using the administrative console as described in this topic, or by using the `addCompUnit` command as described in “Adding an EBA asset to a composition unit using wsadmin commands” on page 899.

An EBA asset can be added to only one business-level application. A business-level application is scoped to cell scope, therefore only one instance of a given OSGi application can be deployed in a cell.

This task makes the following assumptions:

- You have already imported the EBA file as an asset (as described in “Deploying an OSGi application as a business-level application” on page 894), then saved your changes to the master configuration (which causes any bundle dependencies to be downloaded from configured bundle repositories).
- You have already defined the target virtual hosts. To check existing virtual hosts by using the administrative console, click **Environment** > **Virtual hosts**.

- You have already created the JCA authentication alias that you want to associate with each Blueprint resource reference. To check existing JCA authentication aliases using the administrative console, click **Security > Global security > [Authentication] Java Authentication and Authorization Service > J2C authentication data**.

About this task

An OSGi composition unit consists of an EBA asset, (optionally) one or more composite bundle extensions, and some or all of the following configuration information:

- Mappings from the composition unit to a target application server, web server or cluster.
- Configuration of the application's session manager, context roots or virtual hosts.
- Bindings to any associated web applications or blueprint resource references.
- Mappings from security roles to particular users or groups.

You use the Set options settings wizard to add a new composition unit to a business-level application. The contents of the asset determine the specific steps in the wizard. This topic describes the main elements that you configure when adding an EBA asset. For a general description of all the elements that the wizard might prompt you to configure, see *Creating business-level applications with the console*.

As well as specifying the configuration information for the EBA asset through the following procedure, you can also change it later as described in *Modifying the configuration of an OSGi composition unit*. For example, if you update a bundle in an EBA asset, or replace a composite bundle extension, you might introduce a resource that needs additional configuration, such as a new or changed Blueprint resource reference, or security role mapping.

Procedure

1. Start the administrative console.
2. Add the previously-imported asset (the .eba file) as a deployed asset.
 - a. If you have just created a new business-level application, the general properties for the business-level application are already displayed, including the option **[Deployed assets] Add > Add Asset**. Otherwise, navigate to **Applications > Application Types > Business-level applications > *application_name* > [Deployed assets] Add > Add Asset**. A list of available assets is displayed.
 - b. Select the asset to add, then click **Continue**. The Set options settings wizard is displayed.
3. Wizard step: Set options.
Change the composition unit settings as needed, then click **Next**. For more information, see *Set options settings*.
4. Wizard step: Map composition unit to a target.
Select the deployment target application server or web server. For more information, see *Map target settings*.
5. Wizard step: Map context roots.
Select a web application bundle (WAB) from the list, then enter the context root for the WAB. For example, `/sample`. For more information, see *Context root for web application bundles [Settings]*.
6. Wizard step: Map modules to virtual hosts.
The list of available WABs in this asset is displayed. For each WAB, you can change the associated virtual host by selecting a different one from the list. If you specify an existing virtual host in the `ibm-web-bnd.xml` or `.xmi` file for a given WAB, the specified virtual host is set by default. Otherwise, the default virtual host setting is `default_host`. For more information, see *Virtual hosts for web application bundles [Settings]*.
7. Wizard step: Security role to user/group mapping.

Change the security mapping as needed. For more information, see Security role to user or group mapping [Settings].

8. Wizard step: Map RunAs roles to users

You can map a specified user identity and password to a RunAs role. This enables you to specify application-specific privileges for individual users, so that they can run specific tasks using another user identity. For more information, see Map RunAs roles to users [Collection].

9. Wizard step: Bind Blueprint resource references.

The list of available Blueprint resource references in this asset is displayed. For each reference, you can optionally select an authentication alias from the list. Default authentication aliases (from `ibm-eba-bnd.xml` files) are offered only if they exist on every target server or cluster. For more information, see Blueprint resource reference bindings [Settings].

10. Wizard step: Web module message destination and resource environment reference bindings.

The list of available web application message destination and resource environment references in this asset is displayed. That is, resources of type `message-destination-ref` (message destination reference) or `resource-env-ref` (resource environment reference), as defined in the Java specification JSR-250: Common Annotations for the Java Platform. For each reference, specify the JNDI name under which the resource is known in the runtime environment. For more information, see Web module message destination and resource environment reference bindings [Settings].

11. Wizard step: Web module resource reference bindings.

The list of available web application resource references in this asset is displayed. That is, resources of type `resource-ref` (resource reference), as defined in the Java specification JSR-250: Common Annotations for the Java Platform. For each reference, specify the JNDI name under which the resource is known in the runtime environment. Optionally, set authentication properties and extended data source custom properties, which affect how the resource is accessed at run time. To specify the JNDI name mapping, either type the JNDI name into the box, or click **Browse...** then select the resource reference from the list of available resources. To modify the authentication method or set extended data source custom properties, select a single reference then click **Modify Resource Authentication Method...** or **Extended Properties....** For more information, see Web module resource reference bindings [Settings].

12. Wizard step: Summary

A summary of your selections is displayed. To complete the creation of the composition unit, click **Finish**. If there are settings that you want to change, click **Previous** to review the settings.

13. Save your changes to the master configuration.

Results

The product creates composition units for the application, module, or shared library relationships. The unit names are shown in lists of deployed assets on the settings page of your business-level application. To view the settings page, click **Applications > Application Types > Business-level applications > application_name**.

What to do next

Note: After you import the enterprise bundle archive (EBA) file for your OSGi application as an asset, you can update versions of existing bundles but you cannot add extra bundles to the asset. However, after you have added the asset as a composition unit to a business-level application, you can extend the business-level application by adding one or more composite bundles to the composition unit. See Adding or removing extensions for an OSGi composition unit.

You are now ready to start your business-level application

Adding an EBA asset to a composition unit using wsadmin commands

You can use the `addCompUnit` command and the `AdminConfig` commands to add a composition unit that consists of a previously-imported enterprise bundle archive (EBA) asset plus configuration information. The configuration information can include HTTP session management, context roots, virtual hosts, security roles, run-as roles, and web application or Blueprint resource reference bindings for your OSGi application.

Before you begin

You can add an EBA asset to a business-level application by using `wsadmin` commands as described in this topic, or by using the administrative console as described in “Adding an EBA asset to a composition unit using the administrative console” on page 896.

An EBA asset can be added to only one business-level application. A business-level application is scoped to cell scope, therefore only one instance of a given OSGi application can be deployed in a cell.

This task makes the following assumptions:

- You have already imported the EBA file as an asset (for example by using the `importAsset` command as described in step 2 of [Setting up business-level applications using wsadmin scripting](#)), then saved your changes to the master configuration (which causes any bundle dependencies to be downloaded from configured bundle repositories).
- You have already defined the target virtual hosts. To check existing virtual hosts using the `wsadmin` tool, issue the following `jython` command:

```
print AdminConfig.list('VirtualHost')
```
- You have already created the JCA authentication alias that you want to associate with each Blueprint resource reference.

About this task

An OSGi composition unit consists of an EBA asset, (optionally) one or more composite bundle extensions, and some or all of the following configuration information:

- Mappings from the composition unit to a target application server, web server or cluster.
- Configuration of the application's session manager, context roots or virtual hosts.
- Bindings to any associated web applications or blueprint resource references.
- Mappings from security roles to particular users or groups.

To create and configure all elements of the composition unit except the HTTP session manager, you use the `addCompUnit` command. To configure the HTTP session manager, you use the `AdminConfig` commands to configure the deployed object represented by the `appDeploy` variable. The composition unit must be created before the session management options can be applied to it, so you must run the `addCompUnit` command before you configure the HTTP session manager.

As well as specifying the configuration information for the EBA asset through the following procedure, you can also change it later as described in [Modifying the configuration of an OSGi composition unit using wsadmin commands](#). For example, if you update a bundle in an EBA asset, or replace a composite bundle extension, you might introduce a resource that needs additional configuration, such as a new or changed Blueprint resource reference, or security role mapping.

Procedure

1. Create and configure all elements of the composition unit except the HTTP session manager.

Each of the following substeps describes the syntax for adding a single element to the composition unit. However, to create the composition unit you run the `addCompUnit` command only once.

Therefore, when you run the command, you must combine these elements together. An example of the combined syntax is given after the separate substeps.

For several of the elements, the values you specify include bundle identifiers. If your EBA asset includes or references composite bundles, the command syntax is slightly different. For clarity, the differences for composite bundles are described, step by step, in a linked topic.

- a. Add the previously-imported asset (the .eba file) as a deployed asset.

The parameters for this aspect of the command are as follows:

-blaID

Specifies the configuration ID of the business-level application.

-cuSourceID

Specifies the ID of the EBA asset that is being added to the business-level application.

-CUOptions

Specifies the following additional properties for the composition unit.

- parentBLA
- backingID
- name
- description
- startingWeight
- startedOnDistributed
- restartBehaviorOnUpdate

-MapTargets

Specifies additional properties for the composition unit target mapping. That is, it specifies the deployable unit URI (which, for an EBA asset, is ebaDeploymentUnit) and the target node and server, or the target cluster. To add an additional target, you use the plus sign character (+) as a prefix.

-ActivationPlanOptions

Specifies additional properties for the composition unit activation plan. That is, it specifies the deployable unit URI and a list of runtime components. For an EBA asset, use default values as shown in the example below.

If the target is one cluster, the jython syntax for this aspect of the command is as follows:

```
AdminTask.addCompUnit('[
  -blaID WebSphere:blaname=bla_name
  -cuSourceID WebSphere:assetname=asset_name.eba
  -CUOptions [
    [WebSphere:blaname=bla_name.eba
    WebSphere:assetname=asset_name.eba
    cu_name "optional_cu_description" 1 false DEFAULT]]
  -MapTargets [[ebaDeploymentUnit WebSphere:cluster=cluster_name]]
  -ActivationPlanOptions [[default ""]]
  ...
]')
```

For example:

```
AdminTask.addCompUnit('[
  -blaID WebSphere:blaname=helloWorldService
  -cuSourceID WebSphere:assetname=com.ibm.ws.eba.helloWorldService.eba
  -CUOptions [
    [WebSphere:blaname=helloWorldService.eba
    WebSphere:assetname=com.ibm.ws.eba.helloWorldService.eba
    com.ibm.ws.eba.helloWorldService_0001.eba "" 1 false DEFAULT]]
  -MapTargets [[ebaDeploymentUnit WebSphere:cluster=cluster1]]
  -ActivationPlanOptions [[default ""]]
  ...
]')
```

If the target is two servers, the jython syntax for this aspect of the command is as follows::

```
AdminTask.addCompUnit('[
  -blaid WebSphere:blaname=bla_name
  -cuid WebSphere:assetname=asset_name.eba
  -CUOptions [
    [WebSphere:blaname=bla_name.eba
     WebSphere:assetname=asset_name.eba
     cu_name "optional_cu_description" 1 false DEFAULT]]
  -MapTargets [
    [ebaDeploymentUnit WebSphere:node=node_name,server=server_name+
     WebSphere:node=node2_name,server=server2_name]]
  -ActivationPlanOptions [[default ""]]
  ...
]')
```

For example:

```
AdminTask.addCompUnit('[
  -blaid WebSphere:blaname=helloWorldService
  -cuid WebSphere:assetname=com.ibm.ws.eba.helloWorldService.eba
  -CUOptions [
    [WebSphere:blaname=helloWorldService.eba
     WebSphere:assetname=com.ibm.ws.eba.helloWorldService.eba
     com.ibm.ws.eba.helloWorldService_0001.eba "" 1 false DEFAULT]]
  -MapTargets [[ebaDeploymentUnit WebSphere:node=node01,server=server1+
     WebSphere:node=node01,server=web1]]
  -ActivationPlanOptions [[default ""]]
  ...
]')
```

b. Define WAB context roots.

Context roots determine where the web pages of a particular web application bundle (WAB) are found at run time. The context root that you specify here is combined with the defined server mapping to compose the full URL that you enter to access the pages of the WAB. For example, if the application server default host is `www.example.com:8080` and the context root of the WAB is `/sample`, the web pages are available at `www.example.com:8080/sample`.

The jython syntax for this aspect of the command is as follows.

Note: For composite bundles, the syntax is slightly different. See Step: Define context roots for web application bundles (WABs) in composite bundles.

The bundles listed under the **ContextRootStep** need to be all the WABs contained in the OSGi application.

```
AdminTask.addCompUnit('[
  ...
  -ContextRootStep [
    [bundle_symbolic_name_1 bundle_version_1 context_root_1]
    [bundle_symbolic_name_2 bundle_version_2 context_root_2]]
  ...
]')
```

For example, for an EBA file that contains two WABs (`com.ibm.ws.eba.helloWorldService.web` at version 1.0.0, which is to be mapped to `/hello/web`, and `com.ibm.ws.eba.helloWorldService.withContextRoot` at version 0.9.0, which is to be mapped to `/hello/service`), this aspect of the command is as follows:

```
AdminTask.addCompUnit('[
  ...
  -ContextRootStep [
    [com.ibm.ws.eba.helloWorldService.web 1.0.0 "/hello/web"]
    [com.ibm.ws.eba.helloWorldService.withContextRoot 0.9.0 "/hello/service"]]
  ...
]')
```

c. Map WABs to virtual hosts.

You use a virtual host to associate a unique port with a web application. The aliases of a virtual host identify the port numbers defined for that virtual host. A port number specified in a virtual host alias is used in the URL that is used to access artifacts such as servlets and JavaServer Page (JSP) files in a web application. For example, the alias `myhost:8080` is the *host_name:port_number* portion of the URL `http://myhost:8080/sample`.

Each WAB that is contained in a deployed asset must be mapped to a virtual host. WABs can be installed on the same virtual host, or dispersed among several virtual hosts.

If you specify an existing virtual host in the `ibm-web-bnd.xml` or `.xmi` file for a given WAB, the specified virtual host is set by default. Otherwise, the default virtual host setting is `default_host`, which provides several port numbers through its aliases:

- 80** An internal, insecure port used when no port number is specified
- 9080** An internal port
- 9443** An external, secure port

Unless you want to isolate your WAB from other WABs or resources on the same node, `default_host` is a suitable virtual host. In addition to `default_host`, WebSphere Application Server provides `admin_host`, which is the virtual host for the administrative console system application. `admin_host` is on port 9060. Its secure port is 9043. Do not select `admin_host` unless the WAB relates to system administration.

The `jython` syntax for this aspect of the command is as follows.

Note: For composite bundles, the syntax is slightly different. See Step: Map WABs in composite bundles to virtual hosts.

```
AdminTask.addCompUnit('[
...
-VirtualHostMappingStep [
  [bundle_symbolic_name_1 bundle_version_1
  web_module_name_1 virtual_host_1]
  [bundle_symbolic_name_2 bundle_version_2
  web_module_name_2 virtual_host_2]]
...
]')
```

For example, for an EBA file containing two WABs (`com.ibm.ws.eba.helloWorldService.web` at version 1.0.0, which is to be mapped to `default_host`, and `com.ibm.ws.eba.helloWorldService.withContextRoot` at version 0.9.0, which is to be mapped to `test_host`), this aspect of the command is as follows:

```
AdminTask.addCompUnit('[
...
-VirtualHostMappingStep [
  [com.ibm.ws.eba.helloWorldService.web 1.0.0
  "HelloWorld service" default_host]
  [com.ibm.ws.eba.helloWorldService.withContextRoot 0.9.0
  "HelloWorld second service" test_host]]
...
]')
```

d. Map security roles to users or groups.

The `jython` syntax for this aspect of the command is as follows:

```
AdminTask.addCompUnit('[
...
-MapRolesToUsersStep [
  [role_name everyone?
  all_authenticated_in_realm?
  usernames groups]]
...
]')
```

Key:

- *role_name* is a role name defined in the application.

- *everyone?* is set to Yes or No, to specify whether or not everyone is in the role.
- *all_authenticated_in_realm?* is set to Yes or No, to specify whether or not all authenticated users can access the application realm.
- *usernames* is a list of WebSphere Application Server user names, separated by the "|" character.
- *groups* is a list of WebSphere Application Server groups, separated by the "|" character.

Note: For *usernames*, and *groups*, the empty string "" means "use the default or existing value". The default value is usually that no users or groups are bound to the role. However, when an application contains an `ibm-application-bnd.xml` file, the default value for *usernames* is obtained from this file. If you are deploying an application that contains an `ibm-application-bnd.xml` file, and you want to remove the bound users, specify just the "|" character (which is the separator for multiple user names). This explicitly specifies "no users", and therefore guarantees that no users are bound to the role.

For example:

```
AdminTask.addCompUnit('[
...
-MapRolesToUsersStep [
  [ROLE1 No Yes "" ""]
  [ROLE2 No No WABTestUser1 ""]
  [ROLE3 No No "" WABTestGroup1]
  [ROLE4 Yes No "" ""]
...
]')
```

For more information about the `-MapRolesToUsersStep` option, see the information for the `$AdminApp install` command "MapRolesToUsers" option. This is the equivalent option for Java EE applications. For more general information, see Security role to user or group mapping.

e. Map RunAs roles to users

You can map a specified user identity and password to a RunAs role. This enables you to specify application-specific privileges for individual users, so that they can run specific tasks using another user identity. The `jython` syntax for this aspect of the command is as follows:

```
AdminTask.addCompUnit('[
...
-MapRunAsRolesToUsersStep [
  [role_name user_name password]]
]')
```

For example:

```
AdminTask.addCompUnit('[
...
-MapRunAsRolesToUsersStep [
  [Role1 User1 password1]
  [AdminRole User3 password3]]
]')
```

For more information about the `-MapRunAsRolesToUsers` option, see the information for the `$AdminApp install` command "MapRunAsRolesToUsers" option. This is the equivalent option for Java EE applications. For more general information, see Map RunAs roles to users.

f. Add authentication aliases to Blueprint resource references.

Blueprint components can access WebSphere Application Server resource references. Each reference is declared in a Blueprint XML file, and can be secured using a Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) authentication alias. Each bundle in an OSGi application can contain any number of resource reference declarations in its various Blueprint XML files.

When you secure resource references, those resource references can be bound only to JCA authentication aliases that exist on every server or cluster on which the application is deployed. An OSGi application can be deployed to multiple servers and clusters that are in the same security domain. Therefore, each JCA authentication alias must exist in either the security domain of the target servers and clusters, or the global security domain.

You must declare the resource references in the Blueprint XML file. For example:

```
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"
  xmlns:rr="http://www.ibm.com/appserver/schemas/8.0/blueprint/resourcereference">
  <!-- Other Blueprint declarations ... -->

  <rr:resource-reference id="resourceRef"
    interface="javax.sql.DataSource"
    filter="(osgi.jndi.service.name=jdbc/Account)">
    <rr:res-auth>Container</rr:res-auth>
    <rr:res-sharing-scope>Shareable</rr:res-sharing-scope>
  </rr:resource-reference>
</blueprint>
```

This declaration includes the resource reference ID (for example `resourceRef`), the service filter (for example `jdbc/Account`), the authentication type (for example `Container`), and the sharing setting (for example `Shareable`).

The Blueprint resource references to authentication alias bindings for each bundle are stored in a file `ibm-eba-bnd.xml` in the META-INF directory of that bundle. If an OSGi application contains any of these files when it is deployed as an asset, these files provide the default authentication alias values that are used when binding the resource references. For example:

```
<eba-bnd xmlns="http://www.ibm.com/blueprintbinding.xsd">
  <resource-ref>
    <jndi-name>jdbc/Account</jndi-name>
    <authentication-alias>Alias1</authentication-alias>
    <interface>javax.sql.DataSource</interface>
    <authentication>Container</authentication>
    <sharing-scope>Shareable</sharing-scope>
    <id>resourceRef</id>
  </resource-ref>
</eba-bnd>
```

The `jython` syntax for this aspect of the command is as follows.

Note: For composite bundles, the syntax is slightly different. See Step: Add authentication aliases to Blueprint resource references in composite bundles.

```
AdminTask.addCompUnit(['
...
-BlueprintResourceRefBindingStep [
  [
    bundle_symbolic_name
    bundle_version
    blueprint_resource_reference_id
    interface_name
    jndi_name
    authentication_type
    sharing_setting
    authentication_alias_name
  ]
]')
...
]')
```

Note: The value for `jndi_name` must match the jndi name that you declare in the **filter** attribute of the resource reference element in the Blueprint XML file.

For example, for an EBA file that contains a bundle `com.ibm.ws.eba.helloWorldService.properties.bundle.jar` at Version 1.0.0, which is to be bound to authentication alias `alias1`, the command is as follows:

```
AdminTask.addCompUnit('[
...
-BlueprintResourceRefBindingStep[
  [com.ibm.ws.eba.helloWorldService.properties.bundle 1.0.0 resourceRef
  javax.sql.DataSource jdbc/Account Container Shareable alias1]]
...
]')
```

- g. Bind web module message destination and resource environment references.

Binding a resource reference maps a resource dependency of the web application to an actual resource available in the server runtime environment. At a minimum, this can be achieved by using a mapping that specifies the JNDI name under which the resource is known in the runtime environment. By default, the JNDI name is the resource ID that you specified in the `web.xml` file during development of the web application bundle (WAB). Use this option to bind resources of type `message-destination-ref` (message destination reference) or `resource-env-ref` (resource environment reference), as defined in the Java specification JSR-250: Common Annotations for the Java Platform.

The `jython` syntax for this aspect of the command is as follows.

Note: For composite bundles, the syntax is slightly different. See Step: Bind web module message destination and resource environment references in composite bundles.

```
AdminTask.addCompUnit('[
...
-WebModuleMsgDestRefs [
  [
    bundle_symbolic_name
    bundle_version
    resource_reference_id
    resource_type
    target_jndi_name
  ]]
...
]')
```

For example:

```
AdminTask.addCompUnit('[
...
-WebModuleMsgDestRefs [
  [com.ibm.ws.eba.helloWorldService.web 1.0.0
  jms/myQ javax.jms.Queue
  jms/workQ]
  [com.ibm.ws.eba.helloWorldService.web 1.0.0
  jms/myT javax.jms.Topic
  jms/notificationTopic]]
...
]')
```

- h. Bind web module resource references.

Binding a resource reference maps a resource dependency of the web application to an actual resource available in the server runtime environment. At a minimum, this can be achieved by using a mapping that specifies the JNDI name under which the resource is known in the runtime environment. By default, the JNDI name is the resource ID that you specified in the `web.xml` file during development of the web application bundle (WAB). Use this option to bind resources of type `resource-ref` (resource reference), as defined in the Java specification JSR-250: Common Annotations for the Java Platform.

The `jython` syntax for this aspect of the command is as follows.

Note: For composite bundles, the syntax is slightly different. See Step: Bind web module resource references in composite bundles.

```
AdminTask.addCompUnit('[
...
-WebModuleResourceRefs [
  [
    bundle_symbolic_name
    bundle_version
    resource_reference_id
    resource_type
    target_jndi_name
    login_configuration
    login_properties
    extended_properties
  ]
]')
...
]')
```

For example:

```
AdminTask.addCompUnit('[
...
-WebModuleResourceRefs [
  [com.ibm.ws.eba.helloWorldService.web 1.0.0
  jdbc/jtaDs javax.sql.DataSource
  jdbc/helloDs "" "" ""]
  [com.ibm.ws.eba.helloWorldService.web 1.0.0
  jdbc/nonJtaDs javax.sql.DataSource
  jdbc/helloDsNonJta "" "" "extprop1=extval1"]]
]')
...
]')
```

Note: If you use multiple extended properties, the jython syntax is
"extprop1=extval1,extprop2=extval2".

In the following example, the jython syntax from the previous individual substeps is combined so that, by running the addCompUnit command once only, a composition unit is created and added to a business-level application.

Note: If your EBA asset includes or references composite bundles, the command syntax is slightly different. For an equivalent example, see Example: Using the addCompUnit command to add an EBA asset that includes composite bundles.

```
AdminTask.addCompUnit('[
-blaID WebSphere:blaname=helloWorldService
-cuSourceID WebSphere:assetname=com.ibm.ws.eba.helloWorldService.eba
-CUOptions [
  [WebSphere:blaname=helloWorldService.eba
  WebSphere:assetname=com.ibm.ws.eba.helloWorldService.eba
  com.ibm.ws.eba.helloWorldService_0001.eba "" 1 false DEFAULT]]
-MapTargets [[ebaDeploymentUnit WebSphere:cluster=cluster1]]
-ActivationPlanOptions [[default ""]]
-ContextRootStep [
  [com.ibm.ws.eba.helloWorldService.web 1.0.0 "/hello/web"]
  [com.ibm.ws.eba.helloWorldService.withContextRoot 0.9.0 "/hello/service"]]
-VirtualHostMappingStep [
  [com.ibm.ws.eba.helloWorldService.web 1.0.0
  "HelloWorld service" default_host]
  [com.ibm.ws.eba.helloWorldService.withContextRoot 0.9.0
  "HelloWorld second service" test_host]]
-MapRolesToUsersStep [
  [ROLE1 No Yes "" ""]
  [ROLE2 No No WABTestUser1 ""]
  [ROLE3 No No "" WABTestGroup1]
  [ROLE4 Yes No "" ""]]
-MapRunAsRolesToUsersStep [
  [Role1 User1 password1]
  [AdminRole User3 password3]]
]')
```

```

-BlueprintResourceRefBindingStep[
  [com.ibm.ws.eba.helloWorldService.properties.bundle 1.0.0 resourceRef
  javax.sql.DataSource jdbc/Account
  Container Shareable alias1]]
-WebModuleMsgDestRefs [
  [com.ibm.ws.eba.helloWorldService.web 1.0.0
  jms/myQ javax.jms.Queue
  jms/workQ]
  [com.ibm.ws.eba.helloWorldService.web 1.0.0
  jms/myT javax.jms.Topic
  jms/notificationTopic]]
-WebModuleResourceRefs [
  [com.ibm.ws.eba.helloWorldService.web 1.0.0 jdbc/jtaDs javax.sql.DataSource
  jdbc/helloDs "" "" ""]
  [com.ibm.ws.eba.helloWorldService.web 1.0.0 jdbc/nonJtaDs javax.sql.DataSource
  jdbc/helloDsNonJta "" "" "extprop1=extval1"]]
]')

```

2. Configure the HTTP session manager.

To configure the HTTP session manager, you use the AdminConfig commands to configure the deployed object represented by the *appDeploy* variable. Session management for OSGi applications is configured in the same way as for enterprise applications, except for a minor difference in syntax when getting the deployed object.

a. Get the deployed object.

Use the instructions given in Configuring applications for session management using scripting. Note that, for enterprise applications, you use the following two line script:

```

deployments = AdminConfig.getid('/Deployment:myApp/')
appDeploy = AdminConfig.showAttribute(deployments, 'deployedObject')

```

For OSGi applications, the equivalent script is the following single line:

```

appDeploy = AdminTask.getOSGiApplicationDeployedObject('-cuName cu_name')

```

where *cu_name* is the name of the composition unit. For example:

```

appDeploy = AdminTask.getOSGiApplicationDeployedObject('
  -cuName com.ibm.ws.eba.helloWorldService_0001.eba')

```

b. Create the session management options.

Use the instructions given in Configuring applications for session management using scripting. The command usage for creating the session management options is exactly the same for enterprise applications and OSGi applications.

What to do next

After using these commands, save your changes to the master configuration by using the following command:

```

AdminConfig.save()

```

Note: After you import the enterprise bundle archive (EBA) file for your OSGi application as an asset, you can update versions of existing bundles but you cannot add extra bundles to the asset. However, after you have added the asset as a composition unit to a business-level application, you can extend the business-level application by adding one or more composite bundles to the composition unit. See Adding or removing extensions for an OSGi composition unit using wsadmin commands.

You are now ready to start your business-level application.

Adding an EBA asset that includes composite bundles using the addCompUnit command:

You can use the `addCompUnit` command to add a composition unit that contains a previously-imported enterprise bundle archive (EBA) asset plus configuration information. If the EBA asset includes composite bundles, the command syntax is slightly different.

Before you begin

For a full description of how you specify this configuration information, see “Adding an EBA asset to a composition unit using `wsadmin` commands” on page 899. When you work through that task, each step where the syntax is different for composite bundles is linked to an equivalent step in this task.

About this task

An OSGi composition unit includes an EBA asset and some or all of the following configuration information:

- Mappings from the composition unit to a target application server, web server or cluster.
- Configuration of the application's session manager, context roots or virtual hosts.
- Bindings to any associated web applications or blueprint resource references.
- Mappings from security roles to particular users or groups.

For several of the elements, the values you specify include bundle identifiers. If your EBA asset includes or references composite bundles, the command syntax is slightly different. The differences for composite bundles are described in the following steps.

Procedure

- Define context roots for web application bundles (WABs) in composite bundles.

The `python` syntax for this aspect of the command is as follows:

```
AdminTask.addCompUnit(['  
    ...  
    -ContextRootStep [  
        [bundle_symbolic_name_1 bundle_version_1 context_root_1]  
        [bundle_symbolic_name_2 bundle_version_2 context_root_2]]  
    ...  
>'])
```

For composite bundles, the bundle symbolic name has the following syntax:

```
CBA.symbolic.Name_CBA.bundle.version/WAB.symbolic.name
```

For example, for a composite bundle `com.ibm.ws.eba.helloWorldCBA` at version 1.0.0 that contains two WABs (`com.ibm.ws.eba.helloWorldService.web` at version 1.0.0, which is to be mapped to `/hello/web`, and `com.ibm.ws.eba.helloWorldService.withContextRoot` at version 0.9.0, which is to be mapped to `/hello/service`), this aspect of the command is as follows:

```
AdminTask.addCompUnit(['  
    ...  
    -ContextRootStep [  
        [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web 1.0.0  
        "/hello/web"]  
        [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.withContextRoot 0.9.0  
        "/hello/service"]]  
    ...  
>'])
```

Note: For bundles other than composite bundles, the syntax is slightly different. See Step: Define WAB context roots.

- Map WABs in composite bundles to virtual hosts.

The `python` syntax for this aspect of the command is as follows:

```
AdminTask.addCompUnit('[
...
-VirtualHostMappingStep [
  [bundle_symbolic_name_1 bundle_version_1
  web_module_name_1 virtual_host_1]
  [bundle_symbolic_name_2 bundle_version_2
  web_module_name_2 virtual_host_2]]
...
]')
```

For composite bundles, the bundle symbolic name has the following syntax:

```
CBA.symbolic.Name_CBA.bundle.version/WAB.symbolic.name
```

For example, for a composite bundle `com.ibm.ws.eba.helloWorldCBA` at version 1.0.0 that contains two WABs (`com.ibm.ws.eba.helloWorldService.web` at version 1.0.0, which is to be mapped to `default_host`, and `com.ibm.ws.eba.helloWorldService.withContextRoot` at version 0.9.0, which is to be mapped to `test_host`), this aspect of the command is as follows:

```
AdminTask.addCompUnit('[
...
-VirtualHostMappingStep [
  [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
  1.0.0 "HelloWorld service" default_host]
  [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.withContextRoot
  0.9.0 "HelloWorld second service" test_host]]
...
]')
```

Note: For bundles other than composite bundles, the syntax is slightly different. See Step: Map WABs to virtual hosts.

- Add authentication aliases to Blueprint resource references in composite bundles.

The `iython` syntax for this aspect of the command is as follows.

```
AdminTask.addCompUnit('[
...
-BlueprintResourceRefBindingStep [
  [
    bundle_symbolic_name
    bundle_version
    blueprint_resource_reference_id
    interface_name
    jndi_name
    authentication_type
    sharing_setting
    authentication_alias_name
  ]
...
]')
```

Notes:

- For composite bundles, the bundle symbolic name has the following syntax:
`CBA.symbolic.Name_CBA.bundle.version/embedded_bundle.symbolic.name`
- The value for `jndi_name` must match the `jndi` name that you declare in the **filter** attribute of the resource reference element in the Blueprint XML file.

For example, for a composite bundle `com.ibm.ws.eba.helloWorldCBA` at version 1.0.0 that contains a bundle `com.ibm.ws.eba.helloWorldService.properties.bundle.jar` at Version 1.0.0, which is to be bound to authentication alias `alias1`, the command is as follows:

```
AdminTask.addCompUnit('[
...
-BlueprintResourceRefBindingStep[
```

```

        [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.properties.bundle
        1.0.0 resourceRef javax.sql.DataSource jdbc/Account Container Shareable alias1]]
    ...
]')

```

Note: For bundles other than composite bundles, the syntax is slightly different. See Step: Add authentication aliases to Blueprint resource references.

- Bind web module message destination and resource environment references in composite bundles.

The jython syntax for this aspect of the command is as follows

```

AdminTask.addCompUnit('[
    ...
    -WebModuleMsgDestRefs [
        [
            bundle_symbolic_name
            bundle_version
            resource_reference_id
            resource_type
            target_jndi_name
        ]
    ]
    ...
]')

```

For composite bundles, the bundle symbolic name has the following syntax:

CBA.symbolic.Name_CBA.bundle.version/WAB.symbolic.name

For example:

```

AdminTask.addCompUnit('[
    ...
    -WebModuleMsgDestRefs [
        [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
        1.0.0
        jms/myQ javax.jms.Queue
        jms/workQ]
        [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
        1.0.0
        jms/myT javax.jms.Topic
        jms/notificationTopic]]
    ...
]')

```

Note: For bundles other than composite bundles, the syntax is slightly different. See Step: Bind web module message destination and resource environment references.

- Bind web module resource references in composite bundles.

The jython syntax for this aspect of the command is as follows.

```

AdminTask.addCompUnit('[
    ...
    -WebModuleResourceRefs [
        [
            bundle_symbolic_name
            bundle_version
            resource_reference_id
            resource_type
            target_jndi_name
            login_configuration
            login_properties
            extended_properties
        ]
    ]
    ...
]')

```

For composite bundles, the bundle symbolic name has the following syntax:

CBA.symbolic.Name_CBA.bundle.version/WAB.symbolic.name

For example:

```
AdminTask.addCompUnit(' [
  ...
  -WebModuleResourceRefs [
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
    1.0.0
    jdbc/jtaDs javax.sql.DataSource
    jdbc/helloDs "" "" ""]
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
    1.0.0
    jdbc/nonJtaDs javax.sql.DataSource
    jdbc/helloDsNonJta "" "" "extprop1=extval1"]
  ]
  ...
]')
```

Notes:

- If you use multiple extended properties, the jython syntax is "extprop1=extval1,extprop2=extval2".
- For bundles other than composite bundles, the syntax is slightly different. See Step: Bind web module resource references.

Example

In the following example, the jython syntax from the previous steps is combined with the additional steps described in “Adding an EBA asset to a composition unit using wsadmin commands” on page 899 so that, by running the addCompUnit command once only, a composition unit is created and added to a business-level application. In the example, an EBA file com.ibm.ws.eba.helloWorldService.eba contains a composite bundle with symbolic name com.ibm.ws.eba.helloWorldCBA, at version 1.0.0. This composite bundle contains two WABs:

- com.ibm.ws.eba.helloWorldService.web, at version 1.0.0
- com.ibm.ws.eba.helloWorldService.withContextRoot, at version 0.9.0

The composite bundle also contains a bundle with symbolic name com.ibm.ws.eba.helloWorldService.properties.bundle, at version 1.0.0.

```
AdminTask.addCompUnit(' [
  -blaid WebSphere:blaname=helloWorldService
  -cuSourceID WebSphere:assetname=com.ibm.ws.eba.helloWorldService.eba
  -CUOptions [
    [WebSphere:blaname=helloWorldService.eba
    WebSphere:assetname=com.ibm.ws.eba.helloWorldService.eba
    com.ibm.ws.eba.helloWorldService_0001.eba "" 1 false DEFAULT]]
  -MapTargets [[ebaDeploymentUnit WebSphere:cluster=cluster1]]
  -ActivationPlanOptions [[default ""]]
  -ContextRootStep [
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web 1.0.0
    "/hello/web"]
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.withContextRoot 0.9.0
    "/hello/service"]]
  -VirtualHostMappingStep [
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
    1.0.0 "HelloWorld service" default_host]
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.withContextRoot
    0.9.0 "HelloWorld second service" test_host]]
  -MapRolesToUsersStep [
    [ROLE1 No Yes "" ""]
    [ROLE2 No No WABTestUser1 ""]
    [ROLE3 No No "" WABTestGroup1]
    [ROLE4 Yes No "" ""]]
  -MapRunAsRolesToUsersStep [
```

```

    [Role1 User1 password1]
    [AdminRole User3 password3]]
-BlueprintResourceRefBindingStep[
  [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.properties.bundle
  1.0.0 resourceRef javax.sql.DataSource jdbc/Account Container Shareable alias1]]
-WebModuleMsgDestRefs [
  [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
  1.0.0
  jms/myQ javax.jms.Queue
  jms/workQ]
  [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
  1.0.0
  jms/myT javax.jms.Topic
  jms/notificationTopic]]
-WebModuleResourceRefs [
  [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
  1.0.0
  jdbc/jtaDs javax.sql.DataSource
  jdbc/helloDs "" "" ""]
  [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
  1.0.0
  jdbc/nonJtaDs javax.sql.DataSource
  jdbc/helloDsNonJta "" "" "extprop1=extval1"]]
]')

```

Debugging bundles at run time using the command-line console

You can use the wsadmin-based OSGi Applications command-line console to explore or debug the bundles associated with a specific OSGi application or shared bundle framework.

About this task

The OSGi Applications command-line console is a set of wsadmin commands that you can use to explore or debug a specific set of bundles running on an application server. As an aid to debugging applications in a test environment, the console also includes commands to start and stop bundles.

Every OSGi application that is currently running is viewed by the command-line console as a separate framework. On each application server that is running an OSGi application, there is also one shared bundle framework.

To work with a framework that is currently running, you first connect to the framework.

Procedure

1. Start the OSGi Applications command-line console.

At a command prompt, run the `osgiApplicationConsole.bat` command (for Windows systems) or the `osgiApplicationConsole.sh` command (for Linux systems). You can run this command from the `app_server_root/bin` directory or from any `profile_root/bin` directory. The command takes the following optional parameters:

- h The host name of the target machine. For example, `machine1.hursley.ibm.com`.
- o The port number of the SOAP port of the target server. For example, `8880`.
- u The user ID, if the wsadmin connection is secured.
- p The password, if the wsadmin connection is secured.

For example:

```
app_server_root/bin/osgiApplicationConsole -h machine1.hursley.ibm.com -o 8880
```

The wsadmin command prompt is displayed. This instance of wsadmin recognizes OSGi Applications console commands.

2. Connect to an available framework.

You use the connect command to connect to a specific framework.

If you know the framework name and version number, and the node and server on which the framework is running, you can use this information to connect. For example:

```
wsadmin>connect("com.ibm.ws.eba.helloWorldService.eba", "1.0.0", "wasNode1", "server1")
```

Alternatively, use the list command to list all available frameworks and to provide a unique ID for each framework, then use this ID to connect. For example:

a. List all available frameworks:

```
wsadmin>list()
```

If you are connecting to an individual application server, this command might generate the following system response:

ID	Bundle	Version	Node	Server
0	SharedBundles	7.0.0	wasNode1	server1
1	com.ibm.ws.eba.helloWorldService.eba	1.0.0	wasNode1	server1
2	com.ibm.ws.eba.obr.fep.eba5.eba	1.0.0	wasNode1	server1
3	com.ibm.ws.eba.wab.componenttest	1.0.0	wasNode1	server1

b. Connect to the com.ibm.ws.eba.helloWorldService.eba framework:

```
wsadmin>connect(1)
```

If the command completes successfully it generates the following system responses:

```
CWSAJ0035I: Connecting to framework com.ibm.ws.eba.helloWorldService.eba_1.0.0
on node wasNode1 and server server1.
CWSAJ0036I: Successfully connected to framework com.ibm.ws.eba.helloWorldService.eba_1.0.0.
```

To connect to a different framework, run the connect command again. You do not need to disconnect from one framework before connecting to another framework.

3. Work with the connected framework.

Use one or more of the following commands to work with the framework to which you are connected:

- List all available frameworks, and indicate the currently connected framework.

Use the list command:

```
wsadmin>list()
```

This command might generate the following system response:

ID	Bundle	Version	Node	Server
0	SharedBundles	7.0.0	wasNode1	server1
1	com.ibm.ws.eba.helloWorldService.eba	1.0.0	wasNode1	server1 <== Connected
2	com.ibm.ws.eba.obr.fep.eba5.eba	1.0.0	wasNode1	server1
3	com.ibm.ws.eba.wab.componenttest	1.0.0	wasNode1	server1

- Display summary information about each of the bundles in the framework.

Use the ss command:

```
wsadmin>ss()
```

Note: “ss” stands for “short status”.

This command might generate the following system response:

ID	State	Bundle
0	ACTIVE	org.eclipse.osgi_3.6.1.R36x_v20100806
1	ACTIVE	com.ibm.samples.websphere.osgi.blog.app_1.0.0
2	ACTIVE	com.ibm.samples.websphere.osgi.blog_1.0.0
3	ACTIVE	com.ibm.samples.websphere.osgi.blog.persistence_1.0.0
4	ACTIVE	com.ibm.samples.websphere.osgi.blog.web_1.0.0
5	ACTIVE	com.ibm.samples.websphere.osgi.blog.api_1.0.0

- Display comprehensive information about all of the bundles in the framework, and the services that they register or consume.

Use the bundles command:

```
wsadmin>bundles()
```

This command might generate the following system response.

Note: Information about the bundles that you included in your application is listed as bundle 2 and subsequent bundles. Bundles 0 and 1 are system artefacts; do not modify or rely on these bundles. Although the detail for bundle 0 is not shown in the following example, this bundle typically generates much more information than the other bundles.

- Display comprehensive information about a given bundle in the framework.

Use the bundle command. Specify the ID of the bundle that you want to examine. The bundle ID values are one of the outputs of the ss command.

This command lists the information associated with the specified bundle. For example the bundle symbolic name, the bundle version, the services that the bundle registers, the services that are consumed by the bundle, and whether the bundle is a fragment or a host bundle.

For example:

```
wsadmin>bundle(3)
```

This command might generate the following system response:

```
com.ibm.samples.websphere.osgi.blog.persistence_1.0.0 [3]
```

```
Id=3, Status=ACTIVE
```

```
Location=reference:file:/C:/IBM/WebSphere/AppServer/profiles/profile01/

```

- Display header information about a given bundle.

Use the headers command. Specify the ID of the bundle that you want to examine. The bundle ID values are one of the outputs of the ss command.

For example:

```
wsadmin>headers(2)
```

This command might generate the following system response:

```
Ant-Version = Apache Ant 1.7.1
Bundle-ActivationPolicy = lazy
Bundle-ManifestVersion = 2
Bundle-Name = Blog Core Services Bundle
Bundle-SymbolicName = com.ibm.samples.websphere.osgi.blog
Bundle-Vendor = IBM
Bundle-Version = 1.0.0
Created-By = 2.4 (Your Corporation)
Import-Package = com.ibm.samples.websphere.osgi.logging;version="[1.0.0,1.1.0)",
com.ibm.samples.websphere.osgi.blog.api;version="[1.0.0,1.1.0)",
com.ibm.samples.websphere.osgi.blog.comment.persistence.api;version="[1.0.0,1.1.0)",
com.ibm.samples.websphere.osgi.blog.persistence.api;version="[1.0.0,1.1.0)"
Manifest-Version = 1.0
```

- Display information about the packages that are imported or exported by the framework. Use the `packages` command. Optionally, specify either or both of the following parameters to select a particular package or subset of packages:

bundle ID

Display information about the exported packages for this bundle.

The bundle ID values are one of the outputs of the `ss` command.

package name

Display information about the specified package.

Command syntax:

```
wsadmin>packages()
wsadmin>packages(bundle_id)
wsadmin>packages(package_name)
```

Example using a bundle ID:

```
wsadmin>packages(5)
```

This command might generate the following system response:

```
com.ibm.samples.websphere.osgi.blog.persistence.api; version="1.0.0"
<com.ibm.samples.websphere.osgi.blog.api_1.0.0 [5]>
  com.ibm.samples.websphere.osgi.blog_1.0.0 [2] imports
  com.ibm.samples.websphere.osgi.blog.persistence_1.0.0 [3] imports
com.ibm.samples.websphere.osgi.blog.comment.persistence.api; version="1.0.0"
<com.ibm.samples.websphere.osgi.blog.api_1.0.0 [5]>
  com.ibm.samples.websphere.osgi.blog_1.0.0 [2] imports
com.ibm.samples.websphere.osgi.blog.api; version="1.0.0"
<com.ibm.samples.websphere.osgi.blog.api_1.0.0 [5]>
  com.ibm.samples.websphere.osgi.blog_1.0.0 [2] imports
  com.ibm.samples.websphere.osgi.blog.web_1.0.0 [4] imports
```

Example using a package name:

```
wsadmin>packages("com.ibm.samples.websphere.osgi.blog.comment.persistence.api")
```

This command might generate the following system response:

```
com.ibm.samples.websphere.osgi.blog.comment.persistence.api; version="1.0.0"
<com.ibm.samples.websphere.osgi.blog.api_1.0.0 [5]>
  com.ibm.samples.websphere.osgi.blog_1.0.0 [2] imports
```

- Display information about the services that are currently registered by the framework. For each service this information includes the service interfaces, the bundle that registered the service, and any bundles that consume the service.

Use the `services` command. Optionally, specify either or both of the following parameters to select a particular service or subset of services:

service ID

Display information about a specified service.

filter

Display information about all services that match the filter.

The filter must comply with the OSGi filter format as defined in section 3.2.7 of the OSGi Service Platform Release 4 Version 4.2 Core Specification.

Command syntax:

```
wsadmin>services()
wsadmin>services(service_id)
wsadmin>services("&(prop1=value_1)(prop2=value_2)")
```

Example using a service ID:

```
wsadmin>services(2)
```

This command might generate the following system response:

```
{org.osgi.service.packageadmin.PackageAdmin}={service.id=2,
service.ranking=2147483647,service.vendor=Eclipse.org - Equinox,
service.pid=0.org.eclipse.osgi.framework.internal.core.PackageAdminImpl}
Registered by bundle: org.eclipse.osgi_3.6.1.R36x_v20100806 [0]
Bundles using service:
org.eclipse.osgi_3.6.1.R36x_v20100806 [0]
```

Example using a single property filter:

```
wsadmin>services("(objectClass=org.osgi.service.packageadmin.PackageAdmin)")
```

This command might generate the following system response:

```
{org.osgi.service.packageadmin.PackageAdmin}={service.id=2,
service.ranking=2147483647,service.vendor=Eclipse.org - Equinox,
service.pid=0.org.eclipse.osgi.framework.internal.core.PackageAdminImpl}
Registered by bundle: org.eclipse.osgi_3.6.1.R36x_v20100806 [0]
Bundles using service:
org.eclipse.osgi_3.6.1.R36x_v20100806 [0]
```

Example using a multiple property filter:

```
wsadmin>services("&(objectClass=javax.resource.Referenceable)(ibm.private.jndi.object=true)")
```

This command might generate the following system response:

```
{java.lang.reflect.InvocationHandler,com.ibm.websphere.rsadapter.WSDataSource,java.sql.Wrapper,
javax.sql.CommonDataSource,javax.resource.Referenceable,javax.sql.DataSource}={service.id=35,
osgi.jndi.service.name=jdbc/pgc,ibm.private.jndi.object=true}
Registered by bundle: org.eclipse.osgi_3.6.1.R36x_v20100806 [0]
No bundles using service.
{java.lang.reflect.InvocationHandler,com.ibm.websphere.rsadapter.WSDataSource,java.sql.Wrapper,
javax.sql.CommonDataSource,javax.resource.Referenceable,javax.sql.DataSource}={service.id=36,
osgi.jndi.service.name=jdbc/DefaultEJBTimerDataSource,ibm.private.jndi.object=true}
Registered by bundle: org.eclipse.osgi_3.6.1.R36x_v20100806 [0]
No bundles using service.
{java.lang.reflect.InvocationHandler,com.ibm.websphere.rsadapter.WSDataSource,java.sql.Wrapper,
javax.sql.CommonDataSource,javax.resource.Referenceable,javax.sql.DataSource}={service.id=39,
osgi.jndi.service.name=jdbc/lrsched,ibm.private.jndi.object=true}
Registered by bundle: org.eclipse.osgi_3.6.1.R36x_v20100806 [0]
No bundles using service.
{javax.resource.Referenceable,javax.resource.cci.ConnectionFactory}={service.id=40,
osgi.jndi.service.name=eis/jdbc/pgc_CMP,ibm.private.jndi.object=true}
Registered by bundle: org.eclipse.osgi_3.6.1.R36x_v20100806 [0]
No bundles using service.
```

- Update the cached runtime information about the framework.

It can take some time for the system to gather the runtime information about the framework and the bundles running within it. Therefore, when you run the `osgiApplicationConsole` command, the command-line console caches the runtime information. If you make changes to the currently

selected framework, for example by updating or adding bundles, these changes are not reflected in the output of the command-line console commands until you run the refresh command.

Note: You can also update this runtime information by restarting the OSGi Applications command-line console. However, you then have to reconnect to the framework. It is quicker to use the refresh command.

Command syntax:

```
wsadmin>refresh()
```

- Stop a bundle.

Use the stop command to stop the bundle specified by a given bundle ID. The bundle ID values are one of the outputs of the ss command.

Note:

- The OSGi Applications command line console is intended primarily as a method of debugging applications. In a production environment, you would normally use the administrative console or equivalent administrative commands to start and stop applications.
- Do not use the stop command on any bundles under the shared bundle framework, on system bundles, or on the bundles that represent system artefacts (bundle ID 0 and 1), because this can cause serious errors.

For example:

```
wsadmin>stop(5)
```

This command might generate the following system response:

```
CWSAJ0042I: Stopping Bundle com.ibm.samples.websphere.osgi.blog.api_1.0.0.  
CWSAJ0034I: Bundle com.ibm.samples.websphere.osgi.blog.api stopped successfully.
```

- Start a bundle.

Use the start command to start the bundle specified by a given bundle ID. The bundle ID values are one of the outputs of the ss command.

Note:

- The OSGi Applications command line console is intended primarily as a method of debugging applications. In a production environment, you would normally use the administrative console or equivalent administrative commands to start and stop applications.
- Do not use the start command on any bundles under the shared bundle framework, on system bundles, or on bundles that represent applications (bundle ID 0 and 1), because this can cause serious errors.

For example:

```
wsadmin>start(5)
```

This command might generate the following system response:

```
CWSAJ0040I: Starting Bundle com.ibm.samples.websphere.osgi.blog.api_1.0.0.  
CWSAJ0032I: Bundle com.ibm.samples.websphere.osgi.blog.api started successfully.
```

- Display help information about the console commands.

Use the help command to display a summary of the runtime commands and their uses.

Command syntax:

```
wsadmin>help()
```

This command generates the following system response:

CWSAJ0025I: OSGi application console

Display commands: These commands work only if connected to a framework

ss() - This command gives the summary information about the installed bundles.
bundles() - This command gives comprehensive information about the installed bundles.
packages() - This command gives information about the imported/exported packages.
services() - This command gives information about the registered Services.

bundle(<bundleID>) - This command gives information about the specified bundle
headers(<bundleID>) - This command gives information about the headers associated with the specified bundle
packages(<bundle ID>) - This command gives information about the exported packages for this bundle.
packages(<package Name>) - This command gives information about the specified package.
services(<service ID>) - This command gives information about the specified service.
services(<OSGI Filter>) - This command gives information about the services matching the filter.

refresh() - This command refreshes the internal OSGi application console cache with the latest information about the state of the framework.

Framework commands:

list() - This command lists the available frameworks that you can connect to.
connect(<Framework id>) - This command connects to the specified framework.
connect(<Bundle Name>, <Bundle Version>, <Node Name>, <Server Name>)
- This command connects to the specified framework.

Controlling Bundles:

start(<bundleID>) - This command starts the requested bundle.
stop(<bundleID>) - This command stops the requested bundle.

Developing a composite bundle

A composite bundle groups shared bundles together into aggregates. It provides one or more packages at specific versions to an OSGi application. You can also extend a deployed application by adding one or more composite bundles to the composition unit for the application. You can use OSGi application tooling to develop a composite bundle.

About this task

When you want to ensure consistent behavior from a set of shared bundles in an OSGi application, you use a composite bundle to provide that set of bundles to the application. If a required package or service is available at the same version from both a bundle and a composite bundle, the provisioning process selects the package or service from the composite bundle.

When you want to extend a deployed business-level application that contains an OSGi application, and you don't want to stop the application or modify the underlying EBA asset, you add one or more composite bundles to the composition unit.

A composite bundle is packaged as a composite bundle archive (CBA) file. This is a compressed archive file with a .cba file extension. If the composite bundle is part of an enterprise OSGi application, the CBA file can be directly contained within the enterprise bundle archive (EBA) file for the application, or pulled in by reference from the internal bundle repository or from an external repository that can process composite bundles. A composite bundle can directly contain bundles in its CBA file. It can also include by reference bundles that are hosted alongside the CBA file within the same EBA file, or bundles that are installed in the same bundle repository.

A composite bundle is described in a composite bundle manifest file, META-INF/COMPOSITEBUNDLE.MF. This manifest file lists the OSGi bundles that are directly contained in the composite bundle, and the reference bundles that are hosted alongside the composite bundle in the same EBA file, or in the same bundle repository.

If you want to use your composite bundle to extend a deployed application, you must install the CBA file in the internal bundle repository or in an external repository that can process composite bundles. If you install a composite bundle in a bundle repository, and the composite bundle includes bundles by reference, you must ensure that the referenced bundles are also available in the same repository. If you use the internal bundle repository, and the composite bundle directly contains bundles, the contained bundles are not listed separately and are only available as part of the composite bundle. For more information, see Composite bundles.

IBM Rational Application Developer Version 8 provides graphical support for creating and packaging composite bundles. You can also use other tools.

Procedure

1. Develop the bundles.
See “Creating a service bundle” on page 886 and “Creating a client bundle” on page 888. You might also want to explore the sample OSGi applications.
2. Create the composite bundle manifest.
Most OSGi application tooling, including IBM Rational Application Developer Version 8, helps you create the composite bundle manifest. See also Example: OSGi composite bundle manifest file.
3. Package the directly-contained bundles and the composite bundle manifest as a compressed file with a .cba file extension.

Note: The file extension must be .cba, but the composite bundle name need not include “cba”.

4. Check that all referenced bundles are available in the EBA file (if the composite bundle is part of an enterprise OSGi application), or in a bundle repository that can process composite bundles (such as the internal bundle repository).
See Administering bundles in the internal bundle repository or Administering bundles in the internal bundle repository using wsadmin commands.
5. Add the CBA file to the EBA file or to the bundle repository.

What to do next

- If you have configured an enterprise OSGi application to use your composite bundle, you can now import the application as an asset. See “Deploying an OSGi application as a business-level application” on page 894.
- If you want to use your composite bundle to extend a composition unit, see Adding or removing extensions for an OSGi composition unit.

Converting existing applications to OSGi applications

You can convert an enterprise application or a Spring application to an OSGi application.

Procedure

- Convert an enterprise application to an OSGi application.
- Convert a Spring application to an OSGi application.

Converting an enterprise application to an OSGi application

You can automatically convert an enterprise archive (EAR) file that contains web application archive (WAR) files to an enterprise bundle archive (EBA) file.

Before you begin

Ensure that the enterprise application is suitable for conversion to an OSGi application. Check whether any manual conversion steps are required first. See [Conversion of an enterprise application to an OSGi application](#).

About this task

You can automatically convert a web application to an OSGi application, that is, you can convert an EAR file that contains only WAR files. For other enterprise applications, you might require manual migration steps before you use the following procedure.

Procedure

1. Rename the EAR file (.ear) to an EBA file (.eba).
2. In WebSphere Application Server, import the EBA file as an asset.
3. Optional: Modify any converted Java 2 security settings.

When you convert an application from Java EE to OSGi, any existing `was.policy` file is converted into a `permissions.perm` file to be used with the OSGi permissions framework, and all permissions are promoted to the application level. If you need finer granularity, you can modify the file after conversion. For more information, see [Java 2 security and OSGi Applications](#).

Results

The WAR files are automatically converted to web application bundles (WABs). Any Java 2 security `was.policy` file is converted into a `permissions.perm` file. Any Utility JAR or EJB JAR files are not converted and the EJB function is not directly accessible in the EJB container.

Converting a Spring application to an OSGi application

To convert an application that is created using the Spring Framework to an OSGi application and move from the Spring Framework to standards-based technologies, you must modify the application manually. If a Spring application contains only web application archive (WAR) files, you can convert it automatically to run in OSGi Applications, but it still uses the Spring Framework.

About this task

In a Spring application, the Spring Framework manages features such as transactions, persistence, and dependency injection, and handles the communication between the servlets in the web container and the classes that handle the business logic of the application.

After you convert the application to an OSGi application that uses OSGi Applications support, the Blueprint Container manages the transactions, persistence and dependency injection.

If the application is an enterprise archive (EAR) file that contains only web application archive (WAR) files, you can convert it automatically. You might convert a Spring application in this way if a WAR file uses other library JAR files that must remain unchanged for the application to work. See [“Converting an enterprise application to an OSGi application”](#) on page 920.

Otherwise, you need to identify the Spring components and replace them with the equivalent code to make them plain old Java objects (POJOs), then modify the relevant XML files so that the Blueprint container manages those objects.

To convert a Spring application, you change it as follows:

- Create a well-defined interface to delegate to. The interface represents the classes that handle the business logic of the application.

- Create a service for each class, so that the servlet in the web container can use them.
- Change code that is specific to the Spring Framework in the classes to use the equivalent in Java EE, for example Java EE persistence classes.
- Create a handler servlet and interface to replace those from the Spring Framework.
- Modify XML and manifest files to use syntax that is correct for the Blueprint Container.

At the end of each step, the application is still usable, so you can decide whether to make all, or just some, of these changes.

The following procedure describes these steps in more detail.

Procedure

1. Create a well defined interface to delegate to, for example to replace a dispatcher servlet in the Spring application. The following example replaces the Spring `HttpRequestHandler` interface in an example application with the `MyApplicationHandler` interface.

- a. Create an interface to replace the Spring `HttpRequestHandler` interface.

```
package com.ibm.ws.eba.example.springconversion;

import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

interface MyApplicationHandler {

    void setMyApplicationHandle(MyApplicationUserInterface b);

    void handleRequest(HttpServletRequest request, HttpServletResponse response)
    throws Exception;

}
```

- b. In each class that imports and implements the Spring `HttpRequestHandler` interface, implement the new interface. For example, change the following code:

```
implements HttpRequestHandler

to :
implements MyApplicationHandler
```

- c. If the method creates an exception that is not in a base Java package, for example a `ServletException` exception, you can change it to use more general exception handling and avoid additional OSGi package imports. For example, change the following code:

```
handleRequest(HttpServletRequest request, HttpServletResponse response)
throws ServletException, IOException

to:
handleRequest(HttpServletRequest request, HttpServletResponse response)
throws Exception
```

To replace the Spring interface with this new interface, you must also replace the servlet, as described in step 4 on page 924.

2. At this point, you could continue to use the Spring classes and use the Blueprint Container to manage those objects. To do this, change the `blueprint.xml` file, as described in step 7 on page 925. The configuration for dependency injection that the Blueprint Container uses is similar to the configuration for the Spring Framework. For example, if the Spring Framework calls the `setMyApplicationHandle` method to inject the `MyApplicationUserInterface` variable, this injection continues to work in the Blueprint Container, as long as the `blueprint.xml` file is configured correctly.
3. Change the managed bean that handles persistence to use standard Java EE persistence classes. In the following example, the Spring `JpaTemplate` interface handles persistence. It is equally valid if using JPA directly through an entity manager.

- a. Replace the JpaTemplate interface with Java EE persistence classes. For example, remove the following import statement:

```
import org.springframework.orm.jpa.JpaTemplate;
```

Replace it with the following import statements:

```
import javax.persistence.EntityManager;
import javax.persistence.PersistenceContext;
import javax.persistence.Query;
```

- b. Use the relevant calls that are available in the API for those interfaces. For example, to replace the JpaTemplate code with EntityManager code, remove the following code:

```
@PersistenceUnit(unitName = "springExample")
private JpaTemplate jpaTemplate;

public void setJpaTemplate(JpaTemplate j)
{
    jpaTemplate = j;
}
```

Replace it with the following code:

```
@PersistenceContext(unitName = "myApplication")
private EntityManager em;
public void setEntityManager(EntityManager e) {
    em = e;
}
```

- c. If a persistence unit is inside a web application, separate the persistence unit from the WAR and create a persistence bundle. The persistence bundle must contain the entity classes and the persistence.xml file. The bundle manifest must have a Meta-Persistence header that points to the persistence unit, as shown in the following example:

```
Manifest-Version: 1.0
Bundle-ManifestVersion: 2
Bundle-Name: MyPersistenceBundle
Bundle-SymbolicName: com.ibm.ws.eba.example.persistence
Bundle-Version: 1.0.0
Meta-Persistence: WEB-INF/classes/META-INF/persistence.xml
Import-Package: javax.persistence
```

- d. Replace each instance of a call from the bean that handles persistence with an equivalent call that uses the EntityManager interface, the Query interface, or both. For example, in the example Spring application, the following code snippet shows two methods that call the jpaTemplate.find method:

```
@SuppressWarnings("unchecked")
public boolean checkEmailAddressUniqueness(String emailAddress)
{
    boolean result = false;

    List<UserInfo> users = jpaTemplate.find(uniqueEmailAddressQuery, emailAddress);

    if (users.isEmpty()) {
        result = true;
    }

    return result;
}

public boolean checkUsernameUniqueness(String username)
{
    boolean result = false;

    UserInfo user = jpaTemplate.find(UserInfo.class, username);

    if (user == null) {
        result = true;
    }
}
```

```

    }
    return result;
}

```

The following code snippet shows replacement code:

```

private static final String uniqueEmailAddressQuery = "select u from UserInfo u
where u.emailAddress = ?1";

```

```

@SuppressWarnings("unchecked")
public boolean checkEmailAddressUniqueness(String emailAddress)
{
    boolean result = false;

    Query q = em.createQuery(uniqueEmailAddressQuery);
    q.setParameter(1, emailAddress);

    List<UserInfo> users = q.getResultList();

    if (users.isEmpty()) {
        result = true;
    }

    return result;
}

```

```

public boolean checkUsernameUniqueness(String username)
{
    boolean result = false;

    UserInfo user = em.find(UserInfo.class, username);

    if (user == null) {
        result = true;
    }

    return result;
}

```

4. Create and register a handler servlet to replace the one from the Spring Framework.
 - a. Create a servlet to forward requests to the appropriate handler in the Blueprint Container to process the business logic. This servlet is managed by the web container. The JNDI lookup is constructed as follows:

```

osgi:service/class_name/ldap_filter

```

The following code snippet creates the `MyApplicationHandlerServlet` servlet that passes an HTTP request to the `MyApplicationHandler` class in the Blueprint Container:

```

package com.ibm.ws.eba.example.springconversion;

import javax.naming.InitialContext;
import javax.naming.NamingException;
import javax.servlet.http.HttpServlet;
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

public class MyApplicationHandlerServlet extends HttpServlet {

    private static final long serialVersionUID = -3705932907251688199L;

    @Override
    public void service(HttpServletRequest request, HttpServletResponse response)
    {
        // Get servlet name
        String servletName = this.getServletConfig().getServletName();

        // Get business logic class from service registry that is

```

```

// associated with the servlet

try {
    InitialContext ic = new InitialContext();
    MyApplicationHandler myApplicationLogicClass = (MyApplicationHandler)
    ic.lookup("osgi:service/com.ibm.ws.eba.example.springconversion.
    MyApplicationHandler/(servlet.name="+servletName+"");
    myApplicationLogicClass.handleRequest(request, response);
} catch (NamingException e) {
    e.printStackTrace();
} catch (Exception e) {
    // TODO Auto-generated catch block
    e.printStackTrace();
}
}
}
}

```

- b. Register the new servlet by changing the servlet classes to define the servlet you just created, rather than the Spring servlet. To do this, modify the web.xml file in the WEB-INF folder of the WAR file.

For example, change the following servlet definition in the web.xml file:

```

<servlet>
    <servlet-name>RegistrationServlet</servlet-name>
    <servlet-class> org.springframework.web.context.support.HttpRequestHandlerServlet
</servlet-class>
</servlet>

```

to:

```

<servlet>
    <servlet-name>RegistrationServlet</servlet-name>
    <servlet-class>com.ibm.ws.eba.example.springconversion.MyApplicationHandlerServlet
</servlet-class>
</servlet>

```

- c. Delete the following elements from the web.xml file:

```

<context-param>
<listener>

```

5. Separate the persistence unit from the EAR file and create a persistence bundle. The persistence bundle must contain the entity classes and the persistence.xml file. The bundle manifest must have a Meta-Persistence header that points to the persistence unit, as shown in the following example:

```

Manifest-Version: 1.0
Bundle-ManifestVersion: 2
Bundle-Name: MyPersistenceBundle
Bundle-SymbolicName: com.ibm.ws.eba.example.persistence
Bundle-Version: 1.0.0
Meta-Persistence: WEB-INF/classes/META-INF/persistence.xml
Import-Package: javax.persistence

```

6. If you removed the persistence unit from a WAR file, delete the following element from the web.xml file in the WEB-INF folder of the WAR file:

```

<persistence-unit-ref>

```

7. Change the XML so that the Blueprint Container manages the objects, rather than the Spring Framework.
 - a. Delete the springapp-service.xml file in the WEB-INF folder of the WAR file.
 - b. Create the OSGI-INF/blueprint/ directory.
 - c. Create a file named blueprint.xml in the OSGI-INF/blueprint/ directory. The following code shows an example blueprint.xml file:

```

<blueprint xmlns:tx="http://aries.apache.org/xmlns/transactions/v1.0.0"
           xmlns:jpa="http://http://aries.apache.org/xmlns/jpa/v1.0.0">

  <bean id="myApplicationImpl"
        class="com.ibm.ws.eba.example.springconversion.impl.MyApplicationImpl">
    <jpa:context property="entityManager" unitname="myApplication" />
    <tx:transaction method="*" value="Required"/>
  </bean>

  <bean id="RegistrationServlet"
        class="com.ibm.ws.eba.example.springconversion.Registration">
    <tx:transaction method="*" value="Required"/>
    <property name="myApplicationHandle" ref="myApplicationService" />
  </bean>

  <service id="myApplicationService" ref="myApplicationImpl" interface=
    "com.ibm.ws.eba.example.springconversion.MyApplicationUserInterface" />

  <service id="registrationService" ref="RegistrationServlet" interface=
    "com.ibm.ws.eba.example.springconversion.MyApplicationHandler" >
    <service-properties>
      <entry key="servlet.name" value="RegistrationServlet"/>
    </service-properties>
  </service>

</blueprint>

```

8. Update the persistence.xml file in the war/WEB-INF/classes/META-INF/ directory. For example, you can change the JNDI lookups to use a service from a service registry. The following code is an example:

```

<persistence xmlns="http://java.sun.com/xml/ns/persistence"
             xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
             xsi:schemaLocation="http://java.sun.com/xml/ns/persistence
             http://java.sun.com/xml/ns/persistence/persistence_1_0.xsd"
             version="1.0">

  <persistence-unit name="myApplication" transaction-type="JTA">
    <description>Persistence unit for the Spring conversion sample application
    </description>

    <provider>com.ibm.websphere.persistence.PersistenceProviderImpl
    </provider>

    <jta-data-source>osgi:service/javax.sql.DataSource/
      (osgi.jndi.service.name=jdbc/userdb)
    </jta-data-source>
    <non-jta-data-source>osgi:service/javax.sql.DataSource/
      (osgi.jndi.service.name=jdbc/userdbnonjta)
    </non-jta-data-source>
    <class>com.ibm.ws.eba.example.springconversion.Post</class>
    <class>com.ibm.ws.eba.example.springconversion.UserInfo</class>
    <exclude-unlisted-classes/>
  </persistence-unit>
</persistence>

```

9. Create the enterprise bundle archive (EBA) structure for the application.
 - a. Create a META-INF directory in the root of the project and create an application manifest, APPLICATION.MF. The following code shows an example application manifest file:

```

Manifest-Version: 1.0
Application-ManifestVersion: 1.0
Application-Name: MyApplication
Application-SymbolicName: com.ibm.ws.eba.example.springconversion
Application-Version: 1.0
Application-Content: com.ibm.ws.eba.example.springconversion

```

- b. Delete the context.xml file from the war/META-INF/ directory.

- c. In the `war/META-INF/` directory, create a bundle manifest file, `MANIFEST.MF`. The following code shows an example bundle manifest file:

```
Manifest-Version: 1.0
Bundle-ManifestVersion: 2
Bundle-Name: MyApplication
Bundle-SymbolicName: com.ibm.ws.eba.example.springconversion
Bundle-Version: 1.0.0
Bundle-Vendor: IBM
Bundle-ClassPath: WEB-INF/classes,
WEB-INF/lib/aspectjrt.jar,WEB-INF/lib/aspectweaver.jar,
WEB-INF/lib/commons-collections-3.2.jar,WEB-INF/lib/commons-lang-2.1.jar,
WEB-INF/lib/JSON4J.jar,WEB-INF/lib/jstl.jar,WEB-INF/lib/jta.jar,
WEB-INF/lib/openjpa-1.3.0-SNAPSHOT.jar,WEB-INF/lib/persistence.jar,
WEB-INF/lib/serp-1.13.1.jar,WEB-INF/lib/standard.jar
Web-ContextPath: myApplication
Import-Package: javax.servlet;version="2.5",
javax.servlet.http;version="2.5",
javax.servlet.jsp;version="2.1",
javax.servlet.jsp.tagext;version="2.1",
org.osgi.framework;version="1.5.0",
javax.persistence
```

Sample OSGi applications

OSGi Applications support includes sample applications that demonstrate how to write and package bundles into an enterprise bundle archive (EBA) file.

Two sample OSGi applications are provided: “Blog” and “Blabber”. Both applications demonstrate all of the following OSGi Applications features:

- Using Blueprint management.
- Using bean injection.
- Using services from the OSGi service registry.
- Publishing services to the OSGi service registry.
- Using the Java Persistence API (JPA).

The samples are provided in the `OSGi_blogSample.zip` and `OSGi_blabberSample.zip` compressed archive files, which can be downloaded from the [Samples download page](#). The EBA file for each sample application is in the `installableApps` directory of the sample compressed file, and the source code is provided in other subdirectories of the sample compressed file.

For information about how to install and run each sample application, see the `sample_osgi_blog_readme` and `sample_osgi_blabber_readme` respectively. These files are available in the root directory of the associated sample compressed file. They are also available in the information center as topics “OSGi blog sample application” on page 928 and “OSGi blabber sample application” on page 933.

Blog sample application

The blog sample application is a traditional blogging application, used for publishing essay-length articles and allowing readers to comment on them. The application contains the following bundles:

- `com.ibm.ws.eba.example.blog.persistence`.
This bundle contains JPA-related code, and the interfaces that enable the main application code to update and query blog entries.
- `com.ibm.ws.eba.example.blog_1.0.0`.
This bundle contains the main application logic code and interacts between the web front end and the back end persistence code layer.
- `com.ibm.ws.eba.example.blog.web`.

This bundle contains the static web content and backing Java code for the web front end of the application.

- `com.ibm.ws.eba.example.blog.api`.

This bundle contains the API for the sample.

- `com.ibm.ws.eba.example.blog.persistence_1.1.0`.

This bundle contains an optional upgraded persistence bundle that also supplies a comment service.

To run the blog sample application, you can use all the bundles that are listed, or all the bundles except the upgraded persistence bundle (the last in the list).

For more information, see “OSGi blog sample application.”

Blabber sample application

The blabber sample application is a microblogging application, used to enable many different people to share brief comments. The application contains the following bundles:

- `com.ibm.ws.eba.example.blabber.persistence`.

This bundle contains code that relates to the Java Persistence API (JPA) layer and the interface for the main application code.

- `com.ibm.ws.eba.example.blabber`.

This bundle contains the main application code and the code for the web front end of the application.

For more information, see “OSGi blabber sample application” on page 933.

OSGi blog sample application

The blog sample application is a traditional blogging application, used for publishing essay-length articles and allowing readers to comment on them. This sample application shows how to write and package bundles into an enterprise bundle archive (EBA) file. The sample includes example code for Blueprint management, bean injection, using and publishing services from and to the OSGi service registry, and the use of Java persistence.

Before you begin

The blog sample application consists of five bundles, but can be run with four bundles because the fifth bundle is an upgrade to the persistence bundle.

The sample application requires that the supplied `com.ibm.samples.websphere.osgi.logging.api.jar` and `com.ibm.samples.websphere.osgi.logging.impl.jar` bundles are installed into the internal bundle repository. The following procedure describes how to do this. These two JAR files, and the blog sample EBA file, are provided in the `installableApps` directory of the `OSGi_blogSample.zip` compressed archive file.

About this task

The bundles are divided into the following functional areas:

- `com.ibm.samples.websphere.osgi.blog.persistence`, which contains code relating to the Java Persistence API (JPA) layer, and also contains interfaces that are used by the main application code to update and query blog entries.
- `com.ibm.samples.websphere.osgi.blog_1.0.0`, which contains the main application logic code, and interacts between the web front end and the back end persistence code layer.
- `com.ibm.samples.websphere.osgi.blog.web`, which contains the static web content and backing Java code for the web front end for the application.

- `com.ibm.samples.websphere.osgi.blog.api`, which contains the API for the whole sample.
- `com.ibm.samples.websphere.osgi.blog.persistence_1.1.0`, which contains an upgraded persistence bundle that also supplies a comment service.

You can use scripts to completely install the sample application, or you can use scripts to complete the initial configuration of the application then use the administrative console to install the application into the application server. You can also use, modify and remove the sample, and upgrade the persistence service that is provided by the sample.

Procedure

Configure and install the blog sample.

You can either configure and install the sample using scripts (the first optional step below), or you can configure the sample using scripts then install the sample using the administrative console (the second optional step below).

The scripts that you use to do this are provided in the `scripts` directory of the `OSGi_blogSample.zip` compressed archive file. The `createBlogDb.sql` script contains the necessary configuration commands to create the required Derby database and associated tables. The `blogSampleInstall.py` script contains the required jython to create data sources, and to install the blog sample with default configuration. You should fully qualify the path to the script if you do not run it from the directory that contains the script.

Note: If you have data sources already defined in your environment, and these data sources have the same name as the data sources that are specified in the `blogSampleInstall.py` script, then the sample might not install and run successfully.

In the following steps you must substitute your own values for the variables `app_server_root`, `profileName`, `serverName`, `nodeName`, `blogSample.eba_Location`, `com.ibm.samples.websphere.osgi.logging.api.jar_Location`, `com.ibm.samples.websphere.osgi.logging.impl.jar_Location`, `uncompressed_sample_directory`, and `path_to_ant`.

- Optional: Configure and install the sample using scripts.
 1. Create and configure the “BLOGDB” Derby database and associated tables by running the following command.

On UNIX platforms:

```
app_server_root/derby/bin/embedded/ij.sh scripts/createBlogDb.sql
```

On Windows platforms:

```
app_server_root\derby\bin\embedded\ij.bat scripts\createBlogDb.sql
```
 2. Create the data sources, create the business-level application and import the .eba file as an asset by running the following command.

Note: The target application server must be running before you use this script.

On UNIX platforms:

```
app_server_root/profiles/profileName/bin/wsadmin.sh
-f scripts/blogSampleInstall.py fullInstall serverName nodeName
blogSample.eba_Location
com.ibm.samples.websphere.osgi.logging.api.jar_Location
com.ibm.samples.websphere.osgi.logging.impl.jar_Location
```

On Windows platforms:

```
app_server_root\profiles\profileName\bin\wsadmin.bat
-f scripts\blogSampleInstall.py fullInstall serverName nodeName
blogSample.eba_Location
com.ibm.samples.websphere.osgi.logging.api.jar_Location
com.ibm.samples.websphere.osgi.logging.impl.jar_Location
```

- Optional: Configure the sample using scripts, then install the sample using the administrative console.

1. Create and configure the "BLOGDB" Derby database and associated tables by running the following command.
 On UNIX platforms:

```
app_server_root/derby/bin/embedded/ij.sh scripts/createBlogDb.sql
```

 On Windows platforms:

```
app_server_root\derby\bin\embedded\ij.bat scripts\createBlogDb.sql
```
2. Create the data sources by running the following command.
 On UNIX platforms:

```
app_server_root/profiles/profileName/bin/wsadmin.sh
  -f scripts/blogSampleInstall.py setupOnly serverName nodeName
```

 On Windows platforms:

```
app_server_root\profiles\profileName\bin\wsadmin.bat
  -f scripts\blogSampleInstall.py setupOnly serverName nodeName
```
3. Use the administrative console to add the `com.ibm.samples.websphere.osgi.logging.api.jar` file to the internal bundle repository.
 - a. Navigate to **Environment > OSGi bundle repositories > Internal bundle repository**
 - b. Click **New**.
 - c. Select the file system that hosts the `com.ibm.samples.websphere.osgi.logging.api.jar` file, then click **Browse**.
 - d. Browse to the `uncompressed_sample_dir/installableApps` directory.
 - e. Select the `com.ibm.samples.websphere.osgi.logging.api.jar` file, then click **OK**.
 - f. Click **OK**.
 - g. Click **Save**.
4. Repeat the previous step to add the `com.ibm.samples.websphere.osgi.logging.impl.jar` file to the internal bundle repository.
5. Use the administrative console to import the application (EBA file) as an asset, and to configure the business-level application.
 - a. Import the asset.
 - 1) Navigate to **Applications > New application > New Asset**.
 - 2) On the Upload asset panel, browse to the `uncompressed_sample_dir/installableApps` directory.
 - 3) Select the `com.ibm.samples.websphere.osgi.blog.eba` file, then click **Next**.
 - 4) On the Select options for importing an asset panel, click **Next**.
 - 5) On the Summary panel, click **Finish**.
 - 6) Click **Save**.
 - b. Create the business-level application and add the asset.
 - 1) Navigate to **Applications > New application > New Business Level Application**.
 - 2) On the New Application panel, enter a name for the business-level application. For example, "blog".
 - 3) Click **Apply**.
 - 4) In the Deployed assets pane, click **Add > Add Asset**.
 - 5) Select the `com.ibm.samples.websphere.osgi.blog.eba` asset, then click **Continue**.
 - 6) On the Set options panel, click **Next**.
 - 7) Select a target for the composition unit, then click **Next**.
 - 8) Modify the context root if required, then click **Next**.
 - 9) Modify the virtual host if required, then click **Next**.
 - 10) On the Summary panel, click **Finish**.

- 11) Click **Save**.
6. Start the application.
 - a. Select the newly-created business-level application.
 - b. Click **Start**.

Use the blog sample.

- Use your browser to navigate to `http://server:port/context_root/` (by default `http://localhost:9080/blog/`). The View blog screen is displayed.
- Register yourself as an Author. You need to do this before you can create blog entries.
 1. Click **Create Author**.
 2. Fill in the form.
 3. Click **Submit**.
- Create a blog entry.
 1. Navigate back to `http://localhost:9080/blog/` (or click **Blog Home**).
 2. Click **Create New Post**.
 3. Fill in the form. Use the email address that you specified when you created the Author.
 4. Click **Submit**.

The View blog screen is redisplayed, and should contain your post.

Upgrade the persistence service.

To add the new persistence bundle to the blog application, use the administrative console to add the `com.ibm.samples.websphere.osgi.blog.persistence_1.1.0.jar` file to the internal bundle repository, then modify the asset to expect a new bundle version.

- Navigate to **Environment > OSGi bundle repositories > Internal bundle repository**.
- Click **New**.
- Browse to the `uncompressed_sample_dir/installableApps` directory.
- Select the `com.ibm.samples.websphere.osgi.blog.persistence_1.1.0.jar` file, then click **OK**.
- Save your changes to the master configuration.
- Navigate to **Applications > Application types > Assets**.
- Click **com.ibm.samples.websphere.osgi.blog.eba** to view the asset information.
- Scroll to the end of the asset information, then click **Update bundle versions in this application**.
- Find the `com.ibm.samples.websphere.osgi.blog.persistence` bundle in the list.
- Click the down arrow beside the text “no preference”. You are offered a choice between version 1.0.0 or 1.1.0 of the persistence bundle.
- Select version 1.1.0, then work through the preview, commit and save screens.
- Navigate to **Applications > Application types > Business-level applications**.
- Stop then restart the blog sample.

Select the business-level application representing the blog sample application, then click **Stop**. Wait until the status column shows that the application has stopped, then click **Start**.

- Use your browser to navigate to `http://server:port/context_root/` (by default `http://localhost:9080/blog/`) then refresh the screen. The View blog screen is displayed. There is a new option to add comments to blog posts.

Modify the blog sample

All the source code for this application is provided in sub-directories below the `uncompressed_sample_dir` directory. Each part of the project has its own `ant build.xml` script. To build the whole application into a newly-available EBA file, you use the `ant build.xml` file located in the `uncompressed_sample_dir` directory. WebSphere Application Server ships a version of ant in its `bin` directory called `ws_ant`. To build the

sample, you also need several JAR files on the ant classpath. To simplify matters, you can edit the **was.root** property in the supplied `build.properties` file to point to these JAR files.

- Put the following jar files on the ant classpath:
 - `javax.j2ee.persistence.jar`
 - `javax.j2ee.jsp.jar`
 - `javax.j2ee.servlet.jar`

These JAR files are available in the `plugins` directory of WebSphere Application Server. Edit the **was.root** property in the supplied `uncompressed_sample_dir/scripts/build.properties` file, and point it to your `app_server_root` directory. If you have copied the jars to another location, modify the **was.root** property to point to this location.

- Run the following ant command from the `uncompressed_sample_dir` directory:
`path_to_ant -propertyfile scripts/build.properties -buildfile build.xml`

The newly-built binary (EBA file) is in the `uncompressed_sample_dir/output` directory.

Note: This is the only location to which this EBA file is written. The script does not overwrite the original binary located in the `uncompressed_sample_dir/installableApps` directory.

Remove the blog sample.

To remove the blog sample, you complete the following 3 steps:

1. Remove the application configuration and the data sources, either by using a script (the first optional step below), or by using the administrative console (the second optional step below).
2. Remove the shared logging bundles from the internal bundle repository.
3. Remove the database.

Note: Only remove the bundles if you have no other applications installed that use them. Both the blog and blabber sample applications use the shared logging bundles, so if both applications are installed these bundles should not be removed.

The uninstall script is provided in the `scripts` directory of the `OSGi_blogSample.zip` compressed archive file. The `blogSampleUninstall.py` script contains the required `jython` to remove data sources and to remove the installation of the blog sample with default configuration. You should fully qualify the path to the script if you do not run it from the directory that contains the script.

In the following steps you must substitute your own values for the variables `app_server_root`, and `profileName`.

- Optional: Remove the application configuration and the data sources by running the following command.

Note: The target application server must be running before you use this script.

On UNIX platforms:

```
app_server_root/profiles/profileName/bin/wsadmin.sh
-f scripts/blogSampleUninstall.py
```

On Windows platforms:

```
app_server_root\profiles\profileName\bin\wsadmin.bat
-f scripts\blogSampleUninstall.py
```

- Optional: Remove the application configuration and the data sources by using the administrative console.
 1. Remove the application configuration.
 - a. Navigate to **Applications > Application types > Business-level applications**.
 - b. Select the business-level application representing the blog sample application, then click **Stop**.

- c. Click the business-level application representing the blog sample application to view the configuration details.
 - d. Select all the deployed assets, then click **Delete**.
 - e. Click **OK** to confirm removal.
 - f. Click **Save**.
 - g. Select the business-level application representing the blog sample application, then click **Delete**.
 - h. Navigate to **Applications > Application types > Assets**.
 - i. Select the `com.ibm.samples.websphere.osgi.blog.eba` asset, then click **Delete**.
 - j. Click **OK** to confirm removal.
 - k. Click **Save**.
2. Remove the data sources.
 - a. Navigate to **Resources > JDBC > Data sources**.
 - b. Select the two data sources configured for the blog application.
 - c. Click **Delete**.
 - d. Click **Save**.
- Remove the shared logging bundles from the internal bundle repository by using the administrative console.
 1. Navigate to **Environment > OSGi bundle repositories > Internal bundle repository**.
 2. Select the following bundles:
 - `com.ibm.samples.websphere.osgi.logging.api.jar`
 - `com.ibm.samples.websphere.osgi.logging.impl.jar`
 - `com.ibm.samples.websphere.osgi.blog.persistence_1.1.0`
 3. Click **Delete**.
 4. Click **Save**.
 - Remove the database.

On UNIX platforms, open a command prompt, then enter the following command:

```
cd app_server_root/derby
rm -fr BLOGDB
```

On Windows platforms, delete the `app_server_root\derby\BLOGDB` directory.

OSGi blabber sample application

The blabber sample application is a microblogging application, used to enable many different people to share brief comments. This sample application shows how to write and package bundles into an enterprise bundle archive (EBA) file. The sample includes example code for Blueprint management, bean injection, using and publishing services from and to the OSGi service registry, and the use of Java persistence.

Before you begin

The sample application requires that the supplied `com.ibm.samples.websphere.osgi.logging.api.jar` and `com.ibm.samples.websphere.osgi.logging.impl.jar` bundles are installed into the internal bundle repository. The following procedure describes how to do this. These two JAR files, and the blabber sample EBA file, are provided in the `installableApps` directory of the `OSGi_blabberSample.zip` compressed archive file.

About this task

The blabber sample application consists of two bundles, divided into the following functional areas:

- `com.ibm.samples.websphere.osgi.blabber.persistence`, which contains code relating to the Java Persistence API (JPA) layer, and also contains the interface that is used by the main application code.

- `com.ibm.samples.websphere.osgi.blabber`, which contains the main application logic code, and interacts between the web front end and the back end persistence code layer.

You can use scripts to completely install the sample application, or you can use scripts to complete the initial configuration of the application then use the administrative console to install the application into the application server. You can also use, modify and remove the sample.

Procedure

Configure and install the blabber sample.

You can either configure and install the sample using scripts (the first optional step below), or you can configure the sample using scripts then install the sample using the administrative console (the second optional step below).

The scripts that you use to do this are provided in the `scripts` directory of the `OSGi_blabberSample.zip` compressed archive file. The `createblabberDb.sql` script contains the necessary configuration commands to create the required Derby database and associated tables. The `blabberSampleInstall.py` script contains the required jython to create data sources, and to install the blabber sample with default configuration. You should fully qualify the path to the script if you do not run it from the directory that contains the script.

Note: If you have data sources already defined in your environment, and these data sources have the same name as the data sources that are specified in the `blabberSampleInstall.py` script, then the sample might not install and run successfully.

In the following steps you must substitute your own values for the variables `app_server_root`, `profileName`, `serverName`, `nodeName`, `blabberSample.eba_Location`, `com.ibm.samples.websphere.osgi.logging.api.jar_Location`, `com.ibm.samples.websphere.osgi.logging.impl.jar_Location`, `uncompressed_sample_directory`, and `path_to_ant`.

- Optional: Configure and install the sample using scripts.
 1. Create and configure the "BLABBERDB" Derby database and associated tables by running the following command.
On UNIX platforms:

```
app_server_root/derby/bin/embedded/ij.sh scripts/createBlabberDb.sql
```

On Windows platforms:

```
app_server_root\derby\bin\embedded\ij.bat scripts\createBlabberDb.sql
```
 2. Create the data sources, create the business-level application and import the .eba file as an asset by running the following command.

Note: The target application server must be running before you use this script.

On UNIX platforms:

```
app_server_root/profiles/profileName/bin/wsadmin.sh
-f scripts/blabberSampleInstall.py fullInstall serverName nodeName
blabberSample.eba_Location
com.ibm.samples.websphere.osgi.logging.api.jar_Location
com.ibm.samples.websphere.osgi.logging.impl.jar_Location
```

On Windows platforms:

```
app_server_root\profiles\profileName\bin\wsadmin.bat
-f scripts\blabberSampleInstall.py fullInstall serverName nodeName
blabberSample.eba_Location
com.ibm.samples.websphere.osgi.logging.api.jar_Location
com.ibm.samples.websphere.osgi.logging.impl.jar_Location
```

- Optional: Configure the sample using scripts, then install the sample using the administrative console.
 1. Create and configure the "BLABBERDB" Derby database and associated tables by running the following command.

On UNIX platforms:

```
app_server_root/derby/bin/embedded/ij.sh scripts/createBlabberDb.sql
```

On Windows platforms:

```
app_server_root\derby\bin\embedded\ij.bat scripts\createBlabberDb.sql
```

2. Create the data sources by running the following command.

On UNIX platforms:

```
app_server_root/profiles/profileName/bin/wsadmin.sh  
-f scripts/blabberSampleInstall.py setupOnly serverName nodeName
```

On Windows platforms:

```
app_server_root\profiles\profileName\bin\wsadmin.bat  
-f scripts\blabberSampleInstall.py setupOnly serverName nodeName
```

3. Use the administrative console to add the `com.ibm.samples.websphere.osgi.logging.api.jar` file to the internal bundle repository.
 - a. Navigate to **Environment > OSGi bundle repositories > Internal bundle repository**
 - b. Click **New**.
 - c. Select the file system that hosts the `com.ibm.samples.websphere.osgi.logging.api.jar` file, then click **Browse**.
 - d. Browse to the `uncompressed_sample_dir/installableApps` directory.
 - e. Select the `com.ibm.samples.websphere.osgi.logging.api.jar` file, then click **OK**.
 - f. Click **OK**.
 - g. Click **Save**.
4. Repeat the previous step to add the `com.ibm.samples.websphere.osgi.logging.impl.jar` file to the internal bundle repository.
5. Use the administrative console to import the application (EBA file) as an asset, and to configure the business-level application.
 - a. Import the asset.
 - 1) Navigate to **Applications > New application > New Asset**.
 - 2) On the Upload asset panel, browse to the `uncompressed_sample_dir/installableApps` directory.
 - 3) Select the `com.ibm.samples.websphere.osgi.blabber.app.eba` file, then click **Next**.
 - 4) On the Select options for importing an asset panel, click **Next**.
 - 5) On the Summary panel, click **Finish**.
 - 6) Click **Save**.
 - b. Create the business-level application and add the asset.
 - 1) Navigate to **Applications > New application > New Business Level Application**.
 - 2) On the New Application panel, enter a name for the business-level application. For example, "blabber".
 - 3) Click **Apply**.
 - 4) In the Deployed assets pane, click **Add > Add Asset**.
 - 5) Select the `com.ibm.samples.websphere.osgi.blabber.app.eba` asset, then click **Continue**.
 - 6) On the Set options panel, click **Next**.
 - 7) Select a target for the composition unit, then click **Next**.
 - 8) Modify the context root if required, then click **Next**.
 - 9) Modify the virtual host if required, then click **Next**.
 - 10) On the Summary panel, click **Finish**.
 - 11) Click **Save**.
6. Start the application.

- a. Select the newly-created business-level application.
- b. Click **Start**.

Use the blabber sample.

- Use your browser to navigate to `http://server:port/context_root/` (by default `http://localhost:9080/blabber/`). The main blabber screen is displayed.
- Register yourself as a user. You need to do this before you can create blabber entries.
 1. Click **Click here to sign-up!**.
 2. Fill in the form.
 3. Click **Create my account!**.

The status update home page is displayed.

- Explore the blabber application.

From the status update home page, you can select any of the following options:

- Set a status message.
- Search for and track other users.
- View your profile.
- Sign out.

Within each of the previous options, there is an option to return to the status update home page.

Note:

- When you enter some status then click **Update**, your status message is displayed on the current page.
- You can only view or use the tracking option if the application has more than one user.

Modify the blabber sample.

All the source code for this application is provided in sub-directories below the *uncompressed_sample_dir* directory. Each part of the project has its own ant `build.xml` script. To build the whole application into a newly-available EBA file, you use the ant `build.xml` file located in the *uncompressed_sample_dir* directory. WebSphere Application Server ships a version of ant in its `bin` directory called `ws_ant`. To build the sample, you also need several JAR files on the ant classpath. To simplify matters, you can edit the **was.root** property in the supplied `build.properties` file to point to these JAR files.

- Put the following jar files on the ant classpath:
 - `javax.j2ee.persistence.jar`
 - `javax.j2ee.jsp.jar`
 - `javax.j2ee.servlet.jar`
 - `com.ibm.ws.prereq.jaxrs.jar`

These JAR files are available in the `plugins` directory of Websphere Application Server. Edit the **was.root** property in the supplied `uncompressed_sample_dir/scripts/build.properties` file, and point it to your `app_server_root` directory. If you have copied the jars to another location, modify the **was.root** property to point to this location.

- Run the following ant command from the *uncompressed_sample_dir* directory:
`path_to_ant -propertyfile scripts/build.properties -buildfile build.xml`

The newly-built binary (EBA file) is in the *uncompressed_sample_dir/output* directory.

Note: This is the only location to which this EBA file is written. The script does not overwrite the original binary located in the *uncompressed_sample_dir/installableApps* directory.

Remove the blabber sample.

To remove the blabber sample, you complete the following 3 steps:

1. Remove the application configuration and the data sources, either by using a script (the first optional step below), or by using the administrative console (the second optional step below).
2. Remove the shared logging bundles from the internal bundle repository.
3. Remove the database.

Note: Only remove the bundles if you have no other applications installed that use them. Both the blabber and blog sample applications use the shared logging bundles, so if both applications are installed these bundles should not be removed.

The uninstall script is provided in the `scripts` directory of the `OSGi_blabberSample.zip` compressed archive file. The `blabberSampleUninstall.py` script contains the required jython to remove data sources and to remove the installation of the blabber sample with default configuration. You should fully qualify the path to the script if you do not run it from the directory that contains the script.

In the following steps you must substitute your own values for the variables `app_server_root`, and `profileName`.

- Optional: Remove the application configuration and the data sources by running the following command.

Note: The target application server must be running before you use this script.

On UNIX platforms:

```
app_server_root/profiles/profileName/bin/wsadmin.sh
-f scripts/blabberSampleUninstall.py
```

On Windows platforms:

```
app_server_root\profiles\profileName\bin\wsadmin.bat
-f scripts\blabberSampleUninstall.py
```

- Optional: Remove the application configuration and the data sources by using the administrative console.
 1. Remove the application configuration.
 - a. Navigate to **Applications > Application types > Business-level applications**.
 - b. Select the business-level application representing the blabber sample application, then click **Stop**.
 - c. Click the business-level application representing the blabber sample application to view the configuration details.
 - d. Select all the deployed assets, then click **Delete**.
 - e. Click **OK** to confirm removal.
 - f. Click **Save**.
 - g. Select the business-level application representing the blabber sample application, then click **Delete**.
 - h. Navigate to **Applications > Application types > Assets**.
 - i. Select the `com.ibm.samples.websphere.osgi.blabber.app.eba` asset, then click **Delete**.
 - j. Click **OK** to confirm removal.
 - k. Click **Save**.
 2. Remove the data sources.
 - a. Navigate to **Resources > JDBC > Data sources**.
 - b. Select the two data sources configured for the blabber application.
 - c. Click **Delete**.
 - d. Click **Save**.
- Remove the shared logging bundles from the internal bundle repository by using the administrative console.

1. Navigate to **Environment > OSGi bundle repositories > Internal bundle repository**.
 2. Select the following bundles:
 - com.ibm.samples.websphere.osgi.logging.api.jar
 - com.ibm.samples.websphere.osgi.logging.impl.jar
 3. Click **Delete**.
 4. Click **Save**.
- Remove the database.

On UNIX platforms, open a command prompt, then enter the following command:

```
cd app_server_root/derby  
rm -fr BLABBERDB
```

On Windows platforms, delete the *app_server_root*\derby\BLABBERDB directory.

Chapter 23. Developing Portlet applications

This page provides a starting point for finding information about portlet applications, which are special reusable Java servlets that appear as defined regions on portal pages. Portlets provide access to many different applications, services, and web content.

Portlet aggregation and preferences

Supported optional features of the JSR-286 Portlet Specification

The simple portal framework, which builds on top of the portlet container, is JSR-286-compliant. However, the WebSphere Application Server implementation supports a subset of the optional features in the JSR-286 Portlet Specification.

The following table lists the optional features that are available in the JSR-286 Portlet Specification and indicates to what extent these optional features are available in WebSphere Application Server.

Table 100. Optional features in the JSR-286 Portlet Specification. The Availability column states whether the product supports a specification feature.

Feature	Availability
Container runtime options	The following container runtime options are supported: <ul style="list-style-type: none">• javax.portlet.escapeXml• javax.portlet.servletDefaultSessionScope• javax.portlet.actionScopedRequestAttributes
Setting the HTML head section elements using the <code>MimeResponse.MARKUP_HEAD_ELEMENT</code> property	This property is not supported as its setting does not have an effect.
Custom portlet modes and custom window states	The feature is supported, but without special treatment.
Portlet-managed modes	This feature is fully supported.
Dynamically setting the portlet title using the <code>RenderResponse.setTitle(String)</code> method	This feature is partially supported. You need to make use of this feature in a portlet document filter or an aggregation <code>JavaServer Pages (JSP)</code> file.
Dynamically setting the next possible portlet modes using the <code>RenderResponse.setNextPossiblePortletModes(Collection<PortletMode>)</code> method	This feature is not supported.
Expiration and validation-based caching	This feature is fully supported. You need to activate the portlet fragment caching and a <code>cachespec.xml</code> defined as a prerequisite.
Aliases in public render parameters	The aliases in public render parameters are supported in the <code>PortletServingServlet</code> servlet and the aggregation tag library.
Aliases and wild cards in eventing	These aliases and wild cards are not supported as setting these functions does not have an effect.

Aggregation tag library attributes

The aggregation tag library is used to aggregate multiple portlets on one page. This topic describes the attributes within the aggregation tag library.

Supported arguments include:

init

This tag initializes the portlet framework and has to be used in the beginning of the JSP. All other tags described in this section are only valid in the body of this tag, therefore the `init` tag usually encloses the whole body of a JSP. In case the current URL contains an action flag the action method of the corresponding portlet is called. The `state` and `insert` tags are sub-tags of the `init` tag.

The `init` tag has the following attributes:

- `portletURLPrefix` = "<any string>"

This URL defines the prefix used for PortletURLs. Portlet URLs are created either by the state tag or within a portlet's render method, which is called by using the insert tag. This is a required attribute.

- portletURLSuffix = "<any string>"

This URL defines the suffix used for PortletURLs. Portlet URLs are created either by the state tag or within a portlet's render method, which is called by using the insert tag. This is attribute optional.

- portletURLQueryParams = "<any string>"

This URL defines the query parameters used for PortletURLs. Portlet URLs are created either by the state tag or within a portlet's render method, which is called by using the insert tag. This is attribute optional.

scope, portlet

The scope tag and portlet tag are used to provide information that is necessary when a portlet application is installed under a multiple part context root, for example, /context1/context2. These tags also define which portlet windows should participate in portlet coordination via public render parameters, and add a render parameter to the newly created URL.

The urlParam tag has the following attributes:

- context = "/<context1>/<context2>"

Specifies the context root of the portlet application in which the portlet is deployed. This attribute is required.

- portletname = "<portlet-name>"

Specifies the portlet-name. This attribute is required.

- windowId = "<any string>"

Defines the window ID for the concrete portlet instance. This attribute is required.

The following is an example of how to use the scope and portlet tags:

```
<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>

<portlet:scope>
  <portlet:portlet context="/myportletcontext1/myportletcontext2" portletname="MyPortlet" windowId="sample"/>
</portlet:scope>

<portlet:init portletURLPrefix="/myportalcontext/" %>
....
</portlet:init>
```

state

The state tag creates a URL pointing to the given portlet using the given state. You can place this URL either into a variable specified by the var attribute or you can write it directly to the output stream. This tag is useful to create URLs for HTML buttons, images, and other items such that when the URL is invoked, the state changes defined in the URL are applied to the given portlet.

The state tag has the following attributes:

- url = "<context>/<portlet-name>"

Identifies the portlet for this tag by using the context and portlet-name to address the portlet. This attribute is required.

- windowId = "<any string>"

Defines the window ID for the portlet URL created by this tag. This is attribute optional.

- var = "<any string>"

If defined the URL is written into a variable with the given scope and name, not to the output stream. This is attribute optional.

- scope = "page|request|session|application"

This attribute is only valid if the var attribute is specified. If defined, the URL is not written to the output stream but a variable is created in the given scope with the given name. The default is page. This is attribute optional.

- portletMode = "view|help|edit|<custom>"
This attribute sets the portlet mode.
- portletWindowState = "maximized|minimized|normal|<custom>"
This attribute sets the window state.
- action = "true/false"
This attribute defines whether this is an action URL. This is attribute optional. The default is false.

urlParam

Adds a render parameter to the newly created URL.

The urlParam tag has the following attributes:

- name = "<any string>"
Indicates the name of the parameter. This is attribute required.
- value = "<any string>"
Indicates the value of the parameter. This is attribute required.

insert

This tag calls the render method of the portlet and retrieves the content as well as the title. You can optionally place the content and title of the specified portlet into variables using the contentVar and titleVar attributes.

The insert tag has the following attributes:

- url = "<context>/<portlet-name>" (mandatory) Identifies the portlet for this tag by using the context and portlet-name to address the portlet
This is attribute required.
- windowId = "<any string>"
Defines the window ID of the portlet. This is attribute optional.
- contentVar = "<any string>"
If defined, the portlet's content is not written to the output stream but written into a variable with the given scope and name. This is attribute optional.
- contentScope = "page|request|session|application"
This attribute is only valid if the contentVar tag is used. If defined, the portlet's content is written into a variable with the given scope and name, not to the output stream. The default is page. This is attribute optional.
- titleVar = "<any string>"
If defined the portlet's title is written into a variable with the given scope and name. If it is not defined, the title is ignored and not written to the output stream. This is attribute optional.
- titleScope = "page|request|session|application"
This attribute is only valid if titleVar tag is used. If defined, the portlet's title is written into a variable with the given scope and name, not to the output stream. The default is page. This is attribute optional.

Example: Using the portlet aggregation tag library

You can use the aggregation tag library to aggregate multiple portlets to have multiple and different content on one page. The library can be used by every JavaServer Pages (JSP) file that has been included by a servlet.

To use the portlet aggregation tag library, you must declare the tag-lib at the top of the JSP file using, `<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>`, as in the following example. The following JSP file example shows how to aggregate portlets on one page.

```
<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>
<%@ page isELIgnored="false" import="java.util.Enumeration"%>

<portlet:init portletURLPrefix="/dummy/portletTagTest/" portletURLSuffix="/more" portletURLQueryParams="p1=v1&p2=v2">
```

```

<portlet:insert url="worldclock/StdWorldClock" contentVar="worldclockcontent" titleVar="worldclocktitle"/>
<portlet:state url="worldclock/StdWorldClock" portletMode="view" var="worldclockview"
  portletWindowState="maximized">
  <portlet:urlParam name="namea" value="valuea"/>
  <portlet:urlParam name="nameb" value="valueb"/>
</portlet:state>
<portlet:state url="worldclock/StdWorldClock" portletMode="edit" var="worldclockedit" portletWindowState="normal">
  <portlet:urlParam name="name1" value="value1"/>
  <portlet:urlParam name="name2" value="value2"/>
</portlet:state>
<portlet:state url="worldclock/StdWorldClock" portletMode="view" var="worldclockmin"
  portletWindowState="minimized">
  <portlet:urlParam name="namemin" value="valuemin"/>
  <portlet:urlParam name="namemin" value="valuemin"/>
</portlet:state>

<portlet:insert url="worldclock/StdWorldClock" windowId="min" contentVar="simplecontent" titleVar="simpletitle"/>
<portlet:state url="worldclock/StdWorldClock" windowId="min" portletMode="view" var="simpleview"
  portletWindowState="maximized">
  <portlet:urlParam name="name3" value="value3"/>
  <portlet:urlParam name="name4" value="value4"/>
  <portlet:urlParam name="name5" value="value5"/>
  <portlet:urlParam name="name5" value="value5a"/>
  <portlet:urlParam name="name5" value="value5b"/>
  <portlet:urlParam name="name5" value="value5c"/>
</portlet:state>
<portlet:state url="worldclock/StdWorldClock" windowId="min" portletMode="edit" var="simpleedit"
  action="true" portletWindowState="normal">
  <portlet:urlParam name="name6" value="value6"/>
  <portlet:urlParam name="name6" value="value6z"/>
</portlet:state>
<portlet:state url="worldclock/StdWorldClock" windowId="min" portletMode="view" var="simplemin"
  portletWindowState="minimized">
  <portlet:urlParam name="name1" value="value1"/>
  <portlet:urlParam name="name2" value="value2"/>
</portlet:state>

<portlet:insert url="test/TestPortlet1" contentVar="testcontent" titleVar="testtitle"/>
<portlet:state url="test/TestPortlet1" portletMode="view" var="testview" portletWindowState="maximized"/>
<portlet:state url="test/TestPortlet1" portletMode="edit" var="testedit" portletWindowState="maximized"/>

```

```

<!-- This table is the outermost table for creating two-column portal layout -->

```

```

<TABLE border="0" CELLPADDING="3" CELLSPACING="8" WIDTH="100%">
<TR>
<TD VALIGN="top">

</portlet:init>

```

You can include the following formatting to the previous example JSP file immediately after declaring the tag library.

```

<STYLE TYPE="TEXT/CSS">
BODY {
  font-family:Verdana,sans-serif; font-size:70%
}
.portletTitle {
  text-align: left;border-top: #000000 1px solid; border-bottom: #000000 1px solid; FONT-SIZE: 60.0%;
  COLOR: #ffffff; FONT-FAMILY: Verdana, Arial, Helvetica, sans-serif; BACKGROUND-COLOR: #5495d5;
}
.portletTitleControls {
  text-align: right;border-top: #000000 1px solid; border-right: #000000 1px solid; border-bottom: #000000
  1px solid; FONT-SIZE: 60.0%; COLOR: #ffffff; FONT-FAMILY: Verdana, Arial, Helvetica, sans-serif;
  BACKGROUND-COLOR: #5495d5;
}
.portletTitleControls A {
  COLOR: #ffffff; text-decoration:none; border:#5495d5 1px solid;border-left:white 1px solid;
  padding-left:0.5em; padding-right:0.5em;
}
.portletTitleControls A:hover {
  COLOR: #ffffff; text-decoration:none; border-top:white 1px solid;
  border-bottom:white 1px solid;border-right:white 1px solid;
}
.minimizeControl {
  font-weight:bold; font-size:100%;
}
.portletTable {
  border-left: gray 1px solid;
  border-bottom: gray 1px solid;
  border-right: gray 1px solid;
}
.portletBody {
  font-family:Verdana,sans-serif; font-size:70%
}
</STYLE>

```

Portlet aggregation using JavaServer Pages

The aggregation tag library generates a portlet aggregation framework to address one or more portlets on one page. If you write JavaServer Pages, you can aggregate multiple portlets on one page using the aggregation tag library. This tag library does not provide full featured portal aggregation implementation, but provides a good migration scenario if you already have aggregating servlets and JavaServer Pages and want to switch to portlets.

To allow the customer to create a simple portal aggregation, the aggregation tag library also provides the following features.

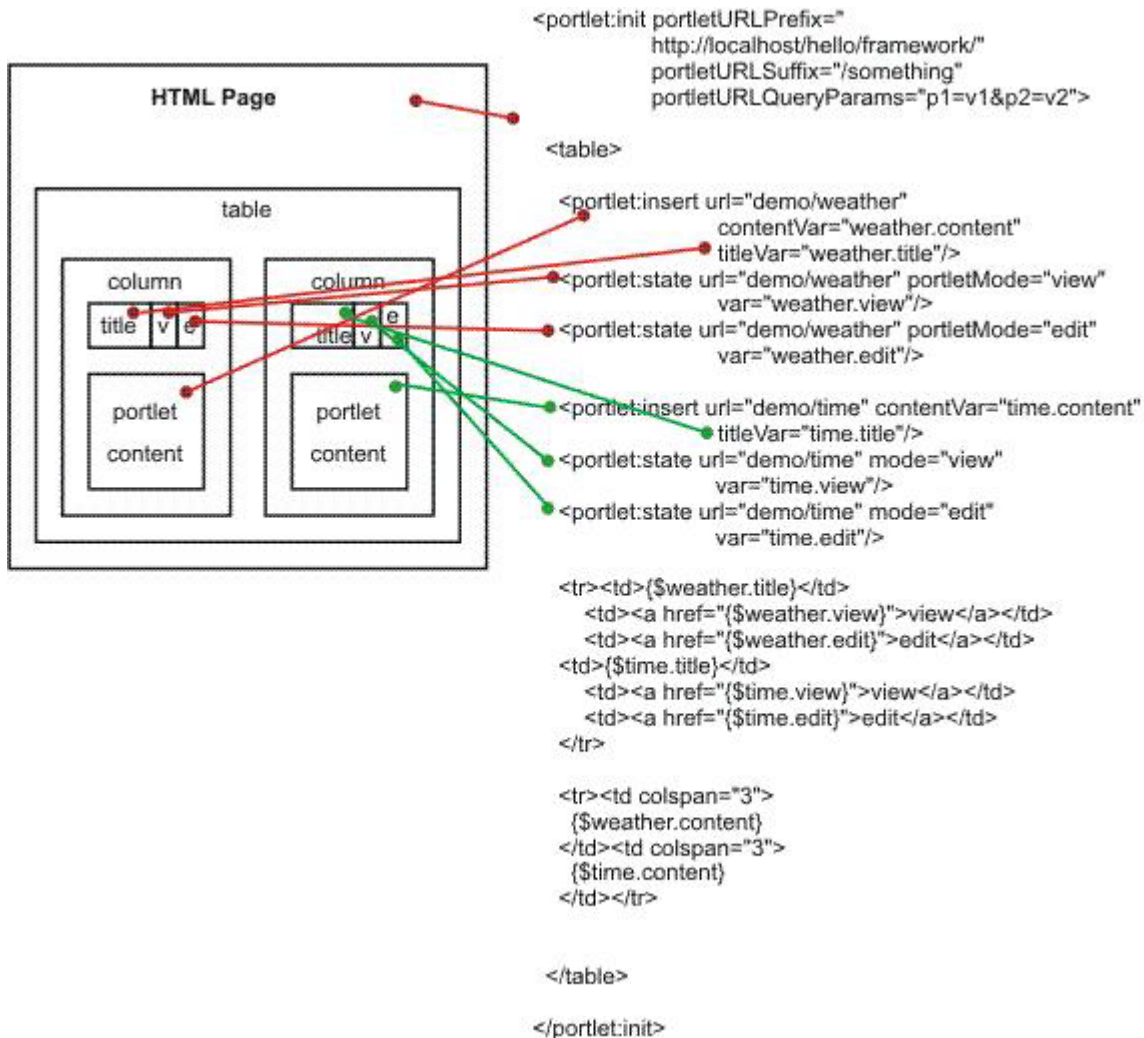

- Invoke a portlet's action method
- Render multiple portlets on one page
- Provide links to change the portlet's mode or window state

- Display the portlet's title
- Retain the portlet cookie state

The aggregation tag library and JavaServer Pages that use the aggregation tag library will only work with the WebSphere Application Server portlet container implementation because the protocol between the tags and the container is not standardized.

Refer to the Aggregation tag library attributes article for information on the aggregation tag library attributes.

The following diagram depicts how an HTML page would look like and what tags are used in order to create the page. Refer to the Aggregation tag library attributes article for information on the aggregation tag library attributes.

When you use the aggregation tag library, you must set the portletUrlPrefix attribute of the init tag to the aggregating application. You need to:

- Ensure that the portletUrlPrefix attribute is set to the following in the aggregator page.
"http://" + <server_address> + ":" + <server_port> + "/" + <aggregator context> + "/" <aggregator mapping>
- Reference the aggregation JSP page within the web.xml file through a servlet mapping ending with /*.
For example, /aggregation/*

When aggregating multiple portlets on a single page, special care must be used with the naming conventions of form attribute names in your portlets. Because your portlets are all on the same page, they all share the same `HttpServletRequest`. When one portlet is viewed the entire page is refreshed and form data is re-posted. Therefore, if there are multiple portlets that are aggregated on a single page with the same form attribute names, there could be logic corruption when form data is re-posted.

Aggregation tag library attributes

The aggregation tag library is used to aggregate multiple portlets on one page. This topic describes the attributes within the aggregation tag library.

Supported arguments include:

init

This tag initializes the portlet framework and has to be used in the beginning of the JSP. All other tags described in this section are only valid in the body of this tag, therefore the `init` tag usually encloses the whole body of a JSP. In case the current URL contains an action flag the action method of the corresponding portlet is called. The `state` and `insert` tags are sub-tags of the `init` tag.

The `init` tag has the following attributes:

- `portletURLPrefix = "<any string>"`

This URL defines the prefix used for PortletURLs. Portlet URLs are created either by the `state` tag or within a portlet's render method, which is called by using the `insert` tag. This is a required attribute.

- `portletURLSuffix = "<any string>"`

This URL defines the suffix used for PortletURLs. Portlet URLs are created either by the `state` tag or within a portlet's render method, which is called by using the `insert` tag. This is attribute optional.

- `portletURLQueryParams = "<any string>"`

This URL defines the query parameters used for PortletURLs. Portlet URLs are created either by the `state` tag or within a portlet's render method, which is called by using the `insert` tag. This is attribute optional.

scope, portlet

The `scope` tag and `portlet` tag are used to provide information that is necessary when a portlet application is installed under a multiple part context root, for example, `/context1/context2`. These tags also define which portlet windows should participate in portlet coordination via public render parameters, and add a render parameter to the newly created URL.

The `urlParam` tag has the following attributes:

- `context = "/<context1>/<context2>"`

Specifies the context root of the portlet application in which the portlet is deployed. This attribute is required.

- `portletname = "<portlet-name>"`

Specifies the portlet-name. This attribute is required.

- `windowId = "<any string>"`

Defines the window ID for the concrete portlet instance. This attribute is required.

The following is an example of how to use the `scope` and `portlet` tags:

```
<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>

<portlet:scope>
  <portlet:portlet context="/myportletcontext1/myportletcontext2" portletname="MyPortlet" windowId="sample"/>
</portlet:scope>

<portlet:init portletURLPrefix="/myportalcontext/" >
....
</portlet:init>
```

state

The state tag creates a URL pointing to the given portlet using the given state. You can place this URL either into a variable specified by the var attribute or you can write it directly to the output stream. This tag is useful to create URLs for HTML buttons, images, and other items such that when the URL is invoked, the state changes defined in the URL are applied to the given portlet.

The state tag has the following attributes:

- url = "<context>/<portlet-name>"
Identifies the portlet for this tag by using the context and portlet-name to address the portlet. This attribute is required.
- windowId = "<any string>"
Defines the window ID for the portlet URL created by this tag. This is attribute optional.
- var = "<any string>"
If defined the URL is written into a variable with the given scope and name, not to the output stream. This is attribute optional.
- scope = "page|request|session|application"
This attribute is only valid if the var attribute is specified. If defined, the URL is not written to the output stream but a variable is created in the given scope with the given name. The default is page. This is attribute optional.
- portletMode = "view|help|edit|<custom>"
This attribute sets the portlet mode.
- portletWindowState = "maximized|minimized|normal|<custom>"
This attribute sets the window state.
- action = "true/false"
This attribute defines whether this is an action URL. This is attribute optional. The default is false.

urlParam

Adds a render parameter to the newly created URL.

The urlParam tag has the following attributes:

- name = "<any string>"
Indicates the name of the parameter. This is attribute required.
- value = "<any string>"
Indicates the value of the parameter. This is attribute required.

insert

This tag calls the render method of the portlet and retrieves the content as well as the title. You can optionally place the content and title of the specified portlet into variables using the contentVar and titleVar attributes.

The insert tag has the following attributes:

- url = "<context>/<portlet-name>" (mandatory) Identifies the portlet for this tag by using the context and portlet-name to address the portlet
This is attribute required.
- windowId = "<any string>"
Defines the window ID of the portlet. This is attribute optional.
- contentVar = "<any string>"
If defined, the portlet's content is not written to the output stream but written into a variable with the given scope and name. This is attribute optional.
- contentScope = "page|request|session|application"

This attribute is only valid if the contentVar tag is used. If defined, the portlet's content is written into a variable with the given scope and name, not to the output stream. The default is page. This is attribute optional.

- titleVar = "<any string>"

If defined the portlet's title is written into a variable with the given scope and name. If it is not defined, the title is ignored and not written to the output stream. This is attribute optional.

- titleScope = "page|request|session|application"

This attribute is only valid if titleVar tag is used. If defined, the portlet's title is written into a variable with the given scope and name, not to the output stream. The default is page. This is attribute optional.

Example: Using the portlet aggregation tag library

You can use the aggregation tag library to aggregate multiple portlets to have multiple and different content on one page. The library can be used by every JavaServer Pages (JSP) file that has been included by a servlet.

To use the portlet aggregation tag library, you must declare the tag-lib at the top of the JSP file using, <%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>, as in the following example. The following JSP file example shows how to aggregate portlets on one page.

```
<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>
<%@ page isELIgnored="false" import="java.util.Enumeration"%>

<portlet:init portletURLPrefix="/dummy/portletTagTest/" portletURLSuffix="/more" portletURLQueryParams="p1=v1&p2=v2">

  <portlet:insert url="worldclock/StdWorldClock" contentVar="worldclockcontent" titleVar="worldclocktitle"/>
  <portlet:state url="worldclock/StdWorldClock" portletMode="view" var="worldclockview"
    portletWindowState="maximized">
    <portlet:urlParam name="namea" value="valuea"/>
    <portlet:urlParam name="nameb" value="valueb"/>
  </portlet:state>
  <portlet:state url="worldclock/StdWorldClock" portletMode="edit" var="worldclockedit" portletWindowState="normal">
    <portlet:urlParam name="name1" value="value1"/>
    <portlet:urlParam name="name2" value="value2"/>
  </portlet:state>
  <portlet:state url="worldclock/StdWorldClock" portletMode="view" var="worldclockmin"
    portletWindowState="minimized">
    <portlet:urlParam name="namemin" value="valuemin"/>
    <portlet:urlParam name="namemin" value="valuemin"/>
  </portlet:state>

  <portlet:insert url="worldclock/StdWorldClock" windowId="min" contentVar="simplecontent" titleVar="simpletitle"/>
  <portlet:state url="worldclock/StdWorldClock" windowId="min" portletMode="view" var="simpleview"
    portletWindowState="maximized">

```

Portlet preferences

Preferences are set by portlets to store customized information. By default, the `PortletServlet` stores the portlet preferences for each portlet window in a cookie. However, you can change the location to store them in either a session, an `.xml` file, or a database.

Storing portlet preferences in cookies

The attributes of the cookie are defined as follows:

Path

context/portlet-name/portletwindow

Name:

The name of the cookie has the fixed value of **PortletPreferenceCookie**.

Value

The value of the cookie contains a list of preferences by mapping to the following structure:

```
*['/' pref-name *['=' pref-value]]
```

All preferences start with '/' followed by the name of the preference. If the preference has one or more values, the values follow the name separated by the '=' character. A null value is represented by the string '#!0_NULL_0!#'. As an example, the cookie value may look like, `/locations=raleigh=boeblingen/regions=nc=bw`

Customizing the portlet preferences storage

You can override how the cookie is handled to store preferences in a session, an `.xml` file or database. To customize the storage, you must create a filter, servlet or JavaServer Pages file as new entry point that wraps the request and response before calling the portlet. Examine the following example wrappers to understand how to change the behavior of the `PortletServlet` to store the preferences in a session instead of cookies.

The following is an example of how the main servlet manages the portlet invocation.

```

public class DispatchServlet extends HttpServlet
{
    ...
    public void service(HttpServletRequest request, HttpServletResponse response)
    throws ServletException, IOException
    {
        response.setContentType("text/html");

        // create wrappers to change preference storage
        RequestProxy req = new RequestProxy(request);
        ResponseProxy resp = new ResponseProxy(request, response);

        // create url prefix to always return to this servlet
        ...
        req.setAttribute("com.ibm.wsspi.portlet.url.prefix", urlPrefix);

        // prepare portlet url
        String portletPath = request.getPathInfo();
    }
}

```

```

...
// include portlet using wrappers
RequestDispatcher rd = getServletContext().getRequestDispatcher(modifiedPortletPath);
rd.include(req, resp);
}
}

```

In the following example, the request wrapper changes the cookie handling to retrieve the preferences out of the session.

```

public class RequestWrapper extends HttpServletRequestWrapper
{
    ...
    public Cookie[] getCookies() {
        Cookie[] cookies = (Cookie[]) session.getAttribute("SessionPreferences");
        return cookies;
    }
}

```

In the following example, the response wrapper changes the cookie handling to store the preferences in the session:

```

public class ResponseProxy extends HttpServletResponseWrapper
{
    ...
    public void addCookie(Cookie cookie) {
        Cookie[] oldCookies = (Cookie[]) session.getAttribute("SessionPreferences");
        int newPos = (oldCookies == null) ? 0 : oldCookies.length;
        Cookie[] newCookies = new Cookie[newPos+1];
        session.setAttribute("SessionPreferences", newCookies);

        if (oldCookies != null) {
            System.arraycopy(oldCookies, 0, newCookies, 0, oldCookies.length);
        }
        newCookies[newPos] = cookie;
    }
}

```

Portlet coordination

You can use either the events mechanism or the public render parameters mechanism to coordinate portlets within a portal.

JSR 286 defines these two mechanisms as follows:

- Events: Loose-coupling of portlets during action phase.
- Public render parameters: Sharing of view state between portlets.

The WebSphere Application Server portlet container supports both concepts with one exception. The wiring of events on a portal level is not supported.

To make use of the public render parameters on a portal page defined with the aggregation tag library, you must explicitly declare the portal scope:

```

<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>
<%@ page isELIgnored="false"%>
<!-- define portal scope for public render parameters -->
<portlet:scope>
    <portlet:portlet context="/simpleportlet" portletname="SimplePortlet1" windowId="id1"/
    <portlet:portlet context="/simpleportlet2" portletname="SimplePortlet2" windowId="id2"/>
</portlet:scope>
<portlet:init portletURLPrefix="/my-webapp-context/my-portal-jsp-url-pattern/">
<!-- insert your portlets here, wrapped with your html markup -->
...
    <portlet:insert url="simpleportlet/SimplePortlet1" windowId="id1" titleVar="portlettitle_1"/>

```

```

...
<portlet:insert url="simpleportlet2/SimplePortlet2" windowId="id2" titleVar="portlettitle_1"/>
...
</portlet:init>

```

The public render parameters are only visible to the portlet windows mentioned within this defined scope. This condition assumes, as a prerequisite, that the corresponding portlets have also declared support for a given public render parameter in their portlet.xml file, according to the JSR 286 specification:

```

...
<portlet>
  <portlet-name>portlet_name1</portlet-name>
  ...
  <supported-public-render-parameter>foo</supported-public-render-parameter>
</portlet>
<portlet>
  <portlet-name>portlet_name2</portlet-name>
  ...
  <supported-public-render-parameter>foo</supported-public-render-parameter>
</portlet>
<public-render-parameter>
  <identifier>foo</identifier>
  <qname xmlns:x="http://example.com/params">x:foo2</qname>
</public-render-parameter>
...

```

Converting portlet fragments to an HTML document

A portlet only delivers fragment output whereas a servlet typically delivers document output. However, you can use the PortletServingServlet servlet, which is similar to the FileServingServlet servlet, to address portlets like servlets.

About this task

A default document servlet filter, the DefaultFilter filter, is applied to the PortletServingServlet servlet to return the portlet's content inside of a document. This filter only applies to requests, not to includes or forwards using the RequestDispatcher method. A servlet filter that is used to embed the portlet's content into a document is called the document servlet filter. You can define additional document servlet filters in a .xml file. The FilterRequestHelper attribute within com.ibm.wsspi.portletcontainer.util is provided to assist the document servlet filters in analyzing a request regarding filter chain and portlet information. It is used in supporting dynamic portlet titles, as a marker for redirection for document servlet filters and to ensure that document conversion is completed once.

Procedure

1. Add a new document servlet filter. The filter capability is a server feature, therefore all filters must be installed into the server to use the filter capability of the server. The filters need to be available in any classes or library directory on a server level. You must also register the filter in a plugin.xml file within the root of a Java archive (JAR) file. The following is an example of how to register the filter in a plugin.xml file.

```

<?xml version="1.0" encoding="UTF-8"?>
<?eclipse version="3.0"?>
<plugin id="sample.plugin" name="Customer_Plugin" provider-name="Customer" version="1.0.0">
  <extension point="com.ibm.ws.portletcontainer.portlet-document-filter-config">
    <portlet-document-filter class-name="sample.filter.CustomFilter" order="200" />
  </extension>
</plugin>

```

2. Optional: Set dynamic portlet titles by providing the dynamic title as a request attribute. The PortletServingServlet servlet supports dynamic portlet titles by providing the dynamic title as a request attribute, FilterRequestHelper.DYNAMIC_TITLE. This attribute returns the dynamic portlet title if it has been set by the portlet, otherwise it returns the static portlet title of the portlet.xml file if defined.

DYNAMIC_TITLE = 'javax.portlet.title' The DefaultFilter uses this request attribute to set the document title while converting the fragment into a document. If you want the filter to support browser caching or dynamic portlet titles, you must cache the complete portlet content.

3. Specify cache handling for the portlet rendering call to support dynamic title. Redirection for document servlet filters

A document servlet filter can set a marker as request attribute, FilterRequestHelper.REDIRECT. This marker ensures that the portlet container returns to the document servlet filter after the portlet action has been called prior to any render calls. You must define the following constants, REDIRECT = 'com.ibm.websphere.portlet.action' and REDIRECT_VALUE = 'redirect'. The DefaultFilter uses this request attribute to provide special cache handling for the portlet rendering call to support dynamic title.

4. Convert the portlet's fragment into a valid document. Document conversion must be completed only once. Therefore each document servlet filter must ensure that the fragment has not yet been converted to a document previously. If the document servlet filter converts the fragment to a document, the request attribute FilterRequestHelper.DOCUMENT must be set to FilterRequestHelper.DOCUMENT_VALUE. This request attribute marks whether the conversion still needs to be completed. The following constants are defined, DOCUMENT = 'com.ibm.websphere.portlet.filter' and DOCUMENT_VALUE = 'document'. The DefaultFilter uses this request attribute to check whether it should convert the fragment to an Hypertext Markup Language (HTML) document. For example, this allows another document servlet filter in front to convert the fragment into a valid Wireless Markup Language (WML) document instead.

Assembling portlets

Portlet Uniform Resource Locator (URL) addressability

You can request a portlet directly through a Uniform Resource Locator (URL) to display its content without portal aggregation. The PortletServingServlet servlet registers each web application that contains portlets. It is similar to the FileServingServlet servlet of the web container that serves resources. The PortletServingServlet servlet supports direct rendering of portlets into a full browser page by a URL request.

You can invoke each portlet by its context root and name with the URL mapping /<portlet-name> that is created for each portlet. The context root and name has the following format:

```
http://<host>:<port>/<context-root>/<portlet-name> For example,  
http://localhost:9080/portlets/TestPortlet1
```

The context root identifies the web application archive (WAR) file that contains the portlet. The portlet name uniquely identifies the portlet with a portlet application of a WAR file. The DefaultDocumentFilter servlet only supports HTML, UTF8 encoding and an extended URL form based on the basic URL form as shown above.

You can only display one portlet at a time using the PortletServingServlet servlet. If you want to aggregate multiple portlets on the page, you need to use the aggregation tag library. Refer to the Portlet aggregation using JavaServer Pages article for additional information.

Because a portlet only delivers fragment output whereas a servlet usually delivers document output, a mechanism is introduced to convert the fragment into a document, called the PortletDocumentFilter filter. By default, the PortletDocumentFilter filter only supports converting HTML. The conversion is implemented using a servlet filter before the PortletServingServlet servlet is initiated to return the portlet's content inside of a document. This default document servlet filter only applies to URL requests, not for includes or forwards using the RequestDispatcher method. You can create servlet filters to support other markups additional document servlet filters. Refer to the Converting portlet fragments to an HTML document article, for additional information.

The PortletServingServlet servlet does not persist portlet preferences in a XML file or database. It places the portlet preferences directly into a cookie to store the preferences persistently. Refer to the Portlet preferences article, for additional information on how to change this behavior.

Portlet URL syntax

You can add additional portal context such as portlet mode or window state. You can access the PortletServingServlet servlet by using a URL mapping that has the following structure:

```
http://host:port/context/portlet-name [/portletwindow[/ver [/action |
/resource[/id=custom-id] [/cacheability]] [/mode] [/state] [rparam] [/?name]]]
```

Any differing URL structure results in a `com.ibm.wsspi.portletcontainer.InvalidURLException` exception. Empty strings are not permitted as parameter values and creates an `InvalidURLException` exception. The following is a list of valid parameters:

http:// host:port/context/portlet-name

This is the minimum URL required to access a portlet. A default portlet window called 'default' is created. The *portlet-name* variable is case-sensitive.

/portletwindow

This parameter identifies the portlet window. You must set this parameter if you choose to add more portal context information to the URL.

/ver=major.minor

This optional parameter is used to define the version of the portlet API that is used. You must set this parameter if you choose to add more portal context information to the URL. Only versions '1.0' and '2.0' are supported. Any other version creates an `InvalidURLException` exception.

/action

This is a required parameter if you call the action method of the portlet. The action parameter causes the action process of the portlet to be called. After the action has been completed, a redirect is automatically issued to call the render process. To control the subsequent render process, a document servlet filter can set a request attribute with name 'com.ibm.websphere.portlet.action' and value 'redirect' to specify that the portlet serving servlet directly returns after action without calling the render process.

/mode=view | edit | help | custom-mode

This optional parameter defines the portlet mode that is used to render the portlet. The default mode is 'view'. The value is not case-sensitive. For example, 'View', 'view' or 'VIEW' results in the same mode.

/state=normal | maximized | minimized | custom-state

This optional parameter defines the window state that is used to render the portlet. The default state is 'normal'. The value is not case-sensitive, for example, 'Normal', 'normal', or 'NORMAL' results in the same state.

*** [/rparam=name *[value]]**

This optional parameter specifies render parameters for the portlet. Repeat this parameter chain to provide more than one render parameter. For example, `/rparam=invitation/rparam=days=Monday=Tuesday`.

?name=value&name2=value2 ...

Query parameters may follow optionally. They are not explicitly supported by the portlet container, but they do not invalidate the URL format.

/action | /resource

This parameter defines the methods of the portlet that is called. Valid values are no, action or resource parameter. No specific method defined calls the render method. The resource parameter is only supported for JSR 286 portlets.

/resource [/id=custom-id] [/cacheability=cacheLevelFull | cacheLevelPortlet | cacheLevelPage]

Set this parameter to define the method of the portlet to be called. No redirection occurs. No other method of the portlet is called. To control the resource parameter, you can add an additional ID parameter to provide a resource serving identifier that is passed through to the portlet. The cacheability parameter defines the cache level of this resource URL. This parameter is only supported with JSR 286 portlets .

The following list includes examples of valid JSR 168 and JSR 286 URLs:

- `http:// your.server.name:9080/sample/WorldClock`
- `http:// your.server.name:9080/sample/WorldClock/myPortlet/ver=1.0/mode=edit/rparam=timezone=UTC`
- `http:// your.server.name:9080/sample/WorldClock/myPortlet/ver=1.0/action/state=maximized?timezone=UTC`
- `http://your.server.name:9080/sample/WorldClock/myPortlet/ver=2.0/resource/id=somePicture.jpg`

Example: Configuring the extended portlet deployment descriptor to disable PortletServingServlet

Portlet URL serving supports direct access to all functions and states of a portlet by creating the appropriate URLs. In a production setup where the portlet is served through an enterprise portal application that applies its own access control, is considered a security risk. By setting the `portletServingEnabled` property to false, an administrator can ensure that a sensitive portlet is never accessed by direct URL serving.

Extensions for the portlet deployment descriptor are defined within a file called `ibm-portlet-ext.xmi`. This deployment descriptor is an optional descriptor that you can use to configure WebSphere extensions for the portlet application and its portlets. For example, you can disable the `PortletServingServlet` servlet for the portlet application in the extended portlet deployment descriptor.

The `ibm-portlet-ext.xmi` extension file is loaded during application startup. If there are no extension files specified with this setting, the default values of the portlet container are used.

The default for the `portletServingEnabled` attribute is true. The following is an example of how to configure the application so that a `PortletServingServlet` servlet is not created for any portlet on the portlet application.

```
<?xml version="1.0" encoding="UTF-8"?>
<portletappext:PortletApplicationExtension xmi:version="1.0"
  xmlns:xmi="http://www.omg.org/XMI"
  xmlns:portletappext="portletapplicationext.xmi"
  xmlns:portletapplication="portletapplication.xmi"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmi:id="PortletApp_ID_Ext"
  portletServingEnabled="false">
  <portletappext:portletApplication href="WEB-INF/portlet.xml#myPortletApp"/>
</portletappext:PortletApplicationExtension>
```

Chapter 24. Developing Scheduler service

This page provides a starting point for finding information about the scheduler service, a WebSphere programming extension responsible for starting actions at specific times or intervals.

Schedulers are persistent and transactional timer services that run Enterprise JavaBeans methods or send Java Message Service messages using any Java Message Service messages using any Java Platform, Enterprise Edition (Java EE) server application.

The scheduler service helps minimize IT costs and increase application speed and responsiveness by maximizing utilization of existing computing resources.

The scheduler service provides the ability to reliably process workloads using parallel processing and schedule resource-intensive tasks to process during low traffic off-hours.

Developing and scheduling tasks

To develop and schedule tasks, use a configured scheduler.

Procedure

1. Look up a configured scheduler. Refer to the Accessing schedules topic. Each configured scheduler is available from two different programming models:
 - A Java Platform, Enterprise Edition (Java EE) server application, such as a servlet or Enterprise JavaBeans (EJB) component, can use the Scheduler API. Schedulers are accessed by looking them up using a Java Naming and Directory Interface (JNDI) name or resource reference.
 - Java Management Extensions (JMX) applications, such as wsadmin scripts, can use the Scheduler API using WASScheduler MBeans.
2. Develop the task.

The Scheduler API supports different implementations of the TaskInfo interface, each of which can be used to schedule a particular type of work. Refer to the Developing a task that calls a session bean topic and Develop a task that sends a Java Message Service (JMS) message topic for details. The task object that is referenced in the Develop a task that sends a Java Message Service (JMS) message topic can send a JMS message to either a queue or a topic.

Attention: Creating and manipulating scheduled tasks through the Scheduler interface is only supported from within the EJB container or Web container (Enterprise beans or servlets). Looking up and using a configured scheduler from a Java EE application client container is not supported.
3. Receive scheduler notifications. A notification sink is set on a task in order to receive the notification events that are generated by a scheduler when it performs an operation on the task.
4. Use custom calendars. You can assign a UserCalendar session bean to a task that allows schedulers to use custom and predefined date algorithms to determine when a task should run. Refer to the UserCalendar interface topic for details.
5. Submit tasks to a scheduler. After a TaskInfo object has been created, it can be submitted to the scheduler for task creation by calling the Scheduler.create() method.
6. Manage tasks with a scheduler.
7. Secure tasks with a scheduler.

Example

You can use the SIMPLE and CRON calendars from any Java EE application. This example illustrates the process.

- Using default scheduler calendars

Using default scheduler calendars. The following code examples illustrates how to use connections correctly and incorrectly.

Using default scheduler calendars involves looking up the default UserCalendarHome Enterprise JavaBeans (EJB) home object, creating the UserCalendar bean and calling the applyDelta() method. For details on the applyDelta method as well as the syntax for the SIMPLE and CRON calendars, see UserCalendar interface topic.

```
import java.util.Date;
import javax.naming.InitialContext;
import javax.rmi.PortableRemoteObject;
import com.ibm.websphere.scheduler.UserCalendar;
import com.ibm.websphere.scheduler.UserCalendarHome;

// Create an initial context
InitialContext ctx = new InitialContext();

// Lookup and narrow the default UserCalendar home.
UserCalendarHome defaultCalHome=(UserCalendarHome)
    PortableRemoteObject.narrow(ctx.lookup(
        UserCalendarHome.DEFAULT_CALENDAR_JNDI_NAME),
        UserCalendarHome.class);

// Create the default UserCalendar instance.
UserCalendar defaultCal = defaultCalHome.create();

// Calculate a date using CRON based on the current
// date and time. Return the next date that is
// Saturday at 2AM
Date newDate =
    defaultCal.applyDelta(new Date(),
        "CRON", "0 0 2 ? * SAT");
```

Accessing schedulers

Each configured scheduler is available using the Scheduler API from a Java Platform, Enterprise Edition (Java EE) server application, such as a servlet or Enterprise JavaBeans (EJB) module. Use a Java Naming and Directory Interface (JNDI) name or resource reference to access schedulers. Each scheduler is also available using the Java™ Management Extensions (JMX) API, using its associated WASScheduler MBean.

About this task

Scheduler and WASScheduler interfaces are the starting point for all scheduler activities. Each scheduler is independent and allows task life cycle operations, such as creating new tasks.

Procedure

1. Locate schedulers using the javax.naming.Context.lookup() method from a Java EE server application, such as a servlet or EJB module like the following example:

```
//lookup the scheduler to be used
import com.ibm.websphere.scheduler.Scheduler;
import javax.naming.InitialContext;
Scheduler scheduler = (Scheduler)new InitialContext.lookup("java:comp/env/sched/MyScheduler");
```

2. Use wsadmin to locate a WASScheduler MBean using JACL scripting:

```
set jndiName sched/MyScheduler

# Map the JNDI name to the mbean name. The mbean name is
# formed by replacing the / in the JNDI namewith . and prepending
# Scheduler
regsub -all_{/} $jndiName "." jndiName
set mbeanName Scheduler_.$jndiName
```

```
puts "Looking-up Scheduler MBean $mbeanName"
set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]
puts $sched
```

Results

The scheduler is now available to use from a Java EE server application or from a JMX API client. To create a task see the topics, [Developing a task that calls a session bean](#) or [Developing a task that sends a JMS message](#).

Developing a task that calls a session bean

The Scheduler API and WASScheduler MBean API support different implementations of the TaskInfo interface, each of which can be used to schedule a particular type of work. This topic describes how to create a task to call a method on a TaskHandler session bean.

About this task

To create a task to call a method on a TaskHandler session bean, use these steps.

Procedure

1. Create a new enterprise application with an Enterprise JavaBeans (EJB) module. This application hosts the TaskHandler EJB module.
2. Create a stateless session bean in the EJB Module that implements the process() method in the com.ibm.websphere.scheduler.TaskHandler remote interface. Place the business logic you want created in the process() method. The process() method is called when the task runs. The Home and Remote interfaces must be set as follows in the deployment descriptor bean:
 - com.ibm.websphere.scheduler.TaskHandlerHome
 - com.ibm.websphere.scheduler.TaskHandler
3. Create an instance of the BeanTaskInfo interface by using the following example factory method. Using a JavaServer Pages (JSP) file, servlet or EJB component, create the instance as shown in the following code example. This code should coexist in the same application as the previously created TaskHandler EJB module:

```
// Assume that a scheduler has already been looked-up in JNDI.
BeanTaskInfo taskInfo = (BeanTaskInfo) scheduler.createTaskInfo(BeanTaskInfo.class)
```

You can also use the wsadmin tool to create the instance as shown in the following JACL scripting example:

```
set taskHandlerHomeJNDIName ejb/MyTaskHandler

# Map the JNDI name to the mbean name. The mbean name is formed by replacing the / in the jndi name
# with . and prepending Scheduler_
regsub -all {/} $jndiName "." jndiName
set mbeanName Scheduler_.$jndiName

puts "Looking-up Scheduler MBean $mbeanName"
set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]
puts $sched

# Get the ObjectName format of the Scheduler MBean
set sched0 [$AdminControl makeObjectName $sched]

# Create a BeanTaskInfo object using invoke_jmx
puts "Creating BeanTaskInfo"
set params [java::new {java.lang.Object[]} 1]
$params set 0 [java::field com.ibm.websphere.scheduler.BeanTaskInfo class]

set sigs [java::new {java.lang.String[]} 1]
$sigs set 0 java.lang.Class
```

```
set ti [$AdminControl invoke_jmx $sched0 createTaskInfo $params $sigs]
set bti [java::cast com.ibm.websphere.scheduler.BeanTaskInfo $ti]
puts "Created the BeanTaskInfo object: $bti"
```

Important: Creating a BeanTaskInfo object does not add the task to the persistent store. Rather, it creates a placeholder for the necessary data. The task is not added to the persistent store until the create() method is called on a Scheduler, as described in the Submitting tasks to schedulers topic.

4. Set parameters on the BeanTaskInfo object. These parameters define which session bean is called and when. The TaskInfo interface contains various set() methods that you can use to control execution of the task, including when the task runs and what work the task does when it runs.

The BeanTaskInfo interface requires that the TaskHandler Java™ Naming and Directory Interface (JNDI) name or TaskHandlerHome is set using the setTaskHandler method. If using the WASScheduler MBean API to set the task handler, then the JNDI name must be the fully-qualified global JNDI name.

The TaskInfo interface specifies additional control points, as documented in the API documentation. Set parameters using the TaskInfo interface API method as shown in the following code example:

```
//create a date object which represents 30 seconds from now
java.util.Date startDate = new java.util.Date(System.currentTimeMillis()+30000);

//find the session bean to be called when the task starts
Object o = new InitialContext().lookup("java:comp/env/ejb/MyTaskHandlerHome");
TaskHandlerHome home = (TaskHandlerHome)javax.rmi.PortableRemoteObject.narrow(o,TaskHandlerHome.class);

//now set the start time and task handler to be called in the task info
taskInfo.setTaskHandler(home);
taskInfo.setStartTime(startDate);
```

You can also set parameters using the following JAACL scripting example:

```
# Setup the task
puts "Setting up the task..."
# Set the startTime if you want the task to run at a specific time, for example:
$bti setStartTime [java::new {java.util.Date long} [java::call System currentTimeMillis]]

# Set the StartTimeInterval so the task runs in 30 seconds from now
$bti setStartTimeInterval 30seconds

# Set JNDI name of the EJB which will get called when the task runs. Since there is no
# application J2EE Context when the task is created by the MBean, this must be a
# global JNDI name.
$bti setTaskHandler $taskHandlerHomeJNDIName

# Do not purge the task when it's complete
$bti setAutoPurge false

# Set the name of the task. This can be any string value.
$bti setName Created_by_MBean

# If the task needs to run with specific authorization you can set the tasks Authentication Alias
# Authentication aliases are created using the Admin Console.
# $bti setAuthenticationAlias {myRealm/myAlias}

puts "Task setup completed."
```

Results

A BeanTaskInfo object has been created that contains all of the relevant data to call an EJB method.

What to do next

Submit the task to a scheduler for creation.

Developing a task that sends a Java Message Service message

The Scheduler API and WASScheduler MBean API support different implementations of the TaskInfo interface, each of which can be used to schedule a particular type of work. This topic describes how to create a task that sends a Java Message Service (JMS) message to a queue or topic.

About this task

To create a task that sends a Java Message Service (JMS) message to a queue or topic, use these steps.

Procedure

1. Create an instance of the MessageTaskInfo interface using the Scheduler.createTaskInfo() factory method. Using a JavaServer Pages (JSP) file, servlet or EJB container, create the instance as shown in the following code example:

```
//lookup the scheduler to be used
Scheduler scheduler = (Scheduler)new InitialContext.lookup("java:comp/env/Scheduler");

MessageTaskInfo taskInfo = (MessageTaskInfo) scheduler.createTaskInfo(MessageTaskInfo.class);
```

You can also use the wsadmin tool, create the instance as shown in the following JACL scripting example:

```
# Sample create a task using MessageTaskInfo task type
# Call this mbean with the following parameters:
#   <scheduler jndiName>      = JNDI name of the scheduler resource,
#                               for example scheduler/myScheduler
#   <JNDI name of the QCF>    = The global JNDI name of the Queue Connection Factory.
#   <JNDI name of the Queue> = The global JNDI name of the Queue destination

set jndiName [lindex $argv 0]
set jndiName_QCF [lindex $argv 1]
set jndiName_Q [lindex $argv 2]

# Map the JNDI name to the mbean name. The mbean name is formed by replacing the / in the jndi name
# with . and prepending Scheduler_
regsub -all {/} $jndiName "." jndiName
set mbeanName Scheduler_.$jndiName

puts "Looking-up Scheduler MBean $mbeanName"
set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]
puts $sched

# Get the ObjectName format of the Scheduler MBean
set sched0 [$AdminControl makeObjectName $sched]

# Create a MessageTaskInfo object using invoke_jmx
puts "Creating MessageTaskInfo"
set params [java::new {java.lang.Object[]} 1]
$params set 0 [java::field com.ibm.websphere.scheduler.MessageTaskInfo class]

set sigs [java::new {java.lang.String[]} 1]
$sigs set 0 java.lang.Class

set ti [$AdminControl invoke_jmx $sched0 createTaskInfo $params $sigs]
set mti [java::cast com.ibm.websphere.scheduler.MessageTaskInfo $ti]
puts "Created the MessageTaskInfo object: $mti"
```

Attention: Creating a MessageTaskInfo object does not add the task to the persistent store. Rather, it creates a placeholder for the necessary data. The task is not added to the persistent store until the create() method is called on a Scheduler, as described in the Submitting a task to a scheduler topic.

2. Set parameters on the MessageTaskInfo object. The TaskInfo interface contains various set() methods that can be used to control execution of the task, including when the task runs and what work the task does when it starts.

The TaskInfo interface specifies additional behavior settings, as documented in the API documentation. Using a JavaServer Pages (JSP) file, servlet or EJB container, create the instance as shown in the following code example:

```
//create a date object which represents 30 seconds from now
java.util.Date startDate = new java.util.Date(System.currentTimeMillis()+30000);

//now set the start time and the JNDI names for the queue connection factory and the queue
taskInfo.setConnectionFactoryJndiName("jms/MyQueueConnectionFactory");
taskInfo.setDestination("jms/MyQueue");
taskInfo.setStartTime(startDate);
```

You can also use the wsadmin tool, to create the instance as shown in the following JACL scripting example:

```
# Setup the task
puts "Setting up the task..."
# Set the startTime if you want the task to run at a specific time, for example:
$mti setStartTime [java::new {java.util.Date long} [java::call System currentTimeMillis]]

# Set the StartTimeInterval so the task runs in 30 seconds from now
$mti setStartTimeInterval 30seconds

# Set the global JNDI name of the QCF & Queue to send the message to.
$mti setConnectionFactoryJndiName $jndiName_QCF
$mti setDestinationJndiName $jndiName_Q

# Set the message
$mti setMessageData "Test Message"

# Do not purge the task when it's complete
$mti setAutoPurge false

# Set the name of the task. This can be any string value.
$mti setName Created_by_MBean

# If the task needs to run with specific authorization you can set the tasks Authentication Alias
# Authentication aliases are created using the Admin Console.
# $mti setAuthenticationAlias {myRealm/myAlias}

puts "Task setup completed."
```

Results

A MessageTaskInfo object has been created that contains all of the relevant data for a task that sends a JMS message.

What to do next

Submit the task to a scheduler for creation, as described in the Submitting a task to a scheduler topic.

Scheduling long-running tasks

The default behavior of the scheduler is designed to run business logic that runs for a short period of time. In version 6.0.2 and later, two API methods on the com.ibm.websphere.scheduler.TaskInfo interface help avoid some of the problems that can occur when running tasks for an extended time.

About this task

The TaskInfo.setQOS method supports tasks with both a transactional and non-transactional quality of service. When running tasks that run for long periods, you can use the TaskInfo.QOS_ATLEASTONCE quality of service to run the task without a global transaction. This process prevents various timeout issues

that can occur when resources are held by a long-running transaction. See the Transactions and schedulers topic for details on the `TaskInfo.setQOS` method and how it can be used.

Using the `TaskInfo.setExpectedDuration` method, the scheduler can to adjust timeout values, as appropriate, for a given task for all qualities of service. The application server attempts to adjust various run-time parameters to accommodate the estimated run time of the task.

Procedure

1. When you assemble the `TaskInfo` object with the Scheduler API or the `WASScheduler` MBean, use the following methods on the `TaskInfo` interface:
 - a. Set the quality of service.
 - 1) If the task must be transactional, use the `setQOS` method with the `QOS_ONLYONCE` constant, which is the default, if not set.
 - 2) If the task does not need to be transactional, use the `setQOS` method with the `QOS_ATLEASTONCE` constant.
 - b. Set the expected duration.
 - 1) Use the `setExpectedDuration` method to set the expected duration of the task in seconds.
2. Schedule the task using the `Scheduler.create` method.

What to do next

View the Access schedulers topic.

Receiving scheduler notifications

Various notification events are generated by a scheduler when it performs an operation on a task. These notifications events are described in this topic.

About this task

The notification events generated by a scheduler when it performs a task include:

Scheduled

A task has been scheduled.

Purged

A task has been permanently deleted from the persistent store.

Suspended

A task was suspended.

Resumed

A task was resumed.

Complete

A task has run completely. If it was a repeating task, all repeats have been performed.

Cancelled

A task has been cancelled. It will not run again.

Firing A task is prepared to run.

Fired A task completed successfully.

Fire failed

A task could not run successfully.

To receive notification events, call the `setNotificationSink()` method on the `TaskInfo` interface before creating the task. The `setNotificationSink()` method enables you to specify the session bean that is to act as the callback, and a mask that restricts which events are generated.

Procedure

1. Create a NotificationSink session bean. Create a stateless session bean that implements the `handleEvent()` method in the `com.ibm.websphere.scheduler.NotificationSink` remote interface. The `handleEvent()` method is called when the notification is fired. The Home and Remote interfaces can be set as follows in the bean's deployment descriptor:

```
com.ibm.websphere.scheduler.NotificationSinkHome
com.ibm.websphere.scheduler.NotificationSink
```

The NotificationSink interface defines the following method:

```
public void handleEvent(TaskNotificationInfo task) throws java.rmi.RemoteException;
```

2. Specify the notification sink session bean prior to submitting the task to the Scheduler using the TaskInfo interface API `setNotificationSink()` method.

If using the WASScheduler MBean API to set the notification sink, then the Java™ Naming and Directory Interface (JNDI) name must be the fully-qualified global JNDI name. Using a JavaServer Pages (JSP) file, servlet or Enterprise JavaBeans (EJB) component, look up and set the notification sink on a task as shown in the following code example:

```
TaskInfo taskInfo = ...
Object o = new InitialContext().lookup("java:comp/env/ejb/NotificationSink");
NotificationSinkHome home = (NotificationSinkHome )javax.rmi.PortableRemoteObject.narrow
(o,NotificationSinkHome.class);
taskInfo.setNotificationSink(home,TaskNotificationInfo.ALL_EVENTS);
```

You can also use the wsadmin tool to set the notification sink callback session bean as shown in the following JACL scripting example:

```
# Use the NotificationSinkHome's Global JNDI name
# Assume that a TaskInfo was already created...
$taskInfo setNotificationSink "ejb/MyNotificationSink"
```

3. Specify the event mask. The event mask is specified as an integer bitmap. You can either use an individual mask such as `TaskNotificationInfo.CREATED` to receive specific events, `TaskNotificationInfo.ALL_EVENTS` to receive all events or a combination of specific events. If you use Java, your script might look like the following example:

```
int eventMask = TaskNotificationInfo.FIRED | TaskNotificationInfo.COMPLETE;
taskInfo.setNotificationSink(home,eventMask);
```

If you use JACL, your script might look like the following example:

```
# Set the event mask based on two event constants.
set eventmask [expr [java::field com.ibm.websphere.scheduler.TaskNotificationInfo FIRED] +
[java::field com.ibm.websphere.scheduler.TaskNotificationInfo COMPLETE]]

# Set our Notification Sink based on our global JNDI name AND event mask.
# Note: We need to use the full method signature here since the
# method resolver can't always detect the right method.
$taskInfo {setNotificationSink String int} "ejb/MyNotificationSink" $eventmask
```

Results

A notification sink bean is now set on a TaskInfo object and can now be submitted to a scheduler using the create method.

Submitting a task to a scheduler

This topic describes the process of submitting a task to a configured scheduler.

Before you begin

This task assumes that you have already configured a scheduler and created and configured a TaskInfo object that calls a session bean or sends a Java Messaging Service (JMS) message.

About this task

Once you have developed a `TaskInfo` object that contains all relevant data for a task, submit the task to a scheduler for creation. When the task is created, the scheduler runs it.

Procedure

Create the task. After you configure `TaskInfo`, submit it to the appropriate scheduler, using the Scheduler API `create` method.

```
// Create the TaskInfo using the Scheduler that you already looked up and print out the Task ID
TaskStatus ts = scheduler.create(taskInfo);
System.out.println("Task created with id: " + ts.getTaskId())
```

You can also create the task using the `wsadmin` tool as shown in the following JACL scripting example:

```
# Create the TaskInfo using the WASScheduler MBean that you previously located and print out the Task ID
puts "Creating the task..."

set params [java::new {java.lang.Object[]} 1]
$params set 0 $taskInfo

set sigs [java::new {java.lang.String[]} 1]
$sigs set 0 com.ibm.websphere.scheduler.TaskInfo

set taskStatus [java::cast com.ibm.websphere.scheduler.TaskStatus [$AdminControl invoke_jmx $sched0
create $params $sigs]]

puts "Task Created. TaskID= [$taskStatus getTaskId]"

puts $taskStatus
```

When the call to the `create()` method is complete, the task exists in the persistent store and is run at the time specified in the `TaskInfo` object. If a global transactional context is present on the thread, and the `create()` transaction rolls back or is aborted, the task does not run.

The `TaskStatus` object, which has been returned by the call to the `create()` method, contains information about the state of the task, as well as the task ID. The task ID is the unique identifier for this task, and is required if the task is to be suspended, resumed, cancelled, and so on, at a later time.

Tip: The `TaskStatus` object is only a snapshot of the current state of the task. Use the `Scheduler.getStatus()` method to receive the current state when needed.

Task management methods using a scheduler

The scheduler provides several task management methods.

When a task is created by calling the `create()` method on a scheduler, a `TaskStatus` object is returned to the caller. The `TaskStatus` object contains the task ID, which is a unique identifier. The Scheduler API and `WASScheduler` MBean define several additional methods that pertain to the management of tasks, each of which accepts the task ID as a parameter. The following task management methods are defined:

suspend()

Suspends a task. The task does not run until it has been resumed.

resume()

Resumes a previously suspended task.

cancel()

Cancels a task. The task is not run and cannot be resumed.

purge()

Permanently deletes a cancelled task from the persistent store.

getStatus()

Returns the current status of the task.

Use the following API example to create and cancel a task:

```
//Create the task.
TaskInfo taskInfo = ...
TaskStatus status = scheduler.create(taskInfo);

//Get the task ID
String taskId = status.getTaskId();

//Cancel the task. Specify the purgeAlso flag so that the task does not remain in the persistent store
scheduler.cancel(taskId,true);
```

Use the following example JACL script operations in the wsadmin tool to create and cancel a task:

```
set jndiName sched/MyScheduler

# Map the JNDI name to the mbean name. The mbean name is
# formed by replacing the / in the jndi name with . and prepending
# Scheduler_
regsub -all_{/} $jndiName "." jndiName
set mbeanName Scheduler_.$jndiName

puts "Looking-up Scheduler MBean $mbeanName"
set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]
puts $sched

# Get the ObjectName format of the Scheduler MBean
set schedO [$AdminControl makeObjectName $sched]

# Create a TaskInfo object...
# (Some code excluded...)
set params [java::new {java.lang.Object[]} 1]
$params set 0 $taskInfo

set sigs [java::new {java.lang.String[]} 1]
$sigs set 0 com.ibm.websphere.scheduler.TaskInfo

set taskStatus [java::cast com.ibm.websphere.scheduler.TaskStatus [$AdminControl invoke_jmx $schedO
create $params $sigs]]

set taskID [$taskStatus getTaskId]
puts "Task Created. TaskID= $taskID"

# Cancel the task using the Task ID from the TaskStatus object returned during create.
set params [java::new {java.lang.Object[]} 1]
$params set 0 false

set sigs [java::new {java.lang.String[]} 1]
$sigs set 0 java.lang.boolean

set taskStatus [java::cast com.ibm.websphere.scheduler.TaskStatus [$AdminControl invoke_jmx $schedO
cancel $params $sigs]]
```

Transactionality. All methods of the Scheduler API are transactional. If a global transactional context is present, it is used to perform the operation. If an unexpected exception is thrown, the transaction is marked to roll back, and the caller must handle it appropriately. If an expected or declared exception is thrown, the transaction remains intact and the caller must choose to roll back or to commit the transaction. If the transaction is rolled back at some point, all scheduler operations performed within the transaction are also rolled back.

If a local transactional context is present, it is suspended and a new global transactional context begins. Likewise, if no transactional context is active, a global transactional context begins. In both cases, if an unexpected exception is thrown, the transaction rolls back. If a declared exception is thrown, the transaction is committed.

If another thread is concurrently modifying the task in question, a `TaskPending` exception is thrown. This is because schedulers lock the database optimistically. The calling application can then retry the operation.

Task management functions may block if the task is currently running. Because the scheduler guarantees that each task will run only once, the task must be locked for the duration of a running task. Likewise, if a task is changed using one of the management functions but the global transaction is not committed, any other management functions issued from another transaction for that task will be blocked.

A stateless session bean task's `TaskHandler.process()` method can change its own state. However, the task must be running within the same transaction as the scheduler. Therefore, a running task can only modify itself if it is using the `Required` or `Mandatory` container managed transaction types. If the `RequiresNew` transaction type is specified on the `process()` method, all management functions will deadlock.

All methods defined by the Scheduler API are described in the API documentation.

Identifying tasks that are currently running

When a task runs, the task database record is locked until the task completes. This topic describes how to determine whether or not a task is running.

About this task

Prior to version 6.0.2, all tasks ran in a single global transaction. This process not only prevented the task from running more than once successfully, but it also blocked all attempts at reading the state of the task, since each task used read-committed transaction isolation.

There are two methods for determining whether a task is running:

1. **NotificationSink**

A `NotificationSink` EJB can be set on the task using the `setNotificationSink` method on the `TaskInfo` object. The `NotificationSink` bean can then log the life cycle of the task to a separate database record in a custom table. This would result in a history log of the task that can be queried independently from the scheduler. This solution works for all versions of the scheduler service. See the `Receiving Scheduler Notifications` topic for details.

2. **Delayed Execution and Uncommitted Read**

In Version 6.0.2 and later, two behaviors enable the scheduler find and retrieve API methods, such as `getTask`, `getTaskStatus` or `findTasksByName`, to see the current state of the task without blocking. To see the current state of the task, including its uncommitted running state, complete the following steps:

Procedure

1. Enable read-uncommitted transaction isolation for the scheduler read methods to prevent these methods from blocking while a task is running. To set the default transaction isolation for read methods, see the `Configuring scheduler default transaction isolation` topic for read operation details.

Important: If the scheduler database does not support uncommitted reads, such as Oracle, it might not be possible to determine if a task is running unless you use the `QOS_ATLEASTONCE` quality of service.

2. Use the `TaskInfo.EXECUTION_DELAYEDUPDATE` option on the `TaskInfo.setTaskExecutionOptions` method to force the scheduler to write the `TaskStatus.RUNNING` state to the task when that task starts running.

Stopping tasks that are failing

The scheduler runs tasks in a global transactional context, by default. If a task is failing due to a configuration problem or application error, the scheduler attempts to retry the task until the scheduler failure threshold is reached. This topic describes how to stop the tasks that are failing.

Before you begin

The default scheduler failure threshold is 10 and can be configured using the `taskFailureThreshold` scheduler custom property. To configure this custom property, in the administrative console click **Resources > Schedulers > *scheduler_name*** and click **Custom Properties**. Valid values are non-negative integers, that is, integers greater than 0.

About this task

When the task reaches the failure threshold, the scheduler stops running the task until the scheduler daemon is restarted using the `WASScheduler` MBean, the scheduler fails over to another server, or until the scheduler is resumed using the `resume` method on the Scheduler API or `WASScheduler` MBean.

Procedure

1. Cancel or suspend a transactional (`QOS_ONLYONCE`) task that is continually failing. This action can be difficult if the scheduler has not yet reached the failure threshold. The cancel and suspend Scheduler API methods or `WASScheduler` MBean operations block until the task fails or the method times out, while waiting for a database lock and throws a `TaskPending` exception. If this occurs, then the application can retry the cancel or suspend operation until it completes.
2. Alternatively, stop the scheduler daemon using the `stopDaemon` operation on the `WASScheduler` MBean to avoid running the task multiple times, and run the cancel or suspend operation while it is stopped. While the daemon is stopped, the scheduler does not run tasks. However, all MBean operations and API methods are still available.

Scheduler tasks and Java EE context

When a task is created using the Scheduler API `create()` method, the Java Platform, Enterprise Edition (Java EE) thread context of the creator is stored with the scheduled task. When the task runs, the original Java EE thread context is reapplied to the thread before calling the customer `TaskInfo` instance.

The scheduler service utilizes the asynchronous beans deferred start mechanism to propagate Java EE service context information to a task when it runs. The amount of service context information that is propagated is controlled by the Service Context settings on the `WorkManager` configuration object that schedulers reference. For example, security and internationalization service contexts can be enabled. See the [Using asynchronous beans](#) topic for details on how to configure the Application Server to propagate these service contexts.

Transactions and schedulers

The scheduler runs a task in a single global transaction, by default. You can use the `QOS_ONLYONCE` or `QOS_ATLEASTONCE` quality of service to specify whether the task runs as a single unit of work once or as independent transactions.

Transaction behavior when running a task

Because the scheduler runs a task in a single global transaction, by default, the transaction is open until the task completes or fails. The resources involved in that transaction are subject to various timeouts and the thread of the task could be identified as hung if the task runs for a long period of time that can span many minutes or hours.

QOS_ONLYONCE

Scheduled tasks execute only one time successfully when using the `QOS_ONLYONCE` quality of service. This action is accomplished by grouping all of the work done in the task as a single unit of work. When each task fires, the following events occur in a single global transactional context:

1. The context of the application that created the task is applied to the thread.
2. A global transactional context is started.

3. The next fire time and start-by time are calculated using the UserCalendar bean or the DefaultUserCalendar.

Important: If using the TaskInfo.setTaskExecutionOptions method with the TaskInfo.EXECUTION_DELAYEDUPDATE option, this step will occur after the record is updated.

4. The task database task record is updated in the database with the state of the next task or deleted if the task is complete and the task's auto-purge setting is true.
5. The task database record is updated in the database with the state of the next task or deleted if the task is complete and the task's auto-purge setting is true. If the EXECUTION_DELAYEDUPDATE option is used, the database will not reflect the next state of the task, but the current state with the TaskStatus.RUNNING state set.
6. If the NotificationSink bean is set, a FIRING notification is fired.
7. The BeanTaskInfo or MessageTaskInfo object starts.
8. If the task fails and the NotificationSink bean is set, a FIRE_FAILED notification is fired on a separate transaction.
9. If the task's NotificationSink bean is set, then the various notifications are fired as required.
10. If the EXECUTION_DELAYEDUPDATE option is used for the task, the database will be updated a second time with the next state of the task.
11. The global transaction is committed.

Because all events belonging to a task are executed in a single global transactional context, consider the following points in order to avoid transaction-related errors:

- Each resource participating in the task transaction must be two-phase XA capable. This includes the Java Database Connectivity (JDBC) datasource that is configured for the scheduler, any Java Messaging Service (JMS) services used by the MessageTaskInfo objects, and any resources used within any of the UserCalendar, TaskHandler, or NotificationSink beans that have a transaction setting of "Required".
- One resource can be single-phase, if last participant support is enabled for the application that created the transaction. Enable last participant support using an assembly tool. You can also enable last participant support through the administrative console. See the Last participant support extension settings topic for details.

All unexpected exceptions are logged to the activity log and all events participating in the task global transaction are rolled back. This includes changes to the task database record, which force the task to be executed again when the scheduler daemon polls the database during the next poll cycle. The UserCalendar, TaskHandler, and NotificationSink beans can choose not to participate in the global transaction by configuring the bean transaction setting to "Requires new".

QOS_ATLEASTONCE

Scheduled tasks that use the QOS_ATLEASTONCE quality of service do not have a single transactional context. In this case, each calendar calculation, event notification and database update occurs in an independent transaction:

1. The context of the application that created the task is applied to the thread.
2. The task's database record is updated with the RUNNING state of the task.
3. UserCalendar, NotificationSink beans are called.
4. The BeanTaskInfo or MessageTaskInfo is started.
5. Result notifications are sent.
6. The database is updated with the next state of the task, if the task has not been changed since the RUNNING state was written.

If a failure happens after the RUNNING state is written to the database and before the result is written, then the task may run more than one time.

When using QOS_ATLEASTONCE, all NotificationSink, UserCalendar and TaskHandler beans must not mandate a transaction (TX_MANDATORY), since there is no global transaction available when the task runs. The EJB components use "Required" or "Requires new" container managed transaction or a bean managed transaction.

Transaction behavior when using the Scheduler API methods or WASScheduler MBean operations

All Scheduler interface methods participate in a single global transactional context. If a global transactional context is already present on the thread when the create(), suspend(), resume(), cancel(), and purge() methods are executed, then the existing global transaction is used. Otherwise, a new global transaction begins.

If the method participates in the global transaction of the caller and an unexpected error occurs, then the transaction is marked to roll back. If the exception is a declared exception, then the exception is resubmitted to the caller, and the transaction is left alone for the caller to commit or roll back.

If the method starts its own global transaction and any exception occurs, then the transaction is rolled back, and the exception is resubmitted to the caller.

Scheduler task user authorization

The scheduler service uses the asynchronous beans deferred start mechanism to propagate Java Platform, Enterprise Edition (Java EE) service context information to a task when it runs. If you plan to secure your application using the JAAS security context of the administrative security mechanism built into WebSphere Application Server, create each task with the correct credentials on the thread.

Tasks run with specified security credentials using the following methods:

- Using the Java Authentication and Authorization Service (JAAS) security context on the thread at the time the task was created. See the Deferred start and security topic in the Asynchronous beans section of the information center.
- Using the setAuthenticationAlias method on the TaskInfo object.
- Using a specified security identity on a BeanTaskInfo task TaskHandler EJB method.

The scheduler service utilizes the asynchronous beans deferred start mechanism to propagate Java EE service context information to a task when it runs. The amount of service context information that is propagated is controlled by the Service Context settings on the WorkManager configuration object that schedulers reference. For example, security and internationalization service contexts can be enabled. See the Using asynchronous beans topic for details on how to configure the Application Server to propagate these service contexts.

Java Authentication and Authorization Service Security context

If you intend to secure your application using the JAAS security context of the administrative security mechanism built into WebSphere Application Server, create each task with the correct credentials on the thread. Once each task has the correct credentials, you can disable and re-enable administrative security without causing any security problems. If you do not set the security context when the scheduler task is created and you later enable security in the target application, a security exception or error message might display, such as SECJ0053E. You might also see this error if two or more schedulers on different servers are accessing the same tables (a clustered or redundant scheduler) and the security settings are different.

The JAAS security context is not set if any of the follow conditions are true:

- Administrative security is disabled.
- Security context policies are disabled on the configured WorkManager for the associated scheduler configuration.

- A credential is not set on the thread. For example, the enterprise bean or servlet that is used to create the scheduled task is not secured, or the task was created with a WASScheduler MBean.

If any of the previously mentioned conditions are true when you create your task and you need to enable security on your application server or application, you must complete the following steps for each task:

1. Find the task using the Scheduler API find or get methods.
2. Cancel the task using the Scheduler.cancel() API.
3. Recreate the task using the Scheduler.create() method with security enabled. Submitting a task that was retrieved from the scheduler using the find or get methods will automatically generate a new task ID.

Security order of precedence

As previously noted, there are three ways of verifying that a task will run with the correct user credentials. In addition, each TaskInfo implementation may have its own way of supplying user information, which may override the standard mechanisms. If multiple methods are used, refer to the following lists to determine which security mechanism is going to be employed.

BeanTaskInfo

1. TaskHandler security identity set on the process() method of the Enterprise Java Bean file
2. Authentication Alias set with the setAuthenticationAlias method on the TaskInfo interface
3. JAAS security context

MessageTaskInfo

1. Authentication Alias set with the setAuthenticationAlias method on the TaskInfo interface
2. The setUsername and setPassword methods on the MessageTaskInfo interface. See the [Deprecated features](#) article for more information.

Securing scheduler tasks

Scheduled tasks are protected using application isolation and administrative roles. This topic describes how to secure scheduler tasks.

About this task

If a task is created using a Java Platform, Enterprise Edition (Java EE) server application, only applications with the same name can access those tasks. Tasks created with a WASScheduler MBean using the AdminClient interface or scripting are not part of a J2EE application and have access to all tasks regardless of the application with which they were created. Tasks created with a WASScheduler MBean are only accessible from the WASScheduler MBean API and are not accessible from the Scheduler API.

If the Use Administration Roles attribute is enabled on a scheduler and administrative security is enabled on the Application Server, all Scheduler API methods and WASScheduler MBean API operations enforce access based on the WebSphere Administration Roles. If either of these attributes are disabled, then all API methods are fully accessible by all users.

Procedure

1. Enable security for all application servers.
2. Manage schedulers.

Scheduler configuration or topology

The scheduler uses a database to persist information concerning which tasks to run and when. Errors might occur when changing the application server topology or when changing the application or server configuration. When you change the configuration or topology, carefully consider how this action affects the scheduler.

Restricting security

If you created tasks with an application server while security is disabled, and you later decide to enable security, then the scheduler might have difficulty running tasks. When you create a task, the security context of the application thread is automatically stored with the task. If security is not stored with the task (see Scheduler task user authorization), and you later enable security on the server or application where the task is to run, then the following errors might be logged:

```
SECJ0053E: Authorization failed for /UNAUTHENTICATED while invoking (Home)com/ibm/websphere/scheduler/TaskHandler create:2 securityName: /UNAUTHENTICATED;accessID: UNAUTHENTICATED is not granted any of the required roles: MySecurityRole
```

Before you enable security on the server or application, determine if any tasks might be adversely affected. If so, use the Scheduler API or WASScheduler MBean to cancel the tasks and recreate them after you configure security.

Application server topology changes

The scheduler stores `javax.ejb.HomeHandle` objects for `TaskHandler`, `NotificationSink` and `UserCalendar` *homes* when the task is created. When you run the task later, these home handles are reinflated and used to access the Enterprise JavaBeans (EJB) component home. When the home handle references an EJB on a single-server environment, the home handles have affinity to that server. When the home handle references an EJB component on a cluster, then the home handles have affinity to the cluster.

If the application server or the Workload Managed (WLM) cluster that a home handle is referencing is not available, then the scheduler fails to run the task, and the following error is logged:

```
SCHD0063E: A task with ID 123 failed to run on Scheduler MyScheduler (sched/MyScheduler) because of an exception: {cause of failure}
```

If you upgrade the application server to a cluster, or if the Object Request Broker (ORB) `ORB_LISTENER_ADDRESS` is not set to a fixed port number (see [Configuring Inbound Transports](#)), then the task might also fail, since the information stored within the home handle does not have the appropriate information to find the desired server.

Upgrading to a scheduler cluster

A scheduler cluster (not to be confused with a WLM cluster) is a collection of scheduler configurations on different application servers that share the same Java Naming and Directory Interface (JNDI) name, Java Database Connectivity (JDBC) data source and table prefix. If you upgrade a stand-alone scheduler to a clustered scheduler, then the application and any associated resources that the application requires must be available. If this is not the case, the scheduled task fails to run and error messages might be logged:

```
SCHD0103W: The Scheduler MyScheduler (sched/MyScheduler) was unable to run task 123 because the application or module is unavailable: MyTaskHandlerEJB
```

To avoid issues with application availability and achieve optimal results, use the same servers in a scheduler cluster as those used in a WLM cluster.

Reusing scheduler tables

When changing any topology, moving from development to production environments, or making any configuration changes that make the environment more restrictive, you might get optimal results if you use

a different set of scheduler tables. Reusing scheduler tables that have scheduled tasks from previous releases without careful planning might cause problems:

- EJB components running on unexpected application servers.
- Tasks failing to run due to invalid or missing security credentials.
- Tasks failing to run due to invalid or missing Java Platform, Enterprise Edition (Java EE) context information.

Diagnosing such problems is challenging and requires analyzing logs on all servers that have a scheduler installed and configured. When the problem tasks are located, the tasks can be cancelled using the Scheduler APIs, or the tables can be dropped and recreated.

Scheduler interface

Use the `com.ibm.websphere.scheduler.Scheduler` Java object (in the Java™ Naming and Directory Interface (JNDI) namespace for the scheduler configuration) to find a reference to a scheduler and work with tasks.

A `com.ibm.websphere.scheduler.Scheduler` Java object exists in the JNDI namespace for each scheduler configuration. A reference to a scheduler can be obtained by performing a lookup on the JNDI name; however, the lookup is valid only from the server process where the scheduler instance exists. Once a reference has been obtained, tasks can be created, suspended, cancelled, and so on, if the caller has access to the scheduler instance.

For details, see Interface Scheduler in the API documentation.

Task creation

The task is created in the persistent store using the global transactional context of the caller, if present. See the topic, “Transactions and schedulers” on page 966, for more details. Since this is a transactional operation, the task cannot be run or modified from another thread until the current transaction commits.

Task modification

Tasks that have been created can be modified with the `suspend()`, `resume()`, `cancel()`, and `purge()` methods. These methods take a Task Identifier string as a parameter, which is generated by the `create()` method and can be found in the `TaskStatus` object. If a task is currently running or being modified by another thread, an operation that attempts to modify the state of the task might block on the attempt. Tasks can only be modified by the same application (EAR file) that was used to create the task.

Task execution

Tasks are run in the thread pool specified by the configuration's work manager. If multiple schedulers are configured to share the same database tables, the scheduler is clustered and the tasks found in the table can be run on any of the schedulers, whether or not they are in the same server, node, or cell.

Task lookup

Tasks can be located using the `Name` property that was assigned at creation time. This is useful when you need to modify a group of tasks and tracking individual task ID's is not convenient.

TaskInfo interface

`TaskInfo` objects contain the information to create a task. Several implementations of this class exist, one for each type of task that can run.

Available `TaskInfo` implementations include:

BeanTaskInfo

Calls a stateless session bean.

MessageTaskInfo

Sends a Java™ Messaging Service (JMS) message to a queue or publishes a message to a topic. For details, see the Interface `TaskInfo` in the API documentation.

After a `TaskInfo` object is created, it can be submitted to the scheduler for task creation by calling the `Scheduler.create()` method.

For details about the `TaskInfo` interface, see the API documentation .

TaskHandler interface

A task handler is a user-defined stateless session bean that is called by tasks created using a `BeanTaskInfo` object.

A task handler bean uses the following home and remote interfaces, which are defined in the deployment descriptor using an assembly tool, such as Rational Application Developer:

```
com.ibm.websphere.scheduler.TaskHandlerHome  
com.ibm.websphere.scheduler.TaskHandler
```

The bean itself needs to implement the `process()` method defined in the remote interface. For details, see the `Interface TaskHandler` in the API documentation.

Once an EJB is created and available within an enterprise application, it can be called by a `BeanTaskInfo` task when it runs. See the `Developing a task that calls a session bean` topic for details.

When a task is created using a `BeanTaskInfo` object, the `process()` method on the `TaskHandler` session bean is called whenever the task runs. Because the `TaskStatus` object for the task is passed as a parameter to the `process()` method, the task handler determines different types of information about the task, such as when it will fire next, the number of repeats remaining, its name and its ID.

The `process()` method can also change its own state. However, the task must be running within the same transaction as the scheduler. Therefore, a running task can only modify itself if it is using the **Required** or **Mandatory** container managed transaction types. If the **Requires New** transaction type is specified on the `process()` method, all management functions deadlock.

NotificationSink interface

A notification sink is a user-defined stateless session bean that is called when the task changes state.

A notification sink bean uses the following home and remote interfaces, which are defined in the deployment descriptor using an assembly tool, such as Rational Application Developer:

```
com.ibm.websphere.scheduler.NotificationSinkHome  
com.ibm.websphere.scheduler.NotificationSink
```

The bean itself needs to implement the `handleEvent()` method defined in the remote interface. For details, see the `Interface NotificationSink` section of the API documentation and the `Receiving scheduler notifications` topic.

A `NotificationSink` provides an event notification callback on a task-by-task basis. A notification sink is set on the `TaskInfo` interface, using the `setNotificationSink()` method. If a notification sink is not specified on a task, all notifications are lost; however, the status of a task can be determined by calling the `getStatus()` method from the `Scheduler` interface. A notification callback is made for each of the following events:

- Scheduled
- Suspended
- Resumed
- Fired
- Firing
- Fire Failed
- Complete
- Purged

UserCalendar interface

A user calendar is a user-defined stateless session bean that is called by tasks when they need to calculate date-related values.

A user calendar bean uses the following home and remote interfaces, which are defined in the deployment descriptor using an assembly tool, such as Rational Application Developer:

```
com.ibm.websphere.scheduler.UserCalendarHome  
com.ibm.websphere.scheduler.UserCalendar
```

The bean itself needs to implement the `applyDelta()`, `validate()`, and `getCalendarNames()` methods defined in the remote interface. For details, see the Interface `UserCalendar` in the API documentation.

User calendars are used to calculate time intervals, such as the time between task runs. A user calendar takes a `java.util.Date` object, applies the interval string and returns the resulting `java.util.Date`.

User calendars are set with the `setUserCalendar()` method on the `TaskInfo` interface and called by the scheduler run-time code when a delta calculation is necessary.

The following methods on the `TaskInfo` interface specify delta strings that use the user calendar for calculation:

- `setStartTimeInterval`
- `setStartByInterval`
- `setRepeatInterval`

Default user calendar

If a user calendar has not been specified using the `TaskInfo.setUserCalendar()` method, a default user calendar is used. The default calendar allows for simple delta specifications, such as seconds, minutes, hours, days, and months. See the API documentation for details on the default calendar. The default user calendar also provides a CRON-like syntax for calculating absolute times versus time deltas.

Calendar identifiers

A single user calendar can contain logic for multiple calendars. A calendar specifier string determines which calendar is used. For example, a calendar bean might be implemented to recognize the interval *day*. However, the identifier also recognizes two calendar implementations: *standard* (for a standard calendar day) and *business* (for a business day).

Internationalization and time zones

Scheduler makes use of the `java.util.Date` class when storing and processing dates. Internally, this class saves the time as milliseconds since the Epoch, Greenwich Mean Time. Since the `Date` is not converted to local time until converted to a string, the scheduler respects the time zone where the date was created.

Writing user calendars

Because the user calendar is a stateless session bean, the same Java Platform, Enterprise Edition (Java EE) programming model available to other session beans is available to the user calendar as well.

Chapter 25. Developing security

Secure specific types of applications, such as applications that include portlets, SIP servlets, enterprise beans, web services. Find security information that focuses on specific concerns, such as messaging, transaction support, naming and directory, data access.

Developing extensions to the WebSphere security infrastructure

WebSphere Application Server provides various plug points so that you can extend the security infrastructure. Extending this security infrastructure involves several activities including: Developing custom user registries, developing applications that use programmatic security, and customizing web application login forms.

About this task

The following topics are covered in this section:

Procedure

- Developing custom user registries
- Developing applications that use programmatic security
- Customizing web application login forms
- Customizing application login forms with Java Authentication and Authorization Service (JAAS)
- Securing transports with Java Secure Sockets Extension (JSSE) and Java Cryptography Extension (JCE) programming interfaces
- Implementing tokens for security attribute propagation
- Implementing a custom authentication provider using JASPI

Developing stand-alone custom registries

This development provides considerable flexibility in adapting WebSphere Application Server security to various environments where some notion of a user registry, other than LDAP or Local OS, already exists in the operational environment.

Before you begin

WebSphere Application Server security supports the use of stand-alone custom registries in addition to the local operating system registry, stand-alone Lightweight Directory Access Protocol (LDAP) registries, and federated repositories for authentication and authorization purposes. A stand-alone custom-implemented registry uses the `UserRegistry` Java interface as provided by WebSphere Application Server. A stand-alone custom-implemented registry can support virtually any type or notion of an accounts repository from a relational database, flat file, and so on.

Implementing a stand-alone custom registry is a software development effort. Implement the methods that are defined in the `com.ibm.websphere.security.UserRegistry` interface to make calls to the appropriate registry to obtain user and group information. The interface defines a general set of methods for encapsulating a wide variety of registries. You can configure a stand-alone custom registry as the selected repository when configuring WebSphere Application Server security on the Global security panel.

In WebSphere Application Server Version 8.0, make sure that your implementation of the stand-alone custom registry does not depend on any WebSphere Application Server components such as data sources, Enterprise JavaBeans (EJB) and Java Naming and Directory Interface (JNDI). You can not have this dependency because security is initialized and enabled prior to most of the other WebSphere Application Server components during startup. If your previous implementation used these components,

make a change that eliminates the dependency. For example, if your previous implementation used data sources to connect to a database, instead use the JDBC `java.sql.DriverManager` interface to connect to the database.

If your previous implementation uses data sources to connect to a database, change the implementation to use Java database connectivity (JDBC) connections.

Procedure

1. Implement all the methods in the interface except for the `CreateCredential` method, which is implemented by WebSphere Application Server.
2. Build your implementation.

To compile your code, you need the `com.ibm.ws.runtime.jar` and the `com.ibm.ws.security.crypto.jar` files in your class path. For example:

```
javac -extdirs app_server_root/java/ext:/QIBM/UserData/Java400/ext:  
/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit/jre/lib/ext:app_server_root/lib  
-classpath app_server_root/plugins/com.ibm.ws.runtime.jar:  
app_server_root/plugins/com.ibm.ws.security.crypto.jar  
com/ibm/websphere/security/FileRegistrySample.java
```

The previous lines of code for your class path are one continuous line.

3. Create a classes subdirectory in your profile for custom classes. For more information, see “Creating a classes subdirectory in your profile for custom classes.”
4. Copy the class files that are generated in the previous step to the product class path.
The preferred location is the `app_server_root\classes` directory. For more information, see “Creating a classes subdirectory in your profile for custom classes.” Copy the class files to all the product process class paths including the cell, all of the node agents.
5. To configure your implementation using the administrative console, follow the steps in topics about configuring stand-alone custom registries. This step is required to implement custom user registries.

Example

Viewing stand-alone custom registries.

Use these links to view registry examples.

A *stand-alone custom registry* is a customer-implemented registry that implements the `UserRegistry` Java interface, as provided by WebSphere Application Server. A custom-implemented registry can support virtually any type or form of an accounts repository from a relational database, flat file, and so on. The custom registry provides considerable flexibility in adapting WebSphere Application Server security to various environments where some form of a registry, other than a federated repository, Lightweight Directory Access Protocol (LDAP) registry, or local operating system registry, already exist in the operational environment.

What to do next

If you enable security, make sure that you complete the remaining steps:

1. Save and synchronize the configuration and restart all of the servers.
2. Try accessing some J2EE resources to verify that the custom registry implementation is correct.

Creating a classes subdirectory in your profile for custom classes

You can create a classes subdirectory in the profile in which you can place your custom security components.

About this task

WebSphere Application Server resides in two main default directories:

app_server_root

Contains product Java archive (JAR) files, scripts, and the master copies of the administrative application, samples, and properties files. This directory is referred to by the `${WAS_INSTALL_ROOT}` WebSphere Application Server variable. Do not modify files in these directories.

profile_root

Contains user profile data, that is a combination of unique files and symmetric links to files in the `app_server_root` directories. This directory is referred to by the `${USER_INSTALL_ROOT}` WebSphere Application Server variable.

The product files are separated for the following reasons:

- To separate the files that run the product from files that you can modify, either by editing or through the administrative interfaces. When you apply product fixes, the separate directory structure keeps these fixes from overwriting user-defined data, such as modifying properties files.
- To isolate configuration differences between profiles. For example, each profile subdirectory can have its own copy of the Java 2 Security files, by which the profile can have a unique Java 2 Security configuration, rather than all profiles conforming to one product-wide configuration only.

WebSphere Application Server provides application programming interfaces (APIs) that you can use to develop your own security components for WebSphere Application Server. For example, you can create custom user registries, custom trust association interceptors, and custom login modules. For other WebSphere Application Server platforms, place the files for your custom security component in the `app_server_root/classes` directory.

For the IBM i platform, this action is not recommended because the files are accessible from all server profiles, which might not be a desirable or secure behavior. Additionally, the `classes` directory is granted Java 2 Security AllPermissions authority, which might not be appropriate for your secured environment.

Therefore, create a `/classes` subdirectory in the profile in which you can place your custom security components. Additionally, the QEJBSVR user profile must have authority to the directory. To create the `classes` subdirectory and grant the necessary authorities, complete the following steps:

Procedure

1. Use the **CRTDIR DIR** command to create the `classes` subdirectory. For example, run the following command from the CL command line:

```
CRTDIR DIR('profile_root/classes')
```

Alternatively, you can map or mount a workstation network drive to the iSeries server and create the `/classes` subdirectory from the workstation command prompt or a graphical file explorer utility such as Windows Explorer.

2. If you are using Java 2 Security, update your `profile_root/properties/server.policy` file to grant the appropriate Java 2 Security permissions to the `classes` in the directory. For more information about the permissions, see “server.policy file permissions” on page 1002.
3. If you create the directory from the Qshell command line, explicitly grant the QEJBSVR user profile read, write, and run (*RWX) authority to the directory because the proper authorities are not inherited from the parent directory. For example, run the following command:

```
CHGAUT OBJ('profile_root/classes') USER(QEJBSVR) DTAUT(*RWX)
```

Results

You have a `classes` subdirectory that you can use for custom classes.

Result.java file

This module is used by user registries in WebSphere Application Server when calling the getUsers and getGroups methods. The user registries use this method to set the list of users and groups and to indicate if more users and groups in the user registry exist than requested.

        throws PasswordCheckFailedException,
            CustomRegistryException,
            RemoteException;

    /**
     * Maps a certificate (of X509 format) to a valid user in the registry.
     * This is used to map the name in the certificate supplied by a browser
     * to a valid userSecurityName in the registry
     *
     * @param cert the X509 certificate chain
     * @return the mapped name of the user userSecurityName
     * @exception CertificateMapNotSupportedException if the particular
     *         certificate is not supported.
     * @exception CertificateMapFailedException if the mapping of the
     *         certificate fails.
     * @exception CustomRegistryException if there is any registry specific
     *         problem
     * @exception RemoteException as this extends java.rmi.Remote
     **/
    public String mapCertificate(X509Certificate[] cert)
        throws CertificateMapNotSupportedException,
            CertificateMapFailedException,
            CustomRegistryException,
            RemoteException;

    /**
     * Returns the realm of the registry.
     *
     * @return the realm. The realm is a registry-specific string indicating
     *         the realm or domain for which this registry
     *         applies. For example, for OS400 or AIX this would be the
     *         host name of the system whose user registry this object
     *         represents.
     *         If null is returned by this method realm defaults to the
     *         value of "customRealm". It is recommended that you use
     *         your own value for realm.
     */
}

```

```

* @exception CustomRegistryException if there is any registry specific
*   problem
* @exception RemoteException as this extends java.rmi.Remote
**/
public String getRealm()
    throws CustomRegistryException,
           RemoteException;

/**
 * Gets a list of users that match a pattern in the registry.
 * The maximum number of users returned is defined by the limit
 * argument.
 * This method is called by administrative console and by scripting (command
 * line) to make available the users in the registry for adding them (users)
 * to roles.
 *
 * @parameter pattern the pattern to match. (For example., a* will match all
 *   userSecurityNames starting with a)
 * @parameter limit the maximum number of users that should be returned.
 * This is very useful in situations where there are thousands of
 * users in the registry and getting all of them at once is not
 * practical. A value of 0 implies get all the users and hence
 * must be used with care.
 * @return a Result object that contains the list of users
 * requested and a flag to indicate if more users exist.
 * @exception CustomRegistryException if there is any registry specific
 *   problem
 * @exception RemoteException as this extends java.rmi.Remote
**/
public Result getUsers(String pattern, int limit)
    throws CustomRegistryException,
           RemoteException;

/**
 * Returns the display name for the user specified by userSecurityName.
 *
 * This method is called only when the user information displays
 * (information purposes only, for example, in the administrative console) and not used
 * in the actual authentication or authorization purposes. If there are no
 * display names in the registry return null or empty string.
 *
 * In WebSphere Application Server Version 4.0 custom registry, if you had a display
 * name for the user and if it was different from the security name, the display name
 * was returned for the EJB methods getCallerPrincipal() and the servlet methods
 * getUserPrincipal() and getRemoteUser().
 * In WebSphere Application Server Version 6.0 for the same methods the security
 * name is returned by default. This is the recommended way as the display name
 * is not unique and might create security holes.
 *
 * See the documentation for more information.
 *
 * @parameter userSecurityName the name of the user.
 * @return the display name for the user. The display name
 * is a registry-specific string that represents a descriptive, not
 * necessarily unique, name for a user. If a display name does
 * not exist return null or empty string.
 * @exception EntryNotFoundException if userSecurityName does not exist.
 * @exception CustomRegistryException if there is any registry specific
 *   problem

```

Implementing custom password encryption

WebSphere Application Server supports the use of custom password encryption.

Before you begin

An installation can implement any password encryption algorithm it chooses.

About this task

Complete the following steps to implement custom password encryption:

Procedure

1. Build your custom password encryption class. An example of a custom password encryption class follows.

```

// CustomPasswordEncryption
// Encryption and decryption functions
public interface CustomPasswordEncryption {
    public EncryptedInfo encrypt(byte[] clearText) throws PasswordEncryptException;
    public byte[] decrypt(EncryptedInfo cipherTextInfo) throws PasswordEncryptException;
    public void initialize(HashMap initParameters);
};
// Encapsulation of cipher text and label
public class EncryptedInfo {
    public EncryptedInfo(byte[] bytes, String keyAlias);
    public byte[] getEncryptedBytes();
    public String getKeyAlias();
};

```

2. If you need to custom encode passwords in property files, manually edit the PropFilePasswordEncoder.sh or PropFilePasswordEncoder.bat file.
 - a. Use a file editor to open the PropFilePasswordEncoder.sh or PropFilePasswordEncoder.bat file.
 - b. Locate the following lines near the end of the file:

```
"%JAVA_HOME%/bin/java" -Dcmd.properties.file=%TMPJAVAPROPPFILE%
"-Dwas.install.root=%WAS_HOME%" com.ibm.ws.bootstrap.WSLauncher
com.ibm.ws.security.util.PropFilePasswordEncoder %1 %2
```

- c. Add following lines to the call.

These custom properties will be passed to the command so that PropFilePasswordEncoder will look for custom encoding classes and utilize it.

```
-Dcom.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled=true
-Dcom.ibm.wsspi.security.crypto.customPasswordEncryptionClass=(customEncoding class file)
```

The updated lines should look like the following lines:

```
"%JAVA_HOME%/bin/java" -Dcmd.properties.file=%TMPJAVAPROPPFILE%
-Dcom.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled=true
-Dcom.ibm.wsspi.security.crypto.customPasswordEncryptionClass=(customEncoding class file)
"-Dwas.install.root=%WAS_HOME%" com.ibm.ws.bootstrap.WSLauncher
com.ibm.ws.security.util.PropFilePasswordEncoder %1 %2
```

3. Enable custom password encryption.
 - a. Set the custom property **com.ibm.wsspi.security.crypto.customPasswordEncryptionClass** to the name of the class that is to be given control.
 - b. Enable the function. Set the custom property, **com.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled** to true.

Results

Custom password encryption at the installation is complete.

Developing applications that use programmatic security

For some applications, declarative security is not sufficient to express the security model of the application. Use this topic to develop applications that use programmatic security.

About this task

IBM WebSphere Application Server provides security components that provide or collaborate with other services to provide authentication, authorization, delegation, and data protection. WebSphere Application Server also supports the security features that are described in the Java Platform, Enterprise Edition (Java EE) specification. An application goes through three stages before it is ready to run:

- Development
- Assembly
- Deployment

Most of the security for an application is configured during the assembly stage. The security that is configured during the assembly stage is called *declarative security* because the security is *declared* or *defined* in the deployment descriptors. The declarative security is enforced by the security runtime. For some applications, declarative security is not sufficient to express the security model of the application. For these applications, you can use *programmatic security*.

Procedure

1. Develop secure web applications. For more information, see “Developing with programmatic security APIs for web applications” on page 1006.
2. Develop servlet filters for form login processing. For more information, see “Developing servlet filters for form login processing” on page 1021.

3. Develop form login pages. For more information, see “Customizing web application login” on page 1017.
4. Develop enterprise bean component applications. For more information, see “Developing with programmatic APIs for EJB applications” on page 1013.
5. Develop with Java Authentication and Authorization Service to log in programmatically.
For more information, see topics about developing programmatic logins with the Java Authentication and Authorization Service.
6. Develop your own Java EE security mapping module.
For more information, see topics about configuring programmatic logins for Java Authentication and Authorization Service.
7. Develop custom user registries. For more information, see “Developing stand-alone custom registries” on page 975.
8. Develop a custom interceptor for trust associations.

Protecting system resources and APIs (Java 2 security) for developing applications

Java 2 security is a programming model that is very pervasive and has a huge impact on application development.

Before you begin

Java 2 security is orthogonal to Java Platform, Enterprise Edition (Java EE) role-based security; you can disable or enable it independently of administrative security.

However, it does provide an extra level of access control protection on top of the Java EE role-based authorization. It particularly addresses the protection of system resources and application programming interfaces (API). Administrators need to consider the benefits against the risks of disabling Java 2 security.

The following recommendations are provided to help enable Java 2 security in a test or production environment:

1. Make sure the application is developed with the Java 2 security programming model. Developers have to know whether or not the APIs that are used in the applications are protected by Java 2 security. It is very important that the required permissions for the APIs used are declared in the policy file (`was.policy`), or the application fails to run when Java 2 security is enabled. Developers can reference the website for Development Kit APIs that are protected by Java 2 security. See the Programming model and decisions section of the Security: Resources for Learning topic to visit this website.
2. Make sure that migrated applications from previous releases are given the required permissions. Because Java 2 security is not supported or partially supported in previous WebSphere Application Server releases, applications developed prior to Version 5 most likely are not using the Java 2 security programming model. No easy way to find out all the required permissions for the application is available. The following are activities you can perform to determine the extra permissions that are required by an application:
 - Code review and code inspection
 - Application documentation review
 - Sandbox testing of migrated enterprise applications with Java 2 security enabled in a preproduction environment. Enable tracing in WebSphere Java 2 security manager to help determine the missing permissions in the application policy file. The trace specification is:
`com.ibm.ws.security.core.SecurityManager=all=enabled.`
 - Use the `com.ibm.websphere.java2secman.norethrow` system property to aid debugging. Do not use this property in a production environment.

The default permission set for applications is the recommended permission set defined in the J2EE 1.3 Specification. The default is declared in the `profile_root/config/cells/cell_name/nodes/node_name/`

app.policy policy file with permissions defined in the Development Kit policy file that grants permissions to everyone. The java.policy file is located in the *java_home* directory depending on the Java virtual machine (JVM) that is enabled for the profile.

Note: Only Java SE 6 has a JRE.(for example, /QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit/jre/lib/ext).

For all Java virtual machines, the java.policy file is used system-wide. Do not edit the java.policy file on the server. Applications are denied permissions that are declared in the *profile_root/config/cells/cell_name/filter.policy* file. Permissions declared in the *filter.policy* file are filtered for applications during the permission check.

Use the showVariables command of the AdminTask object to retrieve JAVA_HOME for the node associated with the server's profile. For example, if the node is myNode:

1. Enter QShell.
2. cd to profile_root/bin
3. Run the following command:

```
wsadmin -conntype NONE -c '$AdminTask showVariables {-scope Node=myNode -variableName JAVA_HOME}'
```

Define the required permissions for an application in a was.policy file and embed the was.policy file in the application enterprise archive (EAR) file as *YOURAPP.ear/META-INF/was.policy*, see “Configuring Java 2 security policy files” on page 988 for details.

The following steps describe how to enforce Java 2 security on the cell level for WebSphere Application Server, Network Deployment and the server level for WebSphere Application Server, Express

Procedure

1. Click **Security > Global security**. The Global security panel is displayed.
2. Select the **Use Java 2 security to restrict application access to local resources** option.
3. Click **OK** or **Apply**.
4. Click **Save** to save the changes.
5. Restart the server for the changes to take effect.

Results

Java 2 security is enabled and enforced for the servers. Java 2 security permission is selected when a Java 2 security protected API is called.

When to use Java 2 security

1. Enable protection on system resources, for example when opening or listening to a socket connection, reading or writing to operating system file systems, reading or writing Java virtual machine system properties, and so on.
2. Prevent application code from calling destructive APIs, for example, calling the System.exit method brings down the application server.
3. Prevent application code from obtaining privileged information (passwords) or gaining extra privileges (obtaining server credentials).

What to do next

The Java 2 security manager is enhanced to dump the Java 2 security permissions that are granted to all classes on the call stack when an application is denied access to a resource. The java.security.AccessControlException exception is created. However, this tracing capability is disabled by default. You can enable this capability by specifying the server trace service with the com.ibm.ws.security.core.SecurityManager=all=enabled trace specification. When the exception is created, the trace dump provides hints to determine whether the application is missing permissions or the

product runtime code or the third-party libraries that are used are not properly marked as privileged when accessing Java 2 security-protected resources.

Using PolicyTool to edit policy files for Java 2 security:

Use the **PolicyTool** utility to update policy files.

Before you begin

Java 2 security uses several policy files to determine the granted permission for each Java program. The Java Development Kit provides the **PolicyTool** tool to edit these policy files. This tool is recommended for editing any policy file to verify the syntax of its contents. Syntax errors in the policy file cause an `AccessControlException` exception when the application runs, including the server start. Identifying the cause of this exception is not easy because the user might not be familiar with the resource that has an access violation. Be careful when you edit these policy files.

You must install either the client or plug-ins component of WebSphere Application Server on a workstation in order to access the **PolicyTool**. It is not currently supported on the iSeries server.

Procedure

1. Map a drive to the operating system to navigate the directory tree to the policy file.
2. Start the **PolicyTool**.
Click **OK**.
3. Click **File > Open**.
4. Navigate the directory tree in the **Open** window to pick up the policy file that you need to update. After selecting the policy file, click **Open**. The code base entries are listed in the window.
5. Create or modify the code base entry.
 - a. Modify the existing code base entry by double-clicking the code base, or click the code base and click **Edit Policy Entry**. The Policy Entry window opens with the permission list defined for the selected code base.
 - b. Create a new code base entry by clicking **Add Policy Entry**.
The Policy Entry window opens. At the code base column, enter the code base information as a URL format.
For example, you can enter:
`profile_root/InstalledApps/testcase.ear`
6. Modify or add the permission specification.
 - a. Modify the permission specification by double-clicking the entry that you want to modify, or by selecting the permission and clicking **Edit Permission**. The Permissions window opens with the selected permission information.
 - b. Add a new permission by clicking **Add Permission**. The Permissions window opens. In the Permissions window are four rows for Permission, Target Name, Actions, and Signed By.
7. Select the permission from the Permission list. The selected permission displays. After a permission is selected, the Target Name, Actions, and Signed By fields automatically show the valid choices or they enable text input in the right text input area.
 - a. Select **Target Name** from the list, or enter the target name in the right text input area.
 - b. Select **Actions** from the list.
 - c. Input **Signed By** if it is needed.

Important: The Signed By keyword is not supported in the following policy files: `app.policy`, `spi.policy`, `library.policy`, `was.policy`, and `filter.policy` files. However, the Signed By keyword is supported in the following policy files: `#java.policy`, `server.policy`, and `client.policy` files. The Java Authentication and Authorization

Service (JAAS) is not supported in the `app.policy`, `spi.policy`, `library.policy`, `was.policy`, and `filter.policy` files. However, the JAAS principal keyword is supported in a JAAS policy file when it is specified by the `java.security.auth.policy` Java virtual machine (JVM) system property.

- Click **OK** to close the Permissions window. Modified permission entries of the specified code base display.
- Click **Done** to close the window. Modified code base entries are listed. Repeat the previous steps until you complete editing.
- Click **File > Save** after you finish editing the file.

Results

A policy file is updated. If any policy files need editing, use the **PolicyTool** utility. Do not edit the policy file manually. Syntax errors in the policy files can potentially cause application servers or enterprise applications to not start or function incorrectly. For the changes in the updated policy file to take effect, restart the Java processes.

Configuring Java 2 security policy files:

Users can configure Java 2 security policy files so that the required permission is granted for the specified WebSphere Application Server enterprise application.

Before you begin

Java 2 security uses several policy files to determine the permissions for each Java programs.

See the Java 2 security policy files topic for the list of available policy files that are supported by WebSphere Application Server.

Two types of policy files are supported by WebSphere Application Server: dynamic policy files and static policy files. Static policy files provide the default permissions. Dynamic policy files provide application permissions. Six dynamic policy files are provided:

Table 101. Dynamic policy files. This table lists the dynamic policy files.

Policy file name	Description
<code>app.policy</code>	Contains default permissions for all of the enterprise applications in the cell. Note: Updates to the <code>app.policy</code> file only apply to the enterprise applications on the node to which the <code>app.policy</code> file belongs.
<code>was.policy</code>	Contains application-specific permissions for an WebSphere Application Server enterprise application. This file is packaged in an enterprise archive (EAR) file.
<code>ra.xml</code>	Contains connector application specific permissions for a WebSphere Application Server enterprise application. This file is packaged in a resource adapter archive (RAR) file.
<code>spi.policy</code>	Contains permissions for Service Provider Interface (SPI) or third-party resources that are embedded in WebSphere Application Server. The default contents grant everything. Update this file carefully when the cell requires more protection against SPI in the cell. This file is applied to all of the SPIs that are defined in the <code>resources.xml</code> file.
<code>library.policy</code>	Contains permissions for the shared library of enterprise applications.
<code>filter.policy</code>	Contains the list of permissions that require filtering from the <code>was.policy</code> file and the <code>app.policy</code> file in the cell. This filtering mechanism only applies to the <code>was.policy</code> and <code>app.policy</code> files.

In WebSphere Application Server, applications must have the appropriate thread permissions specified in the `was.policy` or `app.policy` file. Without the thread permissions specified, the application cannot

manipulate threads and WebSphere Application Server creates a `java.security.AccessControlException` exception. The `app.policy` file applies to a specified node. If you change the permissions in one `app.policy` file, you must incorporate the new thread policy in the same file on the remaining nodes. Also, if you add the thread permissions to the `app.policy` file, you must restart WebSphere Application Server to enforce the new permissions. However, if you add the permissions to the `was.policy` file for a specific application, you do not need to restart WebSphere Application Server. An administrator must add the following code to a `was.policy` or `app.policy` file for an application to manipulate threads:

```
grant codeBase "file:${application}" {
    permission java.lang.RuntimePermission "stopThread";
    permission java.lang.RuntimePermission "modifyThread";
    permission java.lang.RuntimePermission "modifyThreadGroup";
};
```

Important: The Signed By keyword is not supported in the following policy files: `app.policy`, `spi.policy`, `library.policy`, `was.policy`, and `filter.policy` files. However, the Signed By keyword is supported in the following policy files: `java.policy`, `server.policy`, and `client.policy` files. The Java Authentication and Authorization Service (JAAS) is not supported in the `app.policy`, `spi.policy`, `library.policy`, `was.policy`, and `filter.policy` files. However, the JAAS principal keyword is supported in a JAAS policy file when it is specified by the `java.security.auth.policy` Java virtual machine (JVM) system property. You can statically set the authorization policy files in `java.security.auth.policy` with `auth.policy.url.n=URL`, where `URL` is the location of the authorization policy.

Procedure

1. Identify the policy file to update.

- If the permission is required by an application, update the static policy file. Refer to “Configuring static policy files in Java 2 security” on page 1001.
- If the permission is required by all of the WebSphere Application Server enterprise applications in the node, refer to “spi.policy file permissions” on page 996.
- If the permission is required only by specific WebSphere Application Server enterprise applications and the permission is required only by connector, update the `ra.xml` file. Refer to Refer to the Assembling resource adapter (connector) modules article for more information. Otherwise, update the `was.policy` file. Refer to “Configuring the was.policy file for Java 2 security” on page 994 and “Adding the was.policy file to applications for Java 2 security” on page 999.
- If the permission is required by shared libraries, refer to “library.policy file permissions” on page 997.
- If the permission is required by SPI libraries, refer to “spi.policy file permissions” on page 996.

Tip: Pick up the policy file with the smallest scope. You can avoid giving an extra permission to the Java programs and protect the resources. You can update the `ra.xml` file or the `was.policy` file rather than the `app.policy` file. Use specific component symbols (`$(ejbcomponent)`, `$(webComponent)`, `$(connectorComponent)` and `$(jars)`) than `$(application)` symbols. Update dynamic policy files, rather than static policy files.

Add any permission that you never want granted to the WebSphere Application Server enterprise application in the cell to the `filter.policy` file. Refer to “filter.policy file permissions” on page 992.

2. Restart the WebSphere Application Server enterprise application.

Results

The required permission is granted for the specified WebSphere Application Server enterprise application.

Example

If an WebSphere Application Server enterprise application in a cell requires permissions, some of the dynamic policy files need updating. The symptom of the missing permission is the

java.security.AccessControlException exception. The missing permission is listed in the exception data, which will appear as one line, but is split in sections below for readability.

```
java.security.AccessControlException: access denied (java.io.FilePermission
${was.install.root}/java/ext/mail.jar read)
```

When a Java program receives this exception and adding this permission is justified, add a permission to an adequate dynamic policy file.

```
grant codeBase "file:user_client_installed_location" {
    permission java.io.FilePermission
"${was.install.root}/${}/java${}/jre${}/lib${}/ext${}/mail.jar", "read";
};
```

The previous permission information lines are split for the illustration. Enter the permission on one line.

To decide whether to add a permission, refer to the Access control exception for Java 2 security topic.

app.policy file permissions:

Java 2 security uses several policy files to determine the granted permissions for each Java program. The union of the permissions that are contained in these following files is applied to the WebSphere Application Server enterprise application. This union determines the granted permissions.

For the list of available policy files that are supported by WebSphere Application Server, see the topic about Java 2 security policy files. The `app.policy` file is a default policy file that is shared by all of the WebSphere Application Server enterprise applications. The union of the permissions that are contained in the following files is applied to the WebSphere Application Server enterprise application:

- Any policy file that is specified in the `policy.url.*` properties in the `java.security` file.
- The `app.policy` files, which are managed by configuration and file replication services.
- The `server.policy` file.
- The `java.policy` file.
- The `application.was.policy` file.
- The permission specification of the `ra.xml` file.
- The shared library, which is the `library.policy` file.

In WebSphere Application Server, applications that manipulate threads must have the appropriate thread permissions specified in the `was.policy` or `app.policy` file. Without the thread permissions specified, the application cannot manipulate threads and WebSphere Application Server creates a `java.security.AccessControlException` exception. If an administrator adds thread permissions to the `app.policy` file, the permission change requires a restart of the WebSphere Application Server. An administrator must add the following code to a `was.policy` or `app.policy` file for an application to manipulate threads:

```
grant codeBase "file:${application}" {
    permission java.lang.RuntimePermission "stopThread";
    permission java.lang.RuntimePermission "modifyThread";
    permission java.lang.RuntimePermission "modifyThreadGroup";
};
```

Important: The Signed By and the Java Authentication and Authorization Service (JAAS) principal keywords are not supported in the `app.policy` file. However, the Signed By keyword is supported in the following files: `java.policy`, `server.policy`, and the `client.policy` files. The JAAS principal keyword is supported in a JAAS policy file when it is specified by the `java.security.auth.policy` Java virtual machine (JVM) system property. You can statically set the authorization policy files in the `java.security.auth.policy` property with `auth.policy.url.n=URL` where `URL` is the location of the authorization policy.

If the default permissions for enterprise applications (the union of the permissions that is defined in the `java.policy` file, the `server.policy` file and the `app.policy` file) are enough; no action is required. The default `app.policy` file is used automatically. If a specific change is required to all of the enterprise applications in the cell, update the `app.policy` file. Syntax errors in the policy files cause start failures in the application servers. Edit these policy files carefully.

Note: Updates to the `app.policy` file only apply to the enterprise applications on the node to which the `app.policy` file belongs.

To extract the policy file, use a command prompt to enter the following command on one line using the appropriate variable values for your environment:

```
wsadmin> set obj [$AdminConfig extract cells/cell_name/node/node_name/app.policy /temp/test/app.policy]
```

Edit the extracted `app.policy` file with the Policy Tool. For more information, see “Using PolicyTool to edit policy files for Java 2 security” on page 987. Changes to the `app.policy` file are local for the node.

To check in the policy file, use a command prompt to enter the following command on one line using the appropriate variable values for your environment:

```
wsadmin> $AdminConfig checkin cells/cell_name/nodes/node_name/app.policy temp/test/app.policy $obj
```

Table 102. Symbols used to associate permission lists to a specific type of resource. Several product-reserved symbols are defined to associate the permission lists to a specific type of resource.

Symbol	Meaning
<code>file:\${application}</code>	Permissions apply to all resources within the application
<code>file:\${jars}</code>	Permissions apply to all utility Java archive (JAR) files within the application
<code>file:\${ejbComponent}</code>	Permissions apply to enterprise bean resources within the application
<code>file:\${webComponent}</code>	Permissions apply to web resources within the application
<code>file:\${connectorComponent}</code>	Permissions apply to connector resources both within the application and within stand-alone connector resources.

Table 103. Symbols provided to specify the path and name for the `java.io.FilePermission` permission. Five embedded symbols are provided to specify the path and name for the `java.io.FilePermission` permission. These symbols enable flexible permission specifications. The absolute file path is fixed after the installation of the application.

Symbol	Meaning
<code>\${app.installed.path}</code>	Path where the application is installed
<code>\${was.module.path}</code>	Path where the module is installed
<code>\${current.cell.name}</code>	Current cell name
<code>\${current.node.name}</code>	Current node name
<code>\${current.server.name}</code>	Current server name

Tip: You cannot use the `${was.module.path}` in the `${application}` entry.

The `app.policy` file supplied by WebSphere Application Server is located in the `profile_root/config/cells/cell_name/nodes/node_name/app.policy`, which contains the following default permissions:

Attention: In the following code sample, the first two lines that are related to `java.io.FilePermission` permission are split into two lines for illustrative purposes only.

```
grant codeBase "file:${application}" {
  // The following are required by JavaMail
  permission java.io.FilePermission "${was.install.root}${lib{}}activation-impl.jar", "read";
  permission java.io.FilePermission "${was.install.root}${lib{}}mail-impl.jar", "read";
};

grant codeBase "file:${jars}" {
  permission java.net.SocketPermission "*", "connect";
  permission java.util.PropertyPermission "*", "read";
};

grant codeBase "file:${connectorComponent}" {
```

```

permission java.net.SocketPermission "*", "connect";
permission java.util.PropertyPermission "*", "read";
};

grant codeBase "file:${webComponent}" {
permission java.io.FilePermission "${was.module.path}${/}-", "read, write";
permission java.lang.RuntimePermission "loadLibrary.*";
permission java.lang.RuntimePermission "queuePrintJob";
permission java.net.SocketPermission "*", "connect";
permission java.util.PropertyPermission "*", "read";
};

grant codeBase "file:${ejbComponent}" {
permission java.lang.RuntimePermission "queuePrintJob";
permission java.net.SocketPermission "*", "connect";
permission java.util.PropertyPermission "*", "read";
};

```

If all of the WebSphere Application Server enterprise applications in a cell require permissions that are not defined as defaults in the `java.policy` file, the `server.policy` file and the `app.policy` file, then update the `app.policy` file. The symptom of a missing permission is the `java.security.AccessControlException` exception.

Note: Updates to the `app.policy` file only apply to the enterprise applications on the node to which the `app.policy` file belongs.

When a Java program receives this exception and adding this permission is justified, add a permission to the `server.policy` file, for example:

```

grant codeBase "file:user_client_installed_location" {
permission java.io.FilePermission
"${was.install.root}${/}java${/}jre${/}lib${/}ext${/}mail.jar", "read";
};

```

The previous permission information lines are split for the illustration. You actually enter the permission on one line.

To decide whether to add a permission, refer to the `AccessControlException` topic.

Restart all WebSphere Application Server enterprise applications to ensure that the updated `app.policy` file takes effect.

filter.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program. Java 2 security policy filtering is only in effect when Java 2 security is enabled.

Before modifying the `filter.policy` file, you must start the `wsadmin` tool.

Refer to “Protecting system resources and APIs (Java 2 security) for developing applications” on page 985. The filtering policy defined in the `filter.policy` file is cell wide. The `filter.policy` file is the only policy file that is used when restricting the permission instead of granting permission. The permissions that are listed in the filter policy file are filtered out from the `app.policy` file and the `was.policy` file. Permissions that are defined in the other policy files are not affected by the `filter.policy` file.

When a permission is filtered out, an audit message is logged. However, if the permissions that are defined in the `app.policy` file and the `was.policy` file are compound permissions like the `java.security.AllPermission` permission, for example, the permission is not removed. A warning message is logged. If the Issue Permission Warning flag is enabled (default) and if the `app.policy` file and the `was.policy` file contain custom permissions (non-Java API permission, the permission package name begins with characters other than `java` or `javax`), a warning message is logged and the permission is not removed. You can change the value of the **Warn if applications are granted custom permissions** option on the Global security panel. It is not recommended that you use the `AllPermission` permission for the enterprise application.

Some default permissions that are defined in the `filter.policy` file. These permissions are the minimal ones that are recommended by the product. If more permissions are added to the `filter.policy` file, certain operations can fail for enterprise applications. Add permissions to the `filter.policy` file carefully.

You cannot use the Policy Tool to edit the `filter.policy` file. Editing must be completed in a text editor. Be careful and verify that no syntax errors exist in the `filter.policy` file. If any syntax errors exist in the `filter.policy` file, the file is not loaded by the product security runtime, which implies that filtering is disabled.

To extract the `filter.policy` file, enter the following command using information from your environment:

```
set obj [$AdminConfig extract cells/cell_name/filter.policy /temp/test/filter.policy]
```

To check in the policy file, enter the following command using information from your environment:

```
$AdminConfig checkin cells/cell_name/filter.policy /temp/test/filter.policy $obj
```

An updated `filter.policy` file is applied to all of the WebSphere Application Server enterprise applications after the servers are restarted. The `filter.policy` file is managed by configuration and file replication services.

The `filter.policy` file supplied by WebSphere Application Server resides at: `profile_root/config/cells/cell_name/filter.policy`.

This fill contains these permissions as defaults:

```
filterMask {
permission java.lang.RuntimePermission "exitVM";
permission java.lang.RuntimePermission "setSecurityManager";
permission java.security.SecurityPermission "setPolicy";
permission javax.security.auth.AuthPermission "setLoginConfiguration"; };
runtimeFilterMask {
permission java.lang.RuntimePermission "exitVM";
permission java.lang.RuntimePermission "setSecurityManager";
permission java.security.SecurityPermission "setPolicy";
permission javax.security.auth.AuthPermission "setLoginConfiguration"; };
```

The permissions that are defined in `filterMask` filter are for static policy filtering. The security runtime tries to remove the permissions from applications during application startup. Compound permissions are not removed, but are issued with a warning, and application deployment is stopped if applications contain permissions that are defined in the `filterMask` filter, and if scripting is used. The `runtimeFilterMask` filter defines permissions that are used by the security runtime to deny access to those permissions to application thread. Do not add more permissions to the `runtimeFilterMask` filter. Application start failure or incorrect functioning might result. Be careful when adding more permissions to the `runtimeFilterMask` filter. Usually, you only need to add permissions to the `filterMask` stanza.

WebSphere Application Server relies on the filter policy file to restrict or disallow certain permissions that can compromise the integrity of the system. For instance, WebSphere Application Server considers the `exitVM` and `setSecurityManager` permissions as those permissions that most applications never have. If these permissions are granted, the following scenarios are possible:

exitVM

A servlet, JavaServer Pages (JSP) file, enterprise bean, or other library that is used by the aforementioned might call the `System.exit` API and cause the entire WebSphere Application Server process to terminate.

setSecurityManager

An application might install its own security manager and either grant more permissions or bypass the default policy that the WebSphere Application Server security manager enforces.

Important: In application code, do not use the `setSecurityManager` permission to set a security manager. When an application uses the `setSecurityManager` permission, a conflict exists with the internal security manager within WebSphere Application Server. If you must set a security manager in an application for Remote Method Invocation (RMI) purposes, you also must select the **Use Java 2 security to restrict application access to local resources** option on the Global security panel within the WebSphere Application Server administrative console. WebSphere Application Server then registers a security manager, which the application code can verify is registered by using the `System.getSecurityManager` application programming interface (API).

For the updated `filter.policy` file to take effect, restart related Java processes.

Configuring the `was.policy` file for Java 2 security:

You should update the `was.policy` file if the application has specific resources to access.

Before you begin

Java 2 security uses several policy files to determine the granted permission for each Java program. The `was.policy` file is an application-specific policy file for WebSphere Application Server enterprise applications. This file is embedded in the META-INF/`was.policy` enterprise archive (.EAR) file. The `was.policy` file is located in:

```
profile_root/config/cells/cell_name/applications/  
ear_file_name/deployments/application_name/META-INF/was.policy
```

See Java 2 security policy files for the list of available policy files that are supported by WebSphere Application Server Version 6.1.

The union of the permissions that are contained in the following files is applied to the WebSphere Application Server enterprise application:

- Any policy file that is specified in the `policy.url.*` properties in the `java.security` file.
- The `app.policy` files, which are managed by configuration and file replication services.
- The `server.policy` file.
- The `java.policy` file.
- The application `was.policy` file.
- The permission specification of the `ra.xml` file.
- The shared library, which is the `library.policy` file.

Table 104. Symbols defined to associate permission lists to a specific type of resource. Several product-reserved symbols are defined to associate the permission lists to a specific type of resource.

Symbol	Definition
<code>file:\${application}</code>	Permissions apply to all resources used within the application.
<code>file:\${jars}</code>	Permissions apply to all utility Java archive (JAR) files within the application
<code>file:\${ejbComponent}</code>	Permissions apply to enterprise bean resources within the application
<code>file:\${webComponent}</code>	Permissions apply to web resources within the application
<code>file:\${connectorComponent}</code>	Permissions apply to connector resources within the application

In WebSphere Application Server, applications that manipulate threads must have the appropriate thread permissions specified in the `was.policy` or `app.policy` file. Without the thread permissions specified, the

application cannot manipulate threads and WebSphere Application Server creates a `java.security.AccessControlException` exception. If you add the permissions to the `was.policy` file for a specific application, you do not need to restart WebSphere Application Server. An administrator must add the following code to a `was.policy` or `app.policy` file for an application to manipulate threads:

```
grant codeBase "file:${application}" {
    permission java.lang.RuntimePermission "stopThread";
    permission java.lang.RuntimePermission "modifyThread";
    permission java.lang.RuntimePermission "modifyThreadGroup";
};
```

An administrator can add the thread permissions to the `app.policy` file, but the permission change requires a restart of WebSphere Application Server.

Important: The Signed By and the Java Authentication and Authorization Service (JAAS) principal keywords are not supported in the `was.policy` file. The Signed By keyword is supported in the `java.policy`, `server.policy`, and `client.policy` policy file. The JAAS principal keyword is supported in a JAAS policy file when it is specified by the `java.security.auth.policy` Java virtual machine (JVM) system property. You can statically set the authorization policy files in the `java.security.auth.policy` file with the `auth.policy.url.n=URL`, where `URL` is the location of the authorization policy.

Other than these blocks, you can specify the module name for granular settings. For example,

```
grant codeBase "file:DefaultWebApplication.war" {
    permission java.security.SecurityPermission "printIdentity";
};

grant codeBase "file:IncCMP11.jar" {
    permission java.io.FilePermission
        "${user.install.root}${/}bin${/}DefaultDB${/}-",
        "read,write,delete";
};
```

Table 105. Embedded symbols provided to specify the path and name for the `java.io.FilePermission` permission. Five embedded symbols are provided to specify the path and name for the `java.io.FilePermission` permission. These symbols enable flexible permission specification. The absolute file path is fixed after the application is installed.

Symbol	Definition
<code>\${app.installed.path}</code>	Path where the application is installed
<code>\${was.module.path}</code>	Path where the module is installed
<code>\${current.cell.name}</code>	Current cell name
<code>\${current.node.name}</code>	Current node name
<code>\${current.server.name}</code>	Current server name

About this task

If the default permissions for the enterprise application are enough, an action is not required. The default permissions are a union of the permissions that are defined in the `java.policy` file, the `server.policy` file, and the `app.policy` file. If an application has specific resources to access, update the `was.policy` file. The first two steps assume that you are creating a new policy file.

Tip: Syntax errors in the policy files cause the application server to fail. Use care when editing these policy files.

Procedure

1. Create or edit a new `was.policy` file by using the PolicyTool. For more information, see “Using PolicyTool to edit policy files for Java 2 security” on page 987.
2. Package the `was.policy` file into the enterprise archive (EAR) file.

For more information, see “Adding the `was.policy` file to applications for Java 2 security” on page 999. The following instructions describe how to import a `was.policy` file.

 - a. Import the EAR file into an assembly tool.

- b. Open the Project Navigator view.
 - c. Expand the EAR file and click **META-INF**. You might find a `was.policy` file in the META-INF directory. If you want to delete the file, right-click the file name and select **Delete**.
 - d. At the bottom of the Project Navigator view, click **J2EE Hierarchy**.
 - e. Import the `was.policy` file by right-clicking the **Modules** directory within the deployment descriptor and by clicking **Import > Import > File system**.
 - f. Click **Next**.
 - g. Enter the path name to the `was.policy` file in the **From directory** field or click **Browse** to locate the file.
 - h. Verify that the path directory that is listed in the **Into directory** field lists the correct META-INF directory.
 - i. Click **Finish**.
 - j. To validate the EAR file, right-click the EAR file, which contains the Modules directory, and click **Run Validation**.
 - k. To save the new EAR file, right-click the EAR file, and click **Export > Export EAR file**. If you do not save the revised EAR file, the EAR file will contain the new `was.policy` file. However, if the workspace becomes corrupted, you might lose the revised EAR file.
 - l. To generate deployment code, right-click the EAR file and click **Generate Deployment Code**.
3. Update an existing installed application, if one already exists. Modify the `was.policy` file with the Policy Tool. For more information, see “Using PolicyTool to edit policy files for Java 2 security” on page 987.

Results

The updated `was.policy` file is applied to the application after the application restarts.

Example

```
java.security.AccessControlException: access denied (java.io.FilePermission
${was.install.root}/java/ext/mail.jar read)
```

If an application must access a specific resource that is not defined as a default in the `java.policy` file, the `server.policy` file, and the `app.policy`, delete the `was.policy` file for that application. The symptom of the missing permission is the `java.security.AccessControlException` exception. The missing permission is listed in the exception data:

Note: Examples that appear below are split into several lines for illustration only. You actually enter the permission on one line.

```
java.security.AccessControlException: access denied (java.io.FilePermission
${was.install.root}/java/ext/mail.jar read)
```

When a Java program receives this exception and adding this permission is justified, add the following permission to the `was.policy` file:

```
grant codeBase "file:user_client_installed_location" {
    permission java.io.FilePermission
"${was.install.root}/${}/java${}/jre${}/lib${}/ext${}/mail.jar", "read";
};
```

To determine whether to add a permission, see [Access control exception for Java 2 security](#).

What to do next

Restart all applications for the updated `app.policy` file to take effect.

spi.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

For the list of available policy files that are supported by WebSphere Application Server Version 6.0.x, see Java 2 security policy files.

Because the default permission for the Service Provider Interface (SPI) is the AllPermission permission, the only reason to update the `spi.policy` file is a restricted SPI permission. When a change in the `spi.policy` is required, complete the following steps.

Syntax errors in the policy files cause the application server to fail. Edit these policy files carefully.

Important: Do not place the `codebase` keyword or any other keyword after the `filterMask` and `runtimeFilterMask` keywords. The `Signed By` and the Java Authentication and Authorization Service (JAAS) `Principal` keywords are not supported in the `spi.policy` file. The `Signed By` keyword is supported in the `java.policy`, `server.policy`, and `client.policy` policy files. The JAAS `Principal` keyword is supported in a JAAS policy file that is specified by the `java.security.auth.policy` Java virtual machine (JVM) system property. You can statically set the authorization policy files in `java.security.auth.policy` with `auth.policy.url.n=URL`, where `URL` is the location of the authorization policy.

To extract the `filter.policy` file, enter the following command using information from your environment:

```
set obj [$AdminConfig extract profiles/profile_name/cells/cell_name/nodes/node_name/spi.policy
/tmp/test/spi.policy]
```

Edit the file using the Policy Tool. For more information, see “Using PolicyTool to edit policy files for Java 2 security” on page 987.

To check in the policy file, enter the following command using information from your environment:

The updated `spi.policy` is applied to the Service Provider Interface (SPI) libraries after the Java process is restarted.

```
$AdminConfig checkin profiles/profile_name/cells/cell_name/nodes/node_name/spi.policy
/tmp/test/spi.policy $obj
```

Examples

The `spi.policy` file is the template for SPIs or third-party resources embedded in the product. Examples of SPIs are Java Message Services (JMS) (MQSeries) and Java database connectivity (JDBC) drivers. They are specified in the `resources.xml` file. The dynamic policy grants the permissions that are defined in the `spi.policy` file to the class paths defined in the `resources.xml` file. The union of the permission that is contained in the `java.policy` file and the `spi.policy` file are applied to the SPI libraries. The `spi.policy` files are managed by configuration and file replication services.

You can find the `spi.policy` file that is supplied by WebSphere Application Server in the following location: `profile_root/config/cells/cell_name/nodes/node_name/spi.policy`. It contains the following default permission:

```
grant {
    permission java.security.AllPermission;
};
```

Restart the related Java processes for the changes in the `spi.policy` file to become effective.

library.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

For the list of available policy files that are supported by WebSphere Application Server, see Java 2 security policy files.

The `library.policy` file is the template for shared libraries (Java library classes). Multiple enterprise applications can define and use shared libraries. Refer to *Managing shared libraries* for information on how to define and manage the shared libraries.

If the default permissions for a shared library (union of the permissions defined in the `java.policy` file, the `app.policy` file and the `library.policy` file) are enough, no action is required. The default library policy is picked up automatically. If a specific change is required to share a library in the cell, update the `library.policy` file.

Syntax errors in the policy files cause the application server to fail. Edit these policy files carefully.

Important: Do not place the `codebase` keyword or any other keyword after the `grant` keyword. The `Signed By` keyword and the Java Authentication and Authorization Service (JAAS) `Principal` keyword are not supported in the `library.policy` file. The `Signed By` keyword is supported in the `java.policy`, the `server.policy`, and the `client.policy` policy files. The JAAS `Principal` keyword is supported in a JAAS policy file when it is specified by the Java virtual machine (JVM) system property, `java.security.auth.policy`. You can statically set the authorization policy files in the `java.security.auth.policy` file with `auth.policy.url.n=URL` where `URL` is the location of the authorization policy.

To extract the policy file, use a command prompt to enter the following command using the appropriate variable values for your environment: The previous two lines were split onto two lines for illustrative purposes only.

```
wsadmin> set obj [$AdminConfig extract cells/cell_name/nodes/  
node_name/library.policy /temp/test/library.policy]
```

Edit the extracted `library.policy` file with the Policy Tool. For more information, see “Using PolicyTool to edit policy files for Java 2 security” on page 987.

To check in the policy file, use a command prompt to enter the following command using the appropriate variable values for your environment: An updated `library.policy` is applied to shared libraries after the servers restart.

```
wsadmin> $AdminConfig checkin cells/cell_name/nodes/node_name/library.policy  
temp/test/library.policy $obj
```

Example

The union of the permission that is contained in the `java.policy` file, the `app.policy` file, and the `library.policy` file are applied to the shared libraries. The `library.policy` file is managed by configuration and file replication services.

The `library.policy` file supplied by WebSphere Application Server resides in the `profile_root/config/cells/cell_name/nodes/node_name/` directory. The file contains an empty permission entry as a default. For example:

```
grant {  
};
```

If the shared library in a cell requires permissions that are not defined as defaults in the `java.policy` file, the `app.policy` file and the `library.policy` file, update the `library.policy` file. The missing permission causes the `java.security.AccessControlException` exception. The missing permission is listed in the exception data.

For example:

```
java.security.AccessControlException: access denied (java.io.FilePermission
app_server_rootBase/lib/mail-impl.jar read)
```

The previous lines are split into two lines for illustrative purposes only.

When a Java program receives this exception and adding this permission is justified, add a permission to the `library.policy` file.

For example:

```
grant codeBase "file:user_client_installed_location" { permission
java.io.FilePermission "app_server_rootBase/lib/mail-impl.jar", "read"; };
```

The previous lines are split into two lines for illustrative purposes only

To decide whether to add a permission, refer to *Access control exception for Java 2 security*.

Restart the related Java processes for the changes in the `library.policy` file to become effective.

Adding the was.policy file to applications for Java 2 security:

An application might need a `was.policy` file if it accesses resources that require more permissions than those granted in the default `app.policy` file.

About this task

When Java 2 security is enabled for a WebSphere Application Server, all the applications that run on WebSphere Application Server undergo a security check before accessing system resources. An application might need a `was.policy` file if it accesses resources that require more permissions than those granted in the default `app.policy` file. By default, the product security reads an `app.policy` file that is located in each node and grants the permissions in the `app.policy` file to all the applications. Include any additional required permissions in the `was.policy` file. The `was.policy` file is only required if an application requires additional permissions.

The default policy file for all applications is specified in the `app.policy` file. This file is provided by the product security, is common to all applications, and you do not change this file. Add any new permissions that are required for an application in the `was.policy` file.

The `app.policy` file supplied by WebSphere Application Server resides at `app_server_root/config/cells/profile/profile_name/config/cell_name/nodes/node_name/app.policy`. The contents of the `app.policy` file are presented in the following example:

Attention: In the following code sample, the two permissions that are required by JavaMail are split onto two lines for illustration only. You actually enter the permission on one line.

```
// The following permissions apply to all the components under the application.
```

```
grant codeBase "file:${application}" {
    // The following are required by JavaMail

    permission java.io.FilePermission "
        ${was.install.root}${/}lib${/}activation-impl.jar",
    "read";

    permission java.io.FilePermission "
        ${was.install.root}${/}lib${/}mail-impl.jar", "read";
```

```

};
// The following permissions apply to all utility .jar files (other
// than enterprise beans JAR files) in the application.
grant codeBase "file:${jars}" {
    permission java.net.SocketPermission "*", "connect";
    permission java.util.PropertyPermission "*", "read";
};

// The following permissions apply to connector resources within the application
grant codeBase "file:${connectorComponent}" {
    permission java.net.SocketPermission "*", "connect";
    permission java.util.PropertyPermission "*", "read";
};

// The following permissions apply to all the web modules (.war files)
// within the application.
grant codeBase "file:${webComponent}" {
    permission java.io.FilePermission "${was.module.path}${/}-", "read, write";
    // where "was.module.path" is the path where the web module is
    // installed. Refer to Dynamic policy concepts for other symbols.
    permission java.lang.RuntimePermission "loadLibrary.*";
    permission java.lang.RuntimePermission "queuePrintJob";
    permission java.net.SocketPermission "*", "connect";
    permission java.util.PropertyPermission "*", "read";
};

// The following permissions apply to all the EJB modules within the application.
grant codeBase "file:${ejbComponent}" {
    permission java.lang.RuntimePermission "queuePrintJob";
    permission java.net.SocketPermission "*", "connect";
    permission java.util.PropertyPermission "*", "read";
};

```

If additional permissions are required for an application or for one or more modules of an application, use the `was.policy` file for that application. For example, use `codeBase` of `${application}` and add required permissions to grant additional permissions to the entire application. Similarly, use `codeBase` of `${webComponent}` and `${ejbComponent}` to grant additional permissions to all the web modules and all the enterprise bean modules in the application. You can assign additional permissions to each module (.war file or .jar file), as shown in the following example.

This example illustrates adding extra permissions for an application in the `was.policy` file:

Attention: In the following code sample, the permission for the EJB module was split onto two lines for illustration only. You actually enter the permission on one line.

```

// grant additional permissions to a web module
grant codeBase " file:aWebModule.war" {
    permission java.security.SecurityPermission "printIdentity";
};

// grant additional permission to an EJB module
grant codeBase "file:aEJBModule.jar" {
    permission java.io.FilePermission
        "${user.install.root}${/}bin${/}DefaultDB${/}-", "read,write,delete";
    // where, ${user.install.root} is the system property whose value is
    // located in the app_server_root directory.
};

```

To use a `was.policy` file for your application, perform the following steps:

Procedure

1. Create a `was.policy` file using the policy tool. For more information on using the policy tool, see “Using PolicyTool to edit policy files for Java 2 security” on page 987.
2. Add the required permissions in the `was.policy` file using the policy tool.
3. Place the `was.policy` file in the application enterprise archive (EAR) file under the `META-INF` directory. Update the application EAR file with the newly created `was.policy` file by using the `jar` command.
4. Verify that the `was.policy` file is inserted and start an assembly tool.

Note: An assembly tool is not available. Use an assembly tool on another platform such as Linux Intel or Windows.

5. Verify that the `was.policy` file in the application is syntactically correct. In an assembly tool, right-click the enterprise application module and click **Run Validation**.

Results

An application EAR file is now ready to run when Java 2 security is enabled.

Example

This step is required for applications to run properly when Java 2 security is enabled. If the `was.policy` file is not created and it does not contain required permissions, the application might not access system resources.

The symptom of the missing permissions is the `java.security.AccessControlException` exception. The missing permission is listed in the exception data, for example,

```
java.security.AccessControlException: access denied (java.io.FilePermission
${was.install.root}/java/ext/mail.jar read)
```

When an application program receives this exception and adding this permission is justified, include the permission in the `was.policy` file, for example,

```
grant codeBase "file:user_client_installed_location" {
    permission java.io.FilePermission
"${was.install.root}/${}/java/${}/jre/${}/lib/${}/ext/${}/mail.jar", "read";
};
```

The previous permission information lines are split for the illustration. Enter the permission on one line.

What to do next

Install the application.

Configuring static policy files in Java 2 security:

By configuring the static policy files, the required permission will be granted for all of the Java programs.

Before you begin

Java 2 security uses several policy files to determine the granted permission for each Java program.

See the topic about Java 2 security policy files for the list of available policy files that are supported by WebSphere Application Server.

Two types of policy files are supported by WebSphere Application Server: dynamic policy files and static policy files. Static policy files provide the default permissions. Dynamic policy files provide application permissions.

Table 106. Policy Files. This table lists the policy files.

Policy file name	Description
<code>java.policy</code>	Contains default permissions for all of the Java programs on the node. This file seldom changes.
<code>server.policy</code>	Contains default permissions for all of the WebSphere Application Server programs on the node. This file is rarely updated.
<code>client.policy</code>	Contains default permissions for all of the applets and client containers on the node.

The static policy file is not a configuration file that is managed by the repository and the file replication service. Changes to this file are local and do not get replicated to the other machine.

Procedure

1. Identify the policy file to update.
 - If the permission is required only by an application, update the dynamic policy file. Refer to “Configuring Java 2 security policy files” on page 988.

- If the permission is required only by applets and client containers, update the `client.policy` file. Refer to “client.policy file permissions” on page 1004.
- If the permission is required only by WebSphere Application Server (servers, agents, managers and application servers), update the `server.policy` file. Refer to “server.policy file permissions.”
- If the permission is required by all of the Java programs running on the Java virtual machine (JVM), update the `java.policy` file. Refer to “java.policy file permissions.”

2. Stop and restart WebSphere Application Server.

Results

The required permission is granted for all of the Java programs that run with the restarted JVM.

Example

If Java programs on a node require permissions, the policy file needs updating. If the Java program that required the permission is not part of an enterprise application, update the static policy file. The missing permission results in the creation of the `java.security.AccessControlException` exception. The missing permission is listed in the exception data.

For example:

```
java.security.AccessControlException: access denied (java.io.FilePermission
app_server_root/lib/mail-impl.jar read)
```

When a Java program receives this exception and adding this permission is justified, add a permission to an adequate policy file.

For example:

```
grant codeBase "file:user_client_installed_location" {
  permission java.io.FilePermission
    "app_server_root/Base/lib/mail-impl.jar",
    "read";
};
```

To decide whether to add a permission, refer to Access control exception for Java 2 security.

java.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

See Java 2 security policy files for the list of available policy files that are supported by WebSphere Application Server.

For IBM Technology for Java, the `java.policy` file is located in the `java_home/jre/lib/security` directory. For all JVMs, the `java.policy` file is used system-wide. Do not edit the `java.policy` file on the server.

Use the `showVariables` command of the `AdminTask` object to retrieve `java_home` for the node associated with the server's profile. For example, if the node is `myNode`:

1. Enter **QShell**.
2. `cd` to `profile_root/bin`.
3. Invoke `wsadmin -conntype NONE -c '$AdminTask showVariables {-scope Node=myNode -variableName JAVA_HOME}'`.

server.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

See Java 2 security policy files for the list of available policy files that are supported by WebSphere Application Server.

The `server.policy` file is a default policy file that is shared by all of the WebSphere Application Servers on a node. The `server.policy` file is not a configuration file that is managed by the repository and the file replication service. Changes to this file are local and do not replicate to the other machine.

If the default permissions for a server (the union of the permissions that is defined in the `java.policy` file and the `server.policy` file) are enough, no action is required. The default server policy is picked up automatically. If a specific change is required to some of the server programs on a node, update the `server.policy` file with the Policy Tool. Refer to the “Using PolicyTool to edit policy files for Java 2 security” on page 987 topic to edit policy files. Changes to the `server.policy` file are local for the node. Syntax errors in the policy files cause the application server to fail. Edit these policy files carefully. An updated `server.policy` file is applied to all the server programs on the local node. Restart the servers for the updates to take effect.

If you want to add permissions to an application, use the `app.policy` file and the `was.policy` file.

Note: Updates to the `app.policy` file only apply to the enterprise applications on the node to which the `app.policy` file belongs.

When you do need to modify the `server.policy` file, locate this file at: *profile_root/properties/server.policy*. This file contains these default permissions:

```
// Allow to use sun tools
grant codeBase "file:${java.home}/../lib/tools.jar" {
permission java.security.AllPermission;
};

// Allow to use ibm jdk extensions
grant codeBase "file:${was.install.root}/java/ext/-" {
permission java.security.AllPermission;
};

// Allow to use additional ibm jdk extensions with j9
grant codeBase "file:${was.install.root}/java/extj9/-" {
permission java.security.AllPermission;
};

// Allow to use sun and ibm tools
grant codeBase "file:${was.install.root}/java/tools/-" {
permission java.security.AllPermission;
};

// WebSphere system classes
grant codeBase "file:${was.install.root}/plugins/-" {
permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/lib/-" {
permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/classes/-" {
permission java.security.AllPermission;
};

// Allow the WebSphere deploy tool all permissions
grant codeBase "file:${was.install.root}/deploytool/-" {
permission java.security.AllPermission;
};

// Allow the WebSphere deploy tool all permissions
grant codeBase "file:${was.install.root}/optionalLibraries/-" {
permission java.security.AllPermission;
};

// Allow Channel Framework classes all permission
```

```

grant codeBase "file:${was.install.root}/installedChannels/-" {
permission java.security.AllPermission;
};

grant codeBase "file:${was.install.root}/util/-" {
permission java.security.AllPermission;
};

grant codeBase "file:${user.install.root}/lib/-" {
permission java.security.AllPermission;
};

grant codeBase "file:${user.install.root}/classes/-" {
permission java.security.AllPermission;
};

```

If some server programs on a node require permissions that are not defined as defaults in the `server.policy` file and the `server.policy` file, update the `server.policy` file. The missing permission creates the `java.security.AccessControlException` exception. The missing permission is listed in the exception data.

For example:

```

java.security.AccessControlException: access denied (java.io.FilePermission
app_server_rootBase/lib/mail-impl.jar read)

```

The previous two lines are split into two lines for illustrative purposes only.

When a Java program receives this exception and adding this permission is justified, add a permission to the `server.policy` file.

For example:

```

grant codeBase "file:user_client_installed_location" {
permission java.io.FilePermission
"app_server_root/Base/lib/mail-impl.jar", "read"; };

```

To decide whether to add a permission, refer to Access control exception for Java 2 security.

Restart all of the Java processes for the updated `server.policy` file to take effect.

client.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

For the list of available policy files that are supported by WebSphere Application Server, see Java 2 security policy files.

- The `client.policy` file is a default policy file that is shared by all of the WebSphere Application Server client containers and applets on a node.
- The union of the permissions that is contained in the `java.policy` file and the `client.policy` file are given to all of the client containers for WebSphere Application Server and applets running on the node.
- The `client.policy` file is not a configuration file that is managed by the repository and the file replication service. Changes to this file are local and do not replicate to the other machine.
- The `client.policy` file supplied by WebSphere Application Server is located in the `profile_root/properties/client.policy`.
- If the default permissions for a client (union of the permissions defined in the `java.policy` file and the `client.policy` file) are enough, no action is required. The default client policy is picked up automatically.
- If a specific change is required to some of the client containers and applets on a node, modify the `client.policy` file with the Policy Tool. Refer to “Using PolicyTool to edit policy files for Java 2 security” on page 987, to edit policy files. Changes to the `client.policy` file are local for the node.

This file contains these default permissions:

```
grant codeBase "file:${was.install.root}/java/ext/*" {
    permission java.security.AllPermission;
};

// JDK classes
grant codeBase "file:${was.install.root}/java/ext/-" {
    permission java.security.AllPermission;
};

// Allow to use additional ibm jdk extensions with j9
grant codeBase "file:${was.install.root}/java/extj9/-" {
    permission java.security.AllPermission;
};

// Allow to use sun and ibm tools
grant codeBase "file:${was.install.root}/java/tools/-" {
    permission java.security.AllPermission;
};

// WebSphere system classes
grant codeBase "file:${was.install.root}/lib/-" {
    permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/plugins/-" {
    permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/classes/-" {
    permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/installedConnectors/-" {
    permission java.security.AllPermission;
};
grant codeBase "file:${user.install.root}/installedConnectors/-" {
    permission java.security.AllPermission;
};

grant codeBase "file:${was.install.root}/installedChannels/-" {
    permission java.security.AllPermission;
};

grant codeBase "file:${was.install.root}/util/-" {
    permission java.security.AllPermission;
};

grant codeBase "file:${user.install.root}/lib/-" {
    permission java.security.AllPermission;
};

grant codeBase "file:${user.install.root}/classes/-" {
    permission java.security.AllPermission;
};

// J2EE 1.4 permissions for client container WAS applications in $WAS_HOME/installedApps
grant codeBase "file:${user.install.root}/installedApps/-" {
    //Application client permissions
    permission java.awt.AWTPermission "accessClipboard";
    permission java.awt.AWTPermission "accessEventQueue";
    permission java.awt.AWTPermission "showWindowWithoutWarningBanner";
    permission java.lang.RuntimePermission "exitVM";
    permission java.lang.RuntimePermission "loadLibrary";
    permission java.lang.RuntimePermission "queuePrintJob";
    permission java.net.SocketPermission "*", "connect";
    permission java.net.SocketPermission "localhost:1024-", "accept,listen";
    permission java.io.FilePermission "*", "read,write";
    permission java.util.PropertyPermission "*", "read";
};

// J2EE 1.4 permissions for client container - expanded ear file code base
grant codeBase "file:${com.ibm.websphere.client.applicationclient.archivedir}/-" {
    permission java.awt.AWTPermission "accessClipboard";
    permission java.awt.AWTPermission "accessEventQueue";
    permission java.awt.AWTPermission "showWindowWithoutWarningBanner";
    permission java.lang.RuntimePermission "exitVM";
    permission java.lang.RuntimePermission "loadLibrary";
    permission java.lang.RuntimePermission "queuePrintJob";
    permission java.net.SocketPermission "*", "connect";
    permission java.net.SocketPermission "localhost:1024-", "accept,listen";
    permission java.io.FilePermission "*", "read,write";
    permission java.util.PropertyPermission "*", "read";
};
```

All of the client containers and applets on the local node are granted the updated permissions when they start. If some client containers or applets on a node require permissions that are not defined as defaults in

the `java.policy` file and the default `client.policy` file, update the `client.policy` file. The missing permission creates the `java.security.AccessControlException` exception. The missing permission is listed in the exception data, for example,

```
java.security.AccessControlException: access denied (java.io.FilePermission
app_server_root/Base/lib/mail-impl.jar read)
```

The previous two lines of sample code are one continuous line, but presented as such for illustrative purposes only.

When a client program receives this exception and adding this permission is justified, add a permission to the `client.policy` file, for example, grant codebase `"file:user_client_installed_location" { permission java.io.FilePermission "app_server_root/lib/mail-impl.jar", "read"; }`.

To decide whether to add a permission, refer to [Access control exception for Java 2 security](#).

If you update the policy file, you must restart the browser and any client applications.

Developing with programmatic security APIs for web applications

Use this information to programmatically secure APIs for web applications.

Before you begin

Programmatic security is used by security-aware applications when declarative security alone is not sufficient to express the security model of the application.

The `authenticate`, `login`, `logout`, `getRemoteUser`, `isUserInRole` and `getAuthType` servlet security methods are methods of the `javax.servlet.http.HttpServletRequest` interface. For more detailed information about these servlet security methods, read the [Servlet security methods](#) article.

Note:

The `logout`, `login`, and `authenticate` APIs are new for Java Servlet 3.0 in this release of WebSphere Application Server.

You can configure several options for web authentication that determine how the web client interacts with protected and unprotected Uniform Resource Identifiers (URI). Also, you can specify whether WebSphere Application Server challenges the web client for basic authentication information if the certificate authentication for the HTTPS client fails. For more information, see the [Selecting an authentication mechanism](#) article.

When the `isUserInRole` method is used, declare a `security-role-ref` element in the deployment descriptor with a `role-name` subelement containing the role name that is passed to this method, or use the `@DeclareRoles` annotation. Because actual roles are created during the assembly stage of the application, you can use a logical role as the role name and provide enough hints to the assembler in the description of the `security-role-ref` element to link that role to the actual role. During assembly, the assembler creates a `role-link` subelement to link the role name to the actual role. Creation of a `security-role-ref` element is possible if an assembly tool, such as Rational Application Developer, is used. You also can create the `security-role-ref` element during assembly stage using an assembly tool.

Procedure

1. Add the required security methods in the servlet code.
2. Create a `security-role-ref` element with the **role-name** field. If a `security-role-ref` element is not created during development, make sure it is created during the assembly stage.

Results

A programmatically secured servlet application.

Example

These steps are required to secure an application programmatically. This action is particularly useful when a web application needs to access external resources and wants to control the access to external resources using its own authorization table (external-resource to remote-user mapping). In this case, use the `getUserPrincipal` or the `getRemoteUser` methods to get the remote user, then the application can consult its own authorization table to perform authorization. The remote user information also can help retrieve the corresponding user information from an external source such as a database or from an enterprise bean. You can use the `isUserInRole` method in a similar way.

After development, you can create a `security-role-ref` element:

```
<security-role-ref>
  <description>Provide hints to assembler for linking this role
    name to an actual role here</description>
  <role-name>Mgr</role-name>
</security-role-ref>
```

During assembly, the assembler creates a `role-link` element:

```
<security-role-ref>
  <description>Hints provided by developer to map the role
    name to the role-link</description>
  <role-name>Mgr</role-name>
  <role-link>Manager</role-link>
</security-role-ref>
```

You can add programmatic servlet security methods inside any servlet `doGet`, `doPost`, `doPut`, and `doDelete` service methods. The following example depicts using a programmatic security API:

```
public void doGet(HttpServletRequest request,
  HttpServletResponse response) {

  ....
  // to logoff the current user
  request.logout();

  // to login with a new user
  request.login("bob","bobpwd")

  // to get remote user using getUserPrincipal()
  java.security.Principal principal = request.getUserPrincipal();
  String remoteUser = principal.getName();

  // to get remote user using getRemoteUser()
  remoteUser = request.getRemoteUser();

  // to check if remote user is granted Mgr role
  boolean isMgr = request.isUserInRole("Mgr");

  // use the above information in any way as needed by
  // the application
  ....
}
```

You can programmatic login with a user ID and password inside any servlet `doGet`, `doPost`, `doPut`, and `doDelete` service methods. The following example depicts using a programmatic login/logout API:

```
public void doGet(HttpServletRequest request,
  HttpServletResponse response) {

  ....
  // to logout the current user. If you are not already authenticate, then no need to call the logout() method.
  request.logout();

  // to login with a new user
  request.login("utle","mypwd")
}
```

```

// the user utle subject now set on the thread and the LTPA SSO cookie is set in the response
....
}

```

You can programmatic authenticate with a different identity inside any servlet doGet, doPost, doPut, and doDelete service methods. In this example, if the web servlet is configured to use basicAuth, the web server returns a response code 401, the login prompt is displayed, and you can enter the user ID and password to authenticate. The following example depicts using a programmatic login/logout API:

```

public void doGet(HttpServletRequest request,
HttpServletRequest response) {

    ....
    // to logout the current user. If you are not already authenticate, then no need to call the logout() method.

    // to login with a new user
    request.authenticate(response);

    // the new user subject now set on the thread and the LTPA SSO cookie is set in the response
    ....
}

```

When developing Servlet 3.0 modules, the value of the rolename argument in isCallerInRole method can be defined using Java annotations instead of declaring a security-role-ref elements in the deployment descriptor.

```

@javax.annotation.security.DeclareRoles("Mgr")
public void doGet(HttpServletRequest request,
HttpServletRequest response) {

    ....

    // to get remote user using getUserPrincipal()
    java.security.Principal principal = request.getUserPrincipal();
    String remoteUser = principal.getName();

    // to get remote user using getRemoteUser()
    remoteUser = request.getRemoteUser();

    // to check if remote user is granted Mgr role
    boolean isMgr = request.isUserInRole("Mgr");

    // use the above information in any way as needed by
    // the application
    ....
}

```

The following example depicts a web application or servlet using the programmatic security model.

This example illustrates one use and not necessarily the only use of the programmatic security model. The application can use the information that is returned by the getUserPrincipal, isUserInRole, and the getRemoteUser methods in any other way that is meaningful to that application. Use the declarative security model whenever possible.

File : HelloServlet.java

```

public class HelloServlet extends javax.servlet.http.HttpServlet {

    public void doPost(
        javax.servlet.http.HttpServletRequest request,
        javax.servlet.http.HttpServletResponse response)
        throws javax.servlet.ServletException, java.io.IOException {
    }

    public void doGet(
        javax.servlet.http.HttpServletRequest request,
        javax.servlet.http.HttpServletResponse response)
        throws javax.servlet.ServletException, java.io.IOException {

        String s = "Hello";

        // get remote user using getUserPrincipal()
        java.security.Principal principal = request.getUserPrincipal();
        String remoteUserName = "";
        if( principal != null )
            remoteUserName = principal.getName();
        // get remote user using getRemoteUser()
    }
}

```

```

String remoteUser = request.getRemoteUser();

// check if remote user is granted Mgr role
boolean isMgr = request.isUserInRole("Mgr");

// display Hello username for managers and bob.
if ( isMgr || remoteUserName.equals("bob") )
    s = "Hello " + remoteUserName;

String message = "<html> \n" +
    "<head><title>Hello Servlet</title></head>\n" +
    "<body> /n" +
    "<h1> " + s + </h1>/n " +
byte[] bytes = message.getBytes();

// displays "Hello" for ordinary users
// and displays "Hello username" for managers and "bob".
response.getOutputStream().write(bytes);
}
}

```

After developing the servlet, you can create a security role reference for the HelloServlet servlet as shown in the following example:

```

<security-role-ref>
  <description> </description>
  <role-name>Mgr</role-name>
</security-role-ref>

```

What to do next

After developing an application, use an assembly tool to create roles and to link the actual roles to role names in the security-role-ref elements. See the information about securing web applications using an assembly tool.

Servlet security methods:

The authenticate, login, logout, getRemoteUser, isUserInRole and getAuthType servlet security methods are methods of the javax.servlet.http.HttpServletRequest interface.

authenticate

Note: The authenticate, login and logout servlet security methods are new for Java Servlet 3.0 in this release of WebSphere Application Server.

The authenticate method authenticates a user by using the WebSphere Application Server container login mechanism configured for the servlet context.

The syntax of the authenticate method is as follows:

```
boolean authenticate(HttpServletRequest response)
```

The previous example uses the following element:

response

The HttpServletResponse associated with the HttpServletRequest.

The authenticate method returns true when authentication has been established or authentication is successful.

The authenticate method returns false if authentication is incomplete and the underlying login mechanism has committed, in the response, the message and HTTP status code to be returned to the user.

A java.io.IOException occurs if an error occurs while writing the response.

A `ServletException` occurs if the authentication failed, and the caller is responsible for handling the error (for example, the underlying login mechanism did not establish the message and the HTTP status code to be returned to the user).

Note: When the `authenticate` method is called, be aware of the following:

- WebSphere Application Server returns HTTP 401 code to a client.
- The method depends on the WebSphere Application Server container login mechanism that is configured for the servlet context. For example, if you have a form login defined for this servlet, it prompts for a user name and password. The client sends the user ID and password to WebSphere Application Server for authentication.

Important: Make sure that the `authenticate` method returns `true` before using the new subject to call another service. For example:

```
Boolean authResultTrue = req.authenticate(response);
if (!authResultTrue) {
    return;
} else {
    // Use the new invocation subject to call other services.
}
```

login

The `login` method authenticates a user to the WebSphere Application Server with a user ID and password. If authentication is successful, it creates a user subject on the thread and Lightweight Third Party Authentication (LTPA) cookies (if single sign-on (SSO) is enabled).

The syntax of the `login` method is as follows:

```
login(java.lang.String username, java.lang.String password)
```

The previous example uses the following elements:

username

The string value that corresponds to the login identifier of the user.

password

The password of the user.

A `ServletException` occurs if the configured login mechanism does not support username and password authentication, if an identity had already been authenticated (prior to the call to `login`), or if validation of the provided username and password fails.

Note: You can set the security custom property `com.ibm.websphere.security.webAlwaysLogin` to `true` and it will authenticate to the WebSphere application with the username and password, even if it is already authenticated.

For more information about modifying security custom properties, read the [Modifying an existing custom property in a global security configuration or in a security domain configuration](#) article.

Note: The `login` method always uses the user ID and password to authenticate to the WebSphere application server and even the SSO information that is present in the `HttpServletRequest`.

Note: The `authenticate` and `login` methods set the invocation subject to the new subject. If the caller subject is null, it then sets the caller subject to the new subject. If the caller subject is not null, then the caller subject is not set to the new subject.

Since the `authenticate` and `login` methods set the invocation subject to the new subject, the `RunAs` defined by the `run-As` attribute in deployment descriptor, security annotation or dynamic annotation is ignored.

logout

The logout method logs the user out of the WebSphere Application Server and invalidates the HTTP session. During this process, WebSphere Application Server completes the following processes:

- Clears the LTPA cookies if SSO is enabled
- Invalidates the HTTP session
- Removes the user from the authentication cache
- Removes the user subject from the thread
- Clears the caller and invocation subjects
- Sets the authentication type to null

After logging out, access to a protected web resource requires re-authentication and the `getUserPrincipal`, `getRemoteUser` and `getAuthType` methods return null.

The syntax of the logout method is as follows:

```
logout()
```

A `ServletException` occurs if the logout fails.

Audit event types for the authenticate, login and logout methods

To audit `authenticate`, `login` and `logout` methods, you must create or extend some audit event type files. These event type are not part of the default event type files.

Table 107. Audit event types for the authenticate, login, and logout methods.

The audit event types required for the authenticate, login, and logout methods are:

Method	Audit event name	Audit outcome of the event
authenticate/login	SECURITY_AUTHN	SUCCESS and or FAILURE
logout	SECURITY_AUTHN_TERMINATE	SUCCESS
logout	SECURITY_AUTHN_TERMINATE	FAILURE

isUserInRole

(String role name): Returns true if the remote user is granted the specified security role. If the remote user is not granted the specified role, or if no user is authenticated, it returns false.

getRemoteUser

The `getRemoteUser` method returns the login of the user that makes the request if the user has been authenticated. If the user has not been authenticated, the `getRemoteUser` method returns null.

getAuthType

The `getAuthType` method returns the name of the authentication scheme that is used to protect the servlet. If the servlet is not protected, the `getAuthType` method returns null.

The authentication schemes used are:

FORM when form-based authentication is used

BASIC

when basic authentication is used.

CLIENT_CERT

when client certificate authentication is used.

Note:

For both the `getRemoteUser` and `getAuthType` methods, the data that is returned depends upon whether security is enabled in the application server where the servlet is deployed. The following possibilities exist:

- If application security is enabled and a servlet is protected, then the `getRemoteUser` method returns the login and the `getAuthType` method returns the configured authentication scheme.
- If application security is not enabled, both methods return `null`.

Web authentication settings:

Use this page to specify the web authentication settings that are associated with a web client.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under Authentication, expand **Web and SIP security** and click **General settings**.

You can override the global Web authentication settings that you select on this panel by specifying one or more of the following system properties on the server level. Complete the following steps to specify one of these system properties:

1. Click **Servers > Application servers > server_name**.
2. Under Server infrastructure, click **Java and Process Management > Process definition**.
3. Under Additional properties, click **Java Virtual Machine > Custom properties > New**

Table 108. Web authentication system property values. This table lists the web authentication system property values.

Property name	Value	Explanation
<code>com.ibm.wsspi.security.web.webAuthReq</code>	<code>lazy</code>	This value is equivalent to the Authenticate only when the URI is protected option. Note: You can set <code>webAuthReq</code> differently through the administrative console or scripting when using a global or a security domain, but the global level always takes precedence.
<code>com.ibm.wsspi.security.web.webAuthReq</code>	<code>persisting</code>	This value is equivalent to the Use available authentication data when an unprotected URI is accessed option.
<code>com.ibm.wsspi.security.web.webAuthReq</code>	<code>always</code>	This value is equivalent to the Authenticate when any URI is accessed option.
<code>com.ibm.wsspi.security.web.failOverToBasicAuth</code>	<code>true</code>	This value is equivalent to the Default to basic authentication when certificate authentication for the HTTPS client fails option.

Authenticate only when the URI is protected:

The application server challenges the web client to provide authentication data when the web client accesses a Uniform Resource Identifier (URI) that is protected by a Java 2 Platform, Enterprise Edition (J2EE) role. The authenticated identity is available only when the web client accesses a protected URI.

This option is the default J2EE web authentication behavior that is also available in previous releases of WebSphere Application Server.

Note: When you select this option, the administrative console login page is missing images. You might encounter the following error in the administrative console: "CWLAA6003: Could not display the portlet, the portlet may not be started. Check the error logs".

The missing images and the error message are a side-effect of this option. The images do not display because the URIs for the images now need authentication, which requires you to log in. You can ignore this error message.

Default: Enabled

Use available authentication data when an unprotected URI is accessed:

The web client can access validated authenticated data that it previously could not access. This option enables the web client to call the `getRemoteUser`, `isUserInRole`, and `getUserPrincipal` methods to retrieve an authenticated identity from an unprotected URI.

When you select this option with the **Authenticate only when the URI is protected** option, the web client can use authenticated data when the URI is protected or not protected.

When this option is selected and Form-based authentication is being used, a `WASPostParam` cookie is generated during the authentication procedure of the HTTP POST request even if the target URL is unprotected. A `WASPOSTParam` cookie is a temporary cookie used to store HTTP POST parameters. This results in the Web client being sent the unnecessary cookie with an HTTP response. This might cause unexpected behavior when the size of the cookie is larger than the browser limit. To avoid this behavior, a custom property, `com.ibm.websphere.security.util.postParamMaxCookieSize` can be set to cause the security code to stop generating the cookie if the maximum size is reached.

Important: This option does not challenge the web client to provide authenticated data if the web client accesses an unprotected URI without authenticated data.

Default: Enabled

Authenticate when any URI is accessed:

The web client must provide authentication data regardless of whether the URI is protected.

Default: Disabled

Default to basic authentication when certificate authentication for the HTTPS client fails:

When the required HTTPS client certificate authentication fails, the application server uses the basic authentication method to challenge the web client to provide a user ID and password.

The HTTP client certification authentication that is performed by the application server security is different from the client authentication that is performed by the web server plug-in. If you configure the web server plug-in for mutual authentication and client authentication fails, the following situations will occur:

- The web server produces a error and the web request is not processed by application server security.
- The application server cannot fail over to basic authentication.

Default: Disabled

Developing with programmatic APIs for EJB applications

Use this topic to programmatically secure your Enterprise JavaBeans (EJB) applications.

About this task

Programmatic security is used by security-aware applications when declarative security alone is not sufficient to express the security model of the application. The `javax.ejb.EJBContext` application programming interface (API) provides two methods whereby the bean provider can access security information about the enterprise bean caller.

- **isCallerInRole**(String rolename): Returns true if the bean caller is granted the security role that is specified by role name. If the caller is not granted the specified role, or if the caller is not authenticated, it returns false. If the specified role is granted Everyone access, it always returns true.
- **getCallerPrincipal**: Returns the `java.security.Principal` object that contains the bean caller name. If the caller is not authenticated, it returns a principal that contains an unauthorized name.

You can enable a login module to indicate which principal class is returned by these calls.

When the `isCallerInRole` method is used, declare a `security-role-ref` element in the deployment descriptor with a `role-name` that is subelement containing the role name that is passed to this method. Because actual roles are created during the assembly stage of the application, you can use a logical role as the role name and provide enough hints to the assembler in the description of the `security-role-ref` element to link that role to an actual role. During assembly, the assembler creates a `role-link` subelement to link the `role-name` to the actual role. Creation of a `security-role-ref` element is possible if an assembly tool such as Rational Application Developer is used. You also can create the `security-role-ref` element during the assembly stage using an assembly tool.

Procedure

1. Add the required security methods in the EJB module code.
2. Create a `security-role-ref` element with a `role-name` field for all the role names used in the `isCallerInRole` method. If a `security-role-ref` element is not created during development, make sure it is created during the assembly stage.

Results

Performing the previous steps result in a programmatically secured EJB application.

Example

Hard coding security policies in applications is strongly discouraged. The Java Platform, Enterprise Edition (Java EE) security model capabilities of declaratively specifying security policies is encouraged wherever possible. Use these APIs to develop security-aware EJB applications.

Using Java EE security model capabilities to specify security policies declaratively is useful when an EJB application wants to access external resources and wants to control the access to these external resources using its own authorization table (external-resource to user mapping). In this case, use the `getCallerPrincipal` method to get the caller identity and then the application can consult its own authorization table to perform authorization. The caller identification also can help retrieve the corresponding user information from an external source, such as database or from another enterprise bean. You can use the `isCallerInRole` method in a similar way.

After development, you can create a `security-role-ref` element:

```
<security-role-ref>
<description>Provide hints to assembler for linking this role-name to
actual role here<\description>
<role-name>Mgr<\role-name>
</security-role-ref>
```

During assembly, the assembler creates a `role-link` element:

```

<security-role-ref>
<description>Hints provided by developer to map role-name to role-link</description>
<role-name>Mgr</role-name>
<role-link>Manager</role-link>
</security-role-ref>

```

You can add programmatic EJB component security methods for example `isCallerInRole` and `getCallerPrincipal`, inside any business methods of an enterprise bean. The following example of programmatic security APIs includes a session bean:

```

public class aSessionBean implements SessionBean {

    .....

    // SessionContext extends EJBContext. If it is entity bean use EntityContext
    javax.ejb.SessionContext context;

    // The following method will be called by the EJB container
    // automatically
    public void setSessionContext(javax.ejb.SessionContext ctx) {
        context = ctx; // save the session bean's context
    }

    ....

    private void aBusinessMethod() {
        ....

        // to get bean's caller using getCallerPrincipal()
        java.security.Principal principal = context.getCallerPrincipal();
        String callerId= principal.getName();

        // to check if bean's caller is granted Mgr role
        boolean isMgr = context.isCallerInRole("Mgr");

        // use the above information in any way as needed by the
        //application

        ....
    }

    ....
}

```

When developing EJB 3.x modules, the value of the `rolename` argument in `isCallerInRole` method can be defined using Java annotations instead of declaring a `security-role-ref` elements in the deployment descriptor.

```

@javax.annotation.security.DeclareRoles("Mgr")
@Stateless // annotation is used to indicate a session bean
public class aSessionBean implements MyBusinessInterface { //you don't have to extend sessionbean interface
    .....
    // SessionContext extends EJBContext. In EJB 3.0 use Resource annotation to inject context
    @Resource
    javax.ejb.SessionContext context;    }

    ....

    private void aBusinessMethod() {
        ....

        // to get bean's caller using getCallerPrincipal()
        java.security.Principal principal = context.getCallerPrincipal();
        String callerId= principal.getName();

        // to check if bean's caller is granted Mgr role
        boolean isMgr = context.isCallerInRole("Mgr");

        // use the above information in any way as needed by the
        //application

        ....
    }
}

```

```
    }  
    .....  
}
```

What to do next

After developing an application, use an assembly tool to create roles and to link the actual roles to role names in the security-role-ref elements. See the information about securing web applications using an assembly tool.

Example: Enterprise bean application code:

The following Enterprise JavaBeans (EJB) component example illustrates the use of the `isCallerInRole` and the `getCallerPrincipal` methods in an EJB module.

Using declarative security is recommended. The following example is one way of using the `isCallerInRole` and the `getCallerPrincipal` methods. The application can use this result in any way that is suitable.

A remote interface

File : Hello.java

```
package tests;  
import java.rmi.RemoteException;  
/**  
 * Remote interface for Enterprise Bean: Hello  
 */  
public interface Hello extends javax.ejb.EJBObject {  
    public abstract String getMessage()throws RemoteException;  
    public abstract void setMessage(String s)throws RemoteException;  
}
```

A home interface

File : HelloHome.java

```
package tests;  
/**  
 * Home interface for Enterprise Bean: Hello  
 */  
public interface HelloHome extends javax.ejb.EJBHome {  
    /**  
     * Creates a default instance of Session Bean: Hello  
     */  
    public tests.Hello create() throws javax.ejb.CreateException,  
        java.rmi.RemoteException;  
}
```

A bean implementation

File : HelloBean.java

```
package tests;  
/**  
 * Bean implementation class for Enterprise Bean: Hello  
 */  
public class HelloBean implements javax.ejb.SessionBean {  
    private javax.ejb.SessionContext mySessionCtx;  
    /**  
     * getSessionContext  
     */  
    public javax.ejb.SessionContext getSessionContext() {  
        return mySessionCtx;  
    }  
    /**  
     * setSessionContext  
     */  
    public void setSessionContext(javax.ejb.SessionContext ctx) {  
        mySessionCtx = ctx;  
    }  
}
```

```

}
/**
 * ejbActivate
 */
public void ejbActivate() {
}
/**
 * ejbCreate
 */
public void ejbCreate() throws javax.ejb.CreateException {
}
/**
 * ejbPassivate
 */
public void ejbPassivate() {
}
/**
 * ejbRemove
 */
public void ejbRemove() {
}

public java.lang.String message;

    //business methods

    // all users can call getMessage()
    public String getMessage() {
        return message;
    }

    // all users can call setMessage() but only few users can set new message.
    public void setMessage(String s) {

        // get bean's caller using getCallerPrincipal()
        java.security.Principal principal = mySessionCtx.getCallerPrincipal();
        java.lang.String callerId= principal.getName();

        // check if bean's caller is granted Mgr role
        boolean isMgr = mySessionCtx.isCallerInRole("Mgr");

        // only set supplied message if caller is "bob" or caller is granted Mgr role
        if ( isMgr || callerId.equals("bob") )
            message = s;
        else
            message = "Hello";
    }
}

```

After the development of the entity bean, create a security role reference in the deployment descriptor under the session bean, Hello:

```

<security-role-ref>
    <description>Only Managers can call setMessage() on this bean (Hello)</description>
    <role-name>Mgr</role-name>
</security-role-ref>

```

For an explanation of how to create a <security-role-ref> element, see [Securing enterprise bean applications](#). Use the information under [Map security-role-ref and role-name to role-link](#) to create the element.

Customizing web application login

You can create a form login page and an error page to authenticate a user.

Before you begin

A web client or a browser can authenticate a user to a Web server using one of the following mechanisms:

- **HTTP basic authentication:** A web server requests the Web client to authenticate and the web client passes a user ID and a password in the HTTP header.
- **HTTPS client authentication:** This mechanism requires a user (web client) to possess a public key certificate. The web client sends the certificate to a web server that requests the client certificates. This authentication mechanism is strong and uses the Hypertext Transfer Protocol with Secure Sockets Layer (HTTPS) protocol.
- **Form-based Authentication:** A developer controls the look and feel of the login screens using this authentication mechanism.

The Hypertext Transfer Protocol (HTTP) basic authentication transmits a user password from the web client to the web server in simple base64 encoding. Form-based authentication transmits a user password from the browser to the web server in plain text. Therefore, both HTTP basic authentication and form-based authentication are not very secure unless the HTTPS protocol is used.

The web application deployment descriptor contains information about which authentication mechanism to use. When form-based authentication is used, the deployment descriptor also contains entries for login and error pages. A login page can be either an HTML page or a JavaServer Pages (JSP) file. This login page is displayed on the web client side when a secured resource (servlet, JSP file, HTML page) is accessed from the application. On authentication failure, an error page is displayed. You can write login and error pages to suit the application needs and control the look and feel of these pages. During assembly of the application, an assembler can set the authentication mechanism for the application and set the login and error pages in the deployment descriptor.

Form login uses the servlet `sendRedirect` method, which has several implications for the user. The `sendRedirect` method is used twice during form login:

- The `sendRedirect` method initially displays the form login page in the web browser. It later redirects the web browser back to the originally requested protected page. The `sendRedirect(String URL)` method tells the web browser to use the HTTP GET request to get the page that is specified in the web address. If HTTP POST is the first request to a protected servlet or JavaServer Pages (JSP) file, and no previous authentication or login occurred, then HTTP POST is not delivered to the requested page. However, HTTP GET is delivered because form login uses the `sendRedirect` method, which behaves as an HTTP GET request that tries to display a requested page after a login occurs.
- Using HTTP POST, you might experience a scenario where an unprotected HTML form collects data from users and then posts this data to protected servlets or JSP files for processing, but the users are not logged in for the resource. To avoid this scenario, structure your web application or permissions so that users are forced to use a form login page before the application performs any HTTP POST actions to protected servlets or JSP files.

Procedure

1. Create a form login page with the required look and feel, including the required elements to perform form-based authentication.
2. Create an error page. You can program error pages to retry authentication or to display an appropriate error message.
3. Place the login page and error page in the web application archive (.war) file relative to the top directory. For example, if the login page is configured as `/login.html` in the deployment descriptor, place it in the top directory of the WAR file. An assembler can also perform this step using the assembly tool.
4. Create a form logout page and insert it to the application only when the web application requires a form-based authentication mechanism.

By default the URL to the logout page should point to the host to which the request was made or its domain. Otherwise, a generic logout page is displayed. If you need to point this URL to a different host, then you need to set the `com.ibm.websphere.security.logoutExitPageDomainList` property in the

security.xml file with a list of URLs that are allowed for the logout page. You can choose to allow any logout exit page to be used by setting the `com.ibm.websphere.security.allowAnyLogoutExitPageHost` property to a value of `true`. Setting this property to `true` might open your systems to a potential URL redirect attacks.

Example: Form login

You can use the WebSphere Application Server login facilities to implement and configure form login procedures. Use the following technologies for WebSphere Application Server and Java Platform, Enterprise Edition (Java EE) login functionality:

- Java EE form-based login
- Java EE servlet filter with login
- IBM extension: form-based login

The form login sample is part of the Technology Samples package. For more information on how to access the form login sample, see [Accessing the samples](#).

Form login usage

For the authentication to proceed appropriately, the action of the login form must always have the `j_security_check` action. The following example shows how to code the form into the HTML page:

```
<form method="POST" action="j_security_check">
<input type="text" name="j_username">
<input type="text" name="j_password">
</form>
```

Use the `j_username` input field to get the user name, and use the `j_password` input field to get the user password.

On receiving a request from a web client, the web server sends the configured form page to the client and preserves the original request. When the web server receives the completed form page from the web client, the server extracts the user name and password from the form and authenticates the user. On successful authentication, the web server redirects the call to the original request. If authentication fails, the web server redirects the call to the configured error page.

The following example depicts a login page in HTML (`login.html`):

```
<!DOCTYPE HTML PUBLIC "-//W3C/DTD HTML 4.0 Transitional//EN">
<html>
<META HTTP-EQUIV = "Pragma" CONTENT="no-cache">
<title> Security FVT Login Page </title>
<body>
<h2>Form Login</h2>
<FORM METHOD=POST ACTION="j_security_check">
<p>
<font size="2"> <strong> Enter user ID and password: </strong></font>
<BR>
<strong> User ID</strong> <input type="text" size="20" name="j_username">
<strong> Password </strong> <input type="password" size="20" name="j_password">
<BR>
<BR>
<font size="2"> <strong> And then click this button: </strong></font>
<input type="submit" name="login" value="Login">
</p>
</form>
</body>
</html>
```

The following example depicts an error page in a JSP file:

```
<!DOCTYPE HTML PUBLIC "-//W3C/DTD HTML 4.0 Transitional//EN">
<html>
<head><title>A Form login authentication failure occurred</head></title>
<body>
<H1><B>A Form login authentication failure occurred</H1></B>
<P>Authentication may fail for one of many reasons. Some possibilities include:
<OL>
<LI>The user-id or password may be entered incorrectly; either misspelled or the
```

```
wrong case was used.
<LI>The user-id or password does not exist, has expired, or has been disabled.
</OL>
</P>
</body>
</html>
```

After an assembler configures the web application to use form-based authentication, the deployment descriptor contains the login configuration as shown:

```
<login-config id="LoginConfig_1">
<auth-method>FORM</auth-method>
<realm-name>Example Form-Based Authentication Area</realm-name>
<form-login-config id="FormLoginConfig_1">
<form-login-page>/login.html</form-login-page>
<form-error-page>/error.jsp</form-error-page>
</form-login-config>
</login-config>
```

A sample web application archive (WAR) file directory structure that shows login and error pages for the previous login configuration follows:

```
META-INF
  META-INF/MANIFEST.MF
  login.html
  error.jsp
WEB-INF/
  WEB-INF/classes/
  WEB-INF/classes/aServlet.class
```

Form logout

Form logout is a mechanism to log out without having to close all Web-browser sessions. After logging out of the form logout mechanism, access to a protected web resource requires re-authentication. This feature is not required by J2EE specifications, but it is provided as an additional feature in WebSphere Application Server security.

Suppose that you want to log out after logging into a web application and perform some actions. A form logout works in the following manner:

1. The logout-form URI is specified in the web browser and loads the form.
2. The user clicks **Submit** on the form to log out.
3. The WebSphere Application Server security code logs the user out. During this process, the Application Server completes the following processes:
 - a. Clears the Lightweight Third Party Authentication (LTPA) / single sign-on (SSO) cookies
 - b. Invalidates the HTTP session
 - c. Removes the user from the authentication cache
4. Upon logout, the user is redirected to a logout exit page.

Form logout does not require any attributes in a deployment descriptor. The form-logout page is an HTML or a JavaServer Pages (JSP) file that is included with the web application. The form-logout page is like most HTML forms except that like the form-login page, the form-logout page has a special post action. This post action is recognized by the web container, which dispatches the post action to a special internal form-logout servlet. The post action in the form-logout page must be `ibm_security_logout`.

You can specify a logout-exit page in the logout form and the exit page can represent an HTML or a JSP file within the same web application to which the user is redirected after logging out. Additionally, the logout-exit page permits a fully qualified URL in the form of `http://hostname:port/URL`. The logout-exit page is specified as a parameter in the form-logout page. If no logout-exit page is specified, a default logout HTML message is returned to the user.

Here is a sample form logout HTML form. This form configures the logout-exit page to redirect the user back to the login page after logout.

```
<!DOCTYPE HTML PUBLIC "-//W3C/DTD HTML 4.0 Transitional//EN">
<html>
  <META HTTP-EQUIV = "Pragma" CONTENT="no-cache">
  <title>Logout Page </title>
  <body>
```

```

<h2>Sample Form Logout</h2>
<FORM METHOD=POST ACTION="ibm_security_logout" NAME="logout">
  <p>
  <BR>
  <BR>
  <font size="2"><strong> Click this button to log out: </strong></font>
  <input type="submit" name="logout" value="Logout">
  <INPUT TYPE="HIDDEN" name="logoutExitPage" VALUE="/login.html">
  </p>
</form>
</body>
</html>

```

What to do next

After developing login and error pages, add them to the Web application. Use the assembly tool to configure an authentication mechanism and insert the developed login page and error page in the deployment descriptor of the application.

Developing servlet filters for form login processing

You can control the look and feel of the login screen using the form-based login mechanism. In form-based login, you specify a login page that is used to retrieve the user ID and password information. You also can specify an error page that displays when authentication fails.

About this task

If additional authentication or additional processing is required before and after authentication, servlet filters are an option. Servlet filters can dynamically intercept requests and responses to transform or to use the information that is contained in the requests or responses. One or more servlet filters can be attached to a servlet or to a group of servlets. Servlet filters also can attach to JavaServer Pages (JSP) files and HTML pages. All of the attached servlet filters are called before the servlet is invoked.

Both form-based login and servlet filters are supported by any servlet Version 2.3 specification-complaint web container. The form login servlet performs the authentication and servlet filters perform additional authentication, auditing, or logging information.

To perform pre-login and post-login actions using servlet filters, configure these filters for either form login page support or for the `/j_security_check` URL. The `j_security_check` is posted by a form login page with the `j_username` parameter that contains the user name and the `j_password` parameter that contains the password. A servlet filter can use the user name parameter and password information to perform more authentication or other special needs.

Procedure

1. A servlet filter implements the `javax.servlet.Filter` class. Implement three methods in the filter class:
 - **init(javax.servlet.FilterConfig cfg)**. This method is called by the container once, when the servlet filter is placed into service. The `FilterConfig` passed to this method contains the init-parameters of the servlet filter. Specify the init-parameters for a servlet filter during configuration using the assembly tool.
 - **destroy**. This method is called by the container when the servlet filter is taken out of a service.
 - **doFilter(ServletRequest req, ServletResponse res, FilterChain chain)**. This method is called by the container for every servlet request that maps to this filter before invoking the servlet. The `FilterChain` chain that is passed to this method can be used to invoke the next filter in the chain of filters. The original requested servlet runs when the last filter in the chain calls the `chain.doFilter` method. Therefore, all filters call the `chain.doFilter` method for the original servlet to run after filtering. If an additional authentication check is implemented in the filter code and results in failure, the original servlet does not run. The `chain.doFilter` method is not called and can be redirected to some other error page.

2. If a servlet maps to many servlet filters, servlet filters are called in the order that is listed in the web.xml deployment descriptor of the application. Place the servlet filter class file in the WEB-INF/classes directory of the application.

Example

An example of a servlet filter.

This login filter can map to the /j_security_check URL to perform pre-login and post-login actions.

```
import javax.servlet.*;
public class LoginFilter implements Filter {
    protected FilterConfig filterConfig;
    // Called once when this filter is instantiated.
    // If mapped to j_security_check, called
    // very first time j_security_check is invoked.
    public void init(FilterConfig filterConfig) throws ServletException {
        this.filterConfig = filterConfig;
    }
    public void destroy() {
        this.filterConfig = null;
    }
    // Called for every request that is mapped to this filter.
    // If mapped to j_security_check,
    // called for every j_security_check action
    public void doFilter(ServletRequest request,
        ServletResponse response, FilterChain chain)
        throws java.io.IOException, ServletException {
        // perform pre-login action here
        chain.doFilter(request, response);
        // calls the next filter in chain.
        // j_security check if this filter is
        // mapped to j_security_check.
        // perform post-login action here.
    }
}
```

Using servlet filters to perform pre-login and post-login processing during form login

This example illustrates one way that the servlet filters can perform pre-login and post-login processing during form login.

Servlet filter source code: LoginFilter.java

```
/**
 * A servlet filter example: This example filters j_security_check and
 * performs pre-login action to determine if the user trying to log in
 * is in the revoked list. If the user is on the revoked list, an error is
 * sent back to the browser.
 *
 * This filter reads the revoked list file name from the FilterConfig
 * passed in the init() method. It reads the revoked user list file and
 * creates a revokedUsers list.
 *
 * When the doFilter method is called, the user logging in is checked
 * to make sure that the user is not on the revoked Users list.
 */
import javax.servlet.*;
import javax.servlet.http.*;
import java.io.*;

public class LoginFilter implements Filter {

    protected FilterConfig filterConfig;

    java.util.List revokeList;

    /**
     * init() : init() method called when the filter is instantiated.
     * This filter is instantiated the first time j_security_check is
     * invoked for the application (When a protected servlet in the
     * application is accessed).
     */
    public void init(FilterConfig filterConfig) throws ServletException {
        this.filterConfig = filterConfig;

        // read revoked user list
        revokeList = new java.util.ArrayList();
        readConfig();
    }
}
```

```

/**
 * destroy() : destroy() method called when the filter is taken
 * out of service.
 */
public void destroy() {
    this.filterConfig = null;
    revokeList = null;
}

/**
 * doFilter() : doFilter() method called before the servlet to
 * which this filter is mapped is invoked. Since this filter is
 * mapped to j_security_check, this method is called before
 * j_security_check action is posted.
 */
public void doFilter(ServletRequest request, ServletResponse response,
FilterChain chain) throws java.io.IOException, ServletException {

    HttpServletRequest req = (HttpServletRequest)request;
    HttpServletResponse res = (HttpServletResponse)response;

    // pre login action

    // get username
    String username = req.getParameter("j_username");

    // if user is in revoked list send error
    if ( revokeList.contains(username) ) {
        res.sendError(javax.servlet.http.HttpServletResponse.SC_UNAUTHORIZED);
        return;
    }

    // call next filter in the chain : let j_security_check authenticate
    // user
    chain.doFilter(request, response);

    // post login action
}

/**
 * readConfig() : Reads revoked user list file and creates a revoked
 * user list.
 */
private void readConfig() {
    if ( filterConfig != null ) {

        // get the revoked user list file and open it.
        BufferedReader in;
        try {
            String filename = filterConfig.getInitParameter("RevokedUsers");
            in = new BufferedReader( new FileReader(filename));
        } catch ( FileNotFoundException fnfe) {
            return;
        }

        // read all the revoked users and add to revokeList.
        String userName;
        try {
            while ( (userName = in.readLine()) != null )
                revokeList.add(userName);
        } catch (IOException ioe) {
        }

    }
}
}
}

```

Important: In the previous code sample, the line that begins `public void doFilter(ServletRequest request` is broken into two lines for illustrative purposes only. The `public void doFilter(ServletRequest request` line and the line after it are one continuous line.

An example of the `web.xml` file that shows the `LoginFilter` filter configured and mapped to the `j_security_check` URL:

```

<filter id="Filter_1">
    <filter-name>LoginFilter</filter-name>
    <filter-class>LoginFilter</filter-class>
    <description>Performs pre-login and post-login operation</description>
    <init-param>
        <param-name>RevokedUsers</param-name>
    </init-param>
</filter>

```

```

    <param-value>c:\WebSphere\AppServer\installedApps\
        <app-name>\revokedUsers.lst</param-value>
    </init-param>
</filter-id>

<filter-mapping>
  <filter-name>LoginFilter</filter-name>
  <url-pattern>/j_security_check</url-pattern>
</filter-mapping>

```

An example of a revoked user list file:

```

user1
cn=user1,o=ibm,c=us
user99
cn=user99,o=ibm,c=us

```

Configuring servlet filters for form login processing:

IBM Rational Application Developer or an assembly tool can configure the servlet filters. Two steps are involved in configuring a servlet filter.

Procedure

1. Name the servlet filter and assign the corresponding implementation class to the servlet filter.

Optionally, assign initialization parameters that get passed to the init method of the servlet filter. After configuring the servlet filter, the web.xml application deployment descriptor contains a servlet filter configuration similar to the following example:

```

<filter id="Filter_1">
  <filter-name>LoginFilter</filter-name>
  <filter-class>LoginFilter</filter-class>
  <description>Performs pre-login and post-login
    operation</description>
  <init-param>// optional
    <param-name>ParameterName</param-name>
    <param-value>ParameterName</param-value>
  </init-param>
</filter>

```

2. Map the servlet filter to a URL or a servlet.

After mapping the servlet filter to a URL or a servlet, the web.xml application deployment descriptor contains servlet mapping similar to the following example:

```

<filter-mapping>
  <filter-name>LoginFilter</filter-name>
  <url-pattern>/j_security_check</url-pattern>
  // can be servlet <servlet>servletName</servlet>
</filter-mapping>

```

Example

You can use servlet filters to replace the CustomLoginServlet servlet, and to perform additional authentication, auditing, and logging.

The WebSphere Application Server Samples provide a form login sample that demonstrates how to use the WebSphere Application Server login facilities to implement and configure form login procedures. The sample integrates the following technologies to demonstrate the WebSphere Application Server and Java Platform, Enterprise Edition (Java EE) login functionality:

- Java EE form-based login
- Java EE servlet filter with login
- IBM extension: form-based login

The form login sample is part of the Technology Samples package.

Secure transports with JSSE and JCE programming interfaces

This topic provides detailed information about transport security using Java Secure Socket Extension (JSSE) and Java Cryptography Extension (JCE) programming interfaces. Within this topic, there is a description of the IBM version of the Java Cryptography Extension Federal Information Processing Standard (IBMJCE/FIPS).

Java Secure Socket Extension

Java Secure Socket Extension (JSSE) provides the transport security for WebSphere Application Server. JSSE provides the application programming interface (API) framework and the implementation of the APIs for Secure Sockets Layer (SSL) and Transport Layer Security (TLS) protocols, including functionality for data encryption, message integrity, and authentication.

JSSE APIs are integrated into the Java 2 SDK, Standard Edition (J2SDK), Version 5. The API package for JSSE APIs is `javax.net.ssl.*`. Documentation for using JSSE APIs can be found in the J2SE 6 API documentation that is located at <http://java.sun.com/javase/6/docs/technotes/guides/security/jsse/JSSERefGuide.html>.

Several JSSE providers ship with the Java 2 SDK Version 5 that comes with WebSphere Application Server. The IBMJSSE provider is used in previous WebSphere Application Server releases. Associated with the IBMJSSE provider is the IBMJSSE/FIPS provider, which is used when FIPS is enabled on the server. Both of these providers do not work with the Java Message Service (JMS) and HTTP transports in WebSphere Application Server Version 8.0. These transports take advantage of the J2SDK Version 5 network input/output (NIO) asynchronous channels.

For more information on the new IBMJSSE2 provider, please review the documentation located at <http://www.ibm.com/developerworks/java/jdk/security/60/>.

Customizing Java Secure Socket Extension

You can customize a number of aspects of JSSE by plugging in different implementations of Cryptography Package Provider, X509Certificate and HTTPS protocols, or specifying different default keystore files, key manager factories, and trust manager factories. The following table summarizes which aspects can be customized, what the defaults are, and which mechanisms are used to provide customization.

Table 109. Customizable items. You can customize the following key aspects:

Customizable item	Default	How to customize
X509Certificate	X509Certificate implementation from IBM	The <code>cert.provider.x509v1</code> security property
HTTPS protocol	Implementation from IBM	The <code>java.protocol.handler.pkgs</code> system property
Cryptography Package Provider	IBMJSSE2	A <code>security.provider.n=</code> line in security properties file. See description.
Default keystore	None	The <code>* javax.net.ssl.keyStore</code> system property
Default truststore	<code>jssecacerts</code> , if it exists. Otherwise, <code>cacerts</code>	The <code>* javax.net.ssl.trustStore</code> system property
Default key manager factory	<code>IbmX509</code>	The <code>ssl.KeyManagerFactory.algorithm</code> security property
Default trust manager factory	<code>IbmX509</code>	The <code>ssl.TrustManagerFactory.algorithm</code> security property

For aspects that you can customize by setting a system property, statically set the system property by using the `-D` option of the Java command. You can set the system property using the administrative console, or set the system property dynamically by calling the `java.lang.System.setProperty` method in your code: `System.setProperty(propertyName, "propertyValue")`.

For aspects that you can customize by setting a Java security property, statically specify a security property value in the `java.security` properties file. The security property is `propertyName=propertyValue`. Dynamically set the Java security property by calling the `java.security.Security.setProperty` method in your code.

The `java.security` properties file is located in the following directory:

`profile_root/properties` directory.

Application Programming Interface

The JSSE provides a standard application programming interface (API) that is available in packages of the `javax.net` file, `javax.net.ssl` file, and the `javax.security.cert` file. The APIs cover:

- Sockets and SSL sockets
- Factories to create the sockets and SSL sockets
- Secure socket context that acts as a factory for secure socket factories
- Key and trust manager interfaces
- Secure HTTP URL connection classes
- Public key certificate API

You can find more information documented for the JSSE APIs if you access the following information:

Version 1.6

1. Access the <http://www.ibm.com/developerworks/java/jdk/security/> website.
2. Click Java 1.6.
3. Click Javadoc HTML documentation in the Java Secure Socket Extension (JSSE) Guide section.

Samples using Java Secure Socket Extension

The Java Secure Socket Extension (JSSE) also provides samples to demonstrate its functionality. The Java Secure Socket Extension (JSSE) also provides samples to demonstrate its functionality. You can access the samples in the following location:

Version 1.6

1. Access the <http://www.ibm.com/developerworks/java/jdk/security/> website.
2. Click Java 1.6.
3. Click `jsse-docs_samples.zip` in the Java Secure Socket Extension (JSSE) Guide section.

Table 110. Extracted files. This table lists the following extracted files:

Files	Description
<code>ClientJsse.java</code>	Demonstrates a simple client and server interaction using JSSE. All enabled cipher suites are used.
<code>OldServerJsse.java</code>	Back-level samples
<code>ServerPKCS12Jsse.java</code>	Demonstrates a simple client and server interaction using JSSE with the PKCS12 keystore file. All enabled cipher suites are used.
<code>ClientPKCS12Jsse.java</code>	Demonstrates a simple client and server interaction using JSSE with the PKCS12 keystore file. All enabled cipher suites are used.
<code>UseHttps.java</code>	Demonstrates accessing an SSL or non-SSL web server using the Java protocol handler of the <code>com.ibm.net.ssl.www.protocol</code> class. The URL is specified with the <code>http</code> or <code>https</code> prefix. The HTML that is returned from this site is displayed.

See more instructions in the source code. Follow these instructions before you run the samples.

Permissions for Java 2 security

You might need the following permissions to run an application with JSSE: This list is for reference only.

- `java.util.PropertyPermission "java.protocol.handler.pkgs", "write"`

- java.lang.RuntimePermission "writeFileDescriptor"
- java.lang.RuntimePermission "readFileDescriptor"
- java.lang.RuntimePermission "accessClassInPackage.sun.security.x509"
- java.io.FilePermission "\${user.install.root}\${}/etc\${}/.keystore", "read"
- java.io.FilePermission "\${user.install.root}\${}/etc\${}/.truststore", "read"

For the IBMJSSE provider:

- java.security.SecurityPermission "putProviderProperty.IBMJSSE"
- java.security.SecurityPermission "insertProvider.IBMJSSE"

For the SUNJSSE provider:

- java.security.SecurityPermission "putProviderProperty.SunJSSE"
- java.security.SecurityPermission "insertProvider.SunJSSE"

Debugging

By configuring through the `javax.net.debug` system property, JSSE provides the following dynamic debug tracing: `-Djavax.net.debug=true`.

A value of true turns on the trace facility, provided that the debug version of JSSE is installed.

Documentation

See the Security: Resources for learning topic for documentation references to JSSE.

JCE

Java Cryptography Extension (JCE) provides cryptographic, key and hash algorithms for WebSphere Application Server. JCE provides a framework and implementations for encryption, key generation, key agreement, and Message Authentication Code (MAC) algorithms. Support for encryption includes symmetric, asymmetric, block and stream ciphers.

IBMJCE

The IBM version of the Java Cryptography Extension (IBMJCE) is an implementation of the JCE cryptographic service provider that is used in WebSphere Application Server. The IBMJCE is similar to SunJCE, except that the IBMJCE offers more algorithms:

- Cipher algorithm (AES, DES, TripleDES, PBEs, Blowfish, and so on)
- Signature algorithm (SHA1withRSA, MD5withRSA, SHA1withDSA)
- Message digest algorithm (MD5, MD2, SHA1, SHA-256, SHA-384, SHA-512)
- Message authentication code (HmacSHA1, HmacMD5)
- Key agreement algorithm (DiffieHellman)
- Random number generation algorithm (IBMSecureRandom, SHA1PRNG)
- Key store (JKS, JCEKS, PKCS12, JCERACFKS [z/OS only])

The IBMJCE belongs to the `com.ibm.crypto.provider.*` packages.

For further information, see the information on JCE on the following website: <http://www.ibm.com/developerworks/java/jdk/security/60/>.

IBMJCEFIPS

The IBM version of the Java Cryptography Extension Federal Information Processing Standard (IBMJCEFIPS) is an implementation of the JCE cryptographic service provider that is used in WebSphere Application Server. The IBMJCEFIPS service provider implements the following:

- Signature algorithms (SHA1withDSA, SHA1withRSA)

- Cipher algorithms (AES, TripleDES, RSA)
- Key agreement algorithm (DiffieHellman)
- Key (pair) generator (DSA, AES, TripleDES, HmacSHA1, RSA, DiffieHellman)
- Message authentication code (MAC) (HmacSHA1)
- Message digest (MD5, SHA-1, SHA-256, SHA-384, SHA-512)
- Algorithm parameter generator (DiffieHellman, DSA)
- Algorithm parameter (AES, DiffieHellman, DES, TripleDES, DSA)
- Key factory (DiffieHellman, DSA, RSA)
- Secret key factory (AES, TripleDES)
- Certificate (X.509)
- Secure random (IBMSecureRandom)

Application Programming Interface

Java Cryptography Extension (JCE) has a provider-based architecture. Providers can be plugged into the JCE framework by implementing the APIs that are defined by the JCE. The JCE APIs cover:

- Symmetric bulk encryption, such as DES, RC2, and IDEA
- Symmetric stream encryption, such as RC4
- Asymmetric encryption, such as RSA
- Password-based encryption (PBE)
- Key agreement
- Message authentication codes

There is more information documented for the JCE APIs on the <http://www.ibm.com/developerworks/java/jdk/security/> website.

Samples using Java Cryptography Extension

There are samples located on the <http://www.ibm.com/developerworks/java/jdk/security/> website in the `jceDocs_samples.zip` file. Unzip the file and locate the following samples in the `jceDocs/samples` directory:

Table 111. Samples using Java Cryptography Extension. This table describes samples using Java Cryptography Extension.

File	Description
SampleDSASignature.java	Demonstrates how to generate a pair of DSA keys (a public key and a private key) and use the key to digitally sign a message using the SHA1withDSA algorithm
SampleMarsCrypto.java	Demonstrates how to generate a Mars secret key, and how to do Mars encryption and decryption
SampleMessageDigests.java	Demonstrates how to use the message digest for MD2 and MD5 algorithms
SampleRSACrypto.java	Demonstrates how to generate an RSA key pair, and how to do RSA encryption and decryption
SampleRSASignatures.java	Demonstrates how to generate a pair of RSA keys (a public key and a private key) and use the key to digitally sign a message using the SHA1withRSA algorithm
SampleX509Verification.java	Demonstrates how to verify X509 certificates

Documentation

Refer to the Security: Resources for learning topic for documentation on JCE.

Configuring Federal Information Processing Standard Java Secure Socket Extension files

Use this topic to configure Federal Information Processing Standard Java Secure Socket Extension files.

About this task

In WebSphere Application Server, the Java Secure Socket Extension (JSSE) provider used is the IBMJSSE2 provider. This provider delegates encryption and signature functions to the Java Cryptography Extension (JCE) provider. Consequently, IBMJSSE2 does not need to be Federal Information Processing Standard (FIPS)-approved because it does not perform cryptography. However, the JCE provider requires FIPS-approval.

WebSphere Application Server provides a FIPS-approved IBMJCEFIPS provider that IBMJSSE2 can utilize. The IBMJCEFIPS provider that is shipped in WebSphere Application Server Version 8.0 supports the following SSL ciphers:

- SSL_RSA_WITH_AES_128_CBC_SHA
- SSL_RSA_WITH_3DES_EDE_CBC_SHA
- SSL_RSA_FIPS_WITH_3DES_EDE_CBC_SHA
- SSL_DHE_RSA_WITH_AES_128_CBC_SHA
- SSL_DHE_RSA_WITH_3DES_EDE_CBC_SHA
- SSL_DHE_DSS_WITH_AES_128_CBC_SHA
- SSL_DHE_DSS_WITH_3DES_EDE_CBC_SHA

Even though the IBMJSSEFIPS provider is still present, the runtime does not use this provider. If IBMJSSEFIPS is specified as a contextProvider, WebSphere Application Server automatically defaults to the IBMJSSE2 provider (with the IBMJCEFIPS provider) for supporting FIPS. When enabling the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option on the server SSL certificate and key management panel, the runtime always uses IBMJSSE2, despite the contextProvider that you specify for SSL (IBMJSSE, IBMJSSE2 or IBMJSSEFIPS). Also, because FIPS requires the SSL protocol be TLS, the runtime always uses TLS when FIPS is enabled, regardless of the SSL protocol setting in the SSL repertoire. This simplifies the FIPS configuration in Version 8.0 because an administrator needs to enable only the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option on the server SSL certificate and key management panel to enable all transports using SSL.

Procedure

1. Click **Security > SSL certificate and key management**.
2. Select the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option and click **Apply**. This option makes IBMJSSE2 and IBMJCEFIPS the active providers.
3. Accommodate Java clients that must access enterprise beans.
Change the `com.ibm.security.useFIPS` property value from `false` to `true` in the `profile_root/properties/ssl.client.props` file.
4. Ensure that the `com.ibm.ssl.protocol` property within the `profile_root/properties/ssl.client.props` file is set to `SSL_TLS`.
5. Ensure that the `java.security` file includes the provider.
Edit the `java.security` file to insert the IBMJCEFIPS provider (`com.ibm.crypto.fips.provider.IBMJCEFIPS`) before the IBMJCE provider, and also renumber the other providers in the provider list. The IBMJCEFIPS provider must be in the `java.security` file provider list. The `java.security` file is located in the `WAS_HOME/java/jre/lib/security/properties` directory.
Edit the `java.security` file to comment out the line with the IBMJCEFIPS provider and also renumber the rest of the provider list. The IBMJCEFIPS provider must be in the `java.security` file provider list.
Edit the `java.security` file to comment out the line with the IBMJCE provider, uncomment the line with the IBMJCEFIPS provider, and save the file.

The IBM SDK `java.security` file looks like the following example after completing this step:

```

security.provider.1=com.ibm.crypto.fips.provider.IBMJCEFIPS
security.provider.2=com.ibm.crypto.provider.IBMJCE
security.provider.3=com.ibm.jsse.IBMJSSEProvider
security.provider.4=com.ibm.jsse2.IBMJSSEProvider2
security.provider.5=com.ibm.security.jgss.IBMJGSSProvider
security.provider.6=com.ibm.security.cert.IBMCertPath
security.provider.7=com.ibm.i5os.jsse.JSSEProvider
security.provider.8=com.ibm.crypto.pkcs11.provider.IBMPKCS11
security.provider.9=com.ibm.security.jgss.mech.spnego.IBMPNego
security.provider.10=com.ibm.security.cmskeystore.CMSProvider
security.provider.11=com.ibm.security.sasl.IBMSASL
security.provider.12=com.ibm.xml.crypto.IBMXMLCryptoProvider
security.provider.13=com.ibm.xml.enc.IBMXMLEncProvider
security.provider.14=org.apache.harmony.security.provider.PolicyProvider

```

If you are using the Sun Java SE Development Kit, the `java.security` file looks like the following example after completing this step:

```

security.provider.1=sun.security.provider.Sun
security.provider.2=com.ibm.crypto.fips.provider.IBMJCEFIPS
security.provider.3=com.ibm.crypto.provider.IBMJCE
security.provider.4=com.ibm.jsse.IBMJSSEProvider
security.provider.5=com.ibm.jsse2.IBMJSSEProvider2
security.provider.6=com.ibm.security.jgss.IBMJGSSProvider
security.provider.7=com.ibm.security.cert.IBMCertPath
#security.provider.12=com.ibm.crypto.pkcs11.provider.IBMPKCS11
security.provider.8=com.ibm.security.jgss.mech.spnego.IBMPNego
security.provider.9=com.ibm.security.cmskeystore.CMSProvider
security.provider.10=com.ibm.security.sasl.IBMSASL
security.provider.11=com.ibm.xml.crypto.IBMXMLCryptoProvider
security.provider.12=com.ibm.xml.enc.IBMXMLEncProvider

```

What to do next

After completing these steps, a FIPS-approved JSSE or JCE provider offers increased encryption capabilities. However, when you use FIPS-approved providers:

- By default, Microsoft Internet Explorer might not have TLS enabled. To enable TLS, open the Internet Explorer browser and click **Tools > Internet Options**. On the Advanced tab, select the Use TLS 1.0 option.

Note: Netscape Version 4.7.x and earlier versions might not support TLS.

- If you have an administrative client that uses a SOAP connector and you enable FIPS, add the following line to the `profile_root/properties/soap.client.props` file:

```
com.ibm.ssl.contextProvider=IBMJSSEFIPS
```

- When you select the **Use the Federal Information Processing Standard (FIPS)** option on the SSL certificate and key management panel, the Lightweight Third-Party Authentication (LTPA) token format is not backwards-compatible with previous releases of WebSphere Application Server. However, you can import the LTPA keys from a previous version of the application server.

Note: When enabling FIPS, you cannot configure cryptographic token devices in the SSL repertoires. IBMJSSE2 must use IBMJCEFIPS when utilizing cryptographic services for FIPS.

The following FIPS 140-2 approved cryptographic providers that are the only devices that are supported with the FIPS option:

- IBMJCEFIPS (certificate 376)
- IBM Cryptography for C (ICC) (certificate 384)

The relevant certificates are listed on the NIST website: Cryptographic Module Validation Program FIPS 140-1 and FIPS 140-2 Pre-validation List

To unconfigure the FIPS provider, reverse the changes that you made in the previous steps. After you reverse the changes, verify that you have made the following changes to the `soap.client.props`, and `java.security` files:

- In the `ssl.client.props` file, you must change the `com.ibm.security.useFIPS` value to `false`.
- Edit the `java.security` file to remove the FIPS provider and renumber the providers as in the following example:

```
security.provider.1=sun.security.provider.Sun
#security.provider.2=com.ibm.crypto.fips.provider.IBMJCEFIPS
security.provider.2=com.ibm.crypto.provider.IBMJCE
security.provider.3=com.ibm.jsse.IBMJSSEProvider
security.provider.4=com.ibm.jsse2.IBMJSSEProvider2
security.provider.5=com.ibm.security.jgss.IBMJGSSProvider
security.provider.6=com.ibm.security.cert.IBMCertPath
security.provider.7=com.ibm.i5os.jsse.JSSEProvider
#security.provider.8=com.ibm.crypto.pkcs11.provider.IBMPKCS11
security.provider.8=com.ibm.security.jgss.mech.spnego.IBMSPNEGO
```

Implementing tokens for security attribute propagation

As part of an extensible architecture, WebSphere Application Server enables you to implement your own tokens in which to propagate security attributes.

About this task

The following topics are covered in this section:

Procedure

- Implementing a custom propagation token
- Implementing a custom authorization token
- Implementing a custom a single sign-on token
- Implementing a custom authentication token
- Propagating a custom Java serializable object

Implementing a custom propagation token for security attribute propagation

This topic explains how you might create your own propagation token implementation, which is set on the running thread and propagated downstream.

About this task

The default propagation token usually is sufficient for propagating attributes that are not user-specific. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. You must deserialize the bytes at the target and add that information back on the thread by plugging in a custom login module into the inbound system login configurations. This task also might include encryption and decryption.

To implement a custom propagation token, you must complete the following steps:

Procedure

1. Write a custom implementation of the `PropagationToken` interface. Many different methods are available for implementing the `PropagationToken` interface. However, make sure that the methods that are required by the `PropagationToken` interface and the token interface are fully implemented. After you implement this interface, you can place it in the `profile_root/classes` directory. For more information on classes, see “Creating a classes subdirectory in your profile for custom classes” on page 976.

Tip: All of the token types that are defined by the propagation framework have similar interfaces. The token types are marker interfaces that implement the `com.ibm.wsspi.security.token.Token` interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the

com.ibm.wsspi.security.token.Token interface. All of your token implementations, including the propagation token, might extend the abstract class and then most of the work is complete.

To see an implementation of the propagation token, see “Example: com.ibm.wsspi.security.token.PropagationToken implementation.”

2. Add and receive the custom propagation token during WebSphere Application Server logins. This task is typically accomplished by adding a custom login module to the various application and system login configurations. You also can add the implementation from an application. However, to deserialize the information, you need to plug in a custom login module, which is discussed in “Propagating a custom Java serializable object for security attribute propagation” on page 1059. The WSSecurityPropagationHelper class has APIs that are used to set a propagation token on the thread and to retrieve the token from the thread to make updates.

The code sample in “Example: Custom propagation token login module” on page 1036 shows how to determine if the login is an initial login or a propagation login. The difference between these login types is whether the WSTokenHolderCallback callback contains propagation data. If the callback does not contain propagation data, initialize a new custom propagation token implementation and set it on the thread. If the callback contains propagation data, look for your specific custom propagation token TokenHolder instance, convert the byte array back into your custom PropagationToken object, and set it back on the thread. The code sample shows both instances.

You can add attributes any time your custom propagation token is added to the thread. If you add attributes between requests and the getUniqueld method changes, the Common Secure Interoperability Version 2 (CSlv2) client session is invalidated so that it can send the new information downstream. Adding attributes between requests can affect performance. In many cases, you want the downstream requests to receive the new propagation token information.

To add the custom propagation token to the thread, call the WSSecurityPropagationHelper.addPropagationToken method. This call requires the WebSphereRuntimePerMission "setPropagationToken" Java 2 Security permission.

3. Add your custom login module to WebSphere Application Server system login configurations that already contain the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule login module for receiving serialized versions of your custom propagation token. You can also add this login module to any of the application logins where you might want to generate your custom propagation token on the thread during the login. Alternatively, you can generate the custom PropagationToken implementation from within your application. However, to deserialize it, you need to add the implementation to the system login modules.

Results

After completing these steps, you have implemented a custom PropagationToken.

Example: com.ibm.wsspi.security.token.PropagationToken implementation:

Use this file to see an example of a propagation token implementation. The following sample code does not extend an abstract class, but implements the com.ibm.wsspi.security.token.PropagationToken interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if considerable differences exist between how you handle the various token implementations.

For information on how to implement a custom propagation token, see “Implementing a custom propagation token for security attribute propagation” on page 1031.

```
package com.ibm.websphere.security.token;

import com.ibm.websphere.security.WSSecurityException;
import com.ibm.websphere.security.auth.WSLoginFailedException;

}
```

Implementing a custom authorization token for security attribute propagation

This task explains how you might create your own AuthorizationToken implementation, which is set in the login Subject and propagated downstream.

About this task

The default AuthorizationToken usually is sufficient for propagating attributes that are user-specific. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. You must deserialize the bytes at the target and add that information back on the thread. This task also might include encryption and decryption.
- Affect the overall uniqueness of the Subject using the getUniqueID() application programming interface (API).

To implement a custom authorization token, you must complete the following steps:

Procedure

1. Write a custom implementation of the AuthorizationToken interface. There are many different methods for implementing the AuthorizationToken interface. However, make sure that the methods required by the AuthorizationToken interface and the token interface are fully implemented.

After you implement this interface, place it in the *profile_root/classes* directory. For more information on classes, see “Creating a classes subdirectory in your profile for custom classes” on page 976.

Tip: All of the token types defined by the propagation framework have similar interfaces. Basically, the token types are marker interfaces that implement the `com.ibm.wsspi.security.token.Token` interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the `com.ibm.wsspi.security.token.Token` interface. All of your token implementations, including the `AuthorizationToken`, might extend the abstract class and then most of the work is completed.

To see an implementation of `AuthorizationToken`, see “Example: `com.ibm.wsspi.security.token.AuthorizationToken` implementation” on page 1039

2. Add and receive the custom `AuthorizationToken` during WebSphere Application Server logins. This task is typically accomplished by adding a custom login module to the various application and system login configurations. However, in order to deserialize the information, you must plug in a custom login module, which is discussed in “Propagating a custom Java serializable object for security attribute propagation” on page 1059. After the object is instantiated in the login module, you can add the object to the Subject during the `commit()` method.

If you only want to add information to the Subject to get propagated, see “Propagating a custom Java serializable object for security attribute propagation” on page 1059. If you want to ensure that the information is propagated, want to do your own custom serialization, or want to specify the uniqueness for Subject caching purposes, then consider writing your own `AuthorizationToken` implementation.

The code sample in “Example: custom `AuthorizationToken` login module” on page 1043 shows how to determine if the login is an initial login or a propagation login. The difference between these login types is whether the `WSTokenHolderCallback` contains propagation data. If the callback does not contain propagation data, initialize a new custom `AuthorizationToken` implementation and set it into the Subject. If the callback contains propagation data, look for your specific custom `AuthorizationToken` `TokenHolder` instance, convert the `byte[]` back into your custom `AuthorizationToken` object, and set it back into the Subject. The code sample shows both instances.

You can make your `AuthorizationToken` read-only in the commit phase of the login module. If you do not make the token read-only, then attributes can be added within your applications.

3. Add your custom login module to WebSphere Application Server system login configurations that already contain the `com.ibm.ws.security.server.Im.wsMapDefaultInboundLoginModule` for receiving serialized versions of your custom authorization token.

Because this login module relies on information in the `sharedState` added by the `com.ibm.ws.security.server.Im.wsMapDefaultInboundLoginModule`, add this login module after `com.ibm.ws.security.server.Im.wsMapDefaultInboundLoginModule`. For information on how to add your custom login module to the existing login configurations, see [Developing custom login modules for a system login configuration for JAAS](#).

Results

After completing these steps, you have implemented a custom `AuthorizationToken`.

Example: `com.ibm.wsspi.security.token.AuthorizationToken` implementation:

Use this file to see an example of a `AuthorizationToken` implementation. The following sample code does not extend an abstract class, but rather implements the `com.ibm.wsspi.security.token.AuthorizationToken` interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if there are considerable differences between how you handle the various token implementations.

For information on how to implement a custom `AuthorizationToken`, see “Implementing a custom authorization token for security attribute propagation” on page 1038.

```

Implementing a custom single sign-on token for security attribute propagation

You can create your own single sign-on token implementation. The single sign-on token implementation is set in the login Subject and added to the HTTP response as an HTTP cookie.

About this task

The cookie name is the concatenation of the SingleSignonToken.getName application programming interface (API) and the SingleSignonToken.getVersion API. There is no delimiter. When you add a single sign-on token to the Subject, it also gets propagated horizontally and downstream in case the Subject is used for other web requests. You must deserialize your custom single sign-on token when you receive it from a propagation login. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. Encrypt the information because it is out to the HTTP response and is available on the Internet. You must deserialize or decrypt the bytes at the target and add that information back into the Subject.
- Affect the overall uniqueness of the Subject using the getUniqueID API.

To implement a custom single sign-on token, complete the following steps:

Procedure

1. Write a custom implementation of the SingleSignonToken interface.

Many different methods are available for implementing the `SingleSignonToken` interface. However, make sure the methods that are required by the `SingleSignonToken` interface and the token interface are fully implemented.

After you implement this interface, you can place it in the `profile_root/classes` directory. For more information on classes, see “Creating a classes subdirectory in your profile for custom classes” on page 976.

Tip: All of the token types that are defined by the propagation framework have similar interfaces. Basically, the token types are marker interfaces that implement the `com.ibm.wsspi.security.token.Token` interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the `com.ibm.wsspi.security.token.Token` interface. All of your token implementations, including the single sign-on token, might extend the abstract class and then most of the work is complete.

To see an implementation of the single sign-on token, see “Example: A `com.ibm.wsspi.security.token.SingleSignonToken` implementation” on page 1046

2. Add and receive the custom single sign-on token during WebSphere Application Server logins. This task is typically accomplished by adding a custom login module to the various application and system login configurations. However, to deserialize the information, you need to plug in a custom login module, which is discussed in a subsequent step. After the object is instantiated in the login module, you can add it to the Subject during the commit method.

The code sample in “Example: A custom single sign-on token login module” on page 1049, shows how to determine if the login is an initial login or a propagation login. The difference is whether the `WSTokenHolderCallback` callback contains propagation data. If the callback does not contain propagation data, initialize a new custom single sign-on token implementation and set it into the Subject. Also, look for the HTTP cookie from the HTTP request if the HTTP request object is available in the callback. You can get your custom single sign-on token both from a horizontal propagation login and from the HTTP request. However, it is recommended that you make the token available in both places because then the information arrives at any front-end application server, even if that server does not support propagation.

You can make your single sign-on token read-only in the commit phase of the login module. If you make the token read-only, additional attributes cannot be added within your applications.

Restriction:

- HTTP cookies have a size limitation. Size restrictions should be included in the documentation for your specific browser.
 - The WebSphere Application Server runtime does not handle cookies that it does not generate, so this cookie is not used by the runtime.
 - The `SingleSignonToken` object, when in the Subject, does affect the cache lookup of the Subject if you return something in the `getUniqueID` method.
3. Get the HTTP cookie from the HTTP request object during login or from an application. The sample code that is found in “Example: An HTTP cookie retrieval” on page 1051 shows how you can retrieve the HTTP cookie from the HTTP request, decode the cookie so that it is back to your original bytes, and create your custom `SingleSignonToken` object from the bytes.
 4. Add your custom login module to WebSphere Application Server system login configurations that already contain the `com.ibm.ws.security.server.Im.wsMapDefaultInboundLoginModule` for receiving serialized versions of your custom propagation token. Because this login module relies on information in the `sharedState` state that is added by the `com.ibm.ws.security.server.Im.wsMapDefaultInboundLoginModule` login module, add this login module after the `com.ibm.ws.security.server.Im.wsMapDefaultInboundLoginModule` login module.

For information on adding your custom login module into the existing login configurations, see *Developing custom login modules for a system login configuration for JAAS*.

Results

After completing these steps, you have implemented a custom single sign-on token.

Example: A *com.ibm.wsspi.security.token.SingleSignonToken* implementation:

Use this file to see an example of a single sign-on implementation. The following sample code does not extend an abstract class, but implements the `com.ibm.wsspi.security.token.SingleSignonToken` interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if considerable differences exist between how you handle the various token implementations.

For information on how to implement a custom single sign-on token, see “Implementing a custom single sign-on token for security attribute propagation” on page 1044.

                            {
                                subject.getPrivateCredentials().

```

```

        add(customSSTokenPriv);
    }
}
catch (Exception e)
{
    throw new WSLoginFailedException (e.getMessage(), e);
}

return null;
});
}
catch (Exception e)
{
    throw new WSLoginFailedException (e.getMessage(), e);
}
}
}

// Defines your login module variables
com.ibm.wsspi.security.token.SingleSignonToken customSSToken = null;
com.ibm.wsspi.security.token.AuthenticationToken defaultAuthToken = null;
java.util.Map _sharedState = null;
}

```

Example: An HTTP cookie retrieval:

The following example shows you how to retrieve a cookie from an HTTP request, decode the cookie so that it is back to your original bytes, and create your custom SingleSignonToken object from the bytes. This example shows how to complete these steps from a login module. However, you also can complete these steps using a servlet.

For information on what to do during initialization, login and commit, see [Developing custom login modules for a system login configuration for JAAS](#).

```

public customLoginModule()
{
    public void initialize(Subject subject, CallbackHandler callbackHandler,
        Map sharedState, Map options)
    {
        _sharedState = sharedState;
    }
}

public boolean login() throws LoginException
{
    // Handles the WSTokenHolderCallback to see if this is an
    // initial or propagation login.
    Callback callbacks[] = new Callback[2];
    callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");
    callbacks[1] = new WSServletRequestCallback("HttpServletRequest: ");

    try
    {
        callbackHandler.handle(callbacks);
    }
    catch (Exception e)
    {
        // Handles the exception
    }

    // receive the ArrayList of TokenHolder objects (the serialized tokens)
    List authzTokenList = ((WSTokenHolderCallback) callbacks[0]).getTokenHolderList();
    javax.servlet.http.HttpServletRequest request =
        ((WSServletRequestCallback) callbacks[1]).getHttpServletRequest();

    if (request != null)
    {
        // Checks if the cookie is present
        javax.servlet.http.Cookie[] cookies = request.getCookies();
        String[] cookieStrings = getCookieValues (cookies, "myCookieName1");

        if (cookieStrings != null)

```

Implementing a custom authentication token for security attribute propagation

This topic explains how you might create your own authentication token implementation, which is set in the login Subject and propagated downstream.

About this task

With this implementation you can specify an authentication token that can be used by a custom login module or application. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. You must deserialize the bytes at the target and add that information back on the thread. This task also might include encryption and decryption.
- Affect the overall uniqueness of the Subject using the `getUniqueId` application programming interface (API).

Important: Custom authentication token implementations are not used by the security runtime in WebSphere Application Server to enforce authentication. WebSphere Application Security runtime uses this token in the following situations only:

- Call the `getBytes` method for serialization
- Call the `getForwardable` method to determine whether to serialize the authentication token.
- Call the `getUniqueId` method for uniqueness
- Call the `getName` and the `getVersion` methods for adding serialized bytes to the token holder that is sent downstream

All of the other uses are custom implementations.

To implement a custom authentication token, you must complete the following steps:

Procedure

1. Write a custom implementation of the `AuthenticationToken` interface. Many different methods are available for implementing the `AuthenticationToken` interface. However, make sure the methods that are required by the `AuthenticationToken` interface and the token interface are fully implemented. After you implement this interface, you can place it in the `install_dir/classes` directory. Alternatively, you can place the class in any private directory. However, make sure that the WebSphere Application Server class loader can locate the class and that it is granted the appropriate permissions. You can add the Java archive (JAR) file or directory that contains this class into the `server.policy` file so the class has the necessary permissions required by the server code.

Tip: All of the token types that are defined by the propagation framework have similar interfaces. The token types are marker interfaces that implement the `com.ibm.wsspi.security.token.Token` interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the `com.ibm.wsspi.security.token.Token` interface. All of your token implementations, including the authentication token, might extend the abstract class and then most of the work is complete.

To see an implementation of the `AuthenticationToken` interface, see “Example: A `com.ibm.wsspi.security.token.AuthenticationToken` implementation” on page 1054.

2. Add and receive the custom authentication token during WebSphere Application Server logins. This task is typically accomplished by adding a custom login module to the various application and system login configurations. However, to deserialize the information you must plug in a custom login module. After the object is instantiated in the login module, you can add the object to the Subject during the `commit` method.

If you only want to add information to the Subject to get propagated, see “Propagating a custom Java serializable object for security attribute propagation” on page 1059. If you want to ensure that the

information is propagated, do your own custom serialization, or specify the uniqueness for Subject caching purposes, consider writing your own authentication token implementation.

The code sample in “Example: A custom authentication token login module” on page 1058, shows how to determine if the login is an initial login or a propagation login. The difference between these login types is whether the WSTokenHolderCallback callback contains propagation data. If the callback does not contain propagation data, initialize a new custom authentication token implementation and set it into the Subject. If the callback contains propagation data, look for your specific custom authentication token TokenHolder instance, convert the byte array back into your custom AuthenticationToken object, and set it back into the Subject. The code sample shows both instances.

You can make your authentication token read-only in the commit phase of the login module. If you do not make the token read-only, attributes can be added within your applications.

3. Add your custom login module to WebSphere Application Server system login configurations that already contain the `com.ibm.ws.security.server.Im.wsMapDefaultInboundLoginModule` login module for receiving serialized versions of your custom authorization token.

Because this login module relies on information in the shared state that is added by the `com.ibm.ws.security.server.Im.wsMapDefaultInboundLoginModule` login module, add this login module after the `com.ibm.ws.security.server.Im.wsMapDefaultInboundLoginModule` login module. For information on how to add your custom login module to the existing login configurations, see *Developing custom login modules for a system login configuration for JAAS*.

Results

After completing these steps, you have implemented a custom authentication token.

Example: A com.ibm.wsspi.security.token.AuthenticationToken implementation:

The following example illustrates an authentication token implementation. The following sample code does not extend an abstract class, but rather implements the `com.ibm.wsspi.security.token.AuthenticationToken` interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if considerable differences exist between how you handle the various token implementations.

```
package com.ibm.websphere.security.token;

import com.ibm.websphere.security.WSSecurityException;

Example: A custom authentication token login module:

This examples shows how to determine if the login is an initial login or a propagation login.

For information on what to do during initialization, login and commit, see [Developing custom login modules for a system login configuration for JAAS](#).

```

public customLoginModule()
{
    public void initialize(Subject subject, CallbackHandler callbackHandler,
        Map sharedState, Map options)
    {
        _sharedState = sharedState;
    }

    public boolean login() throws LoginException
    {
        // Handles the WSTokenHolderCallback to see if this is an initial or
        // propagation login.
        Callback callbacks[] = new Callback[1];
        callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");

        try
        {
            callbackHandler.handle(callbacks);
        }
        catch (Exception e)
        {
            // Handles exception
        }

        // Receives the ArrayList of TokenHolder objects (the serialized tokens)
        List authzTokenList = ((WSTokenHolderCallback) callbacks[0]).getTokenHolderList();

        if (authzTokenList != null)
        {
            // Iterates through the list looking for your custom token
            for (int i=0; i<authzTokenList.size(); i++)
            {
                TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

                // Looks for the name and version of your custom AuthenticationToken
                // implementation
                if (tokenHolder.getName().equals("your_oid_name") && tokenHolder.getVersion() == 1)
                {
                    // Passes the bytes into your custom AuthenticationToken constructor
                    // to deserialize
                    customAuthzToken = new
                        com.ibm.websphere.security.token.
                            CustomAuthenticationTokenImpl(tokenHolder.getBytes());
                }
            }
        }
        else
        {
            // This is not a propagation login. Create a new instance of your
            // AuthenticationToken implementation
        }
        // Gets the principal from the default AuthenticationToken. This principal
        // should match all default tokens.
    }
}

```

```

        // Note: WebSphere Application Server runtime only enforces this for
        // default tokens. Thus, you can choose
        // to do this for custom tokens, but it is not required.
defaultAuthToken = (com.ibm.wsspi.security.token.AuthenticationToken)
sharedState.get(com.ibm.wsspi.security.auth.callback.Constants.WSAUTHTOKEN_KEY);
String principal = defaultAuthToken.getPrincipal();

        // Adds a new custom authentication token. This is an initial login. Pass
        // the principal into the constructor
customAuthToken = new com.ibm.websphere.security.token.
    CustomAuthenticationTokenImpl(principal);

// Adds any initial attributes
if (customAuthToken != null)
{
    customAuthToken.addAttribute("key1", "value1");
    customAuthToken.addAttribute("key1", "value2");
    customAuthToken.addAttribute("key2", "value1");
    customAuthToken.addAttribute("key3", "something different");
}

        // Note: You can add the token to the Subject during commit in case
        // something happens during the login.
}

public boolean commit() throws LoginException
{
    if (customAuthToken != null)
    {
        // Sets the customAuthToken token into the Subject
        try
        {
            private final AuthenticationToken customAuthTokenPriv = customAuthToken;
            // Do this in a doPrivileged code block so that application code does
            // not need to add additional permissions
            java.security.AccessController.doPrivileged(new java.security.PrivilegedAction()
            {
                public Object run()
                {
                    try
                    {
                        // Adds the custom Authentication token if it is not
                        // null and not already in the Subject
                        if ((customAuthTokenPriv != null) &&
                            (!subject.getPrivateCredentials().
                                contains(customAuthTokenPriv)))
                        {
                            subject.getPrivateCredentials().add(customAuthTokenPriv);
                        }
                    }
                    catch (Exception e)
                    {

```

Propagating a custom Java serializable object for security attribute propagation

This document describes how to add an object into the Subject from a login module and describes other infrastructure considerations to make sure that the Java object gets propagated.

Before you begin

Prior to completing this task, verify that security propagation is enabled in the administrative console.

About this task

With security attribute propagation enabled, you can propagate data either horizontally with single sign-on (SSO) enabled or downstream using Common Secure Interoperability Version 2 (CSlv2). When a login occurs, either through an application login configuration or a system login configuration, a custom login module can be plugged in to add Java serialized objects into the Subject during login. This document describes how to add an object into the Subject from a login module and describes other infrastructure considerations to make sure that the Java object gets propagated.

Procedure

1. Add your custom Java object into the Subject from a custom login module. A two-phase process exists for each Java Authentication and Authorization Service (JAAS) login module. WebSphere Application Server completes the following processes for each login module present in the configuration:

login method

In this step, the login configuration callbacks are analyzed, if necessary, and the new objects or credentials are created.

commit method

In this step, the objects or credentials that are created during login are added into the Subject.

After a custom Java object is added into the Subject, WebSphere Application Server serializes the object on the sending server, deserializes the object on the receiving server, and adds the object back into the Subject downstream. However, some requirements exist for this process to occur successfully. For more information on the JAAS programming model, see the JAAS information provided in the Security: Resources for learning article.

Important: Whenever you plug a custom login module into the login infrastructure of WebSphere Application Server, make sure that the code is trusted. When you add the login module into the *profile_root/classes* directory, the login module has Java 2 Security AllPermissions permissions. For more information, see “Creating a classes subdirectory in your profile for custom classes” on page 976. However, because the login module might be run after the application code on the call stack, you might add `doPrivileged` code so that you do not need to add additional properties to your applications.

The following code sample shows how to add `doPrivileged` code. For information on what to do during initialization, login and commit, see Developing custom login modules for a system login configuration for JAAS.

```
public customLoginModule()
{
    public void initialize(Subject subject, CallbackHandler callbackHandler,
        Map sharedState, Map options)
    {
    }
}

public boolean login() throws LoginException
{
    // Construct callback for the WSTokenHolderCallback so that you
    // can determine if
    // your custom object has propagated
    Callback callbacks[] = new Callback[1];
    callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");

    try
    {
        _callbackHandler.handle(callbacks);
    }
    catch (Exception e)
    {
        throw new LoginException (e.getLocalizedMessage());
    }

    // Checks to see if any information is propagated into this login
    List authzTokenList = ((WSTokenHolderCallback) callbacks[1]).
        getTokenHolderList();

    if (authzTokenList != null)
    {
        for (int i = 0; i < authzTokenList.size(); i++)
```

```

    {
        TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

        // Look for your custom object. Make sure you use
        // "startsWith"because there is some data appended
        // to the end of the name indicating in which Subject
        // Set it belongs. Example from getName():
        // "com.acme.CustomObject (1)". The class name is
        // generated at the sending side by calling the
        // object.getClass().getName() method. If this object
        // is deserialized by WebSphere Application Server,
        // then return it and you do not need to add it here.
        // Otherwise, you can add it below.
        // Note: If your class appears in this list and does
        // not use custom serialization (for example, an
        // implementation of the Token interface described in
        // the Propagation Token Framework), then WebSphere
        // Application Server automatically deserializes the
        // Java object for you. You might just return here if
        // it is found in the list.

        if (tokenHolder.getName().startsWith("com.acme.CustomObject"))
            return true;
    }
}
// If you get to this point, then your custom object has not propagated
myCustomObject = new com.acme.CustomObject();
myCustomObject.put("mykey", "mydata");
}

public boolean commit() throws LoginException
{
    try
    {
        // Assigns a reference to a final variable so it can be used in
        // the doPrivileged block
        final com.acme.CustomObject myCustomObjectFinal = myCustomObject;
        // Prevents your applications from needing a JAAS getPrivateCredential
        // permission.
        java.security.AccessController.doPrivileged(new java.security.
            PrivilegedExceptionAction()
        {
            public Object run() throws java.lang.Exception
            {
                // Try not to add a null object to the Subject or an object
                // that already exists.
                if (myCustomObjectFinal != null && !subject.getPrivateCredentials().
                    contains(myCustomObjectFinal))
                {
                    // This call requires a special Java 2 Security permission,
                    // see the JAAS application programming interface (API)
                    // documentation.
                    subject.getPrivateCredentials().add(myCustomObjectFinal);
                }
                return null;
            }
        });
    }
    catch (java.security.PrivilegedActionException e)
    {
        // Wraps the exception in a WSLoginFailedException
        java.lang.Throwable myException = e.getException();
        throw new WSLoginFailedException (myException.getMessage(), myException);
    }
}

// Defines your login module variables
com.acme.CustomObject myCustomObject = null;
}

```

2. Verify that your custom Java class implements the `java.io.Serializable` interface. An object that is added to the Subject must be serialized if you want the object to propagate. For example, the object must implement the `java.io.Serializable` interface. If the object is not serialized, the request does not fail, but the object does not propagate. To make sure an object that is added to the Subject is propagated, implement one of the token interfaces that is defined in topics about security attribute propagation or add attributes to one of the following existing default token implementations:

AuthorizationToken

Add attributes if they are user-specific.

PropagationToken

Add attributes that are specific to an invocation.

If you are careful adding custom objects and follow all the steps to make sure that WebSphere Application Server can serialize and deserialize the object at each hop, then it is sufficient to use custom Java objects only.

3. Verify that your custom Java class exists on all of the systems that might receive the request. When you add a custom object into the Subject and expect WebSphere Application Server to propagate the object, make sure that the class definition for that custom object exists in the *profile_root/classes* directory on all of the nodes where serialization or deserialization might occur. Also, verify that the Java class versions are the same.
4. Verify that your custom login module is configured in all of the login configurations used in your environment where you need to add your custom object during a login. Any login configuration that interacts with WebSphere Application Server generates a Subject that might be propagated outbound for an Enterprise JavaBeans (EJB) request. If you want WebSphere Application Server to propagate a custom object in all cases, make sure that the custom login module is added to every login configuration that is used in your environment. For more information, see *Developing custom login modules for a system login configuration for JAAS*.
5. Verify that security attribute propagation is enabled on all of the downstream servers that receive the propagated information. When an EJB request is sent to a downstream server and security attribute propagation is disabled on that server, only the authentication token is sent for backwards compatibility. Therefore, you must review the configuration to verify that propagation is enabled in all of the cells that might receive requests. You must check several places in the administrative console to make sure propagation is fully enabled.
6. Add any custom objects to the propagation exclude list that you do not want to propagate. You can configure a property to exclude the propagation of objects that match specific class names, package names, or both. For example, you can have a custom object that is related to a specific process. If the object is propagated, it does not contain valid information. You must tell WebSphere Application Server not to propagate this object. Complete the following steps to specify the object in the propagation exclude list, using the administrative console:
 - a. Click **Security > Global security > Custom properties > New**.
 - b. Add `com.ibm.ws.security.propagationExcludeList` in the **Name** field.
 - c. Add the name of the custom object in the **Value** field. You can add a list of custom objects to the propagation exclude list, separated by a colon (:). For example, you might enter `com.acme.CustomLocalObject:com.acme.private.*`. You can enter a class name such as `com.acme.CustomLocalObject` or a package name such as `com.acme.private.*`. In this example, WebSphere Application Server does not propagate any class that equals `com.acme.CustomLocalObject` or begins with `com.acme.private`.

Although you can add custom objects to the propagation exclude list, you must be aware of a side effect. WebSphere Application Server stores the opaque token, or the serialized Subject contents, in a local cache for the life of the single sign-on (SSO) token. The life of the SSO token, which has a default of two hours, is configured in the SSO properties on the administrative console. The information that is added to the opaque token includes only the objects not in the exclude list.

Ensure that your SSO token timeout value is greater than the authentication cache timeout value. To modify the authentication cache, see the documentation about the authentication cache settings.

Results

As a result of this task, custom Java serializable objects are propagated horizontally or downstream. For more information on the differences between horizontal and downstream propagation, see topics about security attribute propagation or add attributes to one of the following existing default token implementations:

Enabling a plugpoint for custom password encryption

Two properties govern the protection of passwords. By configuring these two properties, you can enable a plugpoint for custom password encryption.

Before you begin

To view an example code sample that illustrates the `com.ibm.wsspi.security.crypto.CustomPasswordEncryption` interface, see “Plug point for custom password encryption” on page 1064.

About this task

The encryption method is called for password processing whenever the custom class is configured and custom encryption is enabled. The decryption method is called whenever the custom class is configured and the password contains the `{custom:alias}` tag. The `custom:alias` tag is stripped prior to decryption.

Procedure

1. To enable custom password encryption, you must configure two properties:
 - **`com.ibm.wsspi.security.crypto.customPasswordEncryptionClass`** - Defines the custom class that implements the `com.ibm.wsspi.security.crypto.CustomPasswordEncryption` password encryption interface.
 - **`com.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled`** - Defines when the custom class is used for default password processing. When the `passwordEncryptionEnabled` option is not specified or set to `false`, and the `passwordEncryptionClass` class is specified, the decryption method is called whenever a `{custom:alias}` tag still exists in the configuration repository.
2. To configure custom password encryption, configure both of these properties in the `security.xml` file. The custom encryption class (`com.acme.myPasswordEncryptionClass`) must be placed in a Java archive (JAR) file in the `${APP_SERVER_ROOT}/classes` directory in all WebSphere Application Server processes. Every configuration document that contains a password (`security.xml` and any application bindings that contain RunAs passwords), must be saved before all of the passwords become encrypted with the custom encryption class. For client side property files such as `sas.client.props` and `soap.client.props`, use the `PropFilePasswordEncoder.bat` or `PropFilePasswordEncode.sh` script to enable custom processing. This script must have the two properties configured as system properties on the Java command line of the script. The same tools that are used for encoding and decoding can be used for encryption and decryption when custom password encryption is enabled.
3. If the custom implementation class defaults to the `com.ibm.wsspi.security.crypto.CustomPasswordEncryptionImpl` interface, and this class is present in the class path, then encryption is enabled by default. This simplifies the enablement process for all nodes. It is not necessary to define any other properties except for those that the custom implementation requires. To disable encryption, but still use this class for decryption, specify the following class.
 - `com.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled=false`

What to do next

Whenever a custom encryption class encryption operation is called, and it creates a run-time exception or a defined `PasswordEncryptException` exception, the WebSphere Application Server runtime uses the `{xor}` algorithm to encode the password. This encoding prevents the storage of the password in plain text. After the problem with the custom class has been resolved, it automatically encrypts the password the next time the configuration document is saved.

When a RunAs role is assigned a user ID and password, it currently is encoded using the WebSphere Application Server encoding function. Therefore, after the custom plug point is configured to encrypt the passwords, it encrypts the passwords for the RunAs bindings as well. If the deployed application is moved to a cell that does not have the same encryption keys, or the custom encryption is not yet enabled, a login failure results because the password is not readable.

One of the responsibilities of the custom password encryption implementation is to manage the encryption keys. This class must decrypt any password that it encrypted. Any failure to decrypt a password renders that password to be unusable, and the password must be changed in the configuration. All encryption keys must be available for decryption there and no passwords are left using those keys. The master secret must be maintained by the custom password encryption class to protect the encryption keys.

You can manage the master secret by using a stash file for the keystore, or by using a password locator that enables the custom encryption class to locate the password so that it can be locked down.

Plug point for custom password encryption

A plug point for custom password encryption can be created to encrypt and decrypt all passwords in WebSphere Application Server that are currently encoded or decoded using Base64-encoding.

The implementation class of this plug point has the responsibility for managing keys, determining the encryption algorithm to use, and for protecting the master secret. The WebSphere Application Server runtime stores the encrypted passwords in their existing locations, preceded with {custom:alias} tags instead of {xor} tags. The custom part of the tag indicates that it is a custom algorithm. The alias part of the tag is specified by the custom implementation, which helps to indicate how the password is encrypted. The implementation can include the key alias, encryption algorithm, encryption mode, or encryption padding.

A custom provider of this plug point must implement an interface that is designed to encrypt and decrypt passwords. The interface is called by the WebSphere Application Server runtime whenever the custom plug point is enabled. The custom algorithm becomes one of the supported algorithms when the plug point is enabled. Other supported algorithms include {xor} (standard base64 encoding) and {os400} which is used on the iSeries platform.

The following example illustrates the com.ibm.wsspi.security.crypto.CustomPasswordEncryption interface:

```
package com.ibm.wsspi.security.crypto;
public interface CustomPasswordEncryption
{
    /**
     * The encrypt operation takes a UTF-8 encoded String in the form of a byte[].
     * The byte[] is generated from String.getBytes("UTF-8").
     * An encrypted byte[] is returned from the implementation in the EncryptedInfo
     * object. Additionally, a logical key alias is returned in the EncryptedInfo
     * object which is passed back into the decrypt method to determine which key was
     * used to encrypt this password. The WebSphere Application Server runtime has
     * no knowledge of the algorithm or the key used to encrypt the data.
     *
     * @param byte[]
     * @return com.ibm.wsspi.security.crypto.EncryptedInfo
     * @throws com.ibm.wsspi.security.crypto.PasswordEncryptException
     */
    public EncryptedInfo encrypt (byte[] decrypted_bytes) throws PasswordEncryptException;

    /**
     * The decrypt operation takes the EncryptedInfo object containing a byte[]
     * and the logical key alias and converts it to the decrypted byte[]. The
     * WebSphere Application Server runtime converts the byte[] to a String
     * using new String (byte[], "UTF-8");
     *
     * @param com.ibm.wsspi.security.crypto.EncryptedInfo
     * @return byte[]
     * @throws com.ibm.wsspi.security.crypto.PasswordDecryptException
     */
    public byte[] decrypt (EncryptedInfo info) throws PasswordDecryptException;

    /**
     * The following is reserved for future use and is currently not
     * called by the WebSphere Application Server runtime.
     *
     * @param java.util.HashMap
     */
    public void initialize (java.util.HashMap initialization_data);
}
```

The `com.ibm.wsspi.security.crypto.EncryptedInfo` class contains the encrypted bytes with the user-defined alias that is associated with the encrypted bytes. This information is passed back into the encryption method to help determine how the password was originally encrypted.

```
package com.ibm.wsspi.security.crypto;
public class EncryptedInfo
{
    private byte[] bytes;
    private String alias;

    /**
     * This constructor takes the encrypted bytes and a keyAlias as parameters.
     * This constructor is used to pass to or from the WebSphere Application Server
     * runtime to enable the runtime to associate the bytes with a specific key that
     * is used to encrypt the bytes.
     */

    public EncryptedInfo (byte[] encryptedBytes, String keyAlias)
    {
        bytes = encryptedBytes;
        alias = keyAlias;
    }

    /**
     * This command returns the encrypted bytes.
     *
     * @return byte[]
     */
    public byte[] getEncryptedBytes()
    {
        return bytes;
    }

    /**
     * This command returns the key alias. The key alias is a logical string that is
     * associated with the encrypted password in the model. The format is
     * {custom:keyAlias}encrypted_password. Typically, just the key alias is placed
     * here, but algorithm information can also be returned.
     *
     * @return String
     */
    public String getKeyAlias()
    {
        return alias;
    }
}
```

The encryption method is called for password processing whenever the custom class is configured and custom encryption is enabled. The decryption method is called whenever the custom class is configured and the password contains the `{custom:alias}` tag . The `custom:alias` tag is stripped prior to decryption. For more information, see [Enabling custom password encryption](#).

Implementing a custom authentication provider using JASPI

You can implement a custom authentication provider using Java Authentication SPI for Containers (JASPI, or sometimes called JASPIC) to handle the Java Platform, Enterprise Edition (Java EE) authentication of HTTP request and response messages destined for web applications.

Before you begin

For JASPI authentication processing to take place, application security must be enabled in the global or domain security configuration and the server must be restarted for the configuration changes to take effect. Read the [Application security](#) topic for more information.

About this task

Note: This release of WebSphere Application Server supports the JSR 196: Java Authentication SPI for Containers (JASPI, or sometimes called JASPIC) specification, which enables third-party security providers to handle the Java Platform, Enterprise Edition (Java EE) authentication of HTTP request and response messages destined for web applications. The JASPI specification extends the pluggable authentication concepts of the Java Authentication and Authorization Service (JAAS) to the authentication of HTTP request and response messages. When application security is enabled,

and a protected web resource is accessed, the web container and the security runtime collaborate to make an authentication decision for the caller. When using a third-party JASPI provider, the authentication decision is delegated to that provider.

The JASPI specification defines standard system programming interfaces that enable developers to write a pluggable custom authentication provider that can handle Java EE web authentication mechanisms as well as any extended authentication processing. The WebSphere Application Server runtime uses these standard system programming interfaces to invoke the JASPI authentication provider. Read the Servlet Container Profile section in the JSR 196: Java Authentication Service Provider Interface for Containers specification for the requirements that third-party authentication providers must satisfy for more information.

If application security is enabled with JASPI authentication, when the web resource (such as a servlet or a JavaServer Pages (JSP) file) is accessed, the security runtime checks if the web resource is mapped to a JASPI provider defined in the security configuration. If so, the runtime invokes the JASPI authentication provider to perform authentication for the HTTP request and response messages.

To implement a custom authentication provider using JASPI you must do the following:

Procedure

1. Develop a custom JASPI authentication provider.

WebSphere Application Server provides support for the development of custom JASPI authentication providers to be used to perform authentication for the HTTP request and response messages destined for web applications. Read “Developing a custom JASPI authentication provider” for more information.

2. Configure a new JASPI authentication provider.

WebSphere Application Server allows an administrator to enable JASPI authentication and to define a third-party JASPI authentication provider as part of the global or domain security configuration. Read “Configuring a new JASPI authentication provider using the administrative console” on page 1070 for more information.

3. Associate a JASPI authentication provider with an application or specific web modules.

During application deployment, the administrator or deployer can use the Map JASPI Provider option to associate web applications and specific web modules with an existing JASPI authentication provider as defined in the security configuration. This association can also be made when editing the options for an existing installed application. By default, an application inherits the JASPI settings defined in the WebSphere Application Server global or domain security configuration, and web modules inherit the application setting. The Map JASPI Provider option can be used to override these defaults. Read “Enabling JASPI authentication using the Map JASPI provider option during application deployment” on page 1073 for more information.

Developing a custom JASPI authentication provider

You can develop a custom Java Authentication SPI for Containers (JASPI) authentication provider by creating classes that implement the required interfaces noted in the JSR 196: Java Authentication Service Provider Interface for Containers specification.

Before you begin

Review the specific interface implementation requirements for JASPI authentication providers and modules in the JSR 196: Java Authentication Service Provider Interface for Containers specification.

About this task

WebSphere Application Server supports the use of third-party authentication providers that are compliant with the servlet container profile specified in Java Authentication SPI for Containers (JASPI) Version 1.0.

The servlet container profile defines interfaces that are used by the security runtime environment in collaboration with the web container in WebSphere Application Server to invoke authentication modules before and after a web request is processed by an application. Authentication using JASPI modules is performed only when JASPI has been enabled in the security configuration and when a configured JASPI provider has been associated with the web module that processes the received web request.

To develop a custom authentication provider, create classes that implement the required interfaces noted in the JSR 196: Java Authentication Service Provider Interface for Containers specification. A provider can use one or more authentication modules for authentication. Modules can use callbacks to perform authentication, or they can manually add the necessary user identity information to the client subject. Depending on the scope of the provider, the implementation classes can be stored in various locations on the application server.

Procedure

1. Create a class that implements the `javax.security.auth.message.config.AuthConfigProvider` interface. The `AuthConfigProvider` implementation class must define a public two-argument constructor and the `getServerAuthConfig` public method:

```
import java.util.Map;
import javax.security.auth.callback.CallbackHandler;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.config.AuthConfigFactory;
import javax.security.auth.message.config.AuthConfigProvider;
import javax.security.auth.message.config.ServerAuthConfig;

public class SampleAuthConfigProvider implements AuthConfigProvider {

    public SampleAuthConfigProvider(Map<String, String> properties, AuthConfigFactory factory) {
        ...
    }
    public ServerAuthConfig getServerAuthConfig(String layer, String appContext, CallbackHandler handler)
        throws AuthException {
        ...
    }
}
```

An instance of the `AuthConfigProvider` implementation class is used by WebSphere Application Server when a request arrives to be processed by the web module of the application. The `getServerAuthConfig` method is used to obtain a `ServerAuthConfig` instance. The `CallbackHandler` argument in the method call is used by the authentication module(s).

2. Create a class that implements the `javax.security.auth.message.config.ServerAuthConfig` interface. The `ServerAuthConfig` implementation class must define the `getAuthContextID` and `getAuthContext` public methods:

```
import java.util.Map;
import javax.security.auth.Subject;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.MessageInfo;
import javax.security.auth.message.config.ServerAuthConfig;
import javax.security.auth.message.config.ServerAuthContext;

public class SampleServerAuthConfig implements ServerAuthConfig {

    public String getAuthContextID(MessageInfo messageInfo) throws IllegalArgumentException {
        ...
    }
    public ServerAuthContext getAuthContext(String authContextID, Subject serviceSubject, Map properties)
        throws AuthException {
        ...
    }
}
```

The `getAuthContextID` and `getAuthContext` methods in the `ServerAuthConfig` implementation class are used to obtain a `ServerAuthContext` instance.

3. Create a class that implements the `javax.security.auth.message.config.ServerAuthContext` interface.

The `ServerAuthContext` implementation class must define the `validateRequest` and `secureResponse` public methods:

```
import javax.security.auth.Subject;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.AuthStatus;
import javax.security.auth.message.MessageInfo;
import javax.security.auth.message.config.ServerAuthContext;

public class SampleServerAuthContext implements ServerAuthContext {

    public AuthStatus validateRequest(MessageInfo messageInfo, Subject clientSubject, Subject serviceSubject)
        throws AuthException {
        ...
    }
    public AuthStatus secureResponse(MessageInfo messageInfo, Subject serviceSubject)
        throws AuthException {
        ...
    }
}
```

The `validateRequest` method in the `ServerAuthContext` implementation class is used to invoke the module that authenticates the received web request message. If the authentication result is successful, the web container dispatches the received web request message that the target web module processes in the application. If the authentication result is not successful, the request is rejected with the appropriate response status.

4. Create a class that implements the `javax.security.auth.message.module.ServerAuthModule` interface.

The `ServerAuthModule` implementation class must define the `initialize`, `validateRequest`, and `secureResponse` public methods:

```
import javax.security.auth.Subject;
import javax.security.auth.callback.CallbackHandler;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.AuthStatus;
import javax.security.auth.message.MessageInfo;
import javax.security.auth.message.MessagePolicy;
import javax.security.auth.message.module.ServerAuthModule;

public class SampleAuthModule implements ServerAuthModule {

    public void initialize(MessagePolicy requestPolicy, MessagePolicy responsePolicy, CallbackHandler handler, Map options)
        throws AuthException {
        ...
    }

    public AuthStatus validateRequest(MessageInfo messageInfo, Subject clientSubject, Subject serviceSubject)
        throws AuthException {
        ...
    }

    public AuthStatus secureResponse(MessageInfo messageInfo, Subject serviceSubject)
        throws AuthException {
        ...
    }
}
```

The `initialize` method in the `ServerAuthModule` implementation class is called by the `ServerAuthContext` implementation class to initialize the authentication module and to associate it with the `ServerAuthContext` instance.

The `validateRequest` and `secureResponse` methods in this class are used respectively to authenticate the `javax.servlet.http.HttpServletRequest` and `javax.servlet.http.HttpServletResponse` contained in the `javax.security.auth.message.MessageInfo` that is received. These methods can use the `CallbackHandler` instance received in the `initialize` method to interact with the WebSphere security runtime to validate a user password, and the active user registry to retrieve a unique-id and membership groups for a user. The retrieved data is placed in a `Hashtable` in the set of private credentials in the client subject. The WebSphere Application Server implementation of `CallbackHandler` supports three callbacks:

- `CallerPrincipalCallback`
- `GroupPrincipalCallback`
- `PasswordValidationCallback`

WebSphere Application Server expects the name values obtained with `PasswordValidationCallback.getUsername()` and `CallerPrincipalCallback.getName()` to be identical. If they are not, unpredictable results occur. The `CallbackHandler`'s `handle()` method processes each callback given in the argument array of the method sequentially. Therefore, the name value set in the private credentials of the client subject is the one obtained from the last callback processed.

Note: Always use `PasswordValidationCallback` to validate a user password and to add the appropriate credentials to the client subject during authentication:

```
import javax.security.auth.Subject;
import javax.security.auth.callback.Callback;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.AuthStatus;
import javax.security.auth.message.MessageInfo;
import javax.security.auth.message.callback.PasswordValidationCallback;

public AuthStatus validateRequest(MessageInfo messageInfo, Subject clientSubject, Subject serviceSubject)
    throws AuthException {
    ...
    PasswordValidationCallback pvcb = new PasswordValidationCallback(clientSubject, username, password);
    handler.handle(new Callback[] {pvcb});
    ...
}
```

If `CallbackHandler` is not used by the authentication module, and `validateRequest` returns a successful status, WebSphere Application Server requires that a `Hashtable` instance be included in the `clientSubject` with user identity information so that a custom login can be performed to obtain the credentials for the user. This `Hashtable` can be added to the client subject as in the following example:

```
import java.util.Hashtable;
import java.util.String;
import javax.security.auth.Subject;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.AuthStatus;
import javax.security.auth.message.MessageInfo;
import com.ibm.wsspi.security.registry.RegistryHelper;
import com.ibm.wsspi.security.token.AttributeNameConstants.AttributeNameConstants;

public AuthStatus validateRequest(MessageInfo messageInfo, Subject clientSubject, Subject serviceSubject)
    throws AuthException {
    ...
    UserRegistry reg = RegistryHelper.getUserRegistry(null);
    String uniqueid = reg.getUniqueUserID(username);

    Hashtable hashtable = new Hashtable();
    hashtable.put(AttributeNameConstants.WSCREDENTIAL_UNIQUEID, uniqueid);
    hashtable.put(AttributeNameConstants.WSCREDENTIAL_SECURITYNAME, username);
    hashtable.put(AttributeNameConstants.WSCREDENTIAL_PASSWORD, password);
    hashtable.put(AttributeNameConstants.WSCREDENTIAL_GROUPS, groupList); //optional
    clientSubject.getPrivateCredentials().add(hashtable);
    ...
}
```

For more information about the `Hashtable` requirements and custom login, read about [Developing custom login modules for a system login configuration for JAAS](#).

To support the login and authenticate methods of the Java Servlet 3.0 specification, the following logic must be added to the `validateRequest` method in the `ServerAuthModule` implementation class:

```
import java.util.Map;
import javax.security.auth.Subject;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.AuthStatus;
import javax.security.auth.message.MessageInfo;
import javax.servlet.http.HttpServletRequest;

public AuthStatus validateRequest(MessageInfo messageInfo, Subject clientSubject, Subject serviceSubject)
    throws AuthException {
    ...
    Map msgMap = messageInfo.getMap();

    if ("login".equalsIgnoreCase(msgMap.get("com.ibm.websphere.jaspi.request"))) {
        // This request is for the login method
        String username = msgMap.get("com.ibm.websphere.jaspi.user");
    }
}
```

```

        String password = msgMap.get("com.ibm.websphere.jaspi.password");
        // Authenticate using the user name and password set above.
    }
    else if ("authenticate".equalsIgnoreCase(msgMap.get("com.ibm.websphere.jaspi.request"))) {
        // this request is for the authenticate method
        String authHeader
            = ((HttpServletRequest) messageInfo.getRequestMessage()).getHeader("Authorization");
        if (authHeader == null) {
            // The user has not provided a username and password yet, return
            // AuthStatus.SEND_CONTINUE to challenge
        }
        else {
            // Authenticate using the user name and password in the authentication header.
        }
    }
    else {
        // This is not a Servlet 3.0 login or authenticate request; handle as usual.
    }
    ...
}

```

5. Compile all newly created classes.

The following JAR files in your WebSphere Application Server installation must be specified in the class path to successfully compile the new classes:

- *app_server_root/dev/JavaEE/j2ee.jar*
- *app_server_root/dev/was_public.jar* (if any public WebSphere APIs were used)

6. Create a JAR file with the compiled classes.

Depending on the requirements, the JAR file can be placed in one of three locations:

- *app_server_root/lib*

This location is always on the classpath for the WebSphere Application Server classloader. Using this location, the provider can be registered for a set of web modules or applications as the cell or domain default provider for all web modules and applications, and it can be registered manually as a persistent provider.

- Shared library

Place the provider JAR file anywhere on the WebSphere Application Server system. Configure a shared library that points to the JAR, and add that shared library to the application or server classpath. In a shared library, the provider can be registered for a set of web modules or applications, but the provider cannot be used as the cell or domain default provider. It also cannot be registered as a persistent provider because the shared library is not in the classpath for provider registration during server startup. For more information about configuring a shared library, read about [Creating shared libraries](#).

- Embedded in the application

Include the provider JAR file in the application's EAR file as a utility JAR, or embed the compiled class files in the web module WAR. The embedded provider can be registered for the web modules in the application as long as the classes are included in the classpath for the web module. This provider cannot be used as a cell or domain default provider, nor can it be registered as a persistent provider. The classes in the application are not available for provider registration during server startup.

7. Configure the provider in the security configuration using the administrative console or an administration script.

Read about [“Configuring a new JASPI authentication provider using the administrative console”](#) for more information.

Configuring a new JASPI authentication provider using the administrative console

You can configure a new Java Authentication SPI (JASPI) authentication provider in the cell or in the given security domain by using the administrative console.

About this task

This release of WebSphere Application Server supports integration of message authentication providers that are compliant with the JASPI for Containers Version 1.0 specification.

When JASPI authentication providers are configured, and WebSphere Application Server receives an HTTP request message, the security runtime environment determines if the target application is configured to use JASPI authentication. If so, the runtime environment invokes the selected authentication provider to validate the received message. Otherwise, authentication of the message request is done according to the authentication mechanism provided by WebSphere Application Server for the appropriate messaging layer.

If you want to use JASPI message authentication services, you must supply an implementation of the required interfaces as defined in the JASPI specification. Read “Developing a custom JASPI authentication provider” on page 1066 for more information on these interfaces.

Authentication of HTTP request and response messages destined for JASPI-enabled deployed applications is performed according to the requirements of the Servlet Container Profile specified in the new specification.

Note: JASPI is supported in a mixed-cell environment, but can only be used in nodes that are version 8 or higher. Back-level nodes use existing authentication mechanisms.

To configure a new JASPI authentication provider using the administrative console, do the following:

Procedure

1. Click **Security > Global security**.
2. Select **Enable Java Authentication SPI (JASPI)** to enable support for JASPI authentication.
3. Click **Providers**.

Note: It is not necessary to select **Enable Java Authentication SPI (JASPI)** until after you have configured a new JASPI authentication provider.

Note: The Default provider option is used to specify a single JASPI authentication provider to perform authentication for all web modules when JASPI authentication is enabled, and you do not override the web module to JASPI provider mapping during application deployment. During application deployment, you can override the default for every web module where it does not apply by choosing not to use JASPI or by naming a different provider to use for authentication. However, it is not recommended that you use this option unless you are certain that your default provider is capable of handling all types of web authentication (basic authentication, form authentication and client certificate authentication).

4. Click **New**.
5. Enter a name that uniquely identifies the JASPI authentication provider in the Provider name field.
6. Optional: Enter a textual description of the authentication provider in the Description field.
7. Enter the package-qualified name of the class that implements the authentication provider interface (`javax.security.auth.message.config.AuthConfigProvider`) in the Class name field.

Note: In the Message layer field, WebSphere Application Server Version 8.0 supports only the `HttpServlet` message layer profile as defined in the JASPI specification. You cannot change this value.

8. Optional: Under Custom Properties, click **New** if you require more than one property. This parameter is a list of key/value pairs.
9. Click **OK** or **Apply**.

What to do next

You can also configure a new JASPI authentication provider by using **wsadmin** commands. Read JspiManagement command group for the AdminTask object for more information.

Verify that your server has been restarted so that the changes to configure the JASPI provider will take effect.

Modifying an existing JASPI authentication provider using the administrative console

You can modify and configure an existing Java Authentication SPI (JASPI) authentication provider in the cell or in the given security domain by using the administrative console.

About this task

To modify and configure an existing JASPI authentication provider using the administrative console, do the following:

Procedure

1. Click **Security > Global security**.
2. Click **Providers**. You also have the option to change the Default provider from the drop-down list.

Note: You can modify the value of the **Enable Java Authentication SPI (JASPI)** checkbox to indicate whether or not JASPI support is enabled at a later time.

3. Select an existing JASPI authentication provider to modify.
4. Enter a textual description of the authentication provider in the Description field.
5. Enter a new package-qualified name of the class that implements the authentication provider interface (javax.security.auth.message.config.AuthConfigProvider) in the Class name field if you wish to change it.

Note: In the Message layer field, WebSphere Application Server Version 8.0 supports only the HttpServlet message layer profile as defined in the JASPI specification. You cannot change this value.

6. Optional: Under Custom Properties, select an existing custom configuration property. Click **Delete** to remove the property, **Edit** to modify the property, or click **New** to create a new property. If you select **Edit** to modify an existing property, you can enter new values for the Name field and Value field if you wish to change them.
7. Click **OK** or **Apply**.

What to do next

You can also modify an existing JASPI authentication provider by using **wsadmin** commands. For more information, read JspiManagement command group for the AdminTask object.

Verify that your server has been restarted so that the changes to configure the JASPI provider will take effect.

Deleting a JASPI authentication provider using the administrative console

You can delete an existing Java Authentication SPI (JASPI) authentication provider in the cell or in the given security domain by using the administrative console.

About this task

To delete an existing JASPI authentication provider using the administrative console, do the following:

Procedure

1. Click **Security > Global security**.
2. Click **Providers**, You can optionally select or deselect the **Enable Java Authentication SPI (JASPI)** check box.

Note: You can modify the value of the **Enable Java Authentication SPI (JASPI)** checkbox to indicate whether or not JASPI support is enabled at a later time.

3. Select an existing JASPI authentication provider to delete.
4. Click **Delete**.

What to do next

You can also delete a JASPI authentication provider by using wsadmin commands. For more information, read JaspManagement command group for the AdminTask object.

Verify that your server has been restarted so that the changes to the JASPI provider configuration will take effect.

Enabling JASPI authentication using the Map JASPI provider option during application deployment

An administrator or deployer can use the Map JASPI Provider option during application deployment to associate web applications and specific web modules with an existing Java Authentication SPI (JASPI) authentication provider as defined in the security configuration. This association can also be made when editing the options for a previously installed application.

Before you begin

Before you perform this task, verify that a JASPI authentication provider is defined as part of the global or domain security configuration. Read about “Configuring a new JASPI authentication provider using the administrative console” on page 1070 for more information.

About this task

By default, an application inherits the JASPI settings defined in the WebSphere Application Server global or domain security configuration, and web modules inherit the application setting. However, you can override these default values by using the Map JASPI Provider option during application deployment. Use this option to associate a specific JASPI provider from the global or domain security configuration with the entire application or with specific web modules. You can also use this option to specify that JASPI authentication not be used for an application or specific web module.

To associate a web application or specific web modules with an existing JASPI provider:

Procedure

1. From the administrative console, click **Applications > New Application > New Enterprise Application**. Complete the required steps until you see the step for Map JASPI Provider, or click the **Map JASPI Provider** step from the installation options. A list containing the application name and associated web modules is displayed. To update a JASPI provider association after an application has been deployed, click **Applications > Application Types > WebSphere enterprise applications**, and then select the application to be modified. Click **JASPI Provider** under the Detail properties.
2. Select the application or specific web module for which the JASPI provider setting is to be modified.
3. Click the **Select JASPI Provider** menu and select one of the following options:

Do not use JASPI

Select to disable JASPI authentication for the selected web module or for the application.

Inherit JASPI provider

Select to inherit the JASPI authentication settings from default values in the cell or domain security configuration, as appropriate.

When **Inherit JASPI provider** is selected for a web module, JASPI authentication settings for the selected module are the settings that are specified for the application.

When **Inherit JASPI provider** is selected for the application, JASPI authentication settings are the settings that are specified in the appropriate cell or domain security configuration.

Provider name

When a specific provider name is selected, that provider name is used to perform authentication of web requests for the selected application or web module.

4. Complete the remaining steps to finish installing and deploying the application.

What to do next

Verify that your server has been restarted to ensure that the configuration changes to define the JASPI provider take effect. Read about “Configuring a new JASPI authentication provider using the administrative console” on page 1070 for more information.

JASPI authentication providers collection

The Java Authentication Service Provider Interface (JASPI) for Containers Version 1.0 specification defines standard system programming interfaces that enable developers to write a pluggable custom authentication provider that can handle Java EE web authentication mechanisms as well as any extended authentication processing. The WebSphere Application Server runtime uses these standard system programming interfaces to invoke the JASPI authentication provider.

Read the Servlet Container Profile section in the JSR 196: Java Authentication Service Provider Interface for Containers specification for the requirements that third-party authentication providers must satisfy for more information.

If application security is enabled, and JASPI authentication is enabled with providers configured, when a web resource (such as a servlet or a JavaServer Page (JSP) file) is accessed, the security runtime checks if the web resource is mapped to a JASPI provider defined in the security configuration. If so, the runtime invokes the JASPI authentication provider to perform authentication for the HTTP request and response messages.

Note: WebSphere Application Server Version 8.0 supports only the HttpServlet message layer profile as defined in the JASPI specification.

To view this administrative console page, click **Security > Global security**. Under Authentication, click **Providers**.

To configure a new custom JASPI authentication provider in the cell or in the given security domain, click **New** and specify provider settings.

Provider name:

Specifies a name that uniquely identifies the authentication provider.

Select an existing custom JASPI authentication provider name to edit and configure it.

JASPI authentication provider details

Use this page to provide configuration details for your custom Java Authentication SPI (JASPI) authentication service provider.

To view this administrative console page, click **Security > Global security**. Under Authentication, click **Providers**. Select an existing authentication service provider name or click **New** to create a new one.

Provider name:

Specifies a name that uniquely identifies the authentication provider.

Description:

Specifies a textual description of the authentication provider.

Class name:

Specifies the package-qualified name of the class that implements the authentication provider interface (javax.security.auth.message.config.AuthConfigProvider).

Message layer:

WebSphere Application Server Version 8.0 supports only the HttpServlet message layer profile as defined in the JASPI specification.

Custom properties:

Specifies additional custom properties needed to initialize the authentication provider. This parameter is a list of key/value pairs.

Click **Delete** to remove a custom property or **Edit** to modify a custom property.

JASPI authentication enablement for applications

Use this page to enable or disable Java Authentication SPI (JASPI) authentication for an application or web module, and to specify the name of a JASPI authentication provider to be used for authenticating messages for the application or web module.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications**. Select an application, and under Detail Properties, select **JASPI provider**.

Select JASPI provider:

Select to indicate the web modules in the application that you wish to specify or to override the default JASPI authentication settings for.

Select one of the JASPI provider names to choose a provider to use to perform authentication of web requests for the selected Web module or the application.

To specify how JASPI authentication is performed for the selected web module or the application, choose one of the following:

Do not use JASPI

Select to disable JASPI authentication for the selected web module or for the application.

Inherit JASPI provider

Select to inherit the JASPI authentication settings from default values in the cell or domain security configuration, as appropriate.

When Inherit JASPI provider is selected for a web module, JASPI authentication settings for the selected module are the settings that are specified for the application.

When Inherit JASPI provider is selected for the application, JASPI authentication settings are the settings that are specified in the appropriate cell or domain security configuration.

Provider name

When a specific provider name is selected, that provider is used to perform authentication of web requests for the selected application or web module.

If JASPI authentication is enabled, and a specific provider name is not specified, then the default provider name is used. For more information, read about configuring a new JASPI authentication provider using the administrative console.

If JASPI authentication is disabled, or if no default provider is selected, JASPI authentication is not performed. Web authentication is then performed according to another authentication mechanism as selected in the cell or domain security configuration.

Chapter 26. Developing Startup beans

This page provides a starting point for finding information about startup beans.

Startup beans allow business logic to run when an application starts or stops.

Using startup beans

There are two types of startup beans: application startup beans and Module startup beans.

About this task

Note: The capabilities provided with startup singleton session beans (EJB 3.1 specification) causes the WebSphere Application Server proprietary startup beans function to be deprecated.

A module startup bean is a session bean that is loaded when an EJB Jar file starts. Module startup beans enable Java Platform Enterprise Edition (Java EE) applications to run business logic automatically, whenever an EJB module starts or stops normally. An application startup bean is a session bean that is loaded when an application starts. Application startup beans enable Java EE applications to run business logic automatically, whenever an application starts or stops normally.

Startup beans are especially useful when used with asynchronous bean features. For example, a startup bean might create an alarm object that uses the Java Message Service (JMS) to periodically publish heartbeat messages on a well-known topic. This enables clients or other server applications to determine whether the application is available. Refer to the Enabling an application to wait for a messaging engine to start article if you are using the default JMS provider.

Procedure

1. For Application startup beans, use the home interface, `com.ibm.websphere.startupservice.AppStartUpHome`, to designate a bean as an Application startup bean. For Module startup beans, use the home interface, `com.ibm.websphere.startupservice.ModStartUpHome`, to designate a bean as a Module startup bean.
2. For Application startup beans, use the remote interface, `com.ibm.websphere.startupservice.AppStartUp`, to define `start()` and `stop()` methods on the bean. For Module startup beans, use the remote interface, `com.ibm.websphere.startupservice.ModStartUp`, to define `start()` and `stop()` methods on the bean.

The startup bean `start()` method is called when the module or application starts and contains business logic to be run at module or application start time.

The `start()` method returns a boolean value. **True** indicates that the business logic within the `start()` method ran successfully. Conversely, **False** indicates that the business logic within the `start()` method failed to run completely. A return value of `False` also indicates to the Application server that application startup is aborted.

The startup bean `stop()` methods are called when the module or application stops and contains business logic to be run at module or application stop time. Any exception thrown by a `stop()` method is logged only. No other action is taken.

The `start()` and `stop()` methods must never use the `TX_MANDATORY` transaction attribute. A global transaction does not exist on the thread when the `start()` or `stop()` methods are invoked. Any other `TX_*` attribute can be used. If `TX_MANDATORY` is used, an exception is logged, and the application start is aborted.

The `start()` and `stop()` methods on the remote interface use **Run-As** mode. **Run-As** mode specifies the credential information to be used by the security service to determine the permissions that a principal has on various resources. If security is on, the **Run-As** mode needs to be defined on all of the methods called. The identity of the bean without this setting is undefined.

There are no restrictions on what code the start() and stop() methods can run, since the full Application Server programming model is available to these methods.

3. Use an *optional* environment property integer, `wasStartupPriority`, to specify the start order of multiple startup beans in the same Java Archive (JAR) file. If the environment property is found and is the wrong type, application startup is aborted. If no priority value is specified, a default priority of 0 is used. It is recommended that you specify the priority property. Beans that have specified a priority are sorted using this property. Beans with numerically lower priorities are run first. Beans that have the same priority are run in an undefined order. All priorities must be positive integers. Beans are stopped in the opposite order to their start priority. The priority values for module startup beans and application startup beans are mutually exclusive. All modules will be started prior to the application being declared as "started" and therefore the start() methods for module startup beans within an application will be invoked prior to the start() methods for any application startup beans. Likewise, all application startup bean stop() methods for a specific Java Archive (JAR) file will be invoked prior to any module startup bean stop() methods for that JAR.
4. For module startup beans, the order in which EJB modules are started can be adjusted via the "Starting weight" value associated with each module
5. To control who can invoke startup bean methods via WebSphere Security do the following:
 - a. Define the method permissions for the Start() and Stop() methods as you would for any EJB module. (See "Defining method permissions for EJB modules".)
 - b. Ensure that the user that is mapped to the Security Role defined for the startup bean methods is the same user that is defined as the Server user ID within the User Registry.

What to do next

View the startup beans service settings.

Enabling startup beans in the administrative console

Enabling startup beans in the administrative console enables Java 2 Platform Enterprise Edition (J2EE) applications to run business logic automatically, whenever an application starts or stops normally.

About this task

Use the following steps to enable startup beans in the administrative console.

Procedure

1. Start the administrative console.
2. Select **Servers > Application Servers > *server_name* > Container Services > Startup beans service**.
3. Select the **Enable service at server startup** check box.
4. Click **Apply** to save the configuration.

What to do next

View the startup beans service settings.

Startup beans service settings

Use this page to enable startup beans that control whether application-defined startup beans function on this server. Startup beans are session beans that run business logic through the invocation of start and stop methods when applications start and stop. If the startup beans service is disabled, then the automatic invocation of the start and stop methods does not occur for deployed startup beans when the parent application starts or stops. This service is disabled by default. Enable this service only when you want to use startup beans. Startup beans are especially useful when used with asynchronous beans.

Note: The capabilities provided with startup singleton session beans (EJB 3.1 specification) causes the WebSphere Application Server proprietary startup beans function to be deprecated.

To view this administrative console page, click **Servers > Server types > WebSphere application servers > *server_name***. Under **Container Settings**, expand **Container Services** then click **Startup beans service**.

Enable service at server startup

Specifies whether the server attempts to initiate the startup beans service.

Default
Range

Cleared

Selected

When the application server starts, it attempts to initiate the startup bean service automatically.

Cleared

The server does not try to initiate the startup beans service. All startup beans do not start or stop with the application. If you use startup beans on this server, then the system administrator must start the startup beans service manually or select this property, and then restart the server.

Chapter 27. Developing Service integration

This page provides a starting point for finding information about service integration.

Service integration provides asynchronous messaging services. In asynchronous messaging, producing applications do not send messages directly to consuming applications. Instead, they send messages to destinations. Consuming applications receive messages from these destinations. A producing application can send a message and then continue processing without waiting until a consuming application receives the message. If necessary, the destination stores the message until the consuming application is ready to receive it.

Programming mediations

Several distinct tasks are involved in programming a mediation. Typically, the mediation code is written by a programmer, and is then deployed and administered by an integrator.

Before you begin

Code examples for writing a mediation are provided in the following topic: “Adding mediation function to handler code” on page 1083.

The following application programming interfaces are provided for you to work with messages:

- You can use the `SIMessage` API to manipulate the contents of the message.
- You can use the `SIMediationSession` API to access the service integration bus so that your mediation can send and retrieve messages.

You can deploy mediations by using tooling such as the Rational Application Developer tools.

About this task

The tasks for programming a mediation are as follows:

Developing

Writing a mediation by adding functional code to a mediation handler.

Deploying

Adding a mediation to a mediation handler list, and deploying it.

Administering

Associating a mediation handler with a destination (optional), and configuring the parameters to be used by the mediation handler at run time.

Take the following steps to program a mediation:

Procedure

1. Create a mediation handler. For more information, see “Writing a mediation handler” on page 1082.
2. Add mediation function code to your mediation handler. For more information, see “Adding mediation function to handler code” on page 1083.
3. Working with the message payload, for example for logging messages within a mediation. For more information, see “Working with the message payload” on page 1090.
4. Use the Rational Application Developer tools to create a handler list, add your mediation handler to the list, and deploy the handler list as an Enterprise Archive (EAR file). See the Rational Application Developer information center for information about how to do this.

Serializing the content of SIMessage

Use this task to convert an SIMessage object to a byte array.

About this task

If you want to save an SIMessage object in your local file system or in a database, you must first convert the object to a byte array and format string. You can reconstruct the message from the byte array and format string. To do this, complete the following steps.

Procedure

1. In your application program, record the format string associated with the SIMessage instance. For example:

```
String savedFormat=message.getFormat();
```

2. Call the getDataGraphAsBytes. For example:

```
Bytes newDataGraph = message.getNewDataGraph(newFormat);
```

This method returns a copy of the payload as a byte stream. You can store the bytes and the associated format string, as you require.

3. To reconstruct the message, call the method createDataGraph provided by the SIDataGraphFactory API. This method requires a byte array and a format string. For example:

```
DataGraph newDataGraph = SIDataGraphFactory.getInstance().createDataGraph(byteArray, newFormat);
```

This method creates a new data graph by parsing the bytes according to the format passed to the method.

What to do next

You can use the newly created datagraph as the payload of an SIMessage instance by using the SIMessage setDataGraph() method. For example:

```
newMessage.setDataGraph(newDataGraph, savedFormat);
```

Writing a mediation handler

You can write a mediation handler, add mediation function to it, and prepare it for installation on an application server.

Before you begin

You should have access to a Java programming environment, and an assembly tool such as IBM Rational Application Developer.

About this task

A mediation handler can be deployed. Each mediation handler executes some specific message processing at run time, for example transforming a message format, or routing a message to a particular destination. A mediation handler is a Java program framework, to which you add the code that performs the mediation function.

You can define a mediation handler class either in a Java project or an EJB project (which is needed for the deployment artifact). Your programming and deployment artifacts can be separated in different projects. The steps below are for an EJB project, but the steps are very similar if you want to create a Java project, because you define a target server for either a Java project or an EJB project and the server runtime plug-in sets the class path correctly.

Procedure

1. Create a new EJB project:
 - a. Switch to the Java EE perspective to work with Java EE projects. Click **Window > Open Perspective > Other > Java EE**.
 - b. From the File menu, select **New > Project**.
 - c. Expand the Java EE folder, and select Enterprise Application Project. Click **Next**.
 - d. Optional: If you have created a Java project instead of an EJB project, right click on the Java project folder icon for the context menu and select Properties. When the Properties panel appears, select the Server properties and target the project to an appropriate server for your system, as in the next step.
 - e. Enter a name for the project and target the project to an appropriate server for your system. (If this is the first time you target this server, click **New....**) Click **Next** to take you to the EAR Module Projects window.
 - f. Click **New Module....**
 - g. Create a new module project by selecting the check box against EJB project, and entering the name of your mediation handler.
 - h. Click **Finish**. You are returned to the EAR Module Projects window.
 - i. Click **Finish** to create the new project.
2. Create a mediation handler class by implementing the `com.ibm.websphere.sib.mediation.handler.MediationHandler` interface.
 - a. From the File menu, select **New > Java Class**.
 - b. Specify the source folder for your mediation EAR project.
 - c. Specify a name for your mediation handler.
 - d. Select Superclass `java.lang.Object`.
 - e. Select Interface `com.ibm.websphere.sib.mediation.handler.MediationHandler`.
 - f. Select the **Inherited abstract methods** check box.
 - g. Click **Finish** to create the new mediation handler class.
3. Add functional code that transforms or routes messages to your mediation handler by using the IBM Rational Application Developer. For more information, see “Adding mediation function to handler code.” Beware that the default return value for the handle method created by the toolkit is `false`, which causes the message to be discarded. You must change the return value to `true` to preserve the message.
4. Generate an EAR file from your mediation handler class. Follow the instructions in the IBM Rational Application Developer documentation.

What to do next

Next, you are ready to install the EAR file containing your mediation handler into the application server.

Adding mediation function to handler code

A mediation handler is a wrapper for the mediation code that operates on the message. You can add mediation function to an existing mediation handler by working with the message context, the message properties, the message header or the message payload.

Before you begin

Create or open a mediation handler in an EJB project. For more information, see “Writing a mediation handler” on page 1082.

About this task

There are four main aspects of the message through which you can change the behavior of the mediation handler code, or influence the routing of a message. You can change the values in the message context and message properties, and you can work with the contents of the message (called the message payload), or with the message header:

- “Working with the message context”
- “Working with message properties” on page 1085
- “Working with the message header” on page 1086
- “Working with the message payload” on page 1090

Example: Using mediations to trace, monitor and log messages

The most straightforward use of a mediation is for tracing, monitoring or logging messages that pass through a destination or topics spaces. This type of mediation does not modify the message; it only extracts information from the message and saves or displays the information elsewhere.

For example, the following mediation handler displays the API message and correlation IDs for each message it is sent:

```
public boolean(MessageContext context)
{
    SIMessageContext msgCtx = (SIMessageContext)context;
    SIMediationSession session = msgCtx.getSession();
    SIMessage msg = msgCtx.getMessage();
    String msgId = msg.getApiMessageId();
    String corrId = msg.getCorrelationId();
    String dest = session.getDestinationName();

    System.out.println(msgId+" (correlation id="+corrId) is passing through "+dest+".");

    return true;
}
```

Working with the message context

You can work with the message properties to affect the way a message is mediated.

Before you begin

Before you start this task, you should read about how information is carried in the mediation context in [Mediation context information](#)

About this task

Interface `SIMessageContext` has a superinterface `MessageContext`. Methods in `MessageContext` allow you to manage a set of message properties, which enable handlers in a handler chain to share processing-related state. Most importantly, you can get the value of a specific property from the `MessageContext` by using the method `getProperty`, and you can set the name and value of a property associated with the `MessageContext` by using the method `setProperty`. You can also view the names of the properties in this `MessageContext` and remove a property (that is, a name-value pair) from the `MessageContext`.

At mediation runtime, all of the user-defined properties that have been set during configuration for the current mediation (see [Configuring mediation context properties](#)) are applied to the `MediationContext` property set.

Procedure

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle (MessageContext context)`. As you are working with the `MessageContext` methods that give you access to message properties, you do not have to cast the interface to `SIMessageContext` **unless** you are also interested in the methods provided by `SIMessageContext`.
2. Get the `SIMessage` from the `MessageContext` object. For example, `SIMessage message = ((SIMessageContext)context).getSIMessage();`
3. Retrieve or set properties, by using the `MessageContext` methods. For instance, if a property has been defined during configuration with the name `streetName`, the type `String`, and the value "Main Street" your code to retrieve and print the street name might look like this:

Example

```
public boolean handle(MessageContext context) throws MessageContextException {  
  
    .....  
    {  
        /* Retrieve the street name property */  
        String myStreetName;  
        myStreetName = (String) getProperty(streetName);  
  
        /* Display property value */  
        System.out.println(myStreetName);  
    }  
}
```

Working with message properties

You can work with the message properties to affect subsequent processing.

Before you begin

Before you start this task, you should read about the properties that are supported by the `SIMessage` interface in `../ae/rjp0023_.dita`.

About this task

There are two different types of message properties:

- System properties (including JMS headers, JMSX properties, and JMS_IBM_properties)
- User properties.

You can work with message properties to affect which messages a later mediation should process, or to affect processing by a downstream application or mediation. The rule set in the selector field during mediation configuration tests values in the message properties.

You can access, modify and clear properties by using the `SIMessage` interface (see "SIMessage" on page 1094.) There are three different sets of methods:

- These properties operate on system properties, plus user properties if the name is qualified with a prefix `user.:`
 - `getMessageProperty`
 - `setMessageProperty`
 - `deleteMessageProperty`
 - `clearMessageProperties`
- These properties operate on user properties only, without the need for the prefix `user.:`
 - `getUserProperty`

- setUserProperty
- deleteUserProperty
- clearUserProperties
- getUserPropertyNames returns a list of the names of the user properties in the message.

Typically, you can work with message properties in the following way, when programming a mediation:

Procedure

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle` (`MessageContext context`). The interface is `MessageContext`, and you should cast this to `SIMessageContext` **unless** you are only interested in the methods provided by `MessageContext`.
2. Get the `SIMessage` from the `MessageContext` object. For example, `SIMessage message = ((SIMessageContext)context).getSIMessage();`
3. Build your mediation header function in a similar way to these examples, by using the reference information in `../ae/rjp0023_.dita` to help:
 - a. Get a user property of the message. For instance, `String task = (String)msg1.getUserProperty("task");`. In this case, the task string might refer to an operation that the mediation should perform.
 - b. Set a user property, where message Properties are stored as name-value pairs. The `setUserProperty` method might only be used to set user properties, so the name passed into the method should not include the "user." prefix. For example, `msg1.setUserProperty("background","green");`
 - c. Delete a user property from the message. For instance, `msg1.deleteUserProperty("task");`

Example

Mediation function code to work with message properties might look similar to the code snippet in this example:

```
String task = (String)msg1.getUserProperty("task");
if (task != null) {
    if (task.equals("addColor")) {
        msg1.setMessageProperty(SIProperties.JMS_IBM_Format, "colorful");
        msg1.setUserProperty("background","green");
        msg1.setUserProperty("foreground","purple");
        msg1.setUserProperty("depth",new Integer(3));
        msg1.deleteUserProperty("task");
    }
    else {
        msg1.clearUserProperties();
    }
}
```

Working with the message header

You can add function to a preexisting mediation handler to operate on the message header.

Before you begin

Create or open a basic mediation handler in an EJB project (see "Writing a mediation handler" on page 1082. It is useful to have understood the elements of the task "Working with the message payload" on page 1090, because some of those elements are used in this task

About this task

There are different types of field that you can set in message headers. Importantly, you can set the forward and return routing addresses for messages after they have been mediated at the current

destination. In addition there are other fields that you can set, such as priority and reliability for the message and its reply, and the remaining time before the message (or the reply) expires.

Procedure

1. To set routing addresses in the message header, see “Setting routing addresses in a message header.”
2. To set all other fields in the message header, see “Working with non-routing path fields in a message header” on page 1089.

Setting routing addresses in a message header:

You can add function to a pre-existing mediation handler to set routing addresses in the message header.

Before you begin

Before you start this task, you should have created the basic mediation handler in an EJB project (see “Writing a mediation handler” on page 1082).

About this task

To work with routing addresses, you will use the `SIDestinationAddress` and `SIDestinationAddressFactory` APIs. The `SIDestinationAddress` is the public interface that represents an service integration bus, and gives your mediation access to the name of the destination and the bus name.

`SIDestinationAddressFactory` enables you to create a new `SIDestinationAddress` to represent an service integration bus destination. For reference information about these APIs, see “`SIDestinationAddress`” on page 1088 and “`SIDestinationAddressFactory`” on page 1089.

Procedure

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle (MessageContext context)`. The interface is `MessageContext`, and you should cast this to `SIMessageContext` **unless** you are only interested in the methods provided by `MessageContext`.

2. Get the `SIMessage` from the `MessageContext` object. For example:

```
SIMessage message = ((SIMessageContext)context).getSIMessage();
```

3. Build your mediation header function by using these basic steps:

- a. Get a handle to the runtime environment. For example:

```
.... SIMediationSession mediationSession = mediationContext.getSession();
```

- b. Create a forward routing path to set on the cloned object. For example, use the `Vector` class to create a extendable array of objects.

- c. Get the `SIDestinationAddressFactory` that is to be used for creating `SIDestinationAddress` instances. For example:

```
SIDestinationAddressFactory destFactory = SIDestinationAddressFactory.getInstance();
```

- d. Create a new `SIDestinationAddress`, representing a service integration bus destination. For example:

```
SIDestinationAddress dest = destFactory.createSIDestinationAddress(remoteDestinationName(),false);
```

In this case, the second parameter, the Boolean “false”, indicates that the destination should not be localized to the local messaging engine, but can be anywhere on the service integration bus.

- e. Use the `add` method of the `Vector` class to add another destination name to the array.
- f. Clone the message, and modify the forward routing path in the cloned message. For example:

```
clonedMessage.setForwardRoutingPath(forwardRoutingPath);
```

- g. Send the cloned message by using the `send` method in the `SIMediationSession` interface to send the message to the service integration bus. For example, if named “clonedMessage”:

```
mediationSession.send(clonedMessage, false);
```

4. Return *true* to ensure the message passed into the handle method of the MediationHandler interface continues along the handler chain.

Example

The complete mediation function code to change the forward routing path might look like this example:

```
/* A sample mediation that clones a message
 * and sends the clone off to another destination */

public class RoutingMediationHandler implements MediationHandler {

    public String remoteDestinationName="newdest";

    public boolean handle(MessageContext context) throws MessageContextException {
        SIMessage clonedMessage = null;
        SIMessageContext mediationContext = (SIMessageContext) context;
        SIMessage message = mediationContext.getSIMessage();
        SIMediationSession mediationSession = mediationContext.getSession();

        // Create a forward routing path that will be set on the cloned message
        Vector forwardRoutingPath = new Vector();
        SIDestinationAddressFactory destFactory =
            SIDestinationAddressFactory.getInstance();
        SIDestinationAddress dest =
            destFactory.createSIDestinationAddress(remoteDestinationName, false);
        forwardRoutingPath.add(dest);

        try {
            // Clone the message
            clonedMessage = (SIMessage) message.clone();
            // Modify the forward routing path for the clone
            clonedMessage.setForwardRoutingPath(forwardRoutingPath);
            // Send the message to the next destination in the frp
            mediationSession.send(clonedMessage, false);
        } catch (SIMediationRoutingException e1) {
            e1.printStackTrace();
        } catch (SIDestinationNotFoundException e1) {
            e1.printStackTrace();
        } catch (SINotAuthorizedException e1) {
            e1.printStackTrace();
        } catch (CloneNotSupportedException e) {
            // SIMessage should clone OK so you shouldn't need to enter this block
            e.printStackTrace();
        }
        // allow original message to continue on its path
        return true;
    }
}
```

SIDestinationAddress:

The *SIDestinationAddress* public interface represents a service integration bus destination.

The API has three methods:

- *isTemporary*: This method determines whether the *SIDestinationAddress* represents a temporary or permanent Destination, returning a Boolean value.
- *getDestinationName*: Method to retrieve the name of the Destination represented by this *SIDestinationAddress*.

- `getBusName`: Method to retrieve the bus name of the Destination represented by this `SIDestinationAddress`.

For more information about the `SIDestinationAddress` interface, see the `SIDestinationAddress` generated API information.

SIDestinationAddressFactory:

The `SIDestinationAddressFactory` public interface extends `java.lang.Object`, and creates an `SIDestinationAddressFactory` at static initialization that is subsequently used for the creation of all instances of `SIDestinationAddress`.

The interface has three methods:

- `getInstance`: This method gets the singleton `SIDestinationAddressFactory` that is used for creating `SIDestinationAddress` instances.
- `createSIDestinationAddress`: These two methods are used to create a `SIDestinationAddress` to represent a service integration bus destination. The first will create a `SIDestination` that exists only on the local service integration bus (and maybe localized to the "local" messaging engine depending on the `localOnly` flag). The second method is used to create a `SIDestination` that exists on a remote service integration bus.

-

For more information about the `SIDestinationAddressFactory` interface, see the `SIDestinationAddressFactory` generated API information.

Working with non-routing path fields in a message header:

You can work with fields in a message header that identify and affect the behavior of messages.

About this task

In addition to the routing fields (see “Setting routing addresses in a message header” on page 1087), there are a number of fields in the message header that you can work with. These fields affect important qualities and characteristics of the message, such as priority and reliability, identity, and so on. See “Message header information” for information about the equivalence of the header fields to JMS message header fields, and the methods available to work with them.

Procedure

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle (MessageContext context)`. The interface is `MessageContext`, and you should cast this to `SIMessageContext` **unless** you are only interested in the methods provided by `MessageContext`.
2. Get the `SIMessage` from the `MessageContext` object. For example, `SIMessage message = ((SIMessageContext)context).getSIMessage();`
3. Build your mediation header function in a similar way to these examples, and using the reference information in “Message header information” to help:
 - a. Set the reliability of the message. For instance, `siMessage.setReliability(Reliability.ASSURED_PERSISTENT);`. In this case, the quality of service is set to the highest level.
 - b. Set the time to live for a message - that is, the time, in milliseconds, that the message is allowed to remain on a queue before it is removed if it is not processed. For example, `siMessage.setRemainingTimeToLive(1000000);` will set the remaining time before the message should expire to 1000 seconds.

Message header information:

The non-routing `SIMessage` header fields, and the methods available to work with them, can be mapped to JMS message header fields.

Header fields

Table 112. Mapping of `SIMessage` header fields to JMS message header fields. The first column of the table lists the `SIMessage` header fields. The second column provides a brief description of the fields. The third column provides the corresponding JMS message header fields. The fourth column lists the `SIMessage` methods.

SIMessage header field	Field description	Corresponding JMS message header field	SIMessage methods
Priority (ReplyPriority)	Integer value 0-9, higher value is higher message priority	JMSPriority (integer)	<ul style="list-style-type: none"> • getPriority • setPriority • getReplyPriority • setReplyPriority
Reliability (ReplyReliability)	Specifies the reliability of message delivery. See ../ae/cj9000_dita for a description of the allowed values.	JMSDeliveryMode (string) supports two levels of reliability: PERSISTENT and NON_PERSISTENT	<ul style="list-style-type: none"> • getReliability • setReliability • getReplyReliability • setReplyReliability
TimeToLive (ReplyTimeToLive, RemainingTimeToLive)	An integer that represents the time in milliseconds that a message can remain on the queue before it expires.	JMSExpiration (long) is the time of expiry, calculated as "current time" plus (+) "time-to-live".	<ul style="list-style-type: none"> • getTimeToLive • getReplyTimeToLive • getRemainingTimeToLive • setTimeToLive • setReplyTimeToLive • setRemainingTimeToLive
Discriminator (ReplyDiscriminator)	A string that contains a topic name that is tested by a selector rule to determine if the message should be mediated.	No corresponding JMS field	<ul style="list-style-type: none"> • getDiscriminator • setDiscriminator • getReplyDiscriminator • setReplyDiscriminator
RedeliveredCount	Read-only field (integer) that holds that counts each time a message is re-delivered.	JMSRedelivered (Boolean) indicates that it is likely, but not guaranteed, that the message was delivered but unacknowledged in the past.	getRedeliveredCount
ApiMessageId	A string that uniquely identifies each message sent.	JMSMessageId (string)	<ul style="list-style-type: none"> • getApiMessageId • setApiMessageId
CorrelationId	A string that links two messages, typically linking a request message with its response.	JMSCorrelationId (string)	<ul style="list-style-type: none"> • getCorrelationId • setCorrelationId
UserId	A string that represents the identity of the user sending the message.	JMSX UserId is a message property not used by WebSphere Application Server.	<ul style="list-style-type: none"> • getUserId • setUserId

Working with the message payload

You can work with the message payload in a pre-existing mediation handler, and transcode the message payload from one message format to another.

Before you begin

Create or open a mediation handler in an EJB project. For more information, see “Writing a mediation handler” on page 1082. You should also read the tips for successfully programming mediations in the topic [../ae/cjy0115.dita](#).

About this task

You can use this task to complete some or all of the following actions on the message payload:

- Locate the data objects within the message payload
- Convert the payload into another format
- Convert the payload into a byte array, for example if you want your mediation to log messages.

To work with the contents of a message, use the `SIMessage` and `SIMessageContext` APIs. Additionally, use `SIMediationSession` to provide your mediation with access to the service integration bus, to send and receive messages. For more information, see:

- `../ae/cjy0000.dita`
- “MediationHandler” on page 1093
- “SIMessageContext” on page 1093

To work with specific fields within a message, use Service Data Objects (SDO) Version 1 data graphs. For more information, see SDO data graphs. For more information about the format of supported message types, and examples of how to work with them, see “Mapping of SDO data graphs for web services messages” on page 1100.

To work with the message payload, take the following steps:

Procedure

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle (MessageContext context)`. The interface is `MessageContext`, and you should cast this to `SIMessageContext` unless you only want to work with the methods provided by `MessageContext`.
2. Retrieve the data graph of the message payload as follows:
 - a. Get the `SIMessage` from the `MessageContext` object. For example:

```
SIMessage message = ((SIMessageContext)context).getSIMessage();
```
 - b. Get the message format string to determine its type. For example:

```
String messageFormat = message.getFormat();
```
 - c. Retrieve the `DataGraph` object from the message. For example:

```
DataGraph dataGraph = message.getDataGraph();
```

For more information, see SDO data graphs.

3. Optional: Locate data objects within the payload:
 - a. Navigate within the graph to a named `DataObject`. For example, where `DataObject` has the name “data”:

```
DataObject dataObject = dataGraph.getRootObject().getDataObject("data");
```
 - b. Retrieve information contained in the data object. For example, if the message is a text message:

```
String textInfo = dataObject.getString("value");
```
4. Work with the fields within the message. For an example of how to do this, see “Example code for message fields” on page 1092.
5. Optional: Transcode the payload into another format:
 - a. Review the topic “Transcoding between message formats” on page 1095 to understand the implications of transcoding the payload.
 - b. Call the method `getNewDataGraph`, passing the new format as a parameter, which returns a copy of the payload in the new format. For example:

```
DataGraph newDataGraph = message.getNewDataGraph(newFormat);
```
 - c. Write the data graph in the new format back to the message using the `setDataGraph` method. For example:

```
message.setDataGraph(newDataGraph, newFormat);
```

6. Optional: Convert the payload into a stream of bytes:
 - a. Review the topics “Transcoding a message payload into a byte array” on page 1097 and “Transcoding a byte array into a message payload” on page 1098 to understand the implications of converting between message format and byte stream, and back again.
 - b. Call the method `getDataGraphAsBytes`, which returns a copy of the payload as a byte stream. For example:

```
byte[] newByteArray = message.getDataGraphAsBytes();
```
 - c. Call the method `createDataGraph` provided by the `SIDataGraphFactory` API, which creates a new data graph by parsing the bytes according to the format passed to the method. For example:

```
DataGraph newDataGraph = SIDataGraphFactory.getInstance().createDataGraph( byteArray, format);
```
 - d. Work with the message as a stream of bytes. For an example of how to do this, see “Example code for message fields”
7. Return `True` in your mediation code so that the `MessageContext` is passed to the next mediation handler in the handler list. If the return value is `False` the `MessageContext` will be discarded and will not be delivered to the destination.

Note: If your mediation handler is the last handler in the handler list, and the forward routing path is empty, the message is made available to consuming applications on that destination. If the forward routing path not empty, the message is not made available to any consumers on that destination. Instead, the message is forwarded to the next destination in the routing path.

Example code for message fields

Below is an example of the code for a mediation for working with a field in a message:

```
public boolean handle(MessageContext context) throws MessageContextException {  
  
    /* Get the SIMessage from the MessageContext object */  
    SIMessage message = ((SIMessageContext)context).getSIMessage();  
  
    /* Get the message format string */  
    String messageFormat = message.getFormat();  
  
    /* If you have a JMS TextMessage then extract the text contained in the message. */  
    if(messageFormat.equals("JMS:text"))  
    {  
        /* Retrieve the DataGraph object from the message */  
        DataGraph dataGraph = message.getDataGraph();  
  
        /* Navigate down the DataGraph to the DataObject named 'data'. */  
        DataObject dataObject = dataGraph.getRootObject().getDataObject("data");  
  
        /* Retrieve the text information contained in the DataObject. */  
        String textInfo = dataObject.get("value");  
  
        /* Use the text information retrieved */  
        System.out.println(textInfo);  
    }  
  
    /* Return true so the MessageContext is passed to any other mediation handlers  
    * in the handler list */  
    return true;  
}
```

The complete mediation function code for working with the message payload as a stream of bytes might look like this example:

```
public boolean handle(MessageContext context) throws MessageContextException {

    /* Get the SIMessage from the MessageContext object */
    SIMessage message = ((SIMessageContext)context).getSIMessage();

    if (!SIApiConstants.JMS_FORMAT_MAP.equals(msg.getFormat()))
    {
        try
        {
            dumpBytes(msg.getDataGraphAsBytes());
        }
        catch(Exception e)
        {
            System.out.println("The message contents could not be retrieved due to a "+e);
        }
    }
    else
    {
        System.out.println("The bytes for a JMS:map format message cannot be shown.");
    }

    return true;
}

private static void dumpBytes(byte[] bytes)
{
    // Subroutine to dump the bytes in a readable form to System.out
}
}
```

MediationHandler:

The public interface `MediationHandler` has just one method: `handle`. This method is used by the runtime to invoke a mediation.

The method `handle` is called by the runtime when a message is to be mediated. The method returns Boolean *True* if the message passed into this method should continue along the handler list, otherwise *False*.

At the end of the handler list, the message is sent to the next destination on the routing path, unless the forward routing path is empty, when the message is made available to consuming applications on the current destination.

For more information about the `MediationHandler` interface, see the `MediationHandler` generated API information.

SIMessageContext:

Public interface `SIMessageContext` extends `javax.xml.rpc.handler.MessageContext`. This is the object that is required on the interface of a mediation handler. In addition to the context information that might be passed from one handler to another, it can return a reference to an `SIMessage` and an `SIMediationSession`.

The `SIMessage` is the service integration technologies representation of the message being processed by the `MediationHandler`. The `SIMediationSession` is a handle to the runtime resources.

The interface `MessageContext` abstracts the message context that is processed by a handler in the `handle` method. The `MessageContext` interface provides methods to manage a property set. `MessageContext` properties enable handlers in a handler chain to share processing related state.

As well as defining the method that is invoked by the mediation runtime environment, the interface might also specify properties following the Enterprise JavaBeans naming pattern, or by providing a `BeanInfo` class. Each property of the bean will be initialized from a single environment entry with the same name as the property. Bean properties of simple type are specified by using Java Platform, Enterprise Edition (Java EE) `env-entry`. If the handler has properties that are of non-simple type, then other environment definitions may be used.

The API has two methods:

- The `getSIMessage` method to get the service integration bus representation of the message being mediated. Read more about the `SIMessage` API in “`SIMessage`.”
- The `getSession` method to get an `SIMediationSession` object that is a handle to the runtime environment. Read more about the `SIMediationSession` API in “`SIMediationSession`” on page 1095.

SIMessage:

The `SIMessage` interface is the public interface to a service integration bus message for use by mediations and other service integration bus components. This interface extends `java.lang.Cloneable` and `java.lang.Serializable`.

The version of Service Data Objects (SDO) supported by mediations is Version 1.

The `SIMessage` interface has many methods allowing you to work with message properties, header contents, routing path, metadata, and others:

- The method `getDataGraph` returns the SDO data graph. This contains the `SIMessage` payload content in a tree representation. Using the data graph, you can work directly with individual fields in the message payload. For more information about SDO data graphs, see `SDO data graphs`.
- You can transcode a message payload by calling the method `getNewDataGraph(format)`. It returns a copy of the payload in the new format. You can write the new datagraph back to the message by using `setDataGraph(DataGraph, format)`. For more information, see “`Transcoding between message formats`” on page 1095.
- If you want to log a message as a simple byte stream, you can retrieve the message payload as a byte array by using the method `getDataGraphAsBytes`. For more information about converting from data graph to bytes, and back again, see “`Transcoding a message payload into a byte array`” on page 1097 and “`Transcoding a byte array into a message payload`” on page 1098.
- There are methods to get, set, delete and clear user properties and message properties. You can also retrieve a list of user property names. For more information about working with properties, see “`Working with message properties`” on page 1085.
- Forward and reverse routing paths define a sequential list of intermediate bus destinations through which messages pass to reach a target bus destination. You use a routing path to apply the mediations configured on several destinations to the messages sent along the path. The following methods allow you to get and set the contents of the `ForwardRoutingPath` and `ReverseRoutingPath` for an `SIMessage`:
 - `getForwardRoutingPath()`
 - `setForwardRoutingPath()`
 - `getReverseRoutingPath()`
 - `setReverseRoutingPath()`

For more information about routing paths, see `Destination routing paths`. For information about how to work with routing addresses, see “`Setting routing addresses in a message header`” on page 1087.

- If your mediation changes the content of the message, there is a risk that the message is no longer valid. If the data graph is not valid, the message cannot be sent through the service integration bus or

stored in the message store. In this case, the message is not **well formed**. A message is well formed when all the values of the message properties might be serialized, and the data graph of the message conforms to the format of the message. You can test your message by using the method `isWellFormed`. It returns `true` when the message contains a well formed data graph. This test has implications for performance. For more information, see Setting tuning properties for a mediation.

- You can work with the time for the message to live, measured in milliseconds from the time when the message was originally sent:
 - The methods `getTimeToLive` and `setTimeToLive` allow you to get and set the value of the `TimeToLive` field in the message header. A value of 0 indicates that the message will never expire.
 - The methods `getRemainingTimeToLive` and `setRemainingTimeToLive` allow you to get the remaining time in milliseconds before the message expires, and set the remaining time in milliseconds before the message should expire.

For more information about `SIMessage`, see the API documentation.

SIMediationSession:

The `SIMediationSession` public interface defines the methods for querying and interacting with the service integration bus. As well as defining the methods for working with the service integration bus, this interface also includes methods that provide information about where the mediation is invoked from, and the criteria that are applied before the message is mediated.

Both selector and discriminator control which messages are sent to the mediation, through a rule specified in a text string. The rule specified by the selector examines the header and properties of the message, whereas the discriminator examines the topic of the message. If a message contains both selector and discriminator, it must match both rules for the message to be mediated. If either the selector or the discriminator rule does not match, the message is not mediated.

The API has these methods:

- `getBusName` returns the name of the bus upon which the mediation is associated.
- `getDestinationName` returns the name of the destination with which the mediation is associated.
- `getDiscriminator` returns the discriminator that is defined in the mediation definition.
- `getMediationName` returns the name of the mediation that is being executed.
- `getMessageSelector` returns the message selector that is defined in the mediation definition.
- `getMessagingEngineName` returns the name of the messaging engine from which the mediation was invoked
- `getSIDestinationConfiguration` returns the `SIDestinationConfiguration` object associated with the destination, specified by `destinationName` or `destinationAddress`.
- `receive` receives an `SIMessage` from the service integration bus. There are four variants.
- `resetIdentity` changes the identity of the given message to the current run-as identity.
- `send` sends a copy of an `SIMessage` to the service integration bus, in addition to the message returned by the message interface.

See also the generated API information for `SIMessageContext`.

Transcoding between message formats:

A mediation can convert a message from one format to another without changing the semantic meaning of the message. This operation is referred to as transcoding a message.

The following code is an example mediation handler that transcodes a message into a new message format, providing that the message can be transcoded:

```

private static final String NEW_FORMAT = "JMS:text";

public boolean(MessageContext context) throws MessageContextException
{
    try
    {
        SIMessageContext msgCtx = (SIMessageContext)context;
        SIMessage msg = msgCtx.getMessage();
        DataGraph newDg = msg.getNewDataGraph(NEW_FORMAT);

        msg.setDataGraph(newDg,NEW_FORMAT);
        return true;
    }
    catch(Exception e)
    {
        // Reroute the original message to the exception destination
        MessageContextException mce =
            new MessageContextException("Unable to transcode to "+NEW_FORMAT",e);
        throw mce;
    }
}

```

The table below describes which messages can be transcoded, and gives the outcome for each format pairing. Note that the abbreviation DG represents "data graph". The numbers within brackets in the table are explained as follows:

- (1) A message with format JMS: cannot have a payload. It does not carry any message data other than the message properties. If a mediation calls `getDataGraph()` on a message with format JMS:, `null` is always returned. All other message formats must have a message payload. This means that a message with format JMS: cannot be transcoded into another format. If a mediation needs to change a message with format JMS: into a message with any other format, the mediation needs to call the methods `SIDataGraphFactory.getInstance().createDataGraph(newFormat)` and `setDataGraph` on the `SIMessage` object to change the message contents.
- (2) `null` is always returned if a mediation calls `getDataGraph()` on a message with format JMS:
- (3) A mediation can call the method `getNewDataGraph()` on a message to return a copy datagraph with the same format as the message. The copy can be edited, leaving the original message unchanged. For SOAP and Beans, you can change the message model by editing the format string to change the value that follows the ":".

Table 113. Message transcoding. The table contains the different formats that can be used to convert the messages from one format to another. The table shows the transcoding options that is possible between the different formats, and it also provides the effect the conversion has on the messages.

	To JMS:	To JMS:text	To JMS:bytes	To JMS:stream	To JMS:object	To SOAP:	To Bean:
From JMS:	DG=null (1)	DG=null (1)	DG=null (1)	DG=null (1)	DG=null (1)	DG=null (1)	DG=null (1)
From JMS:text	DG=null (2)	Yes (3)	Yes, bytes contain UTF-8	Yes, if text contains XML that conforms to the correct schema.	No	Yes, if message content is valid SOAP.	Yes, if message content is valid SOAP.
From JMS:bytes	DG=null (2)	Yes, but only when the bytes can correctly be interpreted as a UTF-8 string.	Yes (3)	Yes, if bytes contain XML that conforms to the correct schema.	Yes, assume that bytes are a serialized object.	Yes, if message content is valid SOAP.	Yes, if message content is valid SOAP.
From JMS:stream	DG=null (2)	Yes, text is XML transcoding.	Yes, bytes contain XML transcoding.	Yes (3)	No	No	No

Table 113. Message transcoding (continued). The table contains the different formats that can be used to convert the messages from one format to another. The table shows the transcoding options that is possible between the different formats, and it also provides the effect the conversion has on the messages.

	To JMS:	To JMS:text	To JMS:bytes	To JMS:stream	To JMS:object	To SOAP:	To Bean:
From JMS:object	DG=null (2)	No	Yes, bytes contain the object serialization.	No	Yes (3)	No	No
From SOAP:	DG=null (2)	Yes	Yes	No	No	Yes (3) - if message content matches the new WSDL.	Yes
From Bean:	DG=null (2)	Yes	Yes	No	No	Yes	Yes (3) - if message content matches the new WSDL.

XML schema definition for JMS stream messages:

This is the XML schema definition for transcoding JMS stream messages to message types.

The following XML schema definition uses the target namespace `http://www.ibm.com/xmlns/prod/websphere/messaging/jms/` to express JMS stream messages in XML. Use this definition to transcode between a byte array and a message payload.

```
<xsd:schema elementFormDefault="qualified" xml:lang="EN"
  targetNamespace="http://www.ibm.com/xmlns/prod/websphere/messaging/jms"
  xmlns="http://www.ibm.com/xmlns/prod/websphere/messaging/jms"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema">

  <xsd:element name="data" type="StreamBody"/>

  <xsd:complexType name="StreamBody">
    <xsd:sequence>
      <xsd:element name="value"
        type="streamTypes"
        minOccurs="0"
        maxOccurs="unbounded"
        nillable="true"/>
    </xsd:sequence>
  </xsd:complexType>

  <xsd:simpleType name="character">
    <xsd:restriction base="xsd:string">
      <xsd:minLength value="1"/>
      <xsd:maxLength value="1"/>
    </xsd:restriction>
  </xsd:simpleType>

  <xsd:simpleType name="streamTypes">
    <xsd:union memberTypes="xsd:long xsd:int xsd:short xsd:byte xsd:boolean
      xsd:float xsd:double xsd:string xsd:hexBinary character"/>
  </xsd:simpleType>
</xsd:schema>
```

Transcoding a message payload into a byte array:

You can transcode the message payload into a byte array.

For example, you might want to write a mediation handler that logs a message as a simple byte stream. You can retrieve the message payload as a byte array by using the method `getDataGraphAsBytes`. The table below describes the rules for transcoding an `SIMessage` data graph into a byte array.

Table 114. Rules for transcoding a message payload into a byte array. The first column of the table contains the datagraph formats used for transcoding a message into a byte array. The second column provides the preconditions for the datagraph format if available. The third column provides the result of the transcode. The fourth column contains the character set encodings if they are applicable for the messages.

Datagraph format	Pre-conditions	Outcome	Character set encoding
JMS:	None	Returns null.	Not applicable.
JMS:text	None	Returns the result of <code>java.lang.String.getBytes(String charSetName)</code> when applied to the <code>data/value</code> element of the graph, where <code>charSetName = "UTF-8"</code>	UTF-8
JMS:bytes	None	Returns a copy of the value of the <code>data/value</code> element of the data graph for the message.	Not applicable.
JMS:stream	None	Returns a byte buffer containing an XML serialization of the stream message according to the XML schema for stream messages.	UTF-8
JMS:object	None	Returns a copy of the value of the <code>data/value</code> element of the data graph for the message.	Not applicable.
SOAP:	If the byte array must be generated by this operation (instead of using an existing byte array available through lazy parsing) then the data graph must be valid with respect to the WSDL model.	Returns a byte buffer containing a SOAP serialization of the data graph. If the SOAP message contains an attachment, the buffer has the multipart MIME format.	Either UTF-8, or that of the source message for the graph, where logically equivalent to the graph state.
Bean:	The data graph must be valid with respect to the WSDL model. In the absence of a SOAP binding the serialization will be performed using RPC/literal encoding.	Returns a byte buffer containing a SOAP serialization of the data graph. If the Bean contains attachments then the buffer will be in multipart MIME format.	UTF-8

Transcoding a byte array into a message payload:

A mediation can transcode a byte array into a message payload without changing the meaning of the message.

A mediation can reconstruct the message payload from a byte array, for example after logging a message. To reconstruct the message, call the method `createDataGraph` provided by the `SIDataGraphFactory` API. This method requires a byte array and a format string and creates a new data graph by parsing the bytes according to the format passed to the method, as shown in the following example:

```
DataGraph newDataGraph = SIDataGraphFactory.getInstance().createDataGraph(byteArray, newFormat);
```

The table below describes the rules for transcoding a byte array into an `SIMessage` data graph.

Table 115. Rules for transcoding a byte array into an *SIMessage* data graph. The first column of the table contains the format arguments used for transcoding a byte array into an *SIMessage* data graph. The second column provides the preconditions if available for the format arguments. The third column provides the resultant *SIMessage* data graphs for the specified format arguments.

Format argument	Pre-conditions	Outcome
JMS:	None	Returns null
JMS:text	<code>java.lang.String(inputBytes, "UTF-8")</code> does not result in an exception.	Returns new data graph instance of format JMS:text. Value of graph at path <code>data/value</code> has value equal to <code>java.lang.String(inputBytes, "UTF-8")</code> .
JMS:bytes	<code>inputBytes</code> is not null.	Returns new data graph instance of format JMS:bytes. Value of graph at path <code>data/value</code> is a copy of the <code>inputBytes</code> byte array.
JMS:stream	Byte array is XML, and is valid with respect to the <code>JmsStreamBody</code> type of the XML schema definition.	Returns new data graph instance of format JMS:stream. Value of graph at path <code>data/value</code> has type List, containing a sequence of simple typed values according to the types and values of each of the elements in the XML document.
JMS:object	Not null Note: You must ensure that the byte array is a valid serialized object.	Returns new data graph instance of format JMS:object. Value of graph at path <code>data/value</code> is a copy of the <code>inputBytes</code> byte array.
SOAP:	The byte buffer contains valid SOAP with respect to the associated WSDL model.	Returns new data graph with type system defined by the WSDL referenced by the byte buffer, and values of the graph defined by the SOAP payload.
Bean:	The byte buffer contains valid Bean with respect to the associated WSDL model.	Returns new data graph with type system defined by the WSDL referenced by the byte buffer, and values of the graph defined by the Bean payload.

Web services messages overview:

To work with the data graph form of web services messages, you need to know the structure of the data graph, and how to develop code that can navigate the data graph.

The format of web services messages

WebSphere Application Server (base) supports two formats for web services messages: SOAP and enterprise beans. (These are similar to Java APIs for XML based RPC, or JAX-RPC.)

To work with web services messages, you need the following information:

- The structure of the Service Data Objects (SDO) Version 1 data graphs for web services messages. See “Mapping of SDO data graphs for web services messages” on page 1100 for more information about the data elements and the shape of the data graph.
- Reference information to help you develop code to navigate the data graphs of the messages that your program mediates. See “Mapping XML schema definitions to the SDO type system” on page 1104.
- For XML representations of the shape of each part of web services messages, sample code snippets and further information about the data graph format, see: “Web Services code example” on page 1107.

Format types

The web services message type is defined by a message format string within the message. The format string is prefixed with a domain identifier, which is either SOAP or Bean, followed by four comma-separated fields as shown below:

SOAP:<wsdlLocation>,<serviceNameSpace>,<serviceName>,<portName>

Bean:<wsdlLocation>,<serviceNameSpace>,<serviceName>,<portName>

The fields are described in the following table:

Field name	Message format string	Field description
WSDL location	<wsdlLocation>	The URI where the WSDL for this message is located. The WSDL is deployed to the SDO repository, by using this location as the key.
Service namespace	<serviceNameSpace>	Service namespace and Service name uniquely identify the Service definition within the WSDL.
Service name	<serviceName>	Service name and Service namespace uniquely identify the correct Service definition within the WSDL.
Port name	<portName>	Locates the Port definition within the Service, giving the PortType and Binding information that is required for message processing.

Mapping of SDO data graphs for web services messages:

The structure of web services messages is described by the Service Data Objects (SDO) Version 1 data graphs for web services messages.

Overall layout of a web services message

A web services message is described by a format string and three metadata fields: operationName, messageName, and messageType. The payload of the message is split across three other sections: headers, attachments and the body.

The Info node is the top of the SDO data graph for all web services messages. The following table describes the Info node properties and associated types.

Property name	Property type	Property description
operationName	java.lang.String	Identifies the WSDL operation that is associated with the message. If the data access service cannot identify the message, this field is null. See "Identifying web services messages" on page 1101.
messageName	java.lang.String	Identifies the WSDL message that is associated with the message. If the data access service cannot identify the message, this field is null. See "Identifying web services messages" on page 1101.

messageType	java.lang.String	Identifies WebService type of message instance. This field can have the values: <i>input</i> , <i>output</i> , <i>fault</i> , <i>ambiguous</i> . If the data access service cannot identify the message, this field is null. See "Identifying web services messages."
headers	java.util.List of data objects.	Contains a list of header entry data objects. Each SOAP header in the message results in a header entry in this list. See "Message header layout" on page 1102.
attachments	java.util.List of data objects.	Contains a list of attachment entry data objects. For SOAP messages with attachments, each MIME part in the message (except the MIME part containing the SOAP envelope) is mapped to an entry in this list. See "Message attachment layout" on page 1102.
body	commonj.sdo.DataObject	A nested data object, which represents the body of the SOAP envelope. See "Message body layout" on page 1103.

Identifying web services messages

Processing of messages depends on whether the messages have WSDL definitions. The minimum amount of information required for processing without WSDL is "SOAP:". The minimum amount of information required for processing with WSDL is: "SOAP:location,namespace,service,port". If the format string does not include all five of these fields, the SOAP data access service attempts to process the message without WSDL.

- **Processing messages without WSDL definitions:** If the format string does not include full WSDL information, the SOAP data access service processes the message without attempting to match the message against definitions in WSDL. As a result, operationName and messageName are set to null, and messageType is set only when processing a fault message.
- **Processing messages with WSDL definitions:** If the format string includes <WSDL location>,<Service namespace>,<Service name>, and <Port name>, the SOAP and Beans data access services process the message by using the WSDL definitions of the service.

Note: In either of the following circumstances, SOAP message processing fails after supplying all the required WSDL information:

- the SOAP data access service fails to locate the WSDL
- the WSDL fails to corroborate the message

When the SOAP data access service processes a SOAP request or reply message, it tries to match it against the message definitions in the WSDL. Usually there is one matching definition, and the operationName, messageName, and messageType are filled in appropriately. If there is more than one matching definition, the data access service selects a message definition, fills in the operationName and messageName. and sets the messageType to *ambiguous*.

When processing fault messages, identification is slightly different. In all cases the messageType is set to *fault*. If the message matches a unique fault definition in the WSDL, the operationName and messageName properties are also set.

Message header layout

The list of headers has two types of entry, header entry or bound header entry, depending on whether the header is based on part of the message or not.

The header entry type is used to handle headers that meet either of the following criteria:

- the header is part of the message that is modeled in WSDL
- the header is part of the message that is not modeled in WSDL, but is based on a part of the message

For a model of this header, see “Header entry.”

The bound header entry type is used when the SOAP binding for the message has bound a part of the body into a MIME attachment. (This occurs when you use a <MIME:content> element to bind a part of the message to an attachment.) For consistent mediation programming, all of the body data is stored in the body node in the graph. Unlike the normal attachment entry, a bound attachment entry is placed into the attachments list. The bound attachment entry contains the MIME meta-data for the attachment and the name of the message part that contains the data taken from this attachment. This allows mediations designed to process attachments to locate the data in the body part of the data graph. For a model of this attachment see “Bound header entry.”

Header entry

Property name	Property type	Property description
mustUnderstand	java.lang.Boolean	Carries the value from the mustUnderstand attribute on the SOAP header, if present.
actor	java.lang.String	Carries the value from the actor attribute on the SOAP header, if present.
any	commonj.sdo.Sequence	Container for the contents of the SOAP header.

Bound header entry

Property name	Property type	Property description
mustUnderstand	java.lang.Boolean	Carries the value from the mustUnderstand attribute on the SOAP header, if present.
actor	java.lang.String	Carries the value from the actor attribute on the SOAP header, if present.
messagePart	java.lang.String	Contains the name of the message part that carries the data from this message header.

Message attachment layout

Message attachments are handled in a similar way to headers, and instances of them populate the attachments list in the Info node.

There are two types of attachment entry to handle MIME attachments: attachment entry and bound attachment entry.

Attachment entry is for general attachments: see “Attachment entry” on page 1103.

Bound attachment entry includes <MIME:content> elements that bind a part of the body into a MIME attachment. If you are programming a mediation, you must know how to locate the data within the graph. For consistent mediation programming, the attachment data is placed in the message body, referred to by the part name in the header entry, which includes the other MIME metadata. For a model of this attachment, see “Bound attachment entry.”

Attachment entry

Property name	Property type	Property description
contentType	java.lang.String	Carries the contentType from the MIME part that is represented by the attachment entry.
contentTransferEncoding	java.lang.String	Carries the contentTransferEncoding from the MIME part that is represented by the attachment entry.
contentId	java.lang.String	Carries the contentId from the MIME part that is represented by the attachment entry.
data	byte[]	Carries the content of the MIME element as a byte array.

Bound attachment entry

Property name	Property type	Property description
contentType	java.lang.String	Carries the contentType from the MIME part that is represented by the attachment entry.
contentTransferEncoding	java.lang.String	Carries the contentTransferEncoding from the MIME part that is represented by the attachment entry.
contentId	java.lang.String	Carries the contentId from the MIME part that is represented by the attachment entry.
messagePart	java.lang.String	Contains the name of the message part that carries the data from this attachment.

Message body layout

The layout of the data object in the body is defined by the service WSDL. The type of the data object is derived from the message definition in the WSDL. The data object has one property for each part in the message definition. The layout of each message part follows the convention for mapping XML Schema into SDO. See “Web Services code example” on page 1107 for more information.

Web services fault message

If the message is a fault message, the messageType field in the Info node of the graph is set to "fault", and the message body has the following properties:

Property name	Property type	Property description
faultcode	javax.xml.namespace.QName	Carries the faultcode value from the SOAP Fault element

faultstring	java.lang.String	Carries the faultstring value from the SOAP Fault element
faultactor	java.lang.String	Carries the faultactor value from the SOAP Fault element
detail	commonj.sdo.DataObject	Carries the content within the detail child of the SOAP Fault element

Note: The detail element definition uses element and attribute wildcards, so the content of the detail data object contains a Sequence. See “Web Services code example” on page 1107 for more information.

Mapping XML schema definitions to the SDO type system:

Each XML schema type is mapped to an SDO type. Use this mapping to help you develop code to navigate the data graphs of the messages that your program mediates.

The version of Service Data Objects (SDO) supported by mediations is Version 1.

XML schemas can be embedded in the WSDL sections that describe the message parts and SOAP headers. However the SOAP header description is more likely to be available as a separate schema, in which case you should load it into the SDO repository where it can be used at run time to process any message with a matching header.

Schema to Java class mapping

Each XML schema complex type is mapped to an SDO type. This means that an element with a complex type is represented by an instance of an SDO data object. The type has a property for each element, attribute, or wildcard that is contained in the schema type definition.

The instance contains a value for each property that has been set. If the property is mapped from a schema complex type, the value is another SDO data object. If the property is mapped from a schema simple type, the value is an instance of a Java class, as shown in the following table.

Table 116. Schema types and corresponding Java classes. The first column of the table lists the schema types. The second column lists the corresponding Java classes. The third column refers you to one of the two notes that is given at the end of the table for your reference.

Schema type	Java class	Notes
anyURI	java.lang.String	
base64Binary	byte[]	See Note 2
boolean	java.lang.Boolean/ boolean	See Note 1
byte	java.lang.Byte / byte	See Note 1
date	java.lang.String	
dateTime	java.lang.String	
decimal	java.math.BigDecimal	
double	java.lang.Double / double	See Note 1
duration	java.lang.String	
ENTITIES	java.util.List	
ENTITY	java.lang.String	
float	ava.lang.Float / float	See Note 1
gDay	java.lang.String	
gMonth	java.lang.String	
gMonthDay	java.lang.String	

Table 116. Schema types and corresponding Java classes (continued). The first column of the table lists the schema types. The second column lists the corresponding Java classes. The third column refers you to one of the two notes that is given at the end of the table for your reference.

gYear	java.lang.String	
gYearMonth	java.lang.String	
hexBinary	byte[]	See Note 2
ID	java.lang.String	
IDREF	java.lang.String	
IDREFS	java.util.List	
int	java.lang.Integer / int	See Note 1
integer	java.math.BigInteger	
language	java.lang.String	
long	java.lang.Long / long	See Note 1
Name	java.lang.String	
NCName	java.lang.String	
negativeInteger	java.math.BigInteger	
NKTOKENS	java.util.List	
NMTOKEN	java.lang.String	
nonNegativeInteger	java.math.BigInteger	
nonPositiveInteger	java.math.BigInteger	
normalisedString	java.lang.String	
NOTATION	javax.xml.namespace.QName	
positiveInteger	java.math.BigInteger	
QName	javax.xml.namespace.QName	
short	java.lang.Short / short	See Note 1
string	java.lang.String	
time	java.lang.String	
token	java.lang.String	
unsignedByte	java.lang.Short / short	See Note 1
unsignedInt	java.lang.Long / long	See Note 1
unsignedLong	java.math.BigInteger	
unsignedShort	java.lang.Integer / int	See Note 1

Notes:

1. SDO automatically converts primitives (int, long and so on) into objects, as needed. This means that you can use a mixture of the specialized methods (getInt, setInt, getLong, setLong) as well as the generic get and set methods.
2. As byte arrays are mutable, you can update the value without setting it back onto the data object. However, when this occurs, the data object may not be aware of implicit update. When working with byte array values, always use the setBytes() method to explicitly update the data object.

Working with global elements and attributes

When a schema is mapped to SDO, a special SDO type - typically called 'DocumentRoot' - is defined. This type is a container for all the global elements and attributes in the schema. Whenever you have to locate an SDO property for a global element or attribute, you should locate the 'DocumentRoot' type and then locate the appropriate property within it.

The following schema defines the layout of web services messages. By comparing this schema with the information in “Mapping of SDO data graphs for web services messages” on page 1100 you can see the schema to SDO mapping in action.

```

<?xml version="1.0"?>
<xsd:schema
  targetNamespace="http://www.ibm.com/ns/2004/05/webservices/messagemodel"
  xmlns:tns="http://www.ibm.com/ns/2004/05/webservices/messagemodel"

</xsd:complexType>
</xsd:schema>

```

Web Services code example:

This Web Services Description Language (WSDL) example and code snippets show how to access fields within a Web services message for programming a mediation.

Web services message definition

This topic contains an example of a web services message. The example is characterized in WSDL, an XML-based language that is used to describe the services a business offers and how those services might be accessed.

This topic shows how to program mediations to work with different parts of a web services message, which are described with the Service Data Objects (SDO) Version 1 representation in “Mapping of SDO data graphs for web services messages” on page 1100. For each part of the message, there is an XML description of the message, representing its SDO data graph. Each XML description is accompanied by code snippets that illustrate how to work with that part of the message.

Note: In the following example, the SOAP header schema is included in the WSDL. Alternatively, it can be included as a separate schema in the SDO repository.

This is a WSDL description of the message that is used as an example for subsequent code snippets:

companyInfo web service message description

```
<wsdl:definitions targetNamespace="http://example.companyInfo"
  xmlns:tns="http://example.companyInfo"
  xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
  xmlns:wsdlsoap="http://schemas.xmlsoap.org/wsdl/soap/"
  xmlns:wsdlmime="http://schemas.xmlsoap.org/wsdl/mime/"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema">

  <wsdl:types>
    <xsd:schema elementFormDefault="qualified"
      targetNamespace="http://example.header">

      <xsd:element name="sampleHeader">
        <xsd:complexType>
          <xsd:all>
            <xsd:element name="priority" type="xsd:int"/>
          </xsd:all>
        </xsd:complexType>
      </xsd:element>
    </xsd:schema>

    <xsd:schema elementFormDefault="qualified"
      targetNamespace="http://example.companyInfo">

      <xsd:element name="getCompanyInfo">
        <xsd:complexType>
          <xsd:all>
            <xsd:element name="tickerSymbol" type="xsd:string"/>
          </xsd:all>
        </xsd:complexType>
      </xsd:element>

      <xsd:element name="getCompanyInfoResult">
        <xsd:complexType>
          <xsd:all>
            <xsd:element name="result" type="xsd:float"/>
          </xsd:all>
        </xsd:complexType>
      </xsd:element>
    </xsd:schema>

  </wsdl:types>

  <wsdl:message name="getCompanyInfoRequest">
    <wsdl:part name="part1" element="tns:getCompanyInfo"/>
  </wsdl:message>

  <wsdl:message name="getCompanyInfoResponse">
    <wsdl:part name="part1" element="tns:getCompanyInfoResult"/>
    <wsdl:part name="part2" type="xsd:string"/>
    <wsdl:part name="part3" type="xsd:base64Binary"/>
  </wsdl:message>

  <wsdl:portType name="CompanyInfo">
    <wsdl:operation name="GetCompanyInfo">
```

```

    <wsdl:input message="tns:getCompanyInfoRequest"
              name="getCompanyInfoRequest"/>
    <wsdl:output message="tns:getCompanyInfoResponse"
               name="getCompanyInfoResponse"/>
  </wsdl:operation>
</wsdl:portType>

<wsdl:binding name="CompanyInfoBinding" type="tns:CompanyInfo">
  <wsdlsoap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http"/>

  <wsdl:operation name="GetCompanyInfo">
    <wsdlsoap:operation soapAction=""/>
    <wsdl:input name="getCompanyInfoRequest">
      <wsdlsoap:body use="literal"/>
    </wsdl:input>
    <wsdl:output name="getCompanyInfoResponse">
      <wsdlsoap:body use="literal"/>
    </wsdl:output>
  </wsdl:operation>
</wsdl:binding>

<wsdl:service name="CompanyInfoService">
  <wsdl:port binding="tns:CompanyInfoBinding" name="SOAPPort">
    <wsdlsoap:address location="http://somewhere/services/CompanyInfoService"/>
  </wsdl:port>
</wsdl:service>

</wsdl:definitions>

```

Working with the info node

This is an example of a simple SOAP request:

```

<env:Envelope
  xmlns:env='http://schemas.xmlsoap.org/soap/envelope/'
  xmlns:ns1='http://example.companyInfo'>
  <env:Body>
    <ns1:getCompanyInfo>
      <ns1:tickerSymbol>IBM</ns1:tickerSymbol>
    </ns1:getCompanyInfo>
  </env:Body>
</env:Envelope>

```

You can access the properties of the info node (see “Overall layout of a web services message” on page 1100) using code snippets such as this:

```

// Get the info node (a child of the graph root object)
DataObject rootNode = graph.getRootObject();
DataObject infoNode = rootNode.getDataObject("Info");

// Query the operationName, and messageType.
String opName = infoNode.getString("operationName");
String type   = infoNode.getString("messageType");

```

Working with a header

This is an example of a SOAP request including a header:

```

<env:Envelope
  xmlns:env='http://schemas.xmlsoap.org/soap/envelope/'
  xmlns:ns1='http://example.companyInfo'>
  <env:Header>
    <example:sampleHeader
      env:mustUnderstand='1'
      xmlns:example='http://example.header'>

```

```

        <example:priority>4</example:priority>
    </example:sampleHeader>
</env:Header>
<env:Body>
    <ns1:getCompanyInfo>
        <ns1:tickerSymbol>IBM</ns1:tickerSymbol>
    </ns1:getCompanyInfo>
</env:Body>
</env:Envelope>

```

For a description of the properties of the header entry with a list of headers, see “Header entry” on page 1102. To work with a header entry and its properties, use code such as this:

```

// Get the info node (a child of the graph root object)
DataObject rootNode = graph.getRootObject();
DataObject infoNode = rootNode.getDataObject("Info");

// Access the list of headers
List headerEntries = infoNode.getList("headers");

// Get the first entry from the list
DataObject headerEntry = (DataObject) headerEntries.get(0);

// Query the mustUnderstand property of the header entry
boolean mustUnderstand = headerEntry.getBoolean("mustUnderstand");

// Get the Sequence that holds the content of the header entry
Sequence headerContent = headerEntry.getSequence("any");

// Get the first piece of content from the Sequence
DataObject header = (DataObject) headerContent.getValue(0);

// Read the priority from the header
int priority = header.getInt("priority");

// Shorthand for the above, using SDO path expressions that start
// from the info node.
mustUnderstand = infoNode.getBoolean("headers[1]/mustUnderstand");
priority = infoNode.getInt("headers[1]/any[1]/priority");

```

Working with an attachment

This is an example of a SOAP request including an XML attachment:

Content-Type: multipart/related; start="<start>"; boundary="boundary"

```

--boundary
Content-Type: text/xml
Content-Transfer-Encoding: 7bit
Content-ID: <start>

<env:Envelope
  xmlns:env='http://schemas.xmlsoap.org/soap/envelope/'
  xmlns:ns1='http://example.companyInfo'>
  <env:Body>
    <ns1:getCompanyInfo>
      <ns1:tickerSymbol>IBM</ns1:tickerSymbol>
    </ns1:getCompanyInfo>
  </env:Body>
</env:Envelope>
--boundary
Content-Type: text/xml; charset=UTF-8
Content-Transfer-Encoding: binary

```

```
Content-ID: <myAttachment>

<info>Some attached information</info>
--boundary--
```

For a description of the properties of the attachment entry with byte array, see “Attachment entry” on page 1103. To work with a header entry and its properties, use code such as this:

```
// Get the info node (a child of the graph root object)
DataObject rootNode = graph.getRootObject();
DataObject infoNode = rootNode.getDataObject("Info");

// Access the list of attachments
List attachmentEntries = infoNode.getList("attachments");

// Get the first entry from the list
DataObject attachmentEntry = (DataObject) attachmentEntries.get(0);

// Query the contentId property of the header entry
String contentId = attachmentEntry.getString("contentId");

// Get the data contained in the attachment
byte[] data = attachmentEntry.getBytes("data");
```

Working with the message body

This is an example of a simple SOAP request:

```
<env:Envelope
  xmlns:env='http://schemas.xmlsoap.org/soap/envelope/'
  xmlns:ns1='http://example.companyInfo'>
  <env:Body>
    <ns1:getCompanyInfo>
      <ns1:tickerSymbol>IBM</ns1:tickerSymbol>
    </ns1:getCompanyInfo>
  </env:Body>
</env:Envelope>
```

To see the properties of the body, see “Message body layout” on page 1103. To work with the contents of the body, use code such as this:

```
// Get the info node (a child of the graph root object)
DataObject rootNode = graph.getRootObject();
DataObject infoNode = rootNode.getDataObject("Info");

// Get hold of the body node
DataObject bodyNode = infoNode.getDataObject("body");

// Get hold of the data object for the first part of the body
DataObject part1Node = bodyNode.getDataObject("part1");

// Query the tickerSymbol
String ticker = part1Node.getString("tickerSymbol");

// Shorthand for the above, using a SDO path expression that
// starts from the info node.
ticker = infoNode.getString("body/part1/tickerSymbol");
```

JMS formats:

To write code that can access the different JMS message types, you need to know how each message type is mapped to SDO, and how to retrieve the message format string from the message.

Format types

Each JMS message type is defined by a message format string within the message. You can retrieve the format string by using the code snippet in the example below. The following table shows the mapping of message format strings to Service Data Objects (SDO):

JMS Message type	Message format string	Mapping to SDO ¹
JMS Bytes message	JMS:bytes	See "JMS Formats - bytes"
JMS Text message	JMS:text	See "JMS Formats - text"
JMS Stream message	JMS:stream	See "JMS formats - Stream" on page 1113
JMS Object message	JMS:object	See "JMS Formats - object" on page 1113
JMS Map message	JMS:map	The retrieval or construction of SDO data graphs for JMS map messages is not supported.

¹ The version of SDO supported by mediations is Version 1.

This code snippet is an example of how to retrieve the message format string from the message:

```
String format = siMsg.getFormat();  
if (format.equals ....
```

JMS Formats - bytes:

Your program can retrieve the payload of a JMS bytes message by mapping the body of the message to an SDO data graph representing the message.

Bytes body

You can retrieve the payload of a JMS bytes message as a Java byte array (`byte[]`). First, you must retrieve a data graph representing the message from the `SIMessage` instance. As is common to all data graphs representing JMS messages, the root data object of the graph contains a property named "data", and that data object in turn contains a property named "value". In JMS bytes messages, the value property might be accessed as a Java byte array.

You can access the data within the data graph with code such as this:

```
SIMessage siMsg;  
String format = siMsg.getFormat();  
if (format.equals("JMS:bytes")) {  
    DataGraph graph = siMsg.getDataGraph();  
    byte[] payload = graph.getRootObject().getBytes("data/value");  
}
```

JMS Formats - text:

Your program can retrieve the payload of a JMS text message by mapping the body of the message to an SDO data graph representing the message.

Text body

You can retrieve the payload of a JMS text message as a Java string value (`java.lang.String`). First, you must retrieve a data graph representing the message from the `SIMessage` instance. As is common to all data graphs representing JMS messages, the root data object of the graph contains a property named

"data", and that data object in turn contains a property named "value". In JMS text messages the value property may be accessed as a Java string value.

You can access the data within the data graph with code such as this:

```
SIMessage siMsg;
String format = siMsg.getFormat();
if (format.equals("JMS:text")) {
    DataGraph graph = siMsg.getDataGraph();
    String payload = graph.getRootObject().getString("data/value");
}
```

JMS formats - Stream:

Your program can retrieve the payload of a JMS stream message by mapping the body of the message to an SDO data graph representing the message.

Stream body

You can retrieve the payload of a JMS Stream message as a Java list value (`java.util.List`). First, you must retrieve a data graph representing the message from the `SIMessage` instance. As is common to all data graphs representing JMS messages, the root data object of the graph contains a property named "data", and that data object in turn contains a property named "value". For a JMS Stream message the value property might be accessed as a List value. The member functions of the List interface can be used to access the individual objects within the JMS Stream message instance. (Note that the JMS standard places constraints on the kinds of objects that might be placed in a Stream message.)

You can access the data within the data graph with code such as this:

```
}SIMessage siMsg;
String format = siMessage.getFormat();
if (format.equals("JMS:stream")) {
    DataGraph graph = siMsg.getDataGraph();
    List payload = graph.getRootObject().getList("data/value");
    int streamLength = payload.size();
    if (streamLength > 0) {
        Object item1 = payload.get(0);
        // You can also access items directly, for example: (for the_same_value)
        item1 = graph.getRootObject().get("data/value[1]");
    }
}
```

JMS Formats - object:

Your program can retrieve the payload of a JMS object message by mapping the body of the message to an SDO data graph representing the message.

Object body

You can retrieve the payload of a JMS object message as a Java byte array (`byte[]`). First, you must retrieve a data graph representing the message from the `SIMessage` instance. As is common to all data graphs representing JMS messages, the root data object of the graph contains a property named "data", and that data object in turn contains a property named "value". For a JMS object message the value property might be accessed as a Java byte array. The original Object instance that the payload represents might be reconstructed from the byte array.

You can access the data within the data graph with code such as this:

```

SIMessage siMsg;
String format = siMsg.getFormat();
if (format.equals("JMS:object")) {
    DataGraph graph = siMsg.getDataGraph();
    byte[] payload = graph.getRootObject().getBytes("data/value");
    if(payload != null) {
        // Need to deserialize to recover original object
        ObjectInputStream in =
            new ObjectInputStream(new ByteArrayInputStream(payload));
        Object obj = in.readObject();
    }
}

```

Writing a routing mediation

Use this topic to create a mediation that chooses a particular forward route for a message.

Before you begin

For an introduction to using mediations with the service integration bus, see [Learning about mediations](#). For details of how to install a mediation into WebSphere Application Server and associate it with a bus destination, see [Working with mediations](#).

This topic assumes that you are familiar with using a Java Platform, Enterprise Edition (Java EE) session bean development environment such as the assembly tools or IBM Rational Application Developer.

About this task

A routing mediation is a mediation application that contains a routing handler. You associate a routing mediation with a service integration bus destination, and use the mediation to choose a particular route from a range of available routes. For example when you create a new outbound service configuration or modify an existing outbound service configuration you can apply a port selection mediation to choose a particular outbound port from the range of ports that are available to the outbound service.

To create a routing mediation, use a Java Platform, Enterprise Edition (Java EE) session bean development environment to complete the following steps:

Procedure

1. Create an empty mediation handler project. This creates the project, and creates the handler class that implements the handler interface. For detailed instructions on how to do this, see [Writing the mediation handler](#).
2. Use the mediation pane on the EJB descriptor to define the handler class as a mediation handler.

Note: When you do this, you specify a name by which the mediation handler list is known. Make a note of this name, for later reference when you create the mediation in the bus.

3. Add the routing function to the handler. Before you begin, review [Adding mediation function to handler code](#), in particular its subtopic [Working with message context](#). Add import statements to your handler class, and modify the handle method by adding your routing code. Specify the routing destination by adding that destination to the front of the forward routing path list. The forward routing path list is available from the message context. For example:

```

import javax.xml.rpc.handler.MessageContext;
import com.ibm.websphere.sib.mediation.handler.MediationHandler;
import com.ibm.websphere.sib.mediation.handler.MessageContextException;
import com.ibm.websphere.sib.mediation.messagecontext.SIMessageContext;
import com.ibm.websphere.sib.SIMessage;
import com.ibm.websphere.sib.SIDestinationAddress;
import com.ibm.websphere.sib.SIDestinationAddressFactory;
import java.util.List;

```

```

public class RouteMediationHandler implements MediationHandler {

    public boolean handle(MessageContext ctx) throws MessageContextException {
        SIMessageContext siCtx = (SIMessageContext) ctx;
        SIMessage msg = siCtx.getSIMessage();
        List frp = msg.getForwardRoutingPath();
        try {
            SIDestinationAddress destination =
                SIDestinationAddressFactory
                    .getInstance()
                    .createSIDestinationAddress(
                        "RoutingDestination", //this is the name of the target destination
                        false);
            frp.add(0, destination);
        } catch (Exception e) {
            return false;
        }
        msg.setForwardRoutingPath(frp);
        return true;
    }
}

```

For more information about the service integration technologies classes, including the mediation handler and message context classes, see the [Generated API documentation - Application programming interfaces](#) .

4. Export the routing mediation enterprise application.

What to do next

You are now ready to install your mediation into WebSphere Application Server and associate it with a bus destination, as described in [Working with mediations](#).

Writing a mediation that maps between attachment encoding styles

Use this topic to create a mediation that maps from SOAP Messages with Attachments encoding style to WS-I Attachments Profile Version 1.0 encoding style.

Before you begin

For an introduction to using mediations with the service integration bus, see [Learning about mediations](#). For details of how to install a mediation into WebSphere Application Server and associate it with a bus destination, see [Working with mediations](#).

This topic assumes that you are familiar with using a Java Platform, Enterprise Edition (Java EE) session bean development environment such as the assembly tools or IBM Rational Application Developer.

The example mediation given in this topic is based upon the WSDL examples that are given in [Supporting bound attachments: WSDL examples](#)

About this task

You can use a mediation to map from a SOAP Messages with Attachments encoding of a message to WS-I Attachments Profile Version 1.0 encoding. The WSDL definition is the same in both cases, so if you create a mediation that rewrites the Content ID values to match the Version 1.0 conventions then the message is encoded by service integration technologies according to Version 1.0 rules.

To create a mapping mediation, use a Java Platform, Enterprise Edition (Java EE) session bean development environment to complete the following steps:

Procedure

1. Create an empty mediation handler project. This creates the project, and creates the handler class that implements the handler interface. For detailed instructions on how to do this, see Writing the mediation handler.
2. Use the mediation pane on the EJB descriptor to define the handler class as a mediation handler.

Note: When you do this, you specify a name by which the mediation handler list is known. Make a note of this name, for later reference when you create the mediation in the bus.

3. Add the mapping function to the handler. Before you begin, review Adding mediation function to handler code. Here is an example of mediation handler code that rewrites the Content ID values to match the Version 1.0 conventions:

```
int uuidBase = 0;
DataObject root = SIMessage.getDataGraph().getRootObject();
List attachments = root.getList("info/attachments");
Iterator entries = attachments.iterator();
while(entries.hasNext()) {
    DataObject entry = (DataObject) entries.next();
    if(entry.getType().equals("BoundMIMEAttachmentEntryType")) {
        String newContentId = entry.getString("messagePart") + "=" +
            Integer.toString(uuidBase++) +
            "@some.domain";
    }
}
```

Note: For messages that use a SOAP with attachments reference (swaref) or some other URI mechanism to refer to the attachments, the URI values might also have to be updated to match the new Content ID values. However such mechanisms are usually used to refer to unbound attachments.

For more information about the service integration technologies classes, including the mediation handler classes, see the Generated API documentation - Application programming interfaces .

4. Export the mapping mediation enterprise application.

What to do next

You are now ready to install your mediation into WebSphere Application Server and associate it with a bus destination, as described in Working with mediations.

Using durable subscriptions

You use *durable subscriptions* for publish/subscribe messaging. A durable subscription can be used to preserve messages published on a topic while the subscriber is not active.

About this task

If there is no active subscriber for a durable subscription, JMS retains the subscription messages until they are received by the subscriber, or until they expire, or until the durable subscription is deleted. This enables subscriber applications to operate disconnected from the JMS provider for periods of time, and then reconnect to the provider and process messages that were published during their absence.

Each JMS durable subscription is identified by a subscription name (*subName*), which is defined when the durable subscription is created. A JMS connection also has an associated client identifier (*clientID*), which is used to associate a connection and its objects with the list of messages (on the durable subscription) that is maintained by the JMS provider for the client. The *subName* assigned to a durable subscription must be unique within a given client ID.

If an application needs to receive messages published on a topic while the subscriber is inactive, it uses a *durable subscriber*.

In normal operation there can be at most one active (connected) subscriber for a durable subscription at a time. However, when running inside an application server it is possible to clone the application server for failover and load-balancing purposes. In this case, a cloned durable subscription can have multiple simultaneous consumers.

For information about durable subscriptions, see the JMS 1.1 Specification (for example, section 9.3.3 “Using Durable Subscriptions”).

The following operations for durable subscriptions are in addition to the usual JMS operations, such as to first look up a connection factory and a JMS destination, and to create a connection and session.

The following are the main operations for using durable subscriptions:

- Creating a new durable subscription
- Reconnecting to an existing durable subscription
- Unsubscribing (deleting) a durable subscription

Procedure

- Define the Durable Subscription Home This property must be set on the JMS connection factory if durable subscriptions are to be created using connections created from this connection factory. The value is the name of the messaging engine where all durable subscriptions accessed through this connection are managed.

You can also set the Durable Subscription Home on the JMS topic destination, which enables a single connection to access durable subscriptions on more than one messaging engine.

To be able to create durable subscriptions, the property on the connection factory must not be null (the default). Setting a value of null or empty string on the property of a destination indicates that the value specified on the connection factory should be inherited.

- Creating a new durable subscription A durable TopicSubscriber can be created by a Session or by a TopicSession.

Having performed the normal setup, an application can create a durable subscriber to a destination. To do this, the client program creates a durable TopicSubscriber, by using `session.createDurableSubscriber`. The name *subName* is used as an identifier of the durable subscription.

```
session.createDurableSubscriber( Topic topic,
                               java.lang.String subName,
                               java.lang.String messageSelector,
                               boolean noLocal);
```

Alternatively, you can use the two-argument form of this operation, which takes only a topic and name (*subName*) as parameters. This alternative form invokes the four-argument operation with null as the `messageSelector` and false as the `noLocal` parameters.

```
session.createDurableSubscriber( Topic topic, java.lang.String subName);
```

A JMS durable subscription is created with a unique identifier of the form `clientId+###+subName`. The characters `##` should not be used in the `clientId` or `subName` if the JMS connection is to use a durable subscription.

Handling exceptions. The following JMS exceptions can be thrown for the reasons listed in the exception messages:

- `InvalidDestination` - The name of this durable subscription (`clientId+###+subName`) clashes with an existing destination.
- `IllegalState` - The method was invoked on a closed connection.
- `IllegalState` - This destination is not accepting consumers. This probably means that there is already an active subscriber for this durable subscription.
- `InvalidDestination` - The mediation named in the parameters cannot be found.
- `InvalidDestination` - The destination cannot be found.

- JMSecurity - The user does not have authorization to perform this operation.
- JMSException - Errors occurred in the MsgStore, Comms or Core layers.
- Reconnecting to an existing durable subscription To reconnect to a topic that has an existing durable subscription, the subscriber application calls `session.CreateDurableSubscriber` again, using the same parameters that it used to originally create the durable subscription. However, consider the following important restrictions:
 - The subscriber must be attached to the same connection.
 - The destination and subscription name must be the same as in the original method call.
 - If a message selector was specified, it must be the same as in the original method call.By calling `createDurableSubscriber` again, the subscriber application reconnects to the topic, and receives any messages that arrived while the subscriber was disconnected.
- Unsubscribing (deleting) a durable subscription To unsubscribe (delete) a durable subscription to a topic, the subscriber application calls `session.unsubscribe(java.lang.String name)`.
Do not call the `unsubscribe` method to delete a durable subscription if there is a `TopicConsumer` currently consuming messages from the topic.

Sending web service messages directly over the bus from a JAX-RPC client

Use this task to send web service messages over a bus by retargeting the JAX-RPC client.

About this task

Java API for XML-based remote procedure calls (JAX-RPC) client applications send and receive web service request and response messages. JAX-RPC client applications that use the IBM JAX-RPC run-time environment can do this in a number of different ways, depending on the bindings in the WSDL document that they are developed against, and the configuration data that is used at run time.

For an introduction to basic JAX-RPC programming concepts, including the JAX-RPC client and server programming models, see *Getting Started with JAX-RPC*.

If you want to use a JAX-RPC client to send messages over the service integration bus, you have two choices:

- Use a SOAP binding (SOAP over HTTP or SOAP over JMS), and pass messages indirectly through an endpoint listener to an inbound service. You would do this if you had SOAP-specific JAX-RPC handlers that must run in the client application context.
- Pass messages directly into the service integration bus at a destination by “retargeting” the JAX-RPC client application as described in this topic.

Note: There are currently limitations regarding the Java types used by services that are retargeted through a JAX-RPC client application.

Retargeting involves setting the following two values into the client application deployment descriptor, or specifying them dynamically at run time from within the client application:

- The *binding namespace* is set to indicate that the client uses the messaging bus directly.
- The *endpoint address* is set to include the particular destination and (optionally) the format of messages that the client uses.

The destination also needs to be configured so that it knows the port type of messages that the JAX-RPC client is using. There are two ways to achieve this:

- Create an outbound service. An outbound service represents an externally-provided web service. In this case, requests from the JAX-RPC client pass through the service destination and are then sent on to the service provider defined by the outbound service configuration.
- Create an inbound service. An inbound service represents a service provided somewhere within or beyond the messaging bus. You can create an inbound service on any existing destination. The creation of an inbound service associates a WSDL port type with the destination. When retargeting to a destination with an inbound service, the client application needs to specify both the destination name and inbound service name, because it is possible to configure more than one inbound service against a single destination. In this case, requests from the JAX-RPC client pass through the destination and then onwards through the service integration bus depending on routing that is done at the initial destination.

To have web service messages sent directly to a destination using a JAX-RPC client, complete the following steps:

Procedure

1. Create the JAX-RPC client application.
2. Create the outbound service or inbound service with which you want the JAX-RPC client application to exchange messages.
3. Use the administrative console to access the port information for your JAX-RPC client application, as described in “Configuring web services client bindings” on page 1402 and Web services client port information.
4. Override the default SOAP binding for your JAX-RPC client application. Change the binding namespace to `http://www.ibm.com/ns/2004/02/wsdl/mp/sib`
5. Override the endpoint that your JAX-RPC client application uses to send web service requests. The new endpoint should use the sib: URL syntax and include either the outbound service destination name, or both the inbound service name and its corresponding destination name.

What to do next

After you change the *binding namespace*, any JAX-RPC handler lists that were configured for the retargeted port are ignored. For clients that are developed against WSDL with a SOAP binding, retargeting directly to the bus causes the handlers to be ignored. However if the client is developed against the non-bound WSDL for the service, retargeting to the bus is not considered to be changing the binding namespace, and so the handler information is retained. In this case the JAX-RPC handlers are called with the `SDOMessageContext` subclass.

Associated reference information:

- “sib: URL syntax”

sib: URL syntax

The sib: URL has the following syntax:

```
sib:[destination|path]?property_1=value_1&property_2=value_2&...
```

where:

- Square brackets (“[]”) indicate that a parameter is optional.
- Transport type is `sib:`, followed by either `/destination` to specify destination type or `/path` to specify a forward routing path, followed by a “query string” that contains one or more properties. The permitted properties are described in the subsequent sections of this topic.

Required properties

The following properties are required. They are used to specify the destination for the request.

Note: All destination names must be fully-qualified. That is, they must include the name of the service integration bus as well as the destination name itself. Use the syntax *bus:destination*. If a bus or destination name contains a colon or comma, wrap the name in double quotation marks (""). If it contains a double quotation mark, repeat the quotation mark.

destinationName

The destination name.

path The forward routing path, in the form of a sequence of destination names separated by commas.

replyDestinationName

The name of the destination to be used for the reply.

inboundService

The name of the inbound service that identifies the specific attachment that the requester application uses. You can omit this value if the destination is a service destination with an associated outbound service configuration, because in that case the requester is attaching to the outbound service through the service destination.

timeout

The time the requester waits for a response. The default value is 60 seconds. A zero value indicates an unlimited wait.

Service integration technologies-related properties

The following properties are optional. If you do not specify a value for a property, then the default value is used. For more information regarding the permitted values for these properties, see the generated API information for the `SIMessage` interface.

reliability

The reliability of the request message.

timeToLive

The amount of time (in milliseconds) before the request times out. A zero value indicates that the request never times out.

Note: The **timeout** property (see the required properties) is the time delay after which the requester application blocks the application thread that is waiting for a response to a request and response operation. The **time to live** and **replyTimeToLive** optional properties indicate how long the request and reply messages should be processed by the messaging engines. This does not include the processing time at the service implementation. You would therefore usually set the timeout to be the sum of the request and response times to live, plus some amount for the service processing time.

priority

The priority of the request message.

user

The user ID required to access the request destination.

password

The password required to access the request destination.

replyReliability

The reliability of the reply message.

replyTimeToLive

The amount of time (in milliseconds) before the reply times out. A zero value indicates that the reply never times out.

replyPriority

The priority of the reply message.

Other properties

You can also include user-defined properties in the URL. These properties must be named with a user. prefix. For example:

```
sib:/destination?destinationName=myBus:myDestination & reliability=assured & user.customData=XYZ
```

After the request is sent, the URL itself is available within the message properties, named `inbound.url`.

Chapter 28. Developing Session Initiation Protocol (SIP) applications

This page provides a starting point for finding information about SIP applications, which are Java programs that use at least one Session Initiation Protocol (SIP) servlet written to the JSR 116 specification.

SIP is used to establish, modify, and terminate multimedia IP sessions including IP telephony, presence, and instant messaging.

Developing SIP applications

A SIP application is a set of SIP servlets packaged in a SIP application archive file (SAR).

About this task

A SIP servlet is an application component managed by the SIP container that performs SIP signaling. The programming and deployment models are analogous to web servlets and therefore will be mapped to the WebSphere administrative model accordingly. It is possible to include web servlets in a SAR file (along with the required web.xml deployment descriptor) to create what is known as a converged application. See JSR 116 for details on SIP applications, servlets, converged applications, and status codes.

Developing SIP applications that support PRACK

A SIP response to an INVITE request can be final or provisional. Final responses are always sent reliably, but provisional responses typically are not. For cases where you need to send a provisional response reliably, you can use the PRACK (Provisional response acknowledgement) method.

Before you begin

For you to be able to develop applications that support PRACK, the following criteria must be met:

- The client that sends the INVITE request must put a 100rel tag in the Supported or the Require header to indicate that the client supports PRACK.
- The SIP servlet must respond by invoking the sendReliably() method instead of the send() method to send the response.

About this task

PRACK is described in the following standards:

- RFC 3262 (“Reliability of Provisional Responses in the Session Initiation Protocol (SIP)”), which extends RFC 3261 (“SIP: Session Initiation Protocol”), adding PRACK and the option tag 100rel.
- Section 6.7.1 (“Reliable Provisional Responses”) of JSR 116 (“SIP Servlet API Version 1.0”).

Procedure

- For an application acting as a proxy, do this:
 - Make your application generate and send a reliable provisional response for any INVITE request that has no tag in the To field.
- For an application acting as a user agent client (UAC), do this:
 - Make your application add the 100rel tag to outgoing INVITE requests. The option tag must appear in either the Supported header or the Require header.
 - Within your application's doProvisionalResponse(...) method, prepare the application to create and send PRACK requests for incoming reliable provisional responses. The application must create the PRACK request on the response's dialog through a SipSession.createRequest(...) method, and it must set the RACK header according to RFC 3262 Section 7.2 (“RACK”).

- The application that acts as an UAC will not receive doPrack() methods. The UAC sends INVITE and receives Reliable responses. When the UAC receives the Reliable response, it sends PRACK a request to the UAS and receives a 200 OK on the PRACK so it should next implement doResponse() in order to receive it.
- For an application acting as a user agent server (UAS), do this:
 - If an incoming INVITE request requires the 100rel tag, trying to send a 101-199 response unreliably by using the send() method causes an Exception.
 - Make the application declare a SipErrorListener to receive noPrackReceived() events when a reliable provisional response is not acknowledged within $64 * T1$ seconds, where T1 is a SIP timer. Within the noPrackReceived() event processing, the application should generate and send a 5xx error response for the associated INVITE request per JSR 116 Section 6.7.1.
 - Make the application have at most one outstanding, unacknowledged reliable provisional response. Trying to send another one before the first's acknowledgement results in an Exception.
 - Make sure that the application enforces the RFC 3262 offer/answer semantics surrounding PRACK requests containing session descriptions. Specifically, a servlet must not send a 2xx final response if any unacknowledged provisional responses contained a session description.

Setting up SIP application composition

The JSR 116 standard for SIP applications states in section 2.4 that multiple applications may be invoked for the same SIP request. The process of setting up applications to comply with this standard is called application composition.

About this task

Application composition requires that implementations use a cascaded services model. The cascaded services model requires that service applications triggered on the same host are triggered in sequence, as if the triggering occurred on different hosts. Therefore responses flow upstream and hit applications in the reverse order of the corresponding requests.

The JSR 116 standard does not specify how to implement application composition, thus there are many ways to comply with this standard. For WebSphere Application Server, composition of the application depends on the deployed application order, and on the order of mapping rules within the deployment descriptor of each application.

- For an initial incoming request, the SIP container tries each potential rule in order. When the container finds the n^{th} match, the container invokes the corresponding servlet.
- If the servlet must proxy the request, the container scans the rules again to search for additional matches. When the container finds the $(n+1)^{th}$ match, the container invokes the corresponding servlet.
- Any servlet in the same application as the previously invoked servlet is excluded from the matching process. No servlet can be invoked twice for the same SIP request.

You can specify load on start-up priority. The `<load-on-startup>` in the `sip.xml` defines the order in which servlets are initialized on startup. If this value is lower than zero, the servlets are initialized when the first request is matched to them according to matching rule and composition order. Zero is a legitimate weight for startup initialization order. If this tag does not exist or if it contains a negative value, the servlet does not initialize at startup.

You should also add `<load-on-startup>` to the same tag in the `web.xml` if you are changing it manually. It is the `WebContainer` that loads servlets (and siplets), and it looks only at the `web.xml`. When deploying a SAR, only the `sip.xml` needs to be changed. The `web.xml` is automatically constructed correctly after deployment.

The load-on-startup tag embedded in the SIP deployment descriptor tag for a servlet dictates the order that the application is loaded on start up of the server. It does not dictate the order that an application gets called when the application is a member of an application composition chain that matches rules to process a new message coming in.

The starting weight for applications and their modules is specified in the deployment.xml file. The order in which modules pickup requests on composition is evaluated by applications weight first and then modules weight. The following steps can be completed in any order to specify applications weight or modules weight from the administrative console.

Procedure

1. To specify the applications (EARs) weight, expand **Enterprise Applications > applicationName > Startup Behavior** and set the startup order.
2. To specify the modules (WARs) weight, expand **Enterprise Applications > applicationName > Manage Modules** and set the starting weight.
3. Restart the changed applications.

Example

Specifying load-on-startup priority example:

sip.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE sip-app
PUBLIC "-//Java Community Process//DTD SIP Application 1.0//EN"
"http://www.jcp.org/dtd/sip-app_1_0.dtd">
<sip-app>
  <display-name>SIPSampleProxy</display-name>

  <servlet>
    <servlet-name>SIPSampleProxy</servlet-name>
    <servlet-class>sipes.test.container.proxy.SIPSampleProxy</servlet-class>
    <load-on-startup>1</load-on-startup>
  </servlet>

  <servlet-mapping>
    <servlet-name>SIPSampleProxy</servlet-name>
    <pattern>
      <equal>
        <var>request.uri.user</var>
        <value>SIPSampleProxy</value>
      </equal>
    </pattern>
  </servlet-mapping>

  <proxy-config>
    <sequential-search-timeout>1000</sequential-search-timeout>
  </proxy-config>
  <session-config>
    <session-timeout>12</session-timeout>
  </session-config>
</sip-app>
```

web.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE web-app PUBLIC "-//Sun Microsystems, Inc.//DTD Web Application 2.3//EN" "http://java.sun.com/dtd/web-app_2_3.dtd">
<web-app id="WebApp">
  <display-name>SIPSampleProxy</display-name>
  <servlet>
    <servlet-name>SIPSampleProxy</servlet-name>
    <display-name>SIPSampleProxy</display-name>
    <servlet-class>sipes.test.container.proxy.SIPSampleProxy</servlet-class>
  </servlet>
  <servlet-mapping>
    <servlet-name>SIPSampleProxy</servlet-name>
    <url-pattern>/SIPSampleProxy</url-pattern>
  </servlet-mapping>
  <welcome-file-list>
    <welcome-file>index.html</welcome-file>
    <welcome-file>index.htm</welcome-file>
    <welcome-file>index.jsp</welcome-file>
    <welcome-file>default.html</welcome-file>
  </welcome-file-list>
```

```

<welcome-file>default.htm</welcome-file>
<welcome-file>default.jsp</welcome-file>
</welcome-file-list>
</web-app>

```

Specifying starting weight example:

The following example is for a stand-alone server.

deployment.xml

```

<?xml version="1.0" encoding="UTF-8" ?>
- <appdeployment:Deployment xmi:version="2.0" xmlns:xmi="http://www.omg.org/XMI"
  xmlns:appdeployment="http://www.ibm.com/websphere/appserver/schemas/5.0/appdeployment.xmi"
  xmi:id="Deployment_1137951186883">
- <deployedObject xmi:type="appdeployment:ApplicationDeployment" xmi:id="ApplicationDeployment_1137951186883"
  deploymentId="0" startingWeight="1" binariesURL="${APP_INSTALL_ROOT}/OrangeNode08Cell/SipContainerTestSuite.ear"
  useMetadataFromBinaries="false" enableDistribution="true" createMBeansForResources="true" reloadEnabled="false"
  appContextIDForSecurity="href:OrangeNode08Cell/SipContainerTestSuite"
  filePermission=".*\,dl=755#.*\,so=755#.*\,a=755#.*\,sl=755" allowDispatchRemoteInclude="false"
  allowServiceRemoteInclude="false">
  <targetMappings xmi:id="DeploymentTargetMapping_1137951186883" enable="true" target="ServerTarget_1137951186883" />
  <classloader xmi:id="ClassLoader_1137951186883" mode="PARENT_FIRST" />
- <modules xmi:type="appdeployment:WebModuleDeployment" xmi:id="WebModuleDeployment_1137951186883"
  deploymentId="1" startingWeight="10000" uri="sipunit.war">
  <targetMappings xmi:id="DeploymentTargetMapping_1137951186884" target="ServerTarget_1137951186883" />
  <classloader xmi:id="ClassLoader_1137951186884" /> </modules>
  <properties xmi:id="Property_1137951186883" name="validateinstall" value="warn" /> </deployedObject>
  <deploymentTargets xmi:type="appdeployment:ServerTarget" xmi:id="ServerTarget_1137951186883"
  name="server1" nodeName="OrangeNode10" /> </appdeployment:Deployment>

```

SIP servlets

This topic describes SIP servlets.

The SIP Servlet 1.0 specification (JSR 116) is standardized through Java Specification Request (JSR) 116. The idea behind the specification is to provide a Java application programming interface (API) similar to HTTP servlets, which provides an easy-to-use SIP programming model. Like the popular HTTP servlet programming model, some flexibility is limited to optimize ease-of-use and time-to-value.

However, the SIP Servlet API is different in many ways from HTTP servlets because the protocol is so different. While SIP is a request-response protocol, there is not necessarily only one response to every one request. This complexity and a need for a high performing solution meant that it was easier to make the SIP servlets natively asynchronous. Also, unlike HTTP servlets, the programming model for SIP servlets sought to make client requests easy to create alongside the other logic being written because many applications act as a client or proxy to other servers or proxies.

SipServlet requests

Like HTTP servlets, each SIP servlet extends a base `javax.servlet.sip.SipServlet` class. All messages come in through the service method, which you can extend. However, because there is not a one-to-one mapping of requests to responses in SIP, the suggested practice is to extend the `doRequest` or `doResponse` methods instead. When extending the `doRequest` or `doResponse` methods, it is important to call the extended method for the processing to complete.

Each request method, which the specification must support, has a `doxxx` method just like HTTP. In HTTP, methods such as `doGet` and `doPost` exist for GET and POST requests. In SIP, `doInvite`, `doAck`, `doOptions`, `doBye`, `doCancel`, `doRegister`, `doSubscribe`, `doNotify`, `doMessage`, `doInfo`, and `doPrack` methods exist for each SIP request method.

Unlike an HTTP servlet, SIP servlets have methods for each of the response types that are supported. So, SIP servlets include the `doProvisionalResponse`, `doSuccessResponse`, `doRedirectResponse`, and `doErrorResponse` responses. Specifically, the provisional responses (1xx responses) are used to indicate status, the success responses (2xx responses) are used to indicate a successful completion of the transaction, the redirect responses (3xx responses) are used to redirect the client to a moved resource or entity, and the error responses (4xx, 5xx, and 6xx responses) are used to indicate a failure or a specific

error condition. These types of response messages are similar to HTTP, but because the SIP Servlet programming model includes a client programming model, it is necessary to have responses handled programmatically as well.

Clarifications of JSR 116

JSR 289 has made some clarifications to JSR 116, as follows:

- JSR 289 Section 4.1.3: Contact Header Field
- JSR 289 Section 5.2: Implicit Transaction State
- JSR 289 Section 5.8: Accessibility of SIP Servlet Messages

SIP SipServletRequest and SipServletResponse classes

The SipServletRequest and SipServletResponse classes are similar to the HttpServletRequest and HttpServletResponse classes.

SipServletRequest and SipServletResponse classes

Each class gives you the capability to access the headers in the SIP message and manipulate them. Because of the asynchronous nature of the requests and responses, this class is also the place to create new responses for the requests. When you extend the doInvite method, only the SipServletRequest class is passed to the method. To send a response to the client, you must call the createResponse method on the Request object to create a response. For example:

```
protected void doInvite(SipServletRequest req) throws
    javax.servlet.ServletException, java.io.IOException {

    //send back a provisional Trying response
    SipServletResponse resp = req.createResponse(100);
    resp.send();
}
```

Because of their asynchronous nature, SIP servlets can seem complicated. However, something as simple as the previous code sample sends a response to a client.

Here is a more complex example of a SIP servlet. With the following method included in a SIP servlet, the servlet blocks all of the calls that do not come from the example.com domain.

```
protected void doInvite(SipServletRequest req) throws
    javax.servlet.ServletException, java.io.IOException {

    //check to make sure that the URI is a SIP URI
    if (req.getFrom().getURI().isSipURI()){
        SipURI uri = (SipURI)req.getFrom().getURI();
        if (!uri.getHost().equals("example.com")) {
            //send forbidden response for calls outside domain
            req.createResponse(SipServletResponse.SC_FORBIDDEN).send();
            return;
        }
    }
    //proxy all other requests on to their original destination
    req.getProxy().proxyTo(req.getRequestURI());
}
```

SIP SipSession and SipApplicationSession classes

Possibly the most complex portions of the SIP Servlet 1.0 specification are the SipSession and SipApplicationSession classes.

SIP SipSession and SipApplicationSession classes

Both of these classes have some useful purposes and can act as the primary place to store data in applications that are designed for distributed or highly available environments.

The SipSession class is the best representative of a specific point-to-point communication between two entities and is the closest to the HttpSession object. Because historically no proxying or forking existed for the HTTP request in HTTP servlets, the need for something higher than a single point-to-point session did not exist. However, even HTTP users can see the growing need for this type of function since portlets began essentially forking HTTP requests. The SIP users expect the proxying and forking activities that require multiple layers of SIP session management. The SipSession class is the lowest point-to-point layer.

The SipApplicationSession class represents the higher layer of SIP session management. One SipApplicationSession class can own one or more SipSession objects. However, each SipSession class can be related to one SipSession object only. The SipApplicationSession class also supports the attachment of any number of other protocol sessions. Currently, only HTTP sessions are supported by any implementations. The SipApplicationSession class has a getSessions method, which takes the requested protocol type as an argument.

You might find it useful for many applications to combine HTTP and SIP. For example, you might use this approach to tie together HTTP and SIP sessions to monitor a phone call or to start a phone call through a rich HTTP graphical user interface.

Example: SIP servlet simple proxy

This is a servlet example of a simple proxy.

Simple proxy

```
import java.io.IOException;

import javax.servlet.ServletException;
import javax.servlet.http.HttpServlet;
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;
import javax.sip.SipFactory;
import javax.sip.SipServlet;
import javax.sip.SipServletRequest;
import javax.sip.SipServletResponse;
import javax.sip.SipSession;
import javax.sip.SipURI;
import javax.sip.URI;

public class SimpleProxy extends SipServlet implements Servlet {

    final static private String SHUTDOWN_KEY = new String("shutdown");
    final static private String STATE_KEY = new String("state");
    final static private int INVITE_RECEIVED = 1;

    /* (non-Java-doc)
     * @see javax.sip.SipServlet#SipServlet()
     */
    public SimpleProxy() {
        super();
    }

    /* (non-Javadoc)
     * @see javax.sip.SipServlet#doInvite(javax.sip.SipServletRequest)
     */
    protected void doInvite(SipServletRequest request) throws ServletException,
        IOException {

        //log("SimpleProxy: doInvite: TOP");

        try {
            if (request.isInitial() == true)
            {
                // This should cause the sip session to be created. This sample only uses the session on receiving
                // a BYE but the Tivoli performance viewer can be used to track the creation of calls by viewing the
```

```

// active session count.
Integer state = new Integer(INVITE_RECEIVED);
SipSession session = request.getSession();
session.setAttribute(STATE_KEY, state);
    log("SimpleProxy: doInvite: setting attribute");

Proxy proxy = request.getProxy();

SipFactory sipFactory = (SipFactory) getServletContext().getAttribute(SIP_FACTORY);
    if (sipFactory == null) {
        throw new ServletException("No SipFactory in context");
    }

    String callingNumber = request.getTo().toString();
    if (callingNumber != null)
    {
        String destStr = format_lookup(callingNumber);
        URI dest = sipFactory.createURI(destStr);

        //log("SimpleProxy: doInvite: Proxying to dest URI = " + dest.toString());

        if (((SipURI)request.getRequestURI()).getTransportParam() != null)
            ((SipURI)dest).setTransportParam(((SipURI)request.getRequestURI()).getTransportParam());

        proxy.setRecordRoute(true);
        proxy.proxyTo(dest);
    }
else
{
    //log("SimpleProxy: doInvite: Request is invalid. Did not contain a To: field.");
    SipServletResponse sipresponse = request.createResponse(400);
    sipresponse.send();
}
else
{
    //log("SimpleProxy: doInvite: target refresh, let container handle invite");
    super.doInvite(request);
}
}
catch (Exception e){
    e.printStackTrace();
}
}

/* (non-Javadoc)
 * @see javax.servlet.sip.SipServlet#doResponse(javax.servlet.sip.SipServletResponse)
 */
protected void doResponse(SipServletResponse response) throws ServletException,
    IOException {
    super.doResponse(response);

    // Example of using the session object to store session state.
    SipSession session = response.getSession();
    if (session.getAttribute(SHUTDOWN_KEY) != null)
    {
        //log("SimpleProxy: doResponse: invalidating session");
        session.invalidate();
    }
}

/* (non-Javadoc)
 * @see javax.servlet.sip.SipServlet#doBye(javax.servlet.sip.SipServletRequest)
 */
protected void doBye(SipServletRequest request) throws ServletException,
    IOException {

```

```

SipSession session = request.getSession();
session.setAttribute(SHUTDOWN_KEY, new Boolean(true));

    //log("SimpleProxy: doBye: invalidate session when responses is received.");
super.doBye(request);
}

protected String format_lookup(String toFormat){
int start_index = toFormat.indexOf('<') + 1;
int end_index = toFormat.indexOf('>');

if(start_index == 0){
    //don't worry about it
}
if(end_index == -1){
    end_index = toFormat.length();
}

return toFormat.substring(start_index, end_index);
}
}

```

Example: SIP servlet SendOnServlet class

The SendOnServlet class is a simple SIP servlet that would perform the basic function of being called on each INVITE and sending the request on from there.

SendOnServlet class

Function could easily be inserted to log this invite request or reject the INVITE based on some specific criteria.

```

package com.example;
import java.io.IOException;
import javax.servlet.sip.*;
import java.servlet.ServletException;
public class SendOnServlet extends SipServlet {
    public void doInvite(SipServletRequest req)
        throws ServletException, java.io.IOException {
        //send on the request
        req.getProxy().proxyTo(req.getRequestURI);
    }
}

```

The doInvite method could be altered to do something such as reject the invite for some specific criteria simply. In the example doInvite method below, all requests from domains outside of example.com will be rejected with a Forbidden response.

```

    public void doInvite(SipServletRequest req)
throws ServletException, java.io.IOException {
if (req.getFrom().getURI().isSipURI()){
    SipURI uri = (SipURI)req.getFrom.getURI();
    if (!uri.getHost().equals("example.com")) {
        //send forbidden response for calls outside domain
req.createResponse(SipServletResponse.SC_FORBIDDEN, "Calls outside example.com not accepted").send();
return;
    }
}
//proxy all other requests on to their original destination
req.getProxy().proxyTo(req.getRequestURI());
}

```

SendOnServlet deployment descriptor:

```

<sip-app>
    <display-name>Send-on Servlet</display-name>
    <servlet>

```

```

        <servlet-name>SendOnServlet</servlet-name>
        <servlet-class>com.example.SendOnServlet</servlet-class>
    </servlet>

    <servlet-mapping>
        <servlet-name>SendOnServlet</servlet-name>
        <pattern>
            <equal>
                <var>request.method</var>
                <value>INVITE</value>
            </equal>
        </pattern>
    </servlet-mapping>
</sip-app>

```

Example: SIP servlet Proxy servlet class

Proxy servlet class

After the initial INVITE, this application will be called on every subsequent SIP message. For each Request and Response, this class will simply print out the action and who it is to or from.

```

package com.example;
import java.io.IOException;
import javax.servlet.sip.*;
import java.servlet.ServletException;
public class ProxyServlet extends SipServlet {
    public void doInvite(SipServletRequest req)
        throws ServletException, java.io.IOException {
        //get the Proxy
        Proxy p=req.getProxy();
        //turn on supervised mode so that all events come through us
        //The default on this is true but it is set to emphasize the function.
        p.setSupervised(true);
        //set record route so we see the ACK, BYE, and OK
        p.setRecordRoute(true);
        //proxy on the request
        p.proxyTo(req.getRequestURI());
    }
    public void doRequest(SipServletRequest req)
        throws ServletException, java.io.IOException {
        System.out.println(req.getMethod()+" Request from "+req.getFrom().getDisplayName());
        super.doRequest(req);
    }
    public void doResponse(SipServletResponse resp)
        throws ServletException, java.io.IOException {
        System.out.println(resp.getReasonPhrase()+" Response from "+resp.getTo().getDisplayName());
        super.doResponse(resp);
    }
}

```

Proxy deployment descriptor

```

<sip-app>
    <display-name>ProxyServlet</display-name>
    <servlet>
        <servlet-name>ProxyServlet</servlet-name>
        <servlet-class>com.example.ProxyServlet</servlet-class>
    </servlet>

    <servlet-mapping>
        <servlet-name>ProxyServlet</servlet-name>
        <pattern>
            <equal>
                <var>request.method</var>
                <value>INVITE</value>
            </equal>
        </pattern>
    </servlet-mapping>
</sip-app>

```

```
        </equal>
    </pattern>
</servlet-mapping>
</sip-app>
```

JSR 289 overview

Version 8.0 includes support for SIP Servlet Specification 1.1, also referred to as Java Specification Request (JSR) 289.

Note: Version 8.0 includes support for SIP Servlet Specification 1.1, also referred to as Java Specification Request (JSR) 289.

The SIP Servlet Specification provides the Java API standards for Session Initiation Protocol (SIP). JSR 289 is an update to the existing SIP Servlet specification that addresses new requirements determined by industry users.

SIP is a signalling protocol used for creating, modifying, and terminating IP communication sessions such as telephony and presence applications. SIP is not limited to voice communication and can mediate any kind of communication session, such as multimedia.

The following is a brief description of new features available in the JSR 289 specification.

- Application router for application selection
Application routing enables developers to build complex services out of smaller applications. On initial requests the container calls the application router to determine which application to invoke based on the type of request. The application router is the central hub for selecting application order. See the topic on configuring a SIP application router for more information.
- Annotation-based programming
Annotations provide a fast way to develop applications by embedding metadata directly in applications. For example, you can use the `@SipServlet` annotation to indicate that a class is a SIP servlet. The `@SipApplication` is a package level annotation. All servlets in the package belong to the same application unless the servlet uses `@SipServlet(applicationName)`. For more information on annotations, see section 18 of the JSR 289.
- Converged applications
JSR 289 provides a new, standardized mechanism for building converged applications. A converged application contains SIP servlet components and other Java EE components, like HTTP servlets and enterprise beans. The specification includes two new classes to support convergence.
 - `ConvergedHttpSession` is an extension to `HttpSession` for converged applications.
 - `SipSessionUtil` handles session management for converged applications.For more information on converged applications, see section 13 of the JSR 289.
- Back-to-back user agent (B2BUA) APIs
JSR 289 simplifies the B2BUA pattern in applications with the use of the B2BUA helper class. The B2BUA is a frequently used application pattern. The B2BUA acts as an endpoint for two or more dialogs and forwards requests and responses between those dialogs. The B2BUA helper has the ability to create a copy of an incoming request. It also automatically maintains links between sessions on both sides of the B2BUA. For more information on B2BUAs, see section 12 of the JSR 289.

SIP application router:

The SIP application router is used by the SIP container to select the order in which applications are run within the container.

The SIP container can invoke multiple applications in order to deploy a complete service or function. This modular and compositional approach makes it easier for application developers to develop new applications. The modular applications can be more easily combined and managed, while individual application implementations remain independent.

The application router is responsible for selecting the correct applications in the correct order to service an incoming message. An application router is required for a container to function, but it is a separate logical entity from the container. The application router is based on the JSR 289 specification. See the specification for more details about the application router function.

The default application router (DAR) can be configured with a standard configuration file, which is supplied to the container through a SIP container custom property, as defined in JSR 289. The DAR configuration file can also be uploaded in the administrative console for each target of the DAR.

Application routing, also referred to as application composition, can be handled in a number of ways:

- Specify the order in which the applications should run using the administrative console.
- Upload a custom application router implementation class either by specifying the path of the Java archive (JAR) file containing the application router implementation and provider through the console or adding it to the class path. A specific provider can be defined with a SIP container custom property.
- Configure the DAR by uploading its properties file and providing its location through a system property.
- Use an interactive wizard to generate a DAR configuration file.

Restriction: WebSphere Application Server has a default way of sorting the order of SIP applications invocation using the Startup behavior settings. The sorting order is based on the application weight. This weighting policy only applies if you do not specify a DAR property file and no custom application router has been associated with the server or cluster.

Note: If CEA features are used, the CEA system application requires special consideration when enabled on the same server or cluster as a custom application router. To deploy an application router and still maintain the capabilities of the CEA system application, use one of the following two options:

- Only enable CEA on an isolated server or cluster that includes no custom application router.
- Make sure the custom application router routes all CEA specific messages to the CEA system application. To do this, the developer of the application router must check the mappings that are defined in the sip.xml file associated with the CEA system application. The sip.xml file associated with the CEA system application can be found in the directory path at *app_server_root/systemApps*.

The following information explains how to configure a custom application router to route to the commsvc system application. The examples show a custom application router configuration with and without the commsvc application.

First, here is an example configuration without commsvc:

```
INVITE: ("TestB2bua", "DAR:To", "NEUTRAL", "", "NO_ROUTE", "0")
```

The first element after the INVITE is the display name of the test application, and this one-line application router routes b2bua calls to the application successfully. With the preceding application router configured on the SIP container, however, CEA Web collaboration attempts fail.

To enable routing to the CEA system application, just clone the routing element and change the application name in the second element instance:

```
INVITE: ("TestB2bua", "DAR:To", "NEUTRAL", "", "NO_ROUTE", "0"), ("commsvc", "DAR:To", "NEUTRAL", "", "NO_ROUTE", "0")
```

This action ensures that CEA messages are routed correctly.

Tuning considerations using the JSR 289 Application Router with multiple applications:

This topic describes performance adjustments and considerations using the JSR 289 Application Router with multiple applications.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using SystemOut.log , SystemErr.log, trace.log, and activity.log files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

When you deploy more than one application, you might see the following errors in the log files when heavy SIP protocol traffic exists for a single application server or cluster of servers:

- Unexpected and excessive SIP application 503 Server Unavailable error messages
- Proxy and Server overload errors

Note: These error messages do not occur when you deploy one application. The proxy server and Session Initiation Protocol (SIP) containers are not synchronized when they are tracking the amount of messages that are flowing through the system. Using the application router, multiple messages might be routed between applications. These messages cause container message counters to increment even though the messages do not flow through the proxy server.

You can diagnose this problem when you have the following conditions:

- Heavy SIP protocol traffic exists.
- Multiple applications are deployed on a single node or cluster.

Check the proxy server, the application server SystemOut.log log files, or both for an unexpected overload condition that is detected at the proxy server, the application server, or both. Also, look for 503 Server unavailable messages that are logged from the SIP application.

Resolving the problem

Messages are shared between applications at the SIP container before they are sent to the proxy server. To avoid these error messages and a decrease in SIP performance, tune the SIP containers to consider the additional SIP messages that are generated when using the application router with multiple applications. Complete the following steps in the administrative console to tune the SIP containers:

1. Expand **Servers > Server Types** and click **WebSphere application servers > server_name**
2. Under **Container Settings**, expand **SIP Container Settings** and click **SIP container**.
3. Increase the **Maximum messages per averaging period** value to compensate for the anticipated increase in messages that are generated by the SIP application router.
4. Increase the **Maximum application sessions** value to compensate for the increased **Maximum messages per averaging period** value.

The proxy server cannot detect the amount of messages that are generated at the server. However, modifications to the following settings might increase the messaging capacity at the containers for the number of applications that are deployed per container.

Table 117. DAR and CAR SIP container tuning values.

This table lists the DAR and CAR SIP container tuning values for the number of applications that are deployed per container.

SIP Container	Single Deployed SIP Application	Three Deployed SIP Applications
Maximum messages per averaging period	value = 26640	value = 79920
Maximum application sessions	value = 36000	value = 96000

Note: The values for the **Maximum messages per averaging period** and **Maximum application sessions** fields depend on the processing power, memory, and the deployed application. Use the values for these fields as listed in the SIP container settings topic and adjust them to meet the needs of your environment.

Developing applications that use the Asynchronous Invocation API

You can use the Asynchronous Invocation API to transfer events that require processing in the context of a Session Initiation Protocol (SIP) application session to any server in a cluster based on the related application session ID. The Asynchronous Invocation API transfers the event task to the correct server.

Before you begin

Read the API documentation for information on the following asynchronous work classes:

- `com.ibm.websphere.sip.AsynchronousWork`
- `com.ibm.websphere.sip.AsynchronousWorkListener`

For more information about the API classes, see the Reference section in the information center and click [APIs - Application Programming Interfaces](#) to view a list of the product API specifications.

About this task

When running code outside of a SIP thread, application developers can use the Asynchronous Invocation API to create an object, and configure the server to run that object either on a different thread in the same container, or on a different server, if that is where the session exists.

The following example shows the class structure for the `AsynchronousWork` class, which is the abstract base class that is extended when using the API.

```
public abstract class AsynchronousWork implements Serializable
{
    private String sessionId;
    public AsynchronousWork(String sessionId)
    {
        this.sessionId = sessionId;
        ....
    }
    public void dispatch (AsynchronousWorkListener listener)
    {
        ....
    }
    public abstract Serializable doAsyncTask();
}
```

Procedure

1. Extend the abstract class `AsynchronousWork` with the SIP related code. The extended implementation of the `doAsyncTask()` method is invoked on the target server that contains the `SipApplicationSession`, and whose ID was set in the constructor that implements the `AsynchronousWork` class. The implementation class must pass the session ID to the base class by calling `super` in the constructor.

```
public class MyClass extends AsynchronousWork
{
    String _sessionId;

    public MyClass(String sessionId) {
        super(sessionId);
        _sessionId = sessionId;
    }

    // This code is invoked on the target machine or thread
    public Serializable doAsyncTask() {
```

```

// Application code goes here; for instance:
appSession = sessionUtils.getApplicationSession(_sessionId);
appSession.createRequest().....

Serializable myResponse = new MyResponse();
myResponse.setStatus(200);
return (myResponse);
}
}

```

2. To receive information about the task completion, implement the `AsynchronousWorkListener` class, as in the following example. The code in these methods are invoked on the source server.

```

public class MyListener implements AsynchronousWorkListener
{
public void workCompleted(Serializable myResponse)
{
....
}
public void workFailed(int reasonCode, String reason)
{
}
}

```

3. To invoke the asynchronous call; for example, when you receive the proprietary message, use this sample code as an example.

```

public void onMyMessage()
{
// Obtain the session ID from the message or
// somewhere else
String sessionId = obtainIdFromMessage();

// Create the runnable
MyClass myClass = new MyClass(sessionId);

// Create the listener
MyListener myListener = new MyListener();

// Dispatch it
myClass.dispatch(myListener);
}

```

Results

The SIP container ensures the task is invoked in the correct server and on the correct thread, so that the application can avoid synchronization on the session level.

Asynchronous Invocation API

Use the Asynchronous Invocation API to transfer events that require processing in a Session Initiation Protocol (SIP) application session to any server in a cluster based on an application session ID.

The Asynchronous Invocation API, also referred to as the asynchronous work dispatcher, can transfer events that require processing in the context of a SIP application session to any server in a cluster, using the related application session ID. These transfers are usually triggered by events that cause a state change to SIP sessions that reside on another server. The asynchronous work dispatcher transfers the event task to the correct server to be run.

In Websphere Application Server, all related SIP messages are delivered to the same server in the cluster, and sessions always reside in the same SIP container. To prevent synchronicity issues and locking, tasks in the same application session cannot be processed simultaneously (that is, on different threads or processes), which limits handling of certain types of events.

For more in-depth information about SIP sessions and SIP application sessions and their relationship, see Section 6 of Java Specification Request (JSR) 289.

The following two scenarios are resolved by implementing the Asynchronous Invocation API.

1. Two requests related to the same SIP application session are simultaneously run on two different threads. For example, a Java EE (J2EE) applications working with a message-driven bean (MDB) can retrieve an event to send a SIP message on a certain SIP application session. At the same time, the SIP container receives an incoming SIP message on another session that is connected to the same application session and handles that on a different thread. It would be necessary to synchronize the session access to avoid race conditions and to ensure that all session attributes are synchronized. To employ the locking mechanism in this case would not be effective, because the SIP application session might contain multiple SIP sessions.
2. A server that does not own a certain SIP application session receives a request, through non-SIP protocol, to send a message in the context of that session. For example, a Web service that is initiating SIP dialogs can reside in a server different from the server that owns the SIP application session it must use.

The Asynchronous Invocation API ensures that the specific application code is run on the correct server and correct thread according to the SIP application session ID.

The Asynchronous Invocation API provides the following benefits:

1. No more than two servers are involved in the asynchronous invocation process: one is the server that retrieves the work task, and the other is the target server that handles the SIP application session for that task and to which the task will be transferred.
2. The asynchronous invocation allows working in a thread-safe manner. This approach ensures that only one thread processes the messages related to the SIP application session. Thus, there is no need to synchronize access to the session.
3. The asynchronous invocation provides a scalable solution. There is no performance impact when more servers are added to the cluster.
4. Cross-server invocation is used only when required, which results in better performance.

Deploying SIP applications

Use the administrative console to customize your Session Initiation Protocol (SIP) application installation

About this task

When you deploy a Session Initiation Protocol (SIP) application, you can perform various tasks such as installing, starting, stopping, upgrading, and uninstalling the application.

SIP applications are installed as Java Platform, Enterprise Edition (Java EE) applications. You can deploy a SIP application from a graphical interface or from a command line.

Deploying SIP applications through the console

You can deploy a Session Initiation Protocol (SIP) application through the administrative console.

Before you begin

SIP applications are deployed as Java 2 Platform Enterprise Edition (J2EE) applications. In order to process requests, a virtual host must be defined when deploying the SIP application. If there is no virtual host defined for the configured SIP container listen port, the installed application will be inaccessible.

Procedure

1. Open the administrative console.

In a browser, go to URL `http://hostname:9090/admin`, where *hostname* is the name of the host computer. Enter the appropriate login information, and click **OK**.

2. In the left frame click **Applications > Install New Application**.
3. Browse and select a SAR file. Specify the context root, beginning with a slash (/), in the **Context Root** field. For example, if your application is named ThisApplication, type /ThisApplication.
4. Click **Next** (under the **Context Root** field not beside the WebSphere Status title). If the SAR file has been assembled correctly, the screen will still have the title “Preparing for the application installation”, but the content will change. If an error message appears, check the contents of the SAR file; in particular, verify the `web.xml` file contents, and try to reload the SAR file.
5. Click **Next**. If you see a screen indicating “Application Security Warnings”, click **Continue**.
6. The **Install New Application** screen should appear with “Step 1: Select application options” highlighted. Select the options you need and click **Next**.
7. “Step 2: Map modules to servers” should appear highlighted now. You can choose the cluster or server where you want to install the application's modules.
 - If you are installing the application in a stand-alone system, click **Next**.
 - If you are installing the application in a clustered system, select **WebSphere:cell=cellname,cluster=cluster_name** in the **Clusters and Servers** field, select the check box beside the web module that you want to install, and click **Apply** and **Next**.
8. Now “Step 3: Map virtual hosts for web modules” should appear highlighted. To the right of the application name there should be a drop-down labeled **Virtual Host**.
 - If you are installing the application in a stand-alone system, set the value of the drop-down to **default_host**, and click **Next**.
 - If you are installing the application in a clustered system, set the value of the drop-down to the name of the virtual host that was chosen during setup, and click **Next**.

Remember: You must define a virtual host for your configured SIP container listen port or else you will not be able to access the application.

9. You should now see “Step 4: Summary” highlighted. In the right panel you will see a **Summary of installation options** table that details your selected options and their values. If you need to change an option, click **Previous** to return to the section where you can make your change. Click **Finish** to install the application with your settings. The screen should display, *Application appname_sar installed successfully*, where *appname* is the name of the application.
10. Click the **Save to Master Configuration** link. A Save to Master Configuration window appears.
11. In the Save to Master Configuration window, click **Save**. The application has now been saved in the current configuration.
12. To confirm that the installation succeeded, in the left frame click **Applications > Enterprise Applications**. The newly installed application should appear in the list of installed applications as *appname_sar*.
13. To start the application so that it can service SIP requests, check the box beside *appname_sar*, and click **Start**. You might also want to look at the logs for a successful startup message.

Results

The application can service SIP requests now.

Deploying SIP applications through scripting

You can deploy a Session Initiation Protocol (SIP) application not only from the administrative console but also from a command line.

About this task

Note: To deploy a SIP application, the application must exist with an enterprise archive (EAR) file, a Session Initiation Protocol (SIP) module (SAR file), or a web application archive (WAR) file.

Use the wsadmin scripting tool to deploy applications from a command line.

Procedure

- Launch a scripting client.
For more information, see AdminApp object for scripted administration.
- List applications.
For more information, see Listing applications using the wsadmin scripting tool.
- Install stand-alone archive files.
For more information about installation, see Installing enterprise applications using wsadmin scripting and Installation options for the AdminApp object.
- Edit application configurations.
For more information, see Editing application configurations using the wsadmin scripting tool.
- Uninstall applications.
For more information, see Uninstalling enterprise applications using the wsadmin scripting tool.

Chapter 29. Developing Spring applications

This page provides a starting point for finding information about how to develop Spring applications that can run successfully in a WebSphere Application Server environment.

The Spring Framework is an open source project that provides a framework for simple Java objects that enables them to use the Java EE container through wrapper classes and XML configuration.

Configuring access to a Spring application data source

You can use WebSphere Application Server to manage access to a data source for a Spring application.

About this task

For a Spring application to access a data source, such as a Java Database Connectivity (JDBC) data source, the application must use a resource provider that is managed by the WebSphere Application Server. For more information about Spring applications and the Spring Framework see the following topics:

- Spring Framework
- Data access and the Spring Framework

Procedure

1. During development, configure the WAR module with a resource reference. For example:

```
<resource-ref>
  <res-ref-name>jdbc/springdb</res-ref-name>
  <res-type>javax.sql.DataSource</res-type>
  <res-auth>Container</res-auth>
  <res-sharing-scope>Shareable</res-sharing-scope>
</resource-ref>
```

2. For Enterprise JavaBeans (EJB) Java archive (JAR) files, declare the same resource reference in each EJB that needs to access the data source. Use one of the following steps:

- Declare a data source proxy bean. In the Spring application configuration, declare a proxy bean that references a resource provider that the application server manages. Set the value of the `jndiName` property to `java:comp/env/` followed by the value of `res-ref-name` property that you declared in the resource reference. For example:

```
<bean id="wasDataSource" class="org.springframework.jndi.JndiObjectFactoryBean">
  <property name="jndiName" value="java:comp/env/jdbc/springdb"/>
  <property name="lookupOnStartup" value="false"/>
  <property name="cache" value="true"/>
  <property name="proxyInterface" value="javax.sql.DataSource"/>
</bean>
```

- Alternatively, for Spring Framework Version 2.5 or later, use the `<j2ee:jndi-lookup/>` approach. Set the value of the `jndi-name` property to the value of the `res-ref-name` property that you declared in the resource reference, and the value of the `resource-ref` property to `true`. For example:

```
<jee:jndi-lookup id=" wasDataSource "
  jndi-name="jdbc/springdb"
  cache="true"
  resource-ref="true"
  lookup-on-startup="false"
  proxy-interface="javax.sql.DataSource"/>
```

The Spring application can then use the data source proxy bean as appropriate.

3. When the application is deployed to an application server, configure a resource provider and resource data source that the Spring application resource reference can use.

Results

The resource reference that is declared in the deployment descriptor of the module will be bound to the configured data source of the application server during deployment.

Chapter 30. Developing Transactions

This page provides a starting point for finding information about Java Transaction API (JTA) support. Applications running on the server can use transactions to coordinate multiple updates to resources as one unit of work, such that all or none of the updates are made permanent.

The product provides advanced transactional capabilities to help application developers avoid custom coding. It provides support for the many challenges related to integrating existing software assets with a Java EE environment. More introduction...

Developing components to use transactions

These topics provide information about developing WebSphere application components to use transactions

About this task

The way that applications use transactions depends on the type of application component, as follows:

- A session bean can either use container-managed transactions (where the bean delegates management of transactions to the container) or bean-managed transactions (component-managed transactions where the bean manages transactions itself).
- Entity beans use container-managed transactions.
- Web components (servlets) and application client components use component-managed transactions.

Use the following tasks to develop WebSphere application components that use transactions:

Procedure

- Configure transactional deployment attributes. This task determines whether EJB components use container- or bean-managed transactions by setting an appropriate value on the Transaction type deployment attribute. You can also configure other transactional deployment descriptor attributes.
- Use component-managed transactions. If you want a session bean, web component, or application client component to manage its own transactions, you must write the code that explicitly demarcates the boundaries of a transaction. There are some limitations to the transaction support available to application client components, as described in the topic about client support for transactions.

Configuring transactional deployment attributes

You can configure the transactional deployment descriptor attributes associated with an EJB or web module, to enable an enterprise application to use transactions.

Before you begin

You must have an enterprise archive (EAR) file for an application component that can be deployed in the application server.

About this task

You can configure the deployment attributes of an application by using an assembly tool.

You can use Rational Application Developer, or an equivalent tool, to configure the deployment attributes of an application.

To use Rational Application Developer to set transactional attributes in the deployment descriptor for an application component (enterprise bean or servlet), complete the following steps.

Procedure

1. Start the assembly tool. For more information, refer to the Rational Application Developer information.
2. Create or edit the application EAR file. For example, to change attributes of an existing application, use the Import wizard to import the EAR file into the assembly tool. To start the Import wizard:
 - a. Click **File > Import > EAR file**.
 - b. Click **Next**, then select the EAR file.
 - c. Click **Finish**.
3. In the Project Explorer view of the Java EE perspective, right-click the component instance, then click **Open With > Deployment Descriptor Editor**. To locate the component instance, use the appropriate step:
 - For a session bean, expand **EJB Modules > ejb_module_instance > Deployment Descriptor > Session Beans**, then select the bean instance.
 - For a servlet, expand **Web Modules > web_application > Deployment Descriptor > web component**, then select the servlet instance.

A property dialog notebook for the deployment descriptor of the component is displayed in the property pane.

4. Optional: For session beans only, set the “Transaction type” attribute, which defines the transactional manner in which the container invokes a method. You can set this attribute to Container or Bean, as follows:
 - To use container-managed transactions, set the attribute to Container.
 - To use bean-managed transactions, set the attribute to Bean.
5. In the deployment descriptor notebook, select the **Bean** tab. Optionally, in the WebSphere Extensions section, configure the Local Transaction attributes. To enable management of local transaction containments, configure the following component extensions attributes. These attributes configure, for the component, the behavior of the local transaction containment (LTC) environment that the container establishes whenever a global transaction is not present.

Boundary

This setting specifies the containment boundary at which all contained resource manager local transactions (RMLTs) must be completed. Possible values are BeanMethod or ActivitySession.

- BeanMethod: This is the default value. If you select this option, RMLTs must be resolved within the same bean method in which they were started.
- [For EJB components only] ActivitySession: RMLTs must be resolved within the scope of any ActivitySession in which they were started or, if no ActivitySession context is present, within the same bean method in which they were started.

Note: The ActivitySession option is not supported in the web container.

Resolver

This setting specifies the component responsible for initiating and ending RMLTs. Possible values are Application or ContainerAtBoundary.

- Application: This is the default value. The application is responsible for starting RMLTs and for completing them within the local transaction containment (LTC) boundary. Any RMLTs that are not completed by the end of the LTC boundary are cleaned up by the container according to the value of the Unresolved action attribute.
- ContainerAtBoundary: The container is responsible for starting RMLTs and for completing them within the LTC boundary. The container begins an RMLT when a connection is first used within the LTC scope, and completes it automatically at the end of the LTC scope. If Boundary is set to ActivitySession, the RMLTs are enlisted as ActivitySession resources and directed to complete by the ActivitySession. If Boundary is set to BeanMethod, the RMLTs are committed at the end of the method by the container.

Unresolved action

Specifies the direction that the container requests RMLTs to take, if those transactions are unresolved at the end of the LTC boundary scope and the Resolver is set to Application. Possible values are Rollback or Commit.

- Rollback: This is the default value. At end of the LTC boundary scope, the container instructs all unresolved RMLTs to roll back.
- Commit: At the end of the LTC boundary scope, the container instructs all unresolved RMLTs to commit. The container instructs the RMLTs to commit only in the absence of an un-handled exception. If the application method that is running in the local transaction context ends with an exception, any unresolved RMLTs are rolled back by the container. This is the same behavior as for global transactions.

Shareable

Specifies whether the component can share an LTC. A new LTC is started only if a shareable LTC does not already exist. Applications that use shareable LTCs cannot explicitly commit or roll back resource manager connections that are used in a shareable LTC (although they can use connections that have an autoCommit capability).

If an application starts any non-autocommit work in an LTC for which the Resolver attribute is set to Application, and the Shareable attribute is set to true, an exception is thrown at run time. For example, on a JDBC Connection, non-autocommit work is work that the application performs after using the setAutoCommit(false) method to switch off the autocommit option on the connection. Enterprise beans that use bean managed transactions (BMT) cannot be assembled with the Shareable attribute set on the LTC configuration.

You must specify the **Shareable** attribute for all components that share the LTC. The component that creates the shareable LTC determines the other properties of the shared LTC, for example the value of the Resolver attribute.

6. In the WebSphere Extensions section, configure the Global Transaction attributes. These attributes configure, for the component, behavior in the presence of a global transaction.

Component Transaction Timeout

For enterprise beans that use container-managed transactions only, specifies the transaction timeout, in seconds, for any new global transaction that the container starts on behalf of the enterprise bean. For transactions started on behalf of the component, the Component Transaction Timeout setting overrides the default total transaction lifetime timeout that is configured in the transaction service settings for the application server.

The following attributes enable WS-AtomicTransaction and WS-BusinessActivity support for JAX-RPC applications only:

Use Web Services Atomic Transaction

For enterprise beans only, when this attribute is selected, if the application component makes any web service requests, any transaction context is propagated with the web service requests in accordance with the WebSphere WS-AtomicTransaction support described in Web Services Atomic Transaction support in the application server. When this attribute is not selected, web service requests do not carry transaction context.

Send Web Services Atomic Transaction on requests

For web components only, when this attribute is selected, if the application component makes any web service requests, any transaction context is propagated with the web service requests in accordance with the WebSphere WS-AtomicTransaction support described in Web Services Atomic Transaction support in the application server. When this attribute is not selected, web service requests do not carry transaction context.

Execute using Web Services Atomic Transaction on incoming requests

For web components only, when this attribute is selected, Web application components are prepared to run under a received WS-AtomicTransaction context. A web application component can run under a received WS-AtomicTransaction context in a similar way to an enterprise bean deployed with a container transaction type of Supports. When this attribute is not selected, the container of the web application component suspends any received

transaction context, in a similar way to the behavior of an EJB container for an enterprise bean deployed with a container transaction type of NotSupported.

If your application uses JAX-WS, enable support for WS-AtomicTransaction or WS-BusinessActivity by creating a policy set, adding the WS-Transaction policy type to the policy set, and attaching the policy set to the service or client.

If a policy set that is attached to a client includes the WS-Transaction policy type, any active global transaction context is propagated with a Web service request, in a similar way to the deployment descriptors Use Web Services Atomic Transaction and Send Web Services Atomic Transaction on requests, described earlier in this topic. Also, when the WS-Transaction policy type is included, the service runs under any received WS-AtomicTransaction context, in a similar way to the deployment descriptor Execute using Web Services Atomic Transaction on incoming requests, described earlier in this topic.

7. For EJB components only, for container-managed transactions, configure how the container manages the transaction boundaries when delegating a method invocation to the business method of an enterprise bean:
 - a. In the deployment descriptor notebook, select the **Assembly** tab. The Container Transactions section displays a table of the methods for enterprise beans.
 - b. For each method of the enterprise bean, set the container transaction type to an appropriate value. The default value for the container transaction type is Required, meaning that the method invocation occurs in the context of a transaction. This transaction is either the (local or remote) client component transaction or, if the client component does not run in a transaction, a new transaction started by the component container.

If the application uses ActivitySessions, how the container manages transaction boundaries when delegating a method invocation depends on both the container transaction type that you set in this task, and the ActivitySession kind attribute, which is described in “Setting EJB module ActivitySession deployment attributes” on page 4. For more detail about the relationship between these two properties, see ActivitySession and transaction container policies in combination.

8. For web services applications that use a SOAP/JMS binding and participates in WS-AtomicTransactions, set the container transaction type of the message-driven bean named “JMS router MDB” to a value of NotSupported, as described in the previous step. Web service applications that use a SOAP/JMS binding include a router message-driven bean named “JMS router MDB” in the assembled EAR. If a web service uses a SOAP/JMS binding and participates in WS-AtomicTransactions, as described in Web Services Atomic Transaction support in the application server, set the container transaction type of the “JMS router MDB” to a value of NotSupported.
For web services applications that use a SOAP/HTTP binding and participate in WS-AtomicTransactions, you do not have to do this.

9. For client application components only, if required, enable support for transaction demarcation by the client. In the deployment descriptor notebook, select the **Allow JTA demarcation** check box. This option directs the client container to bind the Java Transaction API (JTA) UserTransaction interface into JNDI at java:comp/UserTransaction for the client component. There are constraints on transaction support in the client container, which are described in Client support for transactions.
10. Save your changes to the deployment descriptor.
 - a. Close the deployment descriptor editor.
 - b. When prompted, click **Yes** to save changes to the deployment descriptor.
11. Verify the archive files. For more information about verifying files by using Rational Application Developer, refer to the Rational Application Developer information.
12. From the menu of the project, click **Deploy** to generate EJB deployment code.
13. Optional: Test your completed module on an application server installation. Right-click a module, click **Run on Server**, and follow the instructions in the resulting wizard.

Important: Use the **Run On Server** option for unit testing only. The assembly tool controls the application server installation, and when an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use the **Run On Server** option on production servers.

What to do next

After assembling your application, use a systems management tool, for example the administrative console, to deploy the EAR file onto the application server that is to run the application.

Using component-managed transactions

You can enable a session bean, servlet, or application client component to use component-managed transactions, to manage its own transactions directly instead of letting the container manage the transactions.

About this task

Note: Entity beans cannot manage transactions (so cannot use bean-managed transactions).

To enable a session bean, servlet, or application client component to use component-managed transactions, complete the following steps:

Procedure

1. For session beans, set the **Transaction type** attribute in the component deployment descriptor to Bean, as described in “Configuring transactional deployment attributes” on page 1143.
2. For application client components, enable support for transaction demarcation by setting the **Allow JTA Demarcation** attribute in the component deployment descriptor, as described in “Configuring transactional deployment attributes” on page 1143.
3. Write the component code to actively manage transactions.

For stateful session beans, a transaction started in a given method does not have to be completed (that is, committed or rolled back) before completing that method. The transaction can be completed at a later time, for example on a subsequent call to the same method, or even within a different method. However, it is usually preferable to construct the application so that a transaction is begun and completed within the same method call, because it simplifies application debugging and maintenance.

The following code extract shows the standard code required to obtain an object encapsulating the transaction context, and involves the following steps:

- Create a `javax.transaction.UserTransaction` object by calling a lookup on `java:comp/UserTransaction`.
- Use the `UserTransaction` object to demarcate the boundary of a transaction by using transaction methods such as `begin` and `commit`, as needed. If an application component begins a transaction, it must also complete that transaction by invoking either the `commit` method or the `rollback` method.

Code example: Getting an object that encapsulates a transaction context

```
...
import javax.transaction.*;
import javax.naming.InitialContext;
import javax.naming.NamingException;
...
public float doSomething(long arg1) throws NamingException {
    InitialContext initCtx = new InitialContext();
    UserTransaction userTran = (UserTransaction) initCtx.lookup(
        "java:comp/UserTransaction");
    ...
    //Use userTran object to call transaction methods
    userTran.begin ();
    //Do transactional work
    ...
    userTran.commit ();
}
```

```
} ...  
}  
}
```

Using one-phase and two-phase commit resources in the same transaction

Use these topics to help you coordinate the use of a single one-phase commit capable resource with any number of two-phase commit capable resources in the same global transaction.

About this task

You can coordinate the use of a single one-phase commit capable resource with any number of two-phase commit capable resources in the same global transaction. You can have multiple interactions that involve the one-phase commit resource in the same transaction, but only one such resource can be involved. This coordination is enabled by the *last participant support*.

At transaction commit, the two-phase commit resources are prepared first using the two-phase commit protocol, and if this is successful the one-phase commit-resource is then called to commit. The two-phase commit resources are then committed or rolled back depending on the response of the one-phase commit resource.

For more information about using one-phase and two-phase commit resources within the same transaction, see the following topics:

Procedure

- “Approaches to coordinating access to one-phase commit and two-phase commit capable resources in the same transaction” on page 1150
- “Assembling an application to use one-phase and two-phase commit resources in the same transaction”
- Configuring an application server to log heuristic reporting

Assembling an application to use one-phase and two-phase commit resources in the same transaction

Use this task to assemble an application to use one-phase and two-phase commit resources in the same transaction.

Before you begin

This task description assumes that you have an EAR file for an application component that can be deployed in WebSphere Application Server. For more details about assembling applications, see the topic about assembling applications.

About this task

To enable an application to use one-phase and two-phase commit capable resources in the same transaction, you must configure the deployment attributes of the application to accept the heuristic hazard, that is, the increased risk of an heuristic outcome. You can configure the deployment attributes of an application by using an assembly tool.

You can also configure an application to accept the heuristic hazard after deployment, by using the administrative console and the Last participant support extension settings. Alternatively, you can configure the transaction service for an application server to accept the heuristic hazard.

This topic describes the use of Rational Application Developer to configure the deployment attributes of an application.

To configure an application to indicate that you accept the increased risk of an heuristic outcome, complete the following steps:

Procedure

1. Start the assembly tool. For more information, refer to the Rational Application Developer information.
2. Create or edit the application EAR file.

Note: Ensure that you set the target server as WebSphere Application Server Version 7.0.

For example, to change attributes of an existing application, use the Import wizard to import the EAR file into the assembly tool. To start the Import wizard:

- a. Click **File > Import > EAR file**.
 - b. Click **Next**, then select the EAR file.
 - c. In the Target server field, select WebSphere Application Server v7.0.
 - d. Click **Finish**.
3. In the Project Explorer view of the Java EE perspective, complete the following steps:
 - a. Expand the Enterprise Application instance.
 - b. Right click on the Deployment Descriptor.
 - c. Click **Open With > Deployment Descriptor Editor**.

A property dialog notebook for the component is displayed in the property pane.

4. Complete the following steps to display the Extended Services tab.
 - a. Close the Enterprise Application Deployment Descriptor editor.
 - b. In the toolbar, select **Windows > Preferences**.
 - c. In the left pane, select **Capabilities**.
 - d. In the right pane, expand **Advanced Java EE** and select the **WebSphere PME Development** option.
 - e. Click **Apply**.
 - f. Open the Enterprise Application Deployment Descriptor editor.
5. On the Extended Services tab, in the Last Participant Support section, select the **Last participant support** check box.
6. Save your changes to the deployment descriptor.
 - a. Close the Deployment Descriptor Editor.
 - b. When prompted, click **Yes** to save changes to the deployment descriptor.
7. Verify the archive files. For more information about verifying files using Rational Application Developer, refer to the Rational Application Developer information.
8. From the popup menu of the project, click **Deploy** to generate EJB deployment code.
9. Optional: Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard.

Important: Use **Run On Server** only for unit testing. The assembly tool controls the WebSphere Application Server installation and, when an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use the **Run On Server** option on production servers.

What to do next

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that is to run the application; for example, using the administrative console, as described in the topic about deploying and administering enterprise applications.

Last participant support extension settings:

Use this page to configure settings for last participant support. Last participant support is an extension to the transaction service that enables a single one-phase resource to participate in a two-phase transaction with one or more two-phase resources. Values on this panel are ignored if you select **Use configuration information in binary** on the Application binaries panel.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > application_name**. Under **Detailed Properties**, click **Last participant support extension**.

Accept heuristic hazard:

Specifies whether an application accepts the possibility of a heuristic hazard occurring in a two-phase transaction that contains a one-phase resource.

Default	Cleared
Range	Selected The application accepts the increased risk of an heuristic outcome.
	Cleared The application does not accept the increased risk of an heuristic outcome.

Approaches to coordinating access to one-phase commit and two-phase commit capable resources in the same transaction

Last participant support enables the use of a single one-phase commit capable resource with any number of two-phase commit capable resources in the same global transaction. You can have multiple interactions that involve the one-phase commit resource in the same transaction, but only one such resource can be involved.

At transaction commit, the two-phase commit resources are prepared first using the two-phase commit protocol, and if this is successful, the one-phase commit-resource is then called to commit. The two-phase commit resources are then committed or rolled back, depending on the response of the one-phase commit resource.

Last participant support introduces an increased risk of an heuristic outcome to the transaction. That is, the transaction manager cannot be sure that all resources were completed in the same direction (either committed or rolled back). For this reason, to enable an application to coordinate access to one-phase and two-phase commit capable resources in the same transaction, you configure the application to accept the heuristic hazard, that is, accept the increased risk of an heuristic outcome.

An heuristic outcome occurs if the transaction service (JTS) receives no response from the commit one-phase flow on the one-phase commit resource. In this situation, the transaction service cannot determine whether changes for the one-phase commit resource were committed or rolled back, so cannot drive reliably the correct outcome of the global transaction on the other two-phase commit resources.

You can configure the transaction service for an application server to accept the heuristic hazard, or you can configure applications individually to accept the heuristic hazard. You can configure applications individually either when they are assembled, or after they are deployed.

You can configure the transaction service for an application server to indicate whether or not to log that it is about to commit the one-phase commit resource. This does not reduce the heuristic hazard, but ensures that any failure, and subsequent recovery, of the application server during the one-phase commit phase occurs with knowledge of whether or not the one-phase commit resource was asked to commit:

- If the one-phase commit resource was asked to commit, a heuristic outcome is reported to the activity log.
- If the one-phase commit resource was not asked to commit, then the transaction is rolled back consistently.

Last Participant Support: Resources for learning:

Use the links in this topic to find relevant supplemental information about Last Participant Support. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

- WebSphere technical library, including links to white papers

Chapter 31. Developing web applications

This page provides a starting point for finding information about web applications, which are comprised of one or more related files that you can manage as a unit, including:

- HTML files
- Servlets can support dynamic web page content, provide database access, serve multiple clients at one time, and filter data.
- Java ServerPages (JSP) files enable the separation of the HTML code from the business logic in web pages.

IBM extensions to the JSP specification make it easy for HTML authors to add the power of Java technology to web pages, without being experts in Java programming. More introduction...

Developing web applications

Learn about selecting tools for developing web applications.

Before you begin

Design a web application and the required components.

About this task

There are two basic approaches to selecting tools for developing web applications:

- You can use one of the available integrated development environments (IDEs). IDE tools automatically generate significant parts of the servlet and JavaServer Pages (JSP) code, and Hypertext Markup Language (HTML) files. They also contain integrated tools for packaging and testing the web application components.
- If you decide to develop web components without an IDE, you need at least an ASCII text editor. You can also use tools available in the Java SE Development Kit 6 and in this product to assemble, test, and deploy the Web application components.

The following steps support the second approach, development without an IDE.

Procedure

1. If necessary, migrate any pre-existing code to the required version of the servlet and JSP specification.
2. Write and compile the components of the web application. To access classes that were extended, compile your code using the `-classpath` option on the `javac` compiler. This option allows you to reference the `j2ee.jar` file in the product directory:

- `app_server_root/dev/JavaEE`

For example, to compile a servlet for WebSphere Application Server on i5/OS, specify:

```
javac -J-Djava.version=1.5 -classpath app_server_root/dev/JavaEE/j2ee.jar MyServlet.java
```

3. Optionally disable JavaServer Pages (JSP) runtime compilation, if necessary.

What to do next

Assemble the application components in one or more web modules.

Developing servlets

Developing servlets with WebSphere Application Server extensions

Use this task to provide a summary of the WebSphere Application Server extensions that you can use to develop servlets.

About this task

Several WebSphere Application Server extensions are provided for enhancing your servlets. This task provides a summary of the extensions that you can utilize.

Procedure

1. Review the supported specifications.

Create Java components, referring to the Servlet specifications from Sun Microsystems.

The application server includes its own packages that extend and add to the Java Servlet Application Programming Interface (API). These extensions and additions make it easier to manage session states, create personalized Web pages, generate better servlet error reports, and access databases. Locate the API documentation for the application server APIs in the *app_server_root/web/apidocs* directory for the default installation. All of the public Application Server APIs are located in the `com.ibm.websphere` packages, however, `com.ibm.websphere.servlet` package is specific to the product servlet APIs.

2. Use your favorite integrated development environment (IDE), or a text editor, to develop or migrate code artifacts that meet the specifications.
3. Test the code artifacts.

What to do next

Assemble your code artifacts into a web module using assembly tools as a prerequisite to deploying the code to the application server.

Configuring page list servlet client configurations:

You can define PageListServlet configuration information in the IBM Web Extensions file. The IBM Web Extensions file is created and stored in the web applications archive (WAR) file by an assembly tool.

About this task

Attention: The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release. Re-architect your legacy applications to use `javax.servlet.filter` classes instead of `com.ibm.servlet` classes. Starting from the Servlet 2.3 specification, `javax.servlet.filter` classes you can intercept requests and examine responses. You can also use `javax.servlet.filter` classes to achieve chaining functionality, as well as embellishing or truncating responses.

To configure and implement page lists:

Procedure

1. To configure page list information, use the Add Markup Language entry dialog of an assembly tool. On the Servlets tab of a web deployment descriptor editor, select a servlet and click **Add** under WebSphere Extensions.
2. Add the `callPage()` method to your servlet to invoke a JavaServer Page (JSP) file in response to a client request.

The PageListServlet has a `callPage()` method that invokes a JSP file in response to the HTTP request for a page in a page list. The `callPage()` method can be invoked in one of the following ways:

- `callPage(String pageName, HttpServletRequest request, HttpServletResponse response)`
where the method arguments are:
 - pageName**
A page name defined in the PageListServlet configuration
 - request**
The HttpServletRequest object
 - response**
The HttpServletResponse object
 - `callPage(String mlName, String pageName, HttpServletRequest request, HttpServletResponse response)`
where the method arguments are:
 - mlName** A markup language type
 - pageName**
A page name defined in the PageListServlet configuration
 - request**
The HttpServletRequest object
 - response**
The HttpServletResponse object
3. Use the PageList Servlet client type detection support to determine the markup language type a calling client requires for the response.

Extending PageListServlet

The following example shows how a servlet extends the PageListServlet class and determines the markup-language type required by the client. The servlet then uses the `callPage` method to call an appropriate JavaServer Pages (JSP) file. In this example, the JSP file that provides the correct markup-language for the response is *Hello.page*.

```
public class HelloPervasiveServlet extends PageListServlet implements Serializable
{
    /*
    * doGet -- Process incoming HTTP GET requests
    */
    public void doGet(HttpServletRequest request, HttpServletResponse response)
    throws IOException, ServletException
    {
        // This is the name of the page to be called:
        String pageName = "Hello.page";

        // First check if the servlet was invoked with a queryString that contains
        // a markup-language value.
        // For example, if this is how the servlet is invoked:
        // http://localhost/servlets/HeloPervasive?mlname=VXML
        // then use the following method:
        String mlname= getMLNameFromRequest(request);

        // If no markup language type is provided in the queryString,
        // then try to determine the client
        // Type from the request, and use the markup-language name configured in
        // the client_types.xml file.
        if (mlName == null)
        {
            mlName = getMLTypeFromRequest(request);
        }
        try
        {
            // Serve the request page.
            callPage(mlName, pageName, request, response);
        }
        catch (Exception e)
        {
        }
    }
}
```

```

        handleError(mlName, request, response, e);
    }
}

```

Page lists:

Page lists allow you to avoid hard-coding Uniform Resource Locators (URLs) in servlets and JSP files. A page list specifies the location where a request is to be forwarded, but automatically customizes that location depending on the MIME type of the servlet. Use these properties to specify a markup language and an associated MIME type. For the given MIME type, you also specify a set of pages to invoke.

Note: The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release. Re-architect your legacy applications to use `javax.servlet.filter` classes instead of `com.ibm.servlet` classes. Starting from the Servlet 2.3 specification, `javax.servlet.filter` classes you can intercept requests and examine responses. You can also use `javax.servlet.filter` classes to achieve chaining functionality, as well as embellishing or truncating responses.

The following list of classes are deprecated:

- `com.ibm.servlet.ClientList`
- `com.ibm.servlet.ClientListElement`
- `com.ibm.servlet.MLNotFoundException`
- `com.ibm.servlet.PageListServlet`
- `com.ibm.servlet.PageNotFoundException`

WebSphere Application Server supplies the `PageListServlet` servlet, which you can use to call a JavaServer Pages (JSP) file by name based on the configuration data in the `client_types.xml` file. This file maps a JSP file to a Uniform Resource Identifier (URI). When the URI is invoked, it specifies another JSP file in a web module. This support allows you to access multiple URLs without hard-coding them in your servlets.

You can also logically group page lists according to the markup language type, such as, Hypertext Markup Language (HTML) or Wireless Markup Language (WML). This allows applications that use servlets to extend the `PageListServlet` servlet, to call JSP files which return the proper markup-language type for the client request. For example, a request that originates from a PDA device requires WML data. The application server sends the request to a servlet that extends the `PageListServlet` servlet, and the servlet calls a JSP file that returns a WML response.

Client type detection support:

In addition to providing the page list mapping capability, the `PageListServlet` also provides *Client Type Detection* support. A servlet determines the markup language type that a calling client needs in the response, using the configuration information in the `client_types.xml` file.

Client type detection support allows a servlet, extending the `PageListServlet`, to call an appropriate JavaServer Pages (JSP) file. The servlet invokes the `callPage` method, which calls a JSP file based on the markup-language type of the request.

The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release. Re-architect your legacy applications to use `javax.servlet.filter` classes instead of `com.ibm.servlet` classes.

client_types.xml:

The `client_types.xml` file provides client type detection support for servlets extending `PageListServlet`. Using the configuration data in the `client_types.xml` file, servlets can determine the language type that calling clients require for the response.

Attention: The `PageListServlet` custom extension is deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release. Re-architect your legacy applications to use `javax.servlet.filter` classes instead of `com.ibm.servlet` classes.

The client type detection support allows servlets to call appropriate JavaServer Pages (JSP) files with the `callPage` method. Servlets select JSP files based on the markup-language type of the request.

Servlets must use the following version of the `callPage` method to determine the markup language type required by the client:

```
callPage(String mlName, String pageName, HttpServletRequest request,
         HttpServletResponse response)
```

where the arguments are:

- `mlName` - a markup language type
- `pageName` - a page name defined in the `PageListServlet` configuration
- `request` - the `HttpServletRequest` object
- `response` - the `HttpServletResponse` object

Review the Extending the `PageListServlet` code example in the Extending the `PageListServlet` topic, to see how the `callPage` method is invoked by a servlet.

In the example, the client type detection method, `getMLTypeFromRequest(HttpServletRequest request)`, provided by the `PageListServlet`, inspects the `HttpServletRequest` object request headers, and searches for a match in the `client_types.xml` file.

The client type detection method does the following:

- Uses the input `HttpServletRequest` and the `client_types.xml` file, to check for a matching HTTP request name and value.
- Returns the markup-language value configured for the `<client-type>` element, if a match is found.
- If multiple matches are found, this method returns the markup-language for the first `<client-type>` element for which a match is found.
- If no match is found, returns the value of the markup-language for the default page defined in the `PageListServlet` configuration.

Location

The `client_types.xml` file is located in the `app_server_root/properties` directory.

Usage notes

- Is this file read-only?
No
- Is this file updated by a product component?
No
- If so, what triggers its update?
This file is created and updated manually by users.
- How and when are the contents of this file used?

Servlets that extending the `PageListServlet` servlet use this file to determine the language type that calling clients require for the response.

Sample file entry

```
<?xml version="1.0" >
<!DOCTYPE clients [
<!ELEMENT client-type (description, markup-language,request-header+)>
<!ELEMENT description (#PCDATA)>
<!ELEMENT markup-language (#PCDATA)>
<!ELEMENT request-header (name, value)>
<!ELEMENT clients (client-type+)>
<!ELEMENT name (#PCDATA)>
<!ELEMENT value (#PCDATA)>]>
<clients>
  <client-type>
    <description>IBM Speech Client</description>
    <markup-language>VXML</markup-language>
    <request-header>
      <name>user-agent</name>
      <value>IBM VoiceXML pre-release version 000303</value>
    </request-header>
    <request-header>
      <name>accept</name>
      <value>text/vxml</value>
    </request-header>
  </client-type>
  <client-type>
    <description>WML Browser</description>
    <markup-language>WML</markup-language>
    <request-header>
      <name>accept</name>
      <value>text/x-wap.wml</value>
    </request-header>
    <request-header>
      <name>accept</name>
      <value>text/vnd.wap.xml</value>
    </request-header>
  </client-type>
</clients>
```

client_types.xml:

The `client_types.xml` file provides client type detection support for servlets extending `PageListServlet`. Using the configuration data in the `client_types.xml` file, servlets can determine the language type that calling clients require for the response.

Attention: The `PageListServlet` custom extension is deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release. Re-architect your legacy applications to use `javax.servlet.filter` classes instead of `com.ibm.servlet` classes.

The client type detection support allows servlets to call appropriate JavaServer Pages (JSP) files with the `callPage` method. Servlets select JSP files based on the markup-language type of the request.

Servlets must use the following version of the `callPage` method to determine the markup language type required by the client:

```
callPage(String mlName, String pageName, HttpServletRequest request,
         HttpServletResponse response)
```

where the arguments are:

- `mlName` - a markup language type
- `pageName` - a page name defined in the `PageListServlet` configuration
- `request` - the `HttpServletRequest` object
- `response` - the `HttpServletResponse` object

Review the Extending the PageListServlet code example in the Extending the PageListServlet topic, to see how the `callPage` method is invoked by a servlet.

In the example, the client type detection method, `getMLTypeFromRequest(HttpServletRequest request)`, provided by the PageListServlet, inspects the `HttpServletRequest` object request headers, and searches for a match in the `client_types.xml` file.

The client type detection method does the following:

- Uses the input `HttpServletRequest` and the `client_types.xml` file, to check for a matching HTTP request name and value.
- Returns the markup-language value configured for the `<client-type>` element, if a match is found.
- If multiple matches are found, this method returns the markup-language for the first `<client-type>` element for which a match is found.
- If no match is found, returns the value of the markup-language for the default page defined in the PageListServlet configuration.

Location

The `client_types.xml` file is located in the `app_server_root/properties` directory.

Usage notes

- Is this file read-only?

No

- Is this file updated by a product component?

No

- If so, what triggers its update?

This file is created and updated manually by users.

- How and when are the contents of this file used?

Servlets that extending the PageListServlet servlet use this file to determine the language type that calling clients require for the response.

Sample file entry

```
<?xml version="1.0" >
<!DOCTYPE clients [
<!ELEMENT client-type (description, markup-language,request-header+)>
<!ELEMENT description (#PCDATA)>
<!ELEMENT markup-language (#PCDATA)>

    <request-header>
        <name>accept</name>
        <value>text/vnd.wap.xml</value>
    </request-header>
</client-type>
</clients>

```

Java Servlet 3.0 considerations:

When using Servlet 3.0 web modules, keep in mind the following features.

Note: Java Servlet 3.0 has many, new powerful features. Some of these features are not fully documented in the Servlet 3.0 specification or they entail trade-offs. Consider the following topics to make best use of the new features.

Annotations

Note:

Java Servlet 3.0 annotations are picked up in Servlet 2.5 web modules, which can include exposing a servlet on the web. Use caution when upgrading prerequisites of an older application, because the new annotations are processed and the prerequisites JAR file might include annotations that you do not want applied.

File upload

When using the file upload (multipart forms) support that is new to Servlet 3.0, the default location for writing files is the same as the value of the `javax.servlet.context.tempdir` servlet context attribute. For example, `C:\opt\WAS\profiles\node1\temp\node1\server1\fragmentTest\fragmentTest24.war` is produced for a configuration with the following attributes:

- `profile home=C:\opt\WAS\profiles\node1`
- `server name=server1`
- `enterprise application name=fragmentTest`
- `web module name=fragmentTest24.war`

Relative paths are also relative to this default location.

You can change the value of the `javax.servlet.context.tempdir` servlet context attribute to be relative to a different directory by setting the `com.ibm.websphere.servlet.temp.dir` system property. This system property affects all applications on a server-wide basis. For example, if you set `com.ibm.websphere.servlet.temp.dir` to `/foo`, the application temp directory is `/foo/node1/server1/fragmentTest/fragmentTest24.war`. If you want to change the value at an application level, use the `scratchdir` JavaServer Pages (JSP) attribute. View the JSP engine configuration parameters topic for more information about the `scratchdir` attribute.

Programmatic or dynamic HTTP session configuration

Programmatic HTTP session configuration enables an application to modify the session configuration in use, either through `web.xml` file configuration or through API method calls. After the application starts, a dynamically modified cookie name cannot be changed. For security purposes, administrators can disable programmatic session configuration for particular cookies that can be shared between applications. Generally, it is safe to modify the cookie configuration, if the application uses a unique cookie name or path. You can change the default cookie path for each application to use the context root through the session management.

Important: Changing the path can affect certain IBM extensions, such as session sharing or the `IBMSessionExt.invalidateAll` method that rely on using one cookie for multiple applications.

Servlet 3.0 programmatic configuration:

The configuration methods, `addListener`, `addFilter`, and `addServlet` are introduced in the Servlet 3.0 specification.

Note: The new methods for Servlet 3.0 are part of the `ServletContext` interface. You can call these methods from either a `ServletContainerInitializer` or a `ServletContextListener`.

addListener

The `addGlobalListener` method is deprecated in WebSphere Application Server Version 8.0. It is replaced with the `addListener` method.

- Use the following method to add the listener with the given class name to this servlet context:

```
void addListener(java.lang.String className)
```

- Use the following method to add the given listener to this servlet context:

```
<T extends java.util.EventListener> void addListener(T t)
```

- Use the following method to add a listener of the given class type to this servlet context:

```
void addListener(java.lang.Class<? extends java.util.EventListener> listenerClass)
```

The given listener class must implement one or more of the following interfaces:

- `ServletContextAttributeListener`
- `ServletRequestListener`
- `ServletRequestAttributeListener`
- `HttpSessionListener`
- `HttpSessionAttributeListener`

addFilter

The `addMappingFilter` method is deprecated in WebSphere Application Server Version 8.0. It is replaced with the `addFilter` method. This method adds the filter with the given name, description, and class name to the Web application context. The registered filter might be further configured using the returned `FilterRegistration` object.

- Use the following method to add the filter with the given name and class type to this servlet context:

```
addFilter(java.lang.String filterName, java.lang.Class<? extends Filter> filterClass)
```

- Use the following method to register the given filter instance with this servlet context under the given filterName:

```
addFilter(java.lang.String filterName, Filter filter)
```

- Use the following method to add the filter with the given name and class name to this servlet context:

```
addFilter(java.lang.String filterName, java.lang.String className)
```

addServlet

The `addServlet` methods dynamically adds servlets to a `servletContext`. These methods will add the servlet with the given parameters to the web application context. The registered servlet might be further configured using the returned `ServletRegistration` object.

- Use the following method to add the filter with the given name and class type to this servlet context:

```
addFilter(java.lang.String filterName, java.lang.Class<? extends Filter> filterClass)
```

- Use the following method to register the given filter instance with this servlet context under the given filterName:

```
addFilter(java.lang.String filterName, Filter filter)
```

- Use the following method to add the filter with the given name and class name to this servlet context:

```
addFilter(java.lang.String filterName, java.lang.String className)
```

ServletContainerInitializer

When you configure a JAR file for a shared library and a `ServletContainerInitializer` is discovered within the JAR, the `ServletContainerInitializer` is invoked for every application that the shared library associates with.

Deprecated classes in Servlet 3.0

The following classes are deprecated from `com.ibm.websphere.servlet.context.IBMServletContext`:

- `public void addDynamicServlet(String servletName, String servletClass, String mappingURI, Properties initParameters)` throws `ServletException`, `java.lang.SecurityException`;
- `public void removeDynamicServlet(String servletName)` throws `java.lang.SecurityException`

There is no replacement for the `removeDynamicServlet` method because removing a servlet can lead to timing issues if a request was servicing that servlet at the same time. The `addServlet` and `createServlet` methods replace the `addDynamicServlet` method.

Initial parameters for servlets settings:

Use this page to specify initial parameters that are passed to the `init` method of web module servlet filters. You can specify initial parameter values for servlets in web modules during or after installation of an application onto a WebSphere Application Server deployment target. The `<param-value>` values specified in `<init-param>` statements in the `web.xml` file of web modules are used by default.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *application_name* > Init parameters for servlets**. This page is the same as the `Init parameters for servlets` in each web module panel on the application installation and update wizards.

Module:

Specifies the name of a module in the application that you are installing or that you are viewing after installation.

URI:

Specifies the location of the module relative to the root of the application (EAR file).

Servlet:

Specifies a unique name for the servlet within the application.

A *servlet* is a Java program that uses the Java Servlet Application Programming Interface (API). You must package servlets in a Web archive (WAR) file or web module for deployment to an application server. Servlets run on a Java-enabled web server and extend the capabilities of a web server, similar to the way applets run on a browser and extend the capabilities of a browser.

Name:

Specifies the name of the initial parameter passed to the `init` method of the web module servlet filter.

The following example servlet filter statement in a `web.xml` file specifies an initial parameter name of attribute:

```
<init-param>
  <param-name>attribute</param-name>
  <param-value>tests.Filter.DoFilter_Filter.SERVLET_MAPPED</param-value>
</init-param>
```

Value:

Specifies the value assigned to an initial parameter passed to the init method of the web module servlet filter.

The following example servlet filter statement in a web.xml file specifies an initial parameter value of tests.Filter.DoFilter_Filter.SERVLET_MAPPED for the init parameter attribute:

```
<init-param>
  <param-name>attribute</param-name>
  <param-value>tests.Filter.DoFilter_Filter.SERVLET_MAPPED</param-value>
</init-param>
```

Description:

Specifies information on the initial parameter.

Servlet filtering:

Servlet filtering provides a new type of object called a *filter* that can transform a request or modify a response.

You can chain filters together so that a group of filters can act on the input and output of a specified resource or group of resources.

Filters typically include logging filters, image conversion filters, encryption filters, and Multipurpose Internet Mail Extensions (MIME) type filters (functionally equivalent to the servlet chaining). Although filters are not servlets, their life cycle is very similar.

Filters are handled in the following manner:

1. The web container determines whether it needs to construct a `FilterChain` containing the `LoggingFilter` for the requested resource.
The `FilterChain` begins with the invocation of the `LoggingFilter` and ends with the invocation of the requested resource.
2. If other filters need to go in the chain, the web container places them after the `LoggingFilter` and before the requested resource.
3. The web container then instantiates and initializes the `LoggingFilter` (if it was not done previously) and invokes its `doFilter(FilterConfig)` method to start the chain.
4. The `LoggingFilter` preprocesses the request and response objects and then invokes the filter chain `doFilter(ServletRequest, ServletResponse)` method.
This method passes the processing to the next resource in the chain, the requested resource.
5. Upon return from the filter chain `doFilter(ServletRequest, ServletResponse)` method, the `LoggingFilter` performs post-processing on the request and response object before sending the response back to the client.

Java Servlet Specification 2.4 enables you to define a new `<dispatcher>` element in the deployment descriptor with possible values such as `REQUEST`, `FORWARD`, `INCLUDE`, `ERROR`, instead of invoking filters with `RequestDispatcher`.

Java Servlet Specification 3.0 enables you to define a new `<dispatcher>` element in the deployment descriptor with possible values such as ASYNC, REQUEST, FORWARD, INCLUDE, ERROR, instead of invoking filters with RequestDispatcher.

For example:

```
<filter-mapping>
<filter-name>Logging Filter</filter-name>
<url-pattern>/products/*</url-pattern>
<dispatcher>FORWARD</dispatcher>
<dispatcher>REQUEST</dispatcher>
</filter-mapping>
```

This indicates that the filter should be applied to requests directly from the client as well as forward requests. Adding the INCLUDE and ERROR values also indicates that the filter should additionally be applied for included requests and `<error-page>` requests. If you do not specify any `<dispatcher>` elements, then the default is REQUEST.

Filter, FilterChain, FilterConfig classes for servlet filtering

The following interfaces are defined as part of the javax.servlet package:

- Filter interface - methods: doFilter, getFilterConfig, setFilterConfig
- FilterChain interface - methods: doFilter
- FilterConfig interface - methods: getFilterName, getInitParameter, getInitParameterNames, getServletContext

The following classes are defined as part of the javax.servlet.http package:

- HttpServletRequestWrapper - methods: See the Servlet 2.4 Specification
- HttpServletResponseWrapper - methods: See the Servlet 2.4 Specification

autoRequestEncoding and autoResponseEncoding:

Starting with WebSphere Application Server Version 5, the web container no longer automatically sets request and response encodings, and response content types. Programmers are expected to set these values using available methods in the Servlet 2.3 specification or later. If programmers choose not to use the character encoding methods, they can specify the autoRequestEncoding and autoResponseEncoding extensions, which enable the application server to set the encoding values and content type.

The values of the autoRequestEncoding and autoResponseEncoding extensions are either true or false. The default value for both extensions is false. If the value is false for both autoRequestEncoding and autoResponseEncoding, then the request and response character encoding is set to the Servlet Specification default, which is ISO-8859-1. Also, if the value is set to false for a response, the web container cannot set a response content type. Different character encodings are possible if the client defines character encoding in the request header, or if the code includes the setCharacterEncoding(String encoding) method.

If the autoRequestEncoding value is set to true, and the client did not specify character encoding in the request header, and the code does not include the setCharacterEncoding(String encoding) method, the web container tries to determine the correct character encoding for the request parameters and data.

Use an assembly tool to change the default values for the autoRequestEncoding and autoResponseEncoding extensions.

The web container performs each step in the following list until a match is found:

- Looks at the character set (charset) in the *Content-Type* header.
- Attempts to map the servers locale to a character set using defined properties.
- Attempts to use the DEFAULT_CLIENT_ENCODING system property, if one is set.
- Uses the ISO-8859-1 character encoding as the default.

If the `autoResponseEncoding` value is set to `true`, and the client did not specify character encoding in the request header, and the code does not include the `setCharacterEncoding(String encoding)` method, the web container does the following:

- Attempts to determine the response content type and character encoding from information in the request header.
- Uses the ISO-8859-1 character encoding as the default.

Application life cycle listeners and events:

With application life cycle listeners and events, which are now part of the Servlet API, you can notify interested listeners when servlet contexts and sessions change. For example, you can notify users when attributes change and if sessions or servlet contexts are created or destroyed.

The life cycle listeners give the application developer greater control over interactions with `ServletContext` and `HttpSession` objects. Servlet context listeners manage resources at an application level. Session listeners manage resources that are associated with a series of requests from a single client. Listeners are available for life cycle events and for attribute modification events. The listener developer creates a class that implements the `javax.listener` interface, corresponding to the listener functionality that you want.

At application startup time, the container uses *introspection* to create an instance of your listener class and registers it with the appropriate event generator.

When a servlet context is created, the `contextInitialized` method of your listener class is invoked, which creates the database connection for the servlets in your application to use if this context is for your application. All servlet context listeners are notified of context initialization before any servlet in the web application is initialized.

When the servlet context is destroyed, your `contextDestroyed` method is invoked, which releases the database connection, if this context is for your application. You must destroy all servlets before any servlet context listeners are notified of context destruction.

Notifications to session listeners precede notifications to context listeners.

Listener classes for servlet context and session changes

The following methods are defined as part of the `javax.servlet.ServletContextListener` interface:

- `void contextInitialized(ServletContextEvent)`
Notification that the web application is ready to process requests. Place code in this method to see if the created context is for your web application and if it is, allocate a database connection and store the connection in the servlet context.
- `void contextDestroyed(ServletContextEvent)`
Notification that the servlet context is about to shut down. Place code in this method to see if the created context is for your web application and if it is, close the database connection stored in the servlet context.

The following methods are defined as part of the `javax.servlet.ServletRequestListener` interface:

- `public void requestInitialized(ServletRequestEvent re)`
 - Notification that the request is about to come into scope
A request is defined as coming into scope when it is about to enter the first filter in the filter chain that processes the request.
- `public void requestDestroyed(ServletRequestEvent re)`
 - Notification that the request is about to go out of scope
A request is defined as going out of scope when it exits the last filter in its filter chain.

The following listener interfaces are defined as part of the `javax.servlet` package:

- ServletContextListener
- ServletContextAttributeListener

The following filter interface is defined as part of the javax.servlet package:

- FilterChain interface - methods: doFilter()

The following event classes are defined as part of the javax.servlet package:

- ServletContextEvent
- ServletContextAttributeEvent

The following interfaces are defined as part of the javax.servlet.http package:

- HttpSessionListener
- HttpSessionAttributeListener
- HttpSessionActivationListener

The following event class is defined as part of the javax.servlet.http package:

- HttpSessionEvent

Example: Creating a servlet context listener with com.ibm.websphere.DBConnectionListener.java

The following example shows how to create a servlet context listener:

```
package com.ibm.websphere;

import java.io.*;
import javax.servlet.*;

public class DBConnectionListener implements ServletContextListener
{
    // implement the required context init method
    void contextInitialized(ServletContextEvent sce)
    {
    }

    // implement the required context destroy method
    void contextDestroyed(ServletContextEvent sce)
    {
    }
}
```

Developing JSP files

Learn about JSP files.

JSP class file generation

At runtime, the WebSphere Application Server JavaServer Pages (JSP) engine loads JSP class files from either the WebSphere Application Server temp directory or a web module's WEB-INF/classes directory. The JSP engine first searches for a class file in the temp directory and then it searches in the web module's WEB-INF/classes directory.

In a default installation, the WebSphere Application Server temp directory is typically *profile_root/temp*. Figure 1 shows the processing logic of the JSP engine at runtime.

The batch compiler supports the generation of class files in both the WebSphere Application Server temp directory and a web module's WEB-INF/classes directory, depending on the type of batch compiler target. In addition, the batch compiler enables the generation of class files into any directory on the filesystem, outside of the target application. Generating class files into a web module's WEB-INF/classes directory enables you to deploy the web module as a self-contained web application archive (WAR) file, or a WAR file inside an enterprise archive (EAR) file. The following table shows the batch compiler's behavior when compiling class files.

Table 118. Batch compiler behavior. Batch compiler behavior when compiling class files

	ear.path or war.path supplied	enterpriseApp.name supplied
<i>compileToDir</i> not supplied; <i>compileToWebInf</i> not supplied, or is true	The class files are compiled into the web module's WEB-INF/classes directory.	The class files are compiled into the web module's WEB-INF/classes directory.
<i>compileToDir</i> not supplied; <i>compileToWebInf</i> is false	The class files are compiled into the web module's WEB-INF/classes directory.	The class files are compiled into the WebSphere Application Server temp directory, usually <i>profile_root</i> /temp.

Table 118. Batch compiler behavior (continued). Batch compiler behavior when compiling class files

<i>compileToDir</i> is supplied; <i>compileToWebInf</i> not supplied, or is either true or false	The class files are compiled into the directory indicated by <i>compileToDir</i> .	The class files are compiled into the directory indicated by <i>compileToDir</i> .

Web container configuration for JavaServer Pages static file access

The web container searches for static files and JavaServer Pages (JSP) files in up to four different locations, depending on application configuration. This search is relevant to finding the appropriate resource to serve an inbound request and for results returned from the following APIs:

```
URL ServletContext.getResource(String path)
Set ServletContext.getResourcePaths(String path)
```

Attention: Static files are only searched when the **fileServing** property is enabled and the application does not include a `/*` servlet mapping. Also, JSP files include files with the following extensions, in addition to any other patterns that are defined in the `web.xml` file

- .jsp
- .jspx
- .jsw
- .jsv

The four locations, in priority order, are as follows:

Application WAR directory

The web container first searches the application WAR directory for a requested resource. However, you cannot serve resources under the `WEB-INF` or `META-INF` directories for inbound requests, although they are accessible using the `getResource()` and `getResourcePaths()` methods.

Pre-fragment document roots

The web container searches any application defined pre-fragment document roots second. Define a pre-fragment document root in the `ibm-web-ext.xmi` file, located in the `WEB-INF` directory for the application. Define a pre-fragment document root for static files or JSP files, as follows:

```
Static files:
<fileServingAttributes xmi:id="<user-provided name>"
  name="preFragmentExtendedDocumentRoot"
  value="<user provided value>"/>
```

```
JSP files:
<jspAttributes xmi:id="<user provided name>" name="preFragmentExtendedDocumentRoot"
  value="<user provided value>"/>
```

The `<user provided name>` is a comma-separated list of directories that can include JAR or ZIP files from which static files or JSP files can be accessed. The list can be fully qualified or relative to the application ear directory. The attributes can be specified with identical values. Further, you can specify the same values by different applications.

Note: Pre-fragment document roots is a new function in WebSphere Application Server Version 8.0.

META-INF/resources directories of fragments under the WEB-INF/Lib directory in the application WAR file

After searching pre-fragment document roots, the web container searches web fragments. A web fragment comprises a JAR file in an application `WEB-INF/lib` directory. The JAR might include

static resources in a META-INF/resources directory that are defined within the JAR file. To prevent the web container from searching META-INF/resources directories, set the `com.ibm.ws.webcontainer.SkipMetaInfResourcesProcessing` web container custom property to `true`. The default value for the custom property is `false`.

```
com.ibm.ws.webcontainer.SkipMetaInfResourcesProcessing = true
```

Note: META-INF/resources directories of fragments under the WEB-INF/Lib directory in the application WAR file is a new function in WebSphere Application Server Version 8.0.

Extended document roots

Finally, the web container searches any application defined as extended document roots. Extended document roots were available in previous releases and are defined in the `ibm-web-ext.xmi` file, which is located in the application WEB-INF directory. Define extended document root for static files or JSP files, as follows:

```
Static files:  
<fileServingAttributes xmi:id="<user provided name>" name="extendedDocumentRoot"  
  value="<user provided value>"/>
```

```
JSP files:  
<jspAttributes xmi:id="<user provided name>" name="extendedDocumentRoot"  
  value="<user provide value>"/>
```

```
com.ibm.ws.webcontainer.SkipMetaInfResourcesProcessing = true
```

The `<user provided name>` is a comma-separated list of directories that can include JAR or ZIP files from which static files or JSP files can be accessed. The list can be fully qualified, or relative to the application EAR directory. You can specify both attributes with identical values. Also, different applications can specify the same values.

Attention: You might set the `com.ibm.ws.webcontainer.ServeWelcomeFileFromExtendedDocumentRoot` custom property to **true** to enable serving static welcome pages from a static file extended document root. The default value for the custom property is **false**.

```
com.ibm.ws.webcontainer.ServeWelcomeFileFromExtendedDocumentRoot = true
```

When the `com.ibm.ws.webcontainer.ServeWelcomeFileFromExtendedDocumentRoot` property is set to **true**, the web container searches in a static file extended document root for a static welcome file to serve for a request comprising a valid partial URL. For example, if a request specifies only the application context, and a welcome file is specified as `index.html`, the property must be set if `index.html` is to be served from a static file extended document.

```
com.ibm.ws.webcontainer.enablepartialurltoextendeddocumentroot = true
```

The default value is **false**.

If this property is set to **true**, the web container includes the contents of a static file extended document root when determining whether an inbound request is for a valid partial URL. For example, if a request specifies a URL that ends with `<application context>/<text>` and `<text>` does not map to a servlet or static file, the web container considers this URL a valid partial URL only if `<text>` is a valid directory of the application. As a result if directory `<text>` exists only in a static file extended document root, this property must be set for the URI to be considered a valid partial URI.

Important: These properties are not required for static file pre-fragment document roots. Also, when determining a valid partial URL, the web container does not consider JSP pre-fragment and extended document roots.

Packages and directories for generated .java and .class files

By default, the .java files for all JavaServer Pages (JSP) files are generated with the package statement, package com.ibm._jsp;. The JSP engine's class loader knows how to load JSP classes when they are all in the same package. The .java files are located in the filesystem within a directory structure mirroring the JSP source directory structure.

If the JSP engine configuration parameter **useFullPackageNames** is set to true, the .java files are generated with the package statement

```
Package _ibmjsp.<directory structure in which the jsp is located>;
```

The usage of full package names enables the configuration of a JSP as a servlet in the web.xml file. Refer to the JSP class loading settings topic for more information. The table below gives examples of packages and directory structures for generated .java and .class files.

Table 119. Packages and directory structures for generated .java and .class files. Examples of packages and directory structures for generated .java and .class files.

JSP file	Java package		Location of .java or .class files in file system	
	default	useFullPackageNames=true	default	useFullPackageNames=true
/myJsp.jsp	com.ibm._jsp	_ibmjsp	/	/_ibmjsp
/jspFiles/jspOne.jsp	com.ibm._jsp	_ibmjsp.jspFiles	/jspFiles	/_ibmjsp/jspFiles
/dir with spaces/jspTwo.jsp	com.ibm._jsp	_ibmjsp.dir_20_with_20_spaces	/dir with spaces	/_ibmjsp/dir_20_with_20_spaces

Generated .java files:

When the JSP engine's **keepgenerated** configuration parameter is set to true, the .java file that is generated for JavaServer Pages (JSP) is retained. The .java file contains information that is useful in debugging.

Dependency information

In the .java file, immediately following the class declaration, an array of dependent files is defined, if the source JSP has any dependencies. There are three types of files that are tracked as dependencies:

1. Files that are statically included in the JSP
2. Tag files that are used by the JSP, but only tag files that are not in Java Archive (JAR) files
3. TLD files that are used by the JSP, but only TLDs that are not in JAR files

This array is always generated, but the JSP engine uses it, in determining whether a JSP needs to be recompiled, only when the trackDependencies parameter is set to true.

In the example below, three JSP fragments, one TLD and one tag file are dependencies of the JSP jsp1.jsp. There are three parts to each array entry:

1. The path to the dependency, relative to the web module's context root. For example: /dir1/frag1.jspf
2. The long value representing the time the file was last modified. For example: 1082407108000
3. The String representation of the long value. For example: Mon Apr 19 16:38:28 EDT 2004

```

public final class _jsp1 extends com.ibm.ws.jsp.runtime.HttpJspBase
    implements com.ibm.ws.jsp.runtime.JspClassInformation {

    private static String[] _jspx_dependants;
    static {
        _jspx_dependants = new String[5];
        _jspx_dependants[0] = "/Banner.jspf^1082407108000^Mon Apr 19 16:38:28 EDT 2004";
        _jspx_dependants[1] = "/Footer.jspf^1077657462000^Tue Feb 24 16:17:42 EST 2004";
        _jspx_dependants[2] = "/dir1/frag1.jspf^1035396680000^Wed Oct 23 14:11:20 EDT 2002";
        _jspx_dependants[3] = "/utility.tld^1080069938000^Tue Mar 23 14:25:38 EST 2004";
        _jspx_dependants[4] = "/WEB-INF/tags/top.tag^1065440490000^Mon Oct 06 07:41:30 EDT 2003";
    }
}

```

Version, JSP engine options, and WEB.XML information

The generated .java source contains a comment that lists information about the file which is located at the bottom of the generated file. This information includes:

- The date and time the .java file was generated
- The version, build number and build date of the WebSphere Application Server on which the .java file was generated
- The values of the JSP engine configuration parameters that were in effect when the file was generated
- The values of any <jsp-config> elements in the web.xml file that pertained to the source JSP file.

```

/*
profile_root/installedApps/MyCell/sampleApp.ear/examples.war/WEB-INF/classes/_ibmjsp/_jsp1.java
was generated @ Wed May 03 10:05:56 EDT 2006IBM WebSphere Application Server - ND, 6.1.0.0
    Build Number: o0441.04
    Build Date: 05/01/06*****

```

The JSP engine configuration parameters were set as follows:

```

classDebugEnabled =          [false]
debugEnabled =             [false]

JSP batch compilation

As an IBM enhancement to JavaServer Pages (JSP) support, IBM WebSphere Application Server provides a batch JSP compiler that allows JSP page compilation before application deployment. The batch compiler validates the syntax of JSP pages, translates the JSP pages into Java source files, and compiles the Java source files into Java servlet class files. The batch compiler also validates tag files and generates their Java implementation classes.

Batch compilation of JSP pages in a predeployed application simplifies the deployment process and improves the runtime performance of JSP page by eliminating first-request compilations. The batch compiler also operates on enterprise applications that have been deployed into WebSphere Application Server.

The JSP batch compiler works on web modules that support Servlet 2.2 and later. The batch compiler works on JSP pages written to the JSP 2.1 specification or previous specifications back to JSP 1.0. It recognizes a Servlet 2.5 or later deployment descriptor, `web.xml`, and can use any `jsp-config` elements that it may contain. In a Servlet 2.3 (JSP 1.2) or Servlet 2.2 (JSP 1.1) deployment descriptor the batch compiler recognizes and uses any `taglib` elements that the descriptor may contain.

Batch compiling makes the first request for a JSP page much faster because the JSP page is already translated and compiled into a servlet. Batch compiling is also useful as a fast way to resynchronize all of the JSP pages for an application.

The batch compiler supports the generation of class files in both the WebSphere Application Server `temp` directory and a web module's `WEB-INF/classes` directory, depending on the type of batch compiler target. In addition, the batch compiler enables generation of class files into any directory on the filesystem, outside the target application. Generating class files into a web module's `WEB-INF/classes` directory enables the web module to be deployed as a self-contained WAR file, or a WAR inside an EAR.

Also, you can use shared libraries with the JSP batch compiler. When you use the JSP batch compiler, you must either add the JAR to the WAR in the `<WEB-INF>/lib` directory, or add the JAR to the JVM class path to use shared libraries.

You can use the pre-touch tool for batch compilation, which can compile and load JSP class files into the application server JVM. This tool offers improved performance over the JSP batch compiler on iSeries servers. Refer to the [Pre-touch tool for compiling and loading JSP files](#) article for more information.

JSPBatchCompiler command:

The batch compiler validates the syntax of JavaServer Pages, translates the JSP pages into Java source files, and compiles the Java source files into Java Servlet class files. The batch compiler also validates tag files and generates their Java implementation classes. Use this function to batch compile your JSP files and thereby enable faster responses to the initial client requests for the JSP files on your production web server.

The batch compiler can be executed against compressed or expanded enterprise archive (EAR) files and web application archive (WAR) files, as well as enterprise applications and web modules that have been deployed into WebSphere Application Server. When the target is a deployed enterprise application, the server does not need to be running to execute the batch compiler. If the batch compiler is executed while the target sever is running, the server is not aware of an updated class file and does not load that class file unless the enterprise application is restarted. When the target is a compressed EAR file or WAR file, the batch compiler must expand it before executing.

Processing of web modules

The batch compiler operates on one web module at a time. If the target is either an EAR file or an installed enterprise application that contains more than one web module, the batch compiler operates on each web module individually. This is done because JSP pages are configured on a web module basis, through the web module's web.xml deployment descriptor file. Within a web module, the batch compiler processes one directory at a time. It validates and translates each JSP page individually, and then invokes the Java compiler for the entire group of generated Java sources files in that directory. If one JSP page fails during the Java compilation phase, the Java compiler might not create class files for most or all of the JSP pages that successfully compiled in that directory.

JSP file extensions

The batch compiler uses four things to determine what file extensions it should process:

1. Standard JSP file extensions
 - *.jsp
 - *.jspx
 - *.jsw
 - *.jsv
2. The url-pattern property of the jsp-property-group elements in the deployment descriptor file in Servlet 2.4 web modules
3. The **jsp.file.extensions** JSP engine configuration parameter (for pre-Servlet 2.4 web modules)
4. The batch compiler configuration parameter **jsp.file.extensions**

The standard extensions are always used by the batch compiler. If the web module contains a Servlet 2.4 deployment descriptor, the batch compiler also processes any url-patterns found within the jsp-config element. If the batch compiler target contains the JSP engine configuration parameter **jsp.file.extensions**, then those extensions are also processed. If the batch compiler configuration parameter **jsp.file.extensions** is present, the extensions given are also processed and will override the JSP engine configuration parameter **jsp.file.extensions**.

It is a good idea to give JSP 'fragments' an extension that is not processed by the batch compiler. Statically-included fragments that do not stand alone generate translation or compilation errors if processed. The JSP 2.0 Specification suggests that you use the extension `.jspxf` for such files.

Batch compiler command

The JspBatchCompiler script for running the batch compiler from the Qshell command line is found in the `app_server_root/bin` directory. An Ant task is also available for executing the batch compiler using Ant. See the topic, Batch Compiler Ant Task for additional information.

The batch compiler target is the only required parameter. The target is one of `-ear.path`, `-war.path` or `-enterpriseapp.name`.

```
JspBatchCompiler -ear.path | -war.path | -enterpriseapp.name <name>
  [-response.file <filename>]
  [-webmodule.name <name>]
  [-filename <jsp name | directory name>]
  [-recurse <true | false>]
  [-config.root <path>]
  [-cell.name <name>]
  [-node.name <name>]
  [-server.name <name>]
  [-profileName <name>]
  [-extractToDir <path>]
  [-compileToDir <path>]
  [-compileToWebInf <true | false>]
```

```

[-compileToWebInf <true | false>]
[-compileAfterFailure <true | false>]
[-translate <true | false>]
[-compile <true | false>]
[-removeTempDir <true | false>]
[-forceCompilation <true | false>]
[-useFullPackageNames <true | false>]
[-trackDependencies <true | false>]
[-createDebugClassfiles <true | false>]
[-keepgenerated <true | false>]
[-keepGeneratedclassfiles <true | false>]
[-usePageTagPool <true | false>]
[-useThreadTagPool <true | false>]
[-classloader.parentFirst <true | false>]
[-classloader.singleWarClassLoader <true | false>]
[-additional.classpath <classpath to additional JAR files and classes>]

```

```

[-verbose <true | false>]
[-deprecation <true | false>]
[-javaEncoding <encoding>]
[-jdkSourceLevel <13 | 14 | 15 | 16>]
[-compilerOptions <space-separated list of java compiler options>]
[-useJikes <true | false>]
[-jsp.file.extensions <file extensions to process>]
[-log.level <SEVERE | WARNING | INFO | CONFIG | FINE | FINER | FINEST | OFF>]

```

*** See batchcompiler.properties.default in *app_server_root/bin* for more information. ***

*** See JspCBuild.xml in *app_server_root/bin* for information about the public WebSphere Ant task JspC. ***

The batch compiler is aware of three groups of configuration parameters:

1. JSP engine configuration parameters for a web module.
Refer to the JSP engine configuration parameters topic.
2. Batch compiler response file configuration parameters.
These are the parameters that are found in a batch compiler response file. See `-response.file`, below.
3. Batch compiler command line configuration parameters.
These are the parameters entered on the command line when running the batch compiler.

The batch compiler looks at all three groups of configuration parameters in order to determine which value for a parameter is used when compiling JSP pages. When resolving the value for a given parameter, the precedence is:

1. If the parameter is found on the command line, its value is used.
2. If the parameter is not found on the command line, the batch compiler looks for the parameter in a response file named on the command line.
3. If no response file is named, or if the parameter is not found therein, the batch compiler looks for the parameter in the web module's JSP engine configuration parameters.

If a configuration parameter is not found among these three groups, then a default value is used. The default values for the configuration parameters are given below along with the description of the parameters.

With one exception, these parameters are not case sensitive; `-profileName` is case sensitive. If the values specified for these arguments are comprised of two or more words separated by spaces, you must add quotation marks around the values.

The batch compiler does not create, or set the values of, equivalent JSP engine parameters. This means that if a JSP page in a deployed Web module is modified and is recompiled by the JSP engine at run time, the JSP engine's configuration parameters will determine the engine's behavior. For example, if you use the batch compiler to compile a web module and you use the `-useFullPackageNames true` option, the JSP files will be compiled to support that option. But the JSP engine parameter `useFullPackageNames` must

also be set to true in order for the JSP runtime to be able to load the compiled JSP pages. If JSP pages are modified in a deployed web module, then the engine's parameters should be set to the same values used in batch compilation.

To use the JSP batch compiler, enter one of the following commands on a single line at an operating system command prompt.:

- **ear.path | war.path | enterpriseapp.name**

Represents the full path to a single compressed or expanded enterprise application archive (EAR) file or web application archive (WAR) file, or the name of the deployed enterprise application that you want to compile. For example:

```
– JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear
– JspBatchCompiler -war.path /home/wasuser/wars/examples.war
– JspBatchCompiler -enterpriseapp.name myEnterpriseApp -webmodule.name my.war -filename
  mydirectory/main.jsp
```

- **response.file**

Specifies the path to a file that contains configuration parameters used by the batch compiler. The *response.file* is used only if it is given on the command line; it is ignored if it is present in a response file.

The template response file, `batchcompiler.properties.default`, is found in the `app_server_root/properties` directory. Copy this template to create your own response files containing defaults for the parameters in which you are interested. You can configure all the required and optional parameters, except the `response.file` in a response file. **For example:** `JspBatchCompiler -response.file /home/wasuser/myproject/batchc.props`

Default : null

- **webmodule.name**

Represents the name of the specific web module that you want to batch compile. If this argument is not set, all web modules in the enterprise application are compiled. This parameter is used only when *ear.path* or *enterpriseapp.name* is given. This parameter is useful when JSP pages in a specific web module within a deployed enterprise application need to be regenerated, because all shared library dependencies are picked up.

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -webmodule.name myWebModule.war`

Default: All web modules in an EAR file or enterprise application are compiled if this parameter is not given.

- **filename**

Represents the name of a single JSP file that you want to compile. If this argument is not set, all files in the web module are compiled. Alternatively, if *filename* is set to the name of a directory, only the JSP files in that directory and that directory's child directories are compiled. The name is relative to the context root of the web module.

Example 1: If you want to compile the file, `myTest.jsp`, and it is found in `/subdir/myJSPs`, you would enter `-filename /subdir/myJSPs/myTest.jsp`.

Example 2: If you want to compile all JSP files in `/subdir/myJSPs` and its child directories, you would enter `-filename subdir/myJSPs`.

Default: All JSP files in the web module are compiled. Entering `-filename /` is equivalent to the default.

- **recurse**

Determines whether subdirectories beneath the target directory are processed. This parameter is used only when the *filename* parameter is given. Set value to `false` to process only the directory named *filename* parameter; and not its subdirectories.

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -filename /subdir1 -recurse false`.

Default: `true`; All directories beneath the target directory are processed.

- **config.root**

Specifies the location of the WebSphere Application Server configuration directory. This parameter is used only when *enterpriseapp.name* is given.

Default: *profile_root/config*

- **cell.name**

Specifies the name of the cell in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

Default: The default is obtained from the profile script that is used. The symbolic name of this variable is WAS_CELL.

- **node.name**

Specifies the name of the node in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

Default: The default is obtained from the profile script that is used. The symbolic name of this variable is WAS_NODE.

- **server.name**

Represents the name of the server in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

Default: server1

- **profileName**

Specifies the name of the profile you want to use. This parameter is used only when the *enterpriseapp.name* or *-ear.path* is given.

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -profileName AppServer-3`

Default: The default profile is used. This is obtained from the `setupCmdLine` script in the `app_server_root/bin` directory. The symbolic name is DEFAULT_PROFILE_SCRIPT.

- **extractToDir**

Specifies the directory into which predeployed enterprise archive (EAR) files and web application archive (WAR) files will be extracted before the batch compiler operates on them. This parameter is ignored when *enterpriseapp.name* is given. The `extractToDir` parameter is used as described in the table below.

Example: `JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -extractToDir /home/wasuser/mytempdir.`

Use-case: You must extract a compressed archive before it is batch compiled. You can also extract an expanded archive to a new directory as well. In both cases, extraction leaves the original archive untouched, which may be useful while development is underway.

Table 120. *extractToDir*. Default values

	Expanded archive	Compressed archive
extractToDir supplied	The batch compiler extracts the archive to <code>extractToDir</code> before operating on it. If a file or directory of the same name as the archive already exists in the <code>extractToDir</code> , the batch compiler removes the archive completely before extracting that archive. If the batch compiler exits with no errors, it compresses the archive in place in the <code>extractToDir</code> , even if the original EAR file or WAR file was expanded. If errors are encountered during compilation, the EAR file or WAR file is left in the expanded state even if the original EAR file or WAR file was compressed.	
extractToDir not supplied	The batch compiler operates on the EAR file or WAR file in place (does not extract it to another directory) and the archive remains expanded after the batch compiler finishes.	The batch compiler extracts the archive to the directory returned by the JVM property "java.io.tmpdir". The rest of the behavior described above, when <code>extractToDir</code> is supplied, is the same in this case.

The default is server1.

- **compileToDir**

Specifies the directory into which JSP pages are translated into Java source files and compiled into class files. This directory can be anywhere on the filesystem, but the batch compiler's default behavior is usually adequate. The batch compiler's behavior when compiling class files is described in the table below

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -compileToDir /home/wasuser/myTargetDir`

Use-case: This parameter enables you to generate the Java and class files into a directory outside of the target, which may be useful if you want to compare the newly generated files with their previous versions which remain untouched within the target.

Table 121. *compileToDir*. Default values

	ear.path or war.path supplied	enterpriseApp.name supplied
compileToDir not supplied; compileToWebInf not supplied, or is true	The class files are compiled into the web module's WEB-INF/classes directory	The class files are compiled into the web module's WEB-INF/classes directory.
compileToDir not supplied; compileToWebInf is false	The class files are compiled into the web module's WEB-INF/classes directory.	The class files are compiled into the WebSphere Application Server temp directory (usually <i>profile_root/temp</i>).
compileToDir is supplied; compileToWebInf not supplied, or is either true or false	The class files are compiled into the directory indicated by compileToDir.	The class files are compiled into the directory indicated by compileToDir.

- **compileToWebInf**

Specifies whether the target directory for the compiled JSP class files should be the web module's WEB-INF/classes directory. This parameter is used only when *enterpriseApp.name* is given, and it is overridden by *compileToDir* if *compileToDir* is given.

The batch compiler's default behavior is to compile to the web module's WEB-INF/classes directory. The batch compiler's behavior when compiling class files is described in the table above.

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -compileToWebInf false`.

Use-case: Set this parameter to false when *enterpriseApp.name* is supplied and you want the class files to be compiled to the WebSphere Application Server temp directory instead of the web module's WEB-INF/classes directory. Recommendation: if this parameter is set to false, set *forceCompilation* to true if there are any JSP class files in the WEB-INF/classes directory.

Default: true; see the table above.

- **compileAfterFailure**

Specifies whether the JDK JSP batch compiler continues to compile the other JavaServer Pages (JSP) files in the current directory if one or more of the JavaServer Pages (JSP) files in that directory cannot be compiled. Typically when one of the files cannot be compiled, the JSP batch compiler skips all of the remaining JSPs in that directory, and starts to compile the files in the next directory.

If you set this parameter to true, you must also specify the *useJDKCompiler* parameter and set that parameter to true.

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -useJDKCompiler true -compileAfterFailure false`.

Use-case: Set this parameter to true if you want the JSP batch compiler compile the other JavaServer Pages (JSP) files in the current directory even if one or more of the JSP files in that directory cannot be compiled.

Default: false

- **forceCompilation**

Specifies whether the batch compiler is forced to recompile all JSP resources regardless or whether the JSP page is outdated.

Example: `JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -forceCompilation true`.

Use-case: Especially useful when creating an archive for deployment, to make sure all JSP classes are up to date.

Default: false

- **useFullPackageNames**

Specifies whether the batch compiler generates full package names for JSP classes. The default is to generate all JSP classes in the same package. The JSP engine's class loader knows how to load JSP classes when they are all in the same package. The default has the benefit of generating smaller file-system paths. Full package names have the benefit of enabling the configuration of precompiled JSP class files as servlets in the `web.xml` file without use of the `jsp-file` attribute, resulting in a single class loader (the web application's class loader) being used to load all such JSP classes. Similarly, when the JSP engine's configuration attributes **useFullPackageNames** and **disableJspRuntimeCompilation** are both true, a single class loader is used to load all JSP classes, even if the JSP pages are not configured as servlets in the `web.xml` file.

When `useFullPackageNames` is set to true, the batch compiler generates a file called `generated_web.xml` in the web module's `WEB-INF` directory. This file contains servlet configuration information for each JSP page that is successfully translated and compiled. The information can optionally be copied into the web module's `web.xml` file so that the JSP pages are loaded as servlets by the web container. Note that if a JSP page is configured as a servlet in this way, no reloading of the JSP page is done at run time if the JSP page is modified. This is because the JSP page is treated as a regular servlet and requests for it do not pass through the JSP engine.

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -useFullPackageNames true`

Use-case: Enables JSP classes to be loaded by a single class loader.

Default: false

- **removeTempDir**

Specifies whether the web module's temp directory is removed. The batch compiler by default generates JSP class files into a web module's `WEB-INF/classes` directory. JSP class files are generated into the temp directory at run time if a JSP page is modified and JSP reloading is enabled. By batch compiling all the JSP pages in a web module and also removing the temp directory, disk resources are preserved. You can only use the `removeTempDir` parameter when `-enterpriseApp.name` is given.

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -removeTempDir true.`

Use-case: Free up disk space by clearing out a web application's temp directory.

Default: false

- **translate**

Specifies whether JSP pages are translated and compiled. Set `translate` to false if you do not want JSP pages to be translated and compiled. You must use this option in conjunction with `-removeTempDir` to tell the batch compiler to remove only the temp directory and to do no further processing.

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -translate false -removeTempDir true.`

Use-case: Free up disk space by clearing out a web application's temp directory, without invoking JSP processing.

Default: true

- **compile**

Specifies whether JSP pages go through the Java compilation phase. Set `compile` to false if you do not want JSP pages to go through the Java compilation phase.

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -compile false`

Use-case: If you only want JSP pages to be syntax-checked, set `-compile` to false. You can set `-keepgenerated` to true if you want to see the `.java` files that are generated during the translation phase.

Default: true

- **trackDependencies**

Specifies whether the batch compiler recompiles a JSP page when any of its dependencies have changed, even if the JSP page itself has not changed. Tracking dependencies incurs a significant

runtime performance penalty because the JSP Engine checks the filesystem on every request to a JSP page to see if any of its dependencies have changed. The dependencies tracked by WebSphere Application Server are :

1. Files statically included in the JSP page
2. Tag files used by the JSP page (excluding tag files that are in JAR files)
3. TLD files used by the JSP page (excluding TLD files that are in JAR files)

Example: `JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -trackDependencies true.`

Use-case: Useful in a development environment.

Default: false

- **createDebugClassfiles**

Specifies whether the batch compiler generates class files that contain SMAP information, as per JSR 45, **Debugging support for Other Languages**.

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -createDebugClassfiles true`

Use-case: Use this parameter when you want to be able to debug JSP pages in your JSR 45-compliant IDE.

Default: false

- **keepgenerated**

Specifies whether the batch compiler saves or erases the generated Java source files created during the translation phase.

If set to `true`, WebSphere Application Server saves the generated `.java` files used for compilation on your server. By default, this argument is set to `false` and the `.java` files are erased after the class files have compiled.

Example: `JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -keepgenerated true`

Use-case: Use this parameter when you want to review the Java code generated by the batch compiler.

Default: false

- **keepGeneratedclassfiles**

Specifies whether the batch compiler saves or erases the class files generated during the compilation of Java source files.

Example: `JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -keepGeneratedclassfiles false -keepgenerated false`

Use-case: Set this parameter to `false` if you only want to see if there are any translation or compilation errors in your JSP pages. If paired with `-keepgenerated false`, this parameter results in all generated files being removed before the batch compiler completes.

Default: true

- **usePageTagPool**

Enables or disables the reuse of custom tag handlers on an individual JSP page basis.

Example: `JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -usePageTagPool true`

Use-case: Use this parameter to enable JSP-page-based reuse of tag handlers.

Default: false

- **useThreadTagPool**

Enables or disables the reuse of custom tag handlers on a per request thread basis per web module.

Example: `JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -useThreadTagPool true`

Use-case: Use this parameter to enable web module-based reuse of tag handlers.

Default: false

- **classloader.parentFirst**

Specifies the search order for loading classes by instructing the batch compiler to search the parent class loader prior to application class loader. This parameter is only used when *ear.path* or *enterpriseApp.name* is given.

Example: JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -classloader.parentFirst false

Use-case: Set this parameter to false when your web module contains a JAR file that is also found in the server lib directory, and you want your web module's JAR file to be picked up first.

Default: true

- **classloader.singleWarClassloader**

Specifies whether to use one class loader per enterprise archive (EAR) file or one class loader per web application archive (WAR) file. Used only when *ear.path* or *enterpriseApp.name* is given.

Example: JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -classloader.singleWarClassloader true

Use-case: Set this parameter to true when a Web module depends on JAR files and classes in another web module in the same enterprise application.

Default: false; One class loader is created per WAR file with no visibility of classes in other web modules.

- **additional.classpath**

Specifies additional class path entries to be used when parsing and compiling JSP pages. This parameter is used only when *war.path* is given. When *war.path* is the target, WebSphere Shared Libraries are not picked up by the batch compiler. Therefore, if your WAR file relies on, for example, a JAR file that is configured in WebSphere Application Server as a shared library, then use this option to point to that JAR file. In addition, if you give *war.path* and also use the *-extractToDir* parameter, then any JAR files that are in the WAR file's manifest class-path is not added to the class path (since the WAR file has now been extracted by itself outside the EAR file in which it resides). Use *-additional.classpath* in this case to point to the necessary JAR files. Add the full path to needed resources, separated by your system-dependent path separator.

Example: JspBatchCompiler -war.path /home/wasuser/myproject/examples.war -additional.classpath /home/wasuser/myJars/someJar.jar:/home/wasuser/myClasses

Use-case: Use this parameter to add to the class path JAR files and classes outside of your WAR file. At run time, these same JAR files and classes have to be made available through the standard WebSphere Application Server configuration mechanisms.

Default: null

- **verbose**

Specifies whether the batch compiler should generate verbose output while compiling the generated sources.

Example: JspBatchCompiler -war.path /home/wasuser/myproject/examples.war -verbose true

Use-case: Set this parameter to true when you want to see Java compiler class loading and other messages.

Default: false

- **deprecation**

Indicates the compiler should generate deprecation warnings while compiling the generated sources.

Example: JspBatchCompiler -war.path /home/wasuser/myproject/examples.war -deprecation true

Use-case: Set this parameter to true when you want to see Java compiler deprecation messages.

Default: false

- **javaEncoding**

Specifies the encoding that will be used when the .java file is generated, and when it is compiled by the Java compiler. When *-javaEncoding* is set, that encoding is passed to the java compiler via the *-encoding* argument. Note that encoding is not supported by Jikes.

Example: JspBatchCompiler -war.path/home/wasuser/myproject/examples.war -javaEncoding Shift-JIS

Use-case: Set this parameter when the page encoding of your JSP pages is not UTF-8 compatible.

Default value: UTF-8.

- **jdkSourceLevel**

This JSP engine parameter was introduced in WebSphere Application Server version 6.1 to support JDK 5. Use this parameter instead of the compileWithAssert parameter, although compile WithAssert still works in version 6.1.

The default value for this parameter is 16. This parameter requires regeneration of Java source. The following are jdkSourceLevel parameter values:

- **13** - This value will disable all new language features of JDK 1.4, JDK 5.0 and JDK 6.0.
- **14** - This value will enable the use of the assertion facility and will disable all new language features of JDK 5.0 and JDK 6.0.
- **15** - This value will enable the use of the assertion facility and will disable all new language features of JDK 6.0.
- **16** - This value will enable the use of the new features of JDK 6.0.

Example: JspBatchCompiler -war.path c:\myproject\examples.war -jdkSourceLevel 14

Use-case: Set this parameter when you want to enable or disable the language features of JDK 1.4 , JDK 5.0, and JDK 6.0

Default value: 16

- **compilerOptions**

Specifies a list of strings to be passed on the Java compiler command. This is a space-separated list of the form "arg1 arg2 argn".

Example: JspBatchCompiler -war.path /home/wasuser/myproject/examples.war -compilerOptions "-bootclasspath <path>"

Use-case: Use this parameter if you need Java compiler arguments other than verbose, deprecation and Assert facility support.

Default: null

- **useJikes**

Specifies whether Jikes should be used for compiling Java sources. NOTE: Jikes is not shipped with WebSphere Application Server.

Example: JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -useJikes true

Use-case: Set this parameter to true in order for the batch compiler to use Jikes as the Java compiler.

Default value: false

- **jsp.file.extensions**

Specifies the file extensions to be processed by the batch compiler. This is a semicolon- or colon-separated list of the form "*.ext1;*.ext2:*.extn". Note that this parameter is not necessary for Servlet 2.4 web applications because the url-pattern property of the jsp-property-group elements in the deployment descriptor can be used to identify extensions that should be treated as JSP pages.

Example: JspBatchCompiler -enterpriseApp.name sampleApp -jsp.file.extensions *.jspz;*.jspt

Use-case: Use this parameter to add additional extensions to the be processed by the batch compiler.

Default: null. See section, "JSP file extensions", in this topic for additional information.

- **log.level**

Specifies the level of logging that is directed to the console during batch compilation. Values are SEVERE | WARNING | INFO | CONFIG | FINE | FINER | FINEST | OFF

Example: JspBatchCompiler -enterpriseApp.name sampleApp -log.level FINEST

Use-case: Set this parameter higher or lower to control logging output. FINEST generates the most output useful for debugging.

Default: CONFIG

Batch compiler ant task:

The ant task **JspC** exposes all the batch compiler configuration options. It runs the batch compiler under the covers. It is backward compatible with the WebSphere Application Server 5.x version of the **JspC** ant task. The following table lists all of the ant task attributes and their batch compiler equivalents.

Table 122. Ant task attributes and their batch compiler equivalents. JspC attributes and the equivalent batch compiler parameters.

JspC attribute	Equivalent batch compiler parameter
earPath	-ear.path
warPath	-war.path
src	-war.path
Same as warPath, for backward compatibility	
enterpriseAppName	-enterpriseapp.name
responseFile	-response.file
webmoduleName	-webmodule.name
fileName	-filename -config.root
configRoot	-config.root
cellName	-cell.name
nodeName	-node.name
serverName	-server.name
profileName	-profileName
extractToDir	-extractToDir
compileToDir	-compileToDir -compileToDir
same as compileToDir, for backward compatibility	
compileToWebInf	-compileToWebInf
compilerOptions	-compilerOptions
recurse	-recurse
removeTempDir	-removeTempDir
translate	-translate
compile	-compile
forceCompilation	-forceCompilation
useFullPackageNames	-useFullPackageNames
trackDependencies	-trackDependencies
createDebugClassfiles	-createDebugClassfiles
keepgenerated	-keepgenerated
keepGeneratedclassfiles	-keepGeneratedclassfiles
usePageTagPool	-usePageTagPool
useThreadTagPool	-useThreadTagPool
classloaderParentFirst	-classloader.parentFirst
classloaderSingleWarClassLoader	-classloader.singleWarClassLoader
additionalClasspath	-additional.classpath
classpath	-additional.classpath
same as additionalClasspath, for backward compatibility	
verbose	-verbose
deprecation	-deprecation
javaEncoding	-javaEncoding
compileWithAssert	-compileWithAssert
useJikes	-useJikes
jspFileExtensions	-jsp.file.extensions
logLevel	-log.level
wasHome	none

Table 122. Ant task attributes and their batch compiler equivalents (continued). JspC attributes and the equivalent batch compiler parameters.

Classpathref	none
jdkSourceLevel	-jdkSourceLevel

Below is an example of a build script with multiple targets, each with different attributes. The following commands are used to launch the script:

On Windows:

```
ws_ant -Dwas.home=%WAS_HOME% -Dear.path=%EAR_PATH% -Dextract.dir=%EXTRACT_DIR%
ws_ant jspc2 -Dwas.home=%WAS_HOME% -Dapp.name=%APP_NAME% -Dwebmodule.name=%MOD_NAME%
ws_ant jspc3 -Dwas.home=%WAS_HOME% -Dapp.name=%APP_NAME% -Dwebmodule.name=%MOD_NAME% -Ddir.name=%DIR_NAME%
```

On UNIX or i5/OS:

```
ws_ant -Dwas.home=$WAS_HOME -Dear.path=$EAR_PATH -Dextract.dir=$EXTRACT_DIR
ws_ant jspc2 -Dwas.home=$WAS_HOME -Dapp.name=$APP_NAME -Dwebmodule.name=$MOD_NAME
ws_ant jspc3 -Dwas.home=$WAS_HOME -Dapp.name=$APP_NAME -Dwebmodule.name=$MOD_NAME -Ddir.name=$DIR_NAME
```

Example build.xml file using the JspC task

```
<project name="JSP Precompile" default="jspc1" basedir=".">
  <taskdef name="wsjspc" classname="com.ibm.websphere.ant.tasks.JspC"/>
  <target name="jspc1" description="example using a path to an EAR, and extracting the EAR to a directory">
    <wsjspc wasHome="${was.home}"
      earpath="${ear.path}"
      forcecompilation="true"
      extractToDir="${extract.dir}"
      useThreadTagPool="true"
      keepgenerated="true"
    />
  </target>
  <target name="jspc2" description="example using an enterprise app and webmodule">
    <wsjspc wasHome="${was.home}"
      enterpriseAppName="${app.name}"
      webmoduleName="${webmodule.name}"
      removeTempDir="true"
      forcecompilation="true"
      keepgenerated="true"
    />
  </target>
  <target name="jspc3" description="example using an enterprise app, webmodule and specific directory">
    <wsjspc wasHome="${was.home}"
      enterpriseAppName="${app.name}"
      webmoduleName="${webmodule.name}"
      fileName="${dir.name}"
      recurse="false"
      forcecompilation="true"
      keepgenerated="true"
    />
  </target>
</project>
```

Pre-touch tool for compiling and loading JSP files:

When enabled, the pre-touch mechanism causes all JavaServer Pages (JSP) files to be compiled within the web module for which they are configured. You can also configure some or all JSP files to be class loaded and JIT-compiled.

To enable the pre-touch mechanism, use Rational Application Developer to specify the following JSP attributes, which are Assembly Property Extensions for your web module:

- **prepareJSPs (Required)**

When this attribute is present, all JSP files are compiled at application server startup. This activity runs in a separate thread, allowing the application server to finish other startup actions in parallel. The numeric attribute value represents the minimum size in kilobytes that a JSP file must be in order to also be class loaded and JIT-compiled. The default is 0, which causes all JSP files to be class loaded and JIT-compiled.

Note: JSP file compilation is different from JIT compilation. JSP compilation generates bytecodes, whereas JIT translates the bytecodes into machine code at run time.

- **prepareJSPAttribute (Optional)**

The pre-touch mechanism compiles and JIT-compiles JSP files by directly invoking the JSP service method, thus making the JSP file susceptible to incurring exceptions because it is called out of context. Such exceptions are avoided by immediately checking the value of this attribute, causing a quick exit from the service method when the JSP was prepared by this tool. This attribute value is added as a request parameter and is composed of alphanumeric characters that your JSP files do not expect to use during normal initiation.

- **prepareJSPThreadCount (Optional)**

Set this numeric attribute to the number of threads that you would like this mechanism to start up to compile your JSP files. Since a thread makes use of just one processor, multi-processor systems may better utilize this pre-touch mechanism by specifying a value greater than 1. The default setting for this attribute is 1, representing the number of threads that are created to perform pre-touch processing for this web module.

- **prepareJSPClassload (Optional)**

Set this attribute to either a whole number or the word *changed*. By entering *changed*, only those JSP files that have been updated or not previously touched, for example, those JSP files that need to be converted from a .jsp file to a .java file, are class loaded. By entering a numerical value, for example, 1000, the pre-touch tool starts class loading at the 1000th JSP that it processes and all subsequent JSP files. This is convenient in the event that the application server is stopped when starting the pre-touch tool. You can then check the server logs to see how many JSP files have been processed and update the prepareJSPClassload value accordingly to avoid duplicating work. If a JSP file is not class loaded, it cannot be JIT compiled. As a result, if a JSP file does not satisfy the requirements of the prepareJSPClassload attribute, but satisfies the requirements of the prepareJSPs attribute, the JSP file is compiled if it has been updated, but is not class loaded or JIT compiled.

Batch compiler class path:

The batch compiler builds its class path as shown in the table below. When the batch compiler target is a web application archive (WAR) file and war.path is supplied, the configuration *additional.classpath* parameter is used to give extra class path information.

Table 123. Batch compiler. Batch compiler target.

Location added to class path	Batch compiler target		
	enterpriseapp.name	ear.path	war.path
WebSphere Application Server JAR files and classes	yes	yes	yes
JAR files listed in manifest class path for a web module	yes	yes	yes, when the target WAR is inside an EAR and <i>-extractToDir</i> is not used; otherwise, no.
Shared libraries	yes	no	no
Web module JAR files and classes	yes	yes	yes
<i>additional.classpath</i> parameter to batch compiler	no	no	yes

Global tag libraries (deprecated)

JavaServer Pages (JSP) tag libraries contain classes for common tasks such as processing forms and accessing databases from JSP files.

Tag libraries encapsulate, as simple tags, core functionality common to many web applications. The Java Standard Tag Library (JSTL) supports common programming tasks such as iteration and conditional processing, and provides tags for:

- manipulating XML documents
- supporting internationalization
- using Structured Query Language (SQL)

Tag libraries also introduce the concept of an expression language to simplify page development, and include a version of the JSP expression language.

A tag library has two parts - a Tag Library Descriptor (TLD) file and a Java archive (JAR) file.

tsx:dbconnect tag JavaServer Pages syntax (deprecated):

Use the `<tsx:dbconnect>` tag to specify information needed to make a connection to a database through Java DataBase Connectivity (JDBC) or Open Database Connectivity (ODBC) technology.

Support for `tsx` tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the `tsx` tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The `<tsx:dbconnect>` syntax does not establish the connection. Use the `<tsx:dbquery>` and `<tsx:dbmodify>` syntax instead to reference a `<tsx:dbconnect>` tag in the same JavaServer Pages (JSP) file to establish the connection.

When the JSP file compiles into a servlet, the Java processor adds the Java coding for the `<tsx:dbconnect>` syntax to the servlet `service()` method, which means a new database connection is created for each request for the JSP file.

This section describes the syntax of the `<tsx:dbconnect>` tag.

```
<tsx:dbconnect id="connection_id"
  userid="db_user" passwd="user_password"
  url="jdbc:subprotocol:database"
  driver="database_driver_name"
  jndiname="JNDI_context/logical_name">
</tsx:dbconnect>
```

where:

- **id**

Represents a required identifier. The scope is the JSP file. This identifier is referenced by the connection attribute of a `<tsx:dbquery>` tag.

- **userid**

Represents an optional attribute that specifies a valid user ID for the database that you want to access. Specify this attribute to add the attribute and its value to the request object.

Although the `userid` attribute is optional, you must provide the user ID. See `<tsx:userid>` and `<tsx:passwd>` for an alternative to hard coding this information in the JSP file.

- **passwd**

Represents an optional attribute that specifies the user password for the `userid` attribute. (This attribute is not optional if the `userid` attribute is specified.) If you specify this attribute, the attribute and its value are added to the request object.

Although the passwd attribute is optional, you must provide the password. See <tsx:userid> and <tsx:passwd> for an alternative to hard coding this attribute in the JSP file.

- **url and driver**

Represents a required attribute if you want to establish a database connection. You must provide the URL and driver.

The application server supports connection to JDBC databases and ODBC databases.

- For a JDBC database, the URL consists of the following colon-separated elements: jdbc, the subprotocol name, and the name of the database to access. An example for a connection to the Sample database included with IBM DB2 is:

```
url="jdbc:db2:sample"  
driver="com.ibm.db2.jdbc.app.DB2Driver"
```

- For an ODBC database, use the Sun JDBC-to-ODBC bridge driver included in their Java2 Software Developers Kit (SDK) or another vendor's ODBC driver.

The url attribute specifies the location of the database. The driver attribute specifies the name of the driver to use in establishing the database connection.

If the database is an ODBC database, you can use an ODBC driver or the Sun JDBC-to-ODBC bridge. If you want to use an ODBC driver, refer to the driver documentation for instructions on specifying the database location with the url attribute and the driver name.

If you use the bridge, the url syntax is jdbc:odbc:database. An example follows:

```
url="jdbc:odbc:autos"  
driver="sun.jdbc.odbc.JdbcOdbcDriver"
```

Note: To enable the application server to access the ODBC database, use the ODBC Data Source Administrator to add the ODBC data source to the System DSN configuration. To access the ODBC Administrator, click the ODBC icon on the Windows NT Control Panel.

- **jdbcname**

Represents an optional attribute that identifies a valid context in the application server Java Naming and Directory Interface (JNDI) naming context and the logical name of the data source in that context. The web administrator configures the context using an administrative client such as the WebSphere Administrative Console.

If you specify the jdbcname attribute, the JSP processor ignores the driver and url attributes on the <tsx:dbconnect> tag.

An empty element (such as <url></url>) is valid.

dbquery tag JavaServer Pages syntax (deprecated):

Use the <tsx:dbquery> tag to establish a connection to a database, submit database queries, and return the results set.

Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The <tsx:dbquery> tag does the following:

1. References a <tsx:dbconnect> tag in the same JavaServer Pages (JSP) file and uses the information the tag provides to determine the database URL and driver. You can also obtain the user ID and password from the <tsx:dbconnect> tag if those values are provided in the <tsx:dbconnect> tag.
2. Establishes a new connection
3. Retrieves and caches data in the results object.
4. Closes the connection and releases the connection resource.

This section describes the syntax of the <tsx:dbquery> tag.

```

<%-- SELECT commands and (optional) JSP syntax can be placed within the tsx:dbquery. --%>
<%-- Any other syntax, including HTML comments, are not valid. --%>
<tsx:dbquery id="query_id" connection="connection_id" limit="value" >
</tsx:dbquery>

```

where:

- **id**

Represents the identifier of this query. The scope is the JSP file. Use `id` to reference the query. For example, from the `<tsx:getProperty>` tag, use `id` to display the query results.

The `id` is a `tsx` reference to the bean and can be used to retrieve the bean from the page context. For example, if `id` is named `mySingleDBBean`, instead of using:

```
– if (mySingleDBBean.getValue("UISEAM",0).startsWith("N"))
```

use:

```
– com.ibm.ws.webcontainer.jsp.tsx.db.QueryResults bean =
  (com.ibm.ws.webcontainer.jsp.tsx.db.QueryResults)pageContext. findAttribute("mySingleDBBean"); if
  (bean.getValue("UISEAM",0).startsWith("N")). . .
```

The bean properties are dynamic and the property names are the names of the columns in the results set. If you want different column names, use the SQL keyword for specifying an alias on the `SELECT` command. In the following example, the database table contains columns named `FNAME` and `LNAME`, but the `SELECT` statement uses the `AS` keyword to map those column names to `FirstName` and `LastName` in the results set:

```
Select FNAME, LNAME AS FirstName, LastName from Employee where FNAME='Jim'
```

- **connection**

Represents the identifier of a `<tsx:dbconnect>` tag in this JSP file. The `<tsx:dbconnect>` tag provides the database URL, driver name, and optionally, the user ID and password for the connection.

- **limit**

Represents an optional attribute that constrains the maximum number of records returned by a query. If this attribute is not specified, no limit is used. In such a case, the effective limit is determined by the number of records and the system caching capability.

- **SELECT command and JSP syntax**

Represents the only valid SQL command, `SELECT`. The `<tsx:dbquery>` tag must return a results set.

Refer to your database documentation for information about the `SELECT` command. See other articles in this section for a description of JSP syntax for variable data and inline Java code.

dbmodify tag JavaServer Pages syntax (deprecated):

The `<tsx:dbmodify>` tag establishes a connection to a database and then adds records to a database table.

Support for `tsx` tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the `tsx` tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The `<tsx:dbmodify>` tag does the following:

1. References a `<tsx:dbconnect>` tag in the same JavaServer Pages (JSP) file and uses the information provided by that tag to determine the database URL and driver.

Note: You can also obtain the user ID and password from the `<tsx:dbconnect>` tag if those values are provided in the `<tsx:dbconnect>` tag.
2. Establishes a new connection.
3. Updates a table in the database.
4. Closes the connection and releases the connection resource.

This section describes the syntax of the `<tsx:dbmodify>` tag.

```

<%-- Any valid database update commands can be placed within the DBMODIFY tag. -->
<%-- Any other syntax, including HTML comments, are not valid. -->
<tsx:dbmodify connection="connection_id">
</tsx:dbmodify>

```

where:

- **connection**

Represents the identifier of a <tsx:dbconnect> tag in this JSP file. The <tsx:dbconnect> tag provides the database URL, driver name, and (optionally) the user ID and password for the connection.

- Database commands

Represents valid database commands. Refer to your database documentation for details

In the following example, a new employee record is added to a database. The values of the fields are based on user input from this JavaServer Pages (JSP) file and referenced in the database commands using the <tsx:getProperty> tag.

```

<tsx:dbmodify connection="conn" >
insert into EMPLOYEE
  (EMPNO, FIRSTNME, MIDINIT, LASTNAME, WORKDEPT, EDLEVEL)
values
  ('<tsx:getProperty name="request" property=request.getParameter("EMPNO") />',
  '<tsx:getProperty name="request" property=request.getParameter("FIRSTNME") />',
  '<tsx:getProperty name="request" property=request.getParameter("MIDINIT") />',
  '<tsx:getProperty name="request" property=request.getParameter("LASTNAME") />',
  '<tsx:getProperty name="request" property=request.getParameter("WORKDEPT") />',
  '<tsx:getProperty name="request" property=request.getParameter("EDLEVEL") />')
</tsx:dbmodify>

```

tsx:getProperty tag JavaServer Pages syntax and examples (deprecated):

The <tsx:getProperty> tag gets the value of a bean to display in a JavaServer Pages (JSP) file.

Note: Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

This IBM extension of the Sun JSP <jsp:getProperty> tag implements all of the <jsp:getProperty> function and adds the ability to introspect a database bean created using the IBM extension <tsx:dbquery> or <tsx:dbmodify>.

Note: You cannot assign the value from this tag to a variable. The value, generated as output from this tag, displays in the browser window.

This section describes the syntax of the <tsx:getProperty> tag:

```

<tsx:getProperty name="bean_name"
  property="property_name" />

```

where:

- **name**

Represents the name of the bean declared by the id attribute of a <tsx:dbquery> syntax within the JSP file. Refer to the <tsx:dbquery> article for an explanation. The value of this attribute is case-sensitive.

- **property**

Represents the property of the bean to access for substitution. The value of the attribute is case-sensitive and is the locale-independent name of the property.

Tag example:

```

<tsx:getProperty name="userProfile" property="username" />

```

tsx:userid and tsx:passwd tag JavaServer Pages syntax (deprecated):

With the `<tsx:userid>` and `<tsx:passwd>` tags, you do not have to hard code a user ID and password in the `<tsx:dbconnect>` tag.

Note: Support for `tsx` tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the `tsx` tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

Use the `<tsx:userid>` and `<tsx:passwd>` tags to accept user input for the values and then add that data to the request object. You can access the request object with a JavaServer Pages (JSP) file, such as the *JSPEmployee.jsp* example that requests the database connection.

You must use `<tsx:userid>` and `<tsx:passwd>` tags within a `<tsx:dbconnect>` tag.

This section describes the syntax of the `<tsx:userid>` and `<tsx:passwd>` tags.

```
<tsx:dbconnect id="connection_id"
  <font color="red"><userid></font>
  <tsx:getProperty name="request" property=request.getParameter("userid") />
  <font color="red"></userid></font>
  <font color="red"><passwd></font>
  <tsx:getProperty name="request" property=request.getParameter("passwd") />
  <font color="red"></passwd></font>
  url="protocol:database_name:database_table"
  driver="JDBC_driver_name">
</tsx:dbconnect>
```

where:

- **`<tsx:getProperty>`**
Represents the syntax as a mechanism for embedding variable data.
- **`userid`**
Represents a reference to the request parameter that contains the user ID. You must add the parameter to the request object that passes to this JSP file. You can set the attribute and its value in the request object, using an HTML form or a URL query string to pass the user-specified request parameters.
- **`passwd`**
Represents a reference to the request parameter that contains the password. Add the parameter to the request object that passes to this JSP file. You can set the attribute and its value in the request object, using an HTML form or a URL query string, to pass user-specified values.

tsx:repeat tag JavaServer Pages syntax (deprecated):

The `<tsx:repeat>` tag repeats a block of HTML tagging.

Support for `tsx` tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the `tsx` tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

Use the `<tsx:repeat>` syntax to iterate over a database query results set. The `<tsx:repeat>` syntax iterates from the start value to the end value until one of the following conditions is met:

- The end value is reached.
- An exception is thrown.

If an exception of the types **`ArrayIndexOutOfBoundsException`** or **`NoSuchElementException`** is created before a block completes, output is written only for the iterations up to and not including the iteration during which the exception was created. All other exceptions results in no output being written for that tag instance.

This section describes the syntax of the `<tsx:repeat>` tag:

```
<tsx:repeat index="name" start="starting_index" end="ending_index">
</tsx:repeat>
```

where:

- **index**

Represents an optional name used to identify the index of this repeat block. The scope of the index is NESTED. Its type must be integer.

- **start**

Represents an optional starting index value for this repeat block. The default is 0.

- **end**

Represents an optional ending index value for this repeat block. The maximum value is 2,147,483,647.

If the value of the end attribute is less than the value of the start attribute, the end attribute is ignored.

Combining `tsx:repeat` and `tsx:getProperty` JavaServer Pages tags (deprecated)

Support for `tsx` tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the `tsx` tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The following code snippet shows you how to code these tags:

```
<tsx:repeat>
<tr>
  <td><tsx:getProperty name="empqs" property="EMPNO" />
  <tsx:getProperty name="empqs" property="FIRSTNAME" />
  <tsx:getProperty name="empqs" property="WORKDEPT" />
  <tsx:getProperty name="empqs" property="EDLEVEL" />
</td>
</tr>
</tsx:repeat>
```

Example: Using `tsx:repeat` JavaServer Pages tag to iterate over a results set (deprecated):

The `<tsx:repeat>` tag iterates over a results set. The results set is contained within a bean. The bean can be a static bean, for example, a bean created by using the IBM WebSphere Studio database wizard, or a dynamically generated bean, for example, a bean generated by the `<tsx:dbquery>` syntax.

Note: Support for `tsx` tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the `tsx` tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The following table is a graphic representation of the contents of a bean called, *myBean*:

Table 124. Graphic representation of *myBean*.. *myBean* contents.

	col1	col2	col3
row0	friends	Romans	countrymen
row1	bacon	lettuce	tomato
row2	May	June	July

Some observations about the bean:

- The column names in the database table become the property names of the bean. The `<tsx:dbquery>` section describes a technique for mapping the column names to different property names.
- The bean properties are indexed. For example, `myBean.get(Col1(row2))` returns May.

- The query results are in the rows. The `<tsx:repeat>` tag iterates over the rows, beginning at the start row.

The following table compares using the `<tsx:repeat>` tag to iterate over a static bean, versus a dynamically generated bean:

Table 125. Static Bean and `<tsx:repeat>` Bean example. Use this table to compare the two beans.

Static Bean Example	<code><tsx:repeat></code> Bean Example
<p>myBean.class</p> <pre>// Code to get a connection // Code to get the data Select * from myTable; // Code to close the connection</pre> <p>JSP file</p> <pre><tsx:repeat index=abc> <tsx:getProperty name="myBean" property="coll(abc)" /> </tsx:repeat></pre> <p>Notes:</p> <ul style="list-style-type: none"> • The bean (myBean.class) is a static bean. • The method to access the bean properties is myBean.get(<i>property(index)</i>). • You can omit the property index, in which case the index of the enclosing <code><tsx:repeat></code> tag is used. You can also omit the index on the <code><tsx:repeat></code> tag. • The <code><tsx:repeat></code> tag iterates over the bean properties row by row, beginning with the start row. 	<p>JSP file</p> <pre><tsx:dbconnect id="conn" userid="alice"passwd="test" url="jdbc:db2:sample" driver="COM.ibm.db2.jdbc.app.DB2Driver"> </tsx:dbconnect > <tsx:dbquery id="dynamic" connection="conn" > Select * from myTable; </tsx:dbquery> <tsx:repeat index=abc> <tsx:getProperty name="dynamic" property="coll(abc)" /> </tsx:repeat></pre> <p>Notes:</p> <ul style="list-style-type: none"> • The bean (dynamic) is generated by the <code><tsx:dbquery></code> tag and does not exist until the syntax executes. • The method to access the bean properties is dynamic.getValue(<i>"property", index</i>). • You can omit the property index, in which case the index of the enclosing <code><tsx:repeat></code> tag is used. You can also omit the index on the <code><tsx:repeat></code> tag. • The <code><tsx:repeat></code> tag syntax iterates over the bean properties row by row, beginning with the start row.

Implicit and explicit indexing

Examples 1, 2, and 3 show how to use the `<tsx:repeat>` tag. The examples produce the same output if all indexed properties have 300 or fewer elements. If there are more than 300 elements, Examples 1 and 2 display all elements, while Example 3 shows only the first 300 elements.

Example 1 shows *implicit indexing* with the default start and default end index. The bean with the smallest number of indexed properties restricts the number of times the loop repeats.

```
<table>
<tsx:repeat>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="city" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="address" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="telephone" />
  </tr></td>
</tsx:repeat>
</table>
```

Example 2 shows indexing, starting index, and ending index:

```
<table>
<tsx:repeat index=myIndex start=0 end=2147483647>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=city(myIndex) />
  </tr></td>
```

```
|<td><tsx:getProperty name="serviceLocationsQuery" property=address(myIndex) />
</tr></td>
|<td><tsx:getProperty name="serviceLocationsQuery" property=telephone(myIndex) />
</tr></td>
</tsx:repeat>
</table>

|  |

|  |

```

Example 3 shows *explicit indexing* and ending index with implicit starting index. Although the index attribute is specified, you can still implicitly index the indexed property city because the (myIndex) tag is not required.

```

<table>
<tsx:repeat index=myIndex end=299>
|<td><tsx:getProperty name="serviceLocationsQuery" property="city" /t>
</tr></td>
|<td><tsx:getProperty name="serviceLocationsQuery" property="address(myIndex)" />
</tr></td>
|<td><tsx:getProperty name="serviceLocationsQuery" property="telephone(myIndex)" />
</tr></td>
</tsx:repeat>
</table>

|  |

|  |

|  |

```

Nesting <tsx:repeat> blocks

You can nest <tsx:repeat> blocks. Each block is separately indexed. This capability is useful for interleaving properties on two beans, or properties that have subproperties. In the example, two <tsx:repeat> blocks are nested to display the list of songs on each compact disc in the user's shopping cart.

```

<tsx:repeat index=cdindex>
<h1><tsx:getProperty name="shoppingCart" property=cds.title /></h1>
<table>
<tsx:repeat>
|<td><tsx:getProperty name="shoppingCart" property=cds(cdindex).playlist />
</td></tr>
</tsx:repeat>
</table>
</tsx:repeat>

|  |

```

Developing JSF files

Learn about JSF files.

JavaServer Faces

JavaServer Faces (JSF) is a user interface framework or application programming interface (API) that eases the development of Java-based web applications.

Note: WebSphere Application Server supports JavaServer Faces 2.0 at a runtime level.

The JSF runtime also:

- Makes it easy to construct a user interface from a set of reusable user interface components
- Simplifies migration of application data to and from the user interface
- Helps manage user interface state across server requests
- Provides a simple model for wiring client-generated events to server-side application code
- Supports custom user interface components to be easily build and reused

Both the Sun Reference Implementation and Apache MyFaces implementation are shipped with the product.

The Apache MyFaces JSF Implementation provides the foundation of the code used for the JSF support in WebSphere Application Server. The version of the JSF runtime provided by the Application Server resides

in the normal runtime library location and is available to all web applications that use JSF APIs. Loading the JSF servlet works in the same manner as if the run time was packaged with the web application. The bundled version includes enhancements for better integration with the built-in annotation scanning and other runtime components of WebSphere Application Server.

The specification-related classes (`javax.faces.*`) for JSF and the IBM modified version of the Apache MyFaces JSF Implementation and the JSF Sun reference implementation are packaged in the Application Server run time.

Typically, web applications that use this API/Framework embed the JSF API and implementation Java archive (JAR) files within their web application archive (WAR) file. This practice is not required when these web applications are deployed and run within WebSphere Application Server. Only the removal of these JAR files along with any JSTL JAR files from the WAR file is required. However, because JavaServer Faces 2.0 is a part of the Java Platform, Enterprise Edition (Java EE) platform, a web application does not need to bundle a JavaServer Faces implementation when it runs on a web container that is Java EE technology compliant. If a JavaServer Faces implementation is bundled with a web application, it is ignored as the JavaServer Faces implementation provided by the platform always takes precedence.

The JSF run time for WebSphere Application Server does not support the use of a single class loader for the entire application. This support is not available when the application contains multiple web modules and one of those modules is a JSF module. A single class loader for the entire application is not supported because the FacesConfig initialization requires a single class loader for each JSF module to perform the initialization. Therefore, you must use multiple class loaders when the application contains multiple web modules and at least one JSF module.

For using different implementations of JSF, the WebSphere Application Server JSF engine determines if the SUN RI or Apache MyFaces is used from the application server run time. After the JSF engine determines the implementation that is used, the correct listener class is registered with the web container. You do not need to add the `com.sun.faces.ConfigureListener` or the `org.apache.myfaces.StartupConfigureListener` to the `web.xml` file.

If you want to use a third party JSF implementation that is not shipped with the product, leave the configuration set to MyFaces, add the third party listener to the `web.xml` file that is required and add the third party implementation JAR files to the web module as an isolated shared library. Using an isolated shared library, the web application version of the JSF or JSTL classes load before the Application Server.

JavaServer Faces widget library (JWL)

JavaServer Faces widget library (JWL) is an IBM JSF-based web widget library that integrates widgets from a number of sources. The IBM JSF-based web widget library is deprecated, however, you can obtain the latest version from Rational Application Developer version 6 to work with JSF 1.2.

JWL includes the JSF components from Rational Application Developer except for the base JSF components, which are included in the Application Server run time. This includes the IBM extended JSF components and the extended FacesClient Component. JWL also extends JSF with client-side features for rich browser-based experiences in the form of the FacesClient Component.

Important: JWL is not supported in pages using the JSF 2.0 Facelets format.

JWL Java archive files

JWL is packaged into two Java archive (JAR) files, `odc-jsf.jar` and `jsf-ibm.jar`, which are located in the `${WAS_HOME}\optionalLibraries\IBM\jwl\2.0` directory.

To include JWL in your application, you can use the JWL shared library named `JWLLib`, which is created at installation time. To assign the library to an application, see the topic, [Using installed optional packages](#).

Configuring JavaServer Faces implementation

Use this task to specify which JavaServer Faces implementation to use. You can use Apache MyFaces 2.0 or the SUN Reference Implementation 1.2 of JSF, or your own implementation.

Before you begin

Ensure that your application is configured for JavaServer Faces (JSF) using the specific `web.xml` context parameters for the implementation that you have chosen.

Attention: The JSF implementation is a server-wide configuration setting. Thus, if you have multiple applications which require different JSF implementations, you must separate the applications into different application servers or clusters, and specify the implementation by following the steps in this topic for each application server or cluster. Alternatively, you can use an isolated shared library, as described for third-party JSF implementations, as follows.

About this task

Note: The Application Server JSF engine determines if the SUN Reference Implementation (RI) 1.2 or Apache MyFaces 2.0 is used from the Application Server run time. If either is used, the correct listener class is registered with the web container. You do not need to add the `com.sun.faces.ConfigureListener` or the `org.apache.myfaces.StartupConfigureListener` to your `web.xml` file.

Be Aware: If you want to use a third-party JSF implementation that is not shipped with the product, then:

- Keep the configuration set to MyFaces.
- Add the third-party listener to the `web.xml` file that is required.
- Add the third-party implementation Java archive (JAR) files to the application as an isolated shared library and associate it with your application.

You can also configure the JSF implementation on the Provide JSP reloading options for web modules panel for application installation and update wizards.

Procedure

Configure the server or cluster to use the JSF implementation that you want. You can do this task using the administrative console or the wsadmin tool.

- In the administrative console panel, click **Applications > Application Types > WebSphere enterprise applications > *application_name* > JSP and JSF options**

Select one of the following implementations:

- Sun Reference Implementation 1.2 - Select this option to use the Sun Reference Implementation 1.2 JSF implementation.
- MyFaces 2.0 - Select this option to use the MyFaces 2.0 JSF implementation. This option is the default JSF implementation.

- Using the wsadmin tool:

- An example of setting a single server to use the Sun RI 1.2 JSF implementation:

```
wsadmin>set server [$AdminConfig list ApplicationServer *server1*]
server1(cells/myNode01Cell/nodes/myNode01/servers/server1|server.xml#ApplicationServer_1183122130078)
wsadmin>$AdminConfig modify $server {{jsfProvider SunRi1.2}}
```

```
wsadmin>$AdminConfig save
```

- An example of setting a cluster to use the MyFaces 2.0 JSF implementation:

```
wsadmin>set cluster [$AdminConfig list ServerCluster]
cluster1(cells/myNode01Cell/nodes/myNode01/clusters/cluster1|cluster.xml#ServerCluster_1173916133721)
wsadmin>$AdminConfig modify $cluster {{jsfProvider MyFaces}}
```

```
wsadmin>$AdminConfig save
```

Results

Note: Your application server or cluster has now been configured with the JSF implementation you specified. Any application that uses JSF technology uses that implementation, unless it is associated with an isolated shared library that contains a different implementation.

What to do next

Configure JSF engine parameters as necessary.

Configuring JSF engine parameters: About this task

WebSphere Application Server does not support the modification of deployment descriptor extension parameters through the administrative console or through administrative scripting.

To add, change or delete JSF engine configuration parameters, complete the following steps:

Procedure

1. Open the WEB-INF/web.xml file.

JSF engine configuration parameters are stored in a web module's configuration directory or in a web module's binaries directory in the WEB-INF/web.xml file. Open the WEB-INF/web.xml file from:

- The configuration directory, as in the following example: *profile_root/config/cells/cellName/applications/enterpriseAppName/deployments/deployedName/webModuleName/WEB-INF/web.xml*
- The binaries directory if an application was deployed into WebSphere Application Server with the flag "Use Binary Configuration" set to true. An example of a binaries directory is: *profile_root/installedApps/nodeName/applicationName.ear/applicationName.war/WEB-INF/web.xml*

2. Edit the WEB-INF/web.xml file.

- To add configuration parameters, use the following format:

```
<context-param>
  <description>descriptive text</description>
  <param-name>parameter name</param-name>
  <param-value>parameter value</param-value>
</context-param>
```

- To delete configuration parameters, either delete the line from the file, or enclose the statement with `<!-- -->` tags.

3. Save the file.

4. Restart the Enterprise Application. It is not necessary to restart the server for parameter changes to take effect. However, some JSP engine configuration parameters affect the Java source code that is generated for a JSP. If such a parameter is changed, then you must retranslate the JSP files in the web module to regenerate Java source. You can use the batch compiler to retranslate all JSP files in a web module. The batch compiler uses the JSP engine configuration parameters that you have set in the web.xml file, unless you specifically override them. The JSP engine configuration topic identifies the parameters that affect the generated Java source.

Example

The following is a sample of the WEB-INF/web.xml file.

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns="http://java.sun.com/xml/ns/javaee" xmlns:web="http://java.sun.com/xml/ns/javaee/web-app_2_5.xsd"
  xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/web-app_2_5.xsd"
  id="WebApp_ID" version="2.5">
  <display-name>Servlet 2.5 example</display-name>
```

```

<welcome-file-list>
  <welcome-file>index.html</welcome-file>
  <welcome-file>index.htm</welcome-file>
  <welcome-file>index.jsp</welcome-file>
  <welcome-file>default.html</welcome-file>
  <welcome-file>default.htm</welcome-file>
  <welcome-file>default.jsp</welcome-file>
</welcome-file-list>
<context-param>
  <param-name>javax.faces.CONFIG_FILES</param-name>
  <param-value>/WEB-INF/faces-config.xml</param-value>
</context-param>
<context-param>
  <param-name>javax.faces.STATE_SAVING_METHOD</param-name>
  <param-value>server</param-value>
</context-param>
<context-param>
  <param-name>com.ibm.ws.jsf.LOAD_FACES_CONFIG_AT_STARTUP</param-name>
  <param-value>true</param-value>
</context-param>
<servlet>
  <servlet-name>Faces Servlet</servlet-name>
  <servlet-class>javax.faces.webapp.FacesServlet</servlet-class>
</servlet>
<servlet-mapping>
  <servlet-name>Faces Servlet</servlet-name>
  <url-pattern>/faces/*</url-pattern>
</servlet-mapping>
<servlet-mapping>
  <servlet-name>Faces Servlet</servlet-name>
  <url-pattern>*.faces</url-pattern>
</servlet-mapping>
</web-app>

```

JSF engine configuration parameters:

In WebSphere Application Server, you can configure the JavaServer Faces (JSF) engine configuration parameters for optimal performance in a production server environment and for the needs of developers in a development environment.

The JSF engine parameters are case-sensitive. If the value specified for a parameter is composed of two or more words separated by spaces, you must add quotation marks around the value.

JSF options using SUN RI

Table 126. JSF options using SUN RI. The table shows SUN RI parameter names, descriptions and default values.

SUN RI parameter name	Description	Default value
com.sun.faces.numberOfViewsInSession	Specifies the number of views that are stored in the session when Server-Side State Saving is used. If set to true while client-side state saving is being used, reduces the number of bytes sent to the client by compressing the state before it is encoded and written as a hidden field.	15
com.sun.faces.numberOfLogicalViews	Specifies the number of logical views that are stored in the session when Server-Side State Saving is used.	15
com.sun.faces.enableHighAvailability	If set to true while server-side state saving is used, a serialized representation of the view is stored on the server. This provides failover and server clustering support.	false
com.sun.faces.injectionProvider	Defines an injection provider that is used for JSF annotations.	
com.sun.faces.serializationProvider	Defines a serialization provider that is used for serializing JSF objects into session.	
com.sun.faces.responseBufferSize	Define the size of the response buffer for a JSF response.	1048
com.sun.faces.clientStateWriteBufferSize		8192
com.sun.faces.expressionFactory	Specifies the default EL Expression Factory to use.	org.apache.el.ExpressionFactoryImpl
com.sun.faces.clientStateTimeout	The timeout value used for client side state saving. When the value set has been reached then the state is lost.	infinite
com.sun.faces.displayConfiguration		false

Table 126. JSF options using SUN RI (continued). The table shows SUN RI parameter names, descriptions and default values.

SUN RI parameter name	Description	Default value
com.sun.faces.validateXml	When set to true, tag library XML files and faces configuration XML files using schema are validated during application start.	false
com.sun.faces.verifyObjects		false
com.sun.faces.forceLoadConfiguration		false
com.sun.faces.disableVersionTracking		false
com.sun.faces.enableHtmTagLibValidator		false
com.sun.faces.preref XHTML		false
com.sun.faces.compressViewState		true
com.sun.faces.compressJavaScript		true
com.sun.faces.sendPoweredByHeader		true
com.sun.faces.enableJSStyleHiding		false
com.sun.faces.writeStateAtFormEnd		true
com.sun.faces.enableLazyBeanValidation		true
com.sun.faces.enableLoadBundle11Compatibility		false
com.sun.faces.enableRestoreView11Compatibility		false
com.sun.face.serializeServerState		false
com.ibm.ws.jsf.JSP_UPDATE_CHECK	This parameter monitors Faces JavaServer Pages (JSP) files for modifications and synchronizes a running server with the changes without restarting the server. If this parameter is set to false or removed from the deployment descriptor, any changes made to Faces JSP files might not be seen by the server until it is restarted. Set this parameter to true while developing and debugging the Faces JSP files to improve the performance of the development environment.	
com.ibm.ws.jsf.JSF_IMPL_CHECK	Set the com.ibm.ws.jsf.JSF_IMPL_CHECK parameter to true to check at application restart if the SUN RI and MyFaces implementations were switched. If the implementation has switched, then the runtime removes any generated JSP files from the temp directory and the JSP file is retranslated the next time it is requested.	
com.ibm.ws.jsf.associateLabelWithId	<p>The com.ibm.ws.jsf.associateLabelWithId custom property changes the rendering behavior for both the <h:selectOneRadio> and <h:selectManyCheckbox> components. The label no longer wraps the input element. Instead, each input element has a unique ID and the label is associated with that ID used for that attribute. Define and set the com.ibm.ws.jsf.associateLabelWithId context parameter to true in the web.xml file.</p> <p>Use the following code as an example.</p> <pre><context-param> <description> Set to true to explicitly associate labels with their input elements for select one radio buttons and select many check box lists. </description> <param-name>com.ibm.ws.jsf.associateLabelWithId </param-name> <param-value>true</param-value> </context-param></pre>	

Table 126. JSF options using SUN RI (continued). The table shows SUN RI parameter names, descriptions and default values.

SUN RI parameter name	Description	Default value
com.ibm.ws.jsf.disableEnqueuedMessagesWarning	<p>The com.ibm.ws.jsf.disableEnqueuedMessagesWarning custom property disables the FacesMessage(s) have been enqueued, but may not have been displayed warning message. When this property is set to true in the web.xml file, this warning message is not included in the SystemOut.log file .</p> <p>gotcha: This context parameter only applies to JSF applications that use the Sun Reference Implementation (RI) for JSF implementation.</p> <p>Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using SystemOut.log , SystemErr.log, trace.log, and activity.log files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.</p> <p>Use the following code as an example of how to define and set the com.ibm.ws.jsf.disableEnqueuedMessagesWarning context parameter to true in the web.xml file.</p> <pre><context-param> <description> Set to true to disable the following warning message: FacesMessage(s) have been enqueued, but might not have been displayed </description> <param-name> com.ibm.ws.jsf.disableEnqueuedMessagesWarning </param-name> <param-value>true</param-value> </context-param></pre>	
com.ibm.ws.jsf.disableStylePassthroughForCheckboxList	<p>This custom property prevents passing the style information into the items in the check box list. This property defaults to false to maintain the current behavior. Define and set the com.ibm.ws.jsf.disableStylePassthroughForCheckboxList context parameter to true in the web.xml file prevent passing style information into items in the check box list. Use the following code as an example.</p> <pre><context-param> <description> Set to true if style information should not be passed into items of check box list </description> <param-name> com.ibm.ws.jsf.disableStylePassthroughForCheckboxList </param-name> <param-value>true</param-value> </context-param></pre>	
com.ibm.ws.jsf.DISABLE_UIDATA_NESTED_CHECK	<p>The com.ibm.ws.jsf.DISABLE_UIDATA_NESTED_CHECK custom property determines whether unique IDs are generated for UIData components that are nested inside iterator components that are not UIData components. When this property is set to true in the web.xml file, unique IDs are generated for UIData components even if they are nested inside iterator components that are not UIData components.</p> <p>When this property is set to false, if a JSF dataTable component is nested within a component that does not extend UIData, such as the Java Widget Library (JWL) dataIterator component, the IDs that are generated for the rows do not increment properly. This situation can result in duplicate IDs being assigned to multiple JSF components.</p> <p>Use the following code as an example of how to define and set the com.ibm.ws.jsf.DISABLE_UIDATA_NESTED_CHECK context parameter to true in the web.xml file.</p> <pre><context-param> <description> Set to true to enable unique IDs to be generated for UIData components even if they are nested inside iterator components that are not UIData components. </description> <param-name> com.ibm.ws.jsf.DISABLE_UIDATA_NESTED_CHECK </param-name> <param-value>true</param-value> </context-param></pre>	

Table 126. JSF options using SUN RI (continued). The table shows SUN RI parameter names, descriptions and default values.

SUN RI parameter name	Description	Default value
com.ibm.ws.jsf.loadExternalDtd	<p>When parsing the faces-config.xml file from included libraries, the Faces configuration parser attempts to load the DTD even when validation is disabled. The Faces configuration parser uses a SAXParser to read the faces-config.xml. The default behavior of the SAXParser parser is to always load the DTD even if validation is disabled. This behavior can lead to errors initializing the Faces Servlet on systems isolated from the internet.</p> <p>In your web.xml file, set the com.ibm.ws.jsf.loadExternalDtd context parameter to false to have the Faces configuration parser set the "http://apache.org/xml/features/nonvalidating/load-external-dtd" feature to false.</p> <pre><context-param> <description> When set to false, this property sets a feature on the SAX parser to prevent loading the external DTD. </description> <param-name>com.ibm.ws.jsf.loadExternalDtd</param-name> <param-value>>false</param-value> </context-param></pre>	
enableRestoreView11Compatibility	<p>A JSF 1.2 application might create the ViewExpiredException exception under load when using the Sun Reference Implementation. If your view is not found in session, you can use a compatibility mode in JSF to create a new view. This can have adverse behaviors because it is a new view and items that are usually in the view, such as state, will no longer be available. Use the following code as an example to set the com.sun.faces.enableRestoreView11Compatibility context parameter to true in the web.xml file. This is only applicable when the Sun Reference Implementation is in use.</p> <pre><context-param> <param-name> com.sun.faces.enableRestoreView11Compatibility </param-name> <param-value>>true</param-value> </context-param></pre>	
enableViewStateIdRendering	<p>The com.sun.faces.enableViewStateIdRendering custom property controls the rendering of the id attribute of the javax.faces.ViewState hidden field. Use the following code as an example to set the com.sun.faces.enableViewStateIdRendering context parameter to true in the web.xml file.</p> <pre><context-param> <param-name>com.sun.faces.enableViewStateIdRendering </param-name> <param-value>>true</param-value> </context-param></pre>	

JSF options for MyFaces

Table 127. JSF options for MyFaces. The table shows JSF parameter names, descriptions and default values.

JSF parameter name	Description	Default value
org.apache.myfaces.RESOURCE_VIRTUAL_PATH		/faces/myFacesExtensionResource
org.apache.myfaces.PRETTY_HTML	If this value is true, rendered HTML code is formatted so that it is human-readable. Additional line separators and white space are written that do not influence the HTML code.	true
org.apache.myfaces.ALLOW_JAVASCRIPT	This parameter tells MyFaces if javascript code is allowed in the rendered HTML output. If javascript is allowed, command_link anchors have javascript code that submits the corresponding form. If javascript is not allowed, the state saving information and nested parameters are added as URL parameters.	true
org.apache.myfaces.DETECT_JAVASCRIPT		false
org.apache.myfaces.AUTO_SCROLL	If true, a javascript function is rendered that can restore the former vertical scroll on every request. This feature is convenient if you have pages with long lists and you do not want the browser page to jump to the top of the page if you trigger a link or button action that stays on the same page.	false
org.apache.myfaces.ADD_RESOURCE_CLASS		org.apache.myfaces.renderkit.html.util.DefaultAddResource
org.apache.myfaces.CHECK_EXTENSIONS_FILTER	This parameter checks for a properly-configured Extensions-Filter if it is needed by the web application.	true
org.apache.myfaces.READONLY_AS_DISABLED_FOR_SELECTS		true

Table 127. JSF options for MyFaces (continued). The table shows JSF parameter names, descriptions and default values.

JSF parameter name	Description	Default value
org.apache.myfaces.SERIALIZE_STATE_IN_SESSION	Set this option to true to serialize the state to a byte stream before it is written to the session. If this option is set to false, the state is not serialized to a byte stream. This option is only applicable if the state saving method is set to server.	true
org.apache.myfaces.COMPRESS_STATE_IN_SESSION	Set this option to true to compress the serialized state before it is written to the session. If this option is set to false, the state is not compressed. This option is only applicable if the state saving method is set to server and if org.apache.myfaces.SERIALIZE_STATE_IN_SESSION is set to true.	true
org.apache.myfaces.NUMBER_OF_VIEWS_IN_SESSION	Defines the number of the latest views that are stored in session. This option is only applicable if the state saving method is set to server.	20
com.ibm.ws.jsf.disablealternatefacesconfigsearch	Disables MyFaces searching for META-INF/*.faces-config.xml for only the web application that this context parameter is set on. If the context parameter and the web container custom property are set, the context parameter takes precedence.	false

JSF options using SUN RI or MyFaces

The following options are valid for both the SUN RI and the MyFaces implementations.

Table 128. JSF options using SUN RI or MyFaces. The table shows JSF parameter names, descriptions and default values.

JSF parameter name	Description	Default value
javax.faces.STATE_SAVING_METHOD	Specifies the location where state information is saved. Valid values are 'server', which is saved in HttpSession, and 'client', which is saved as a hidden field in the form.	server
javax.faces.CONFIG_FILES	Use this parameter to specify a comma-delimited list of context-relative resource paths under which the JSF implementation looks for application configuration resources before loading a configuration resource named /WEB-INF/facesconfig.xml, if a resource exists.	n/a
javax.faces.DEFAULT_SUFFIX	Specifies the default suffix for extension-mapped resources that contain JSF components.	.jsp
javax.faces.LIFECYCLE_ID	Use this parameter to configure an alternate life cycle ID.	n/a
com.ibm.ws.jsf.JSF_IMPL_CHECK	Specifies that the JSP files in a web module must be recompiled when the application is restarted because the implementation of JSF that is used has changed. After the application is restarted, the next time a JSP file is accessed for this module the JSP file is recompiled against the selected implementation of JSF specified in the administration console. Subsequent calls to the JSP file do not recompile. The default setting for this option is false. Use this option for development and not in a production environment.	n/a

Sun RI context parameters that have an equivalent behavior in MyFaces

Table 129. Sun RI context parameters and equivalent MyFaces behavior. The table shows SUN RI parameters names and MyFaces equivalent.

SUN RI parameter name	Description	RI default	MyFaces equivalent	MyFaces default
com.sun.faces.numberOfViewsInSession	Defines the maximum number of serialized views stored in the session. Works with server state saving.	15	org.apache.myfaces.NUMBER_OF_VIEWS_IN_SESSION	20

Table 129. Sun RI context parameters and equivalent MyFaces behavior (continued). The table shows SUN RI parameters names and MyFaces equivalent.

SUN RI parameter name	Description	RI default	MyFaces equivalent	MyFaces default
com.sun.faces.compressViewState	When true the view is compressed after it is serialized and before base64 encoded. Works with client state saving. As of 1.2_09, this option also affects server-side state saving when com.sun.faces.serializeServerState is set to true (this has a large impact of the size of the state in the session when using this option, at the expense of more CPU.)	true	org.apache.myfaces.COMPRESS_STATE_IN_CLIENT for client-side state saving or org.apache.myfaces.COMPRESS_STATE_IN_SESSION for server-side state saving	false for client-side state saving, true for server-side state saving
com.sun.faces.validateXml	When true JSF validates the configuration files.	false	org.apache.myfaces.VALIDATE	false
com.sun.faces.injectionProvider	This parameter specifies a class that implements the InjectionProvider.	n/a	injection provider is provided by the WebSphere Application Server run time	n/a
com.sun.faces.serializationProvider	This parameter specifies a class that implements the SerializationProvider SPI. This implementation represents a hook the JSF implementation uses to enable using alternate Serialization implementations.	n/a	org.apache.myfaces.SERIAL_FACTORY - class must implement org.apache.myfaces.shared_impl.util.serial.SerialFactory SPI instead of com.sun.faces.spi.SerializationProvider	n/a
com.sun.faces.enabledJSStyleHiding	If true, inline JavaScript rendered by the HTML ResponseWriter implementation is rendered so that the script is hidden from older browser implementations.	false	org.apache.myfaces.WRAP_SCRIPT_CONTENT_WITH_XML_COMMENT_TAG	true
com.sun.faces.serializeServerState	If enabled the component state (not the tree) is serialized before being stored in the session. This might be desirable for applications that have issues with view state being sensitive to model changes.	false	org.apache.myfaces.SERIALIZE_STATE_IN_SESSION	true

Defining an extension for the registry filter

The registry filter specifies if an extensions is applicable to all registry instances or to specified instances.

Before you begin

You must have an extensible application to define an extension for the registry filter.

About this task

Complete the following steps to filter out extensions for an application.

Procedure

1. Define an extension for the registry filter extension point for a named registry instance in the plugin.xml file.

```
<extension point="org.eclipse.extensionregistry.RegistryFilter">
  <filter name="AdminConsole*"
    class="com.ibm.ws.admin.AdminConsoleExtensionFilter"/>
</extension>
```

2. Add the filter implementation to the application by creating a class to implement the com.ibm.workplace.extension.IExtensionRegistryFilter interface.

```
package com.ibm.ws.admin;
import com.ibm.workplace.extension.IExtensionRegistryFilter;
public class AdminConsoleExtensionFilter implements IExtensionRegistryFilter {
    :
}
```

3. The extensible application declares the registry name by defining an extension for the RegistryInstance extension point. This way, the registry can prepare an IExtensionRegistry instance and put it in JNDI in advance.

```
<extension point="org.eclipse.extensionregistry.RegistryInstance">
  <registry name="AdminConsole"/>
</extension>
```

4. The extensible application obtains a named instance of the registry to activate any associated filters:

```
InitialContext ic = new InitialContext();
String lookupName = "services/extensionregistry/AdminConsole";
IExtensionRegistry reg = (IExtensionRegistry)ic.lookup( lookupName );
```

Application extension registry

WebSphere Application Server has enabled the Eclipse extension framework for applications to use. Applications are extensible when they contain a defined extension point and provide the extension processing code for the extensible area of the application.

An application can be plugged in to another extensible application by defining an extension that adheres to what the target extension point requires. The extension point can find the newly added extension dynamically and the new function is seamlessly integrated in the existing application. It works on a cross Java Platform, Enterprise Edition (Java EE) module basis. The application extension registry uses the Eclipse plug-in descriptor format and application programming interfaces (APIs) as the standard extensibility mechanism for WebSphere applications. Developers that build WebSphere application modules can use WebSphere Application Server extensions to implement their functionality to an extensible application, which defines an extension point. This is done through the application extension registry mechanism.

The architecture of extensible Java EE applications follow a modular design to add new functional modules or to replace an existing module, particularly by those outside of its core development team. Each module is a pluggable unit, or plug-in that is either deployed into the portal or removed from the Java EE application using a deployment tool that is based upon standard Java EE and portal web module deployment tooling. A plug-in module describes where it is extensible and what capability it provides to other plug-ins in the `plugin.xml` file. The `plugin.xml` manifest file can be created with a simple text editor or in Eclipse's Plug-in Development Environment (PDE), which provides a simplified view of the same underlying XML data.

WebSphere Application Server implementations to the Eclipse model

Some minor differences exist in the WebSphere Application Server implementation of this architecture because of platforms, specifically, Eclipse Workbench or Java 2 Platform, Enterprise Edition (Java EE). The highlights of the WebSphere Application Server implementation include:

- Implementing all of the extension registry-related interfaces from Eclipse 3.1.
- The identical `plugin.xml` syntax, however, some attributes are not used, for example, `<runtime>`.
- The discovery and addition of plug-ins to the registry, when the containing Java EE module starts, and plug-ins are dismissed and removed from the registry when the containing Java EE module stops.
- Access to an `IExtensionRegistry` object is through the Java Naming and Directory Interface (JNDI), instead of by using the `Platform.getExtensionRegistry` method in the Eclipse Workbench.
- Filtering capability is available by providing a filter implementation and using a named registry instance that finds and invokes the filter as necessary. See the developer API documentation for the `IExtensionRegistryFilter` interface for more details.

Available Eclipse 3.1 interfaces

The following Eclipse 3.1 interfaces are available on WebSphere Application Server:

- Extension registry API

- Extension point API
- Extension API
- Configuration element API
- Registry change listener API
- Registry change event API
- Extension delta API
- Status API

The following interfaces are recognized and processed the same as in Eclipse:

- Executable extension API
- Executable extension factory API

Application extension registry filtering

The extension registry exposes the registry filter extension point. The registry filter removes elements within the extension registry for client applications. Extensions that are attached to the registry filter extension point and that also implement this interface are called as necessary when a client operates on a named registry instance that matches the target specification.

You can create a filter extension for all registry instances or for named instances that are specified by the extension. In the first case, the filter is applied to all instances of the extension registry, and all client applications use the filter without requesting the filter. In the latter case, a client application must predefine the registry name by defining an extension, called *RegistryInstance*, which is another extension point that is exposed by the extension registry. After the registry name is defined, the client can obtain the named registry instance and use that registry instance. The filter extension is invoked by the named registry instance as necessary.

Registry filter API

Supported arguments include:

```
org.eclipse.core.runtime.IExtension[]
doFilter(org.eclipse.core.runtime.IExtension[] extensions)
```

This code returns an array of IExtension objects that are included in the valid extension list.

Registry instance extension point

The extension registry exposes the *RegistryInstance*. The instance name is declared in the application's `plugin.xml` file, and the application requests an registry instance for that name at runtime.

plugin.xml file

A plug-in is described in an XML manifest file, called `plugin.xml`, which is part of the plug-in deployment files. The manifest file tells the portal application's runtime what it needs to know to register and activate the plug-in. The manifest file essentially serves as the contract between the pluggable component and the portal application's runtime. Although the WebSphere Application Server `plugin.xml` closely follows the one provided for the Eclipse workbench, it does diverge from the Eclipse workbench in several places as outlined below.

Location

The `plugin.xml` file must reside in the `WEB-INF` directory under the context of the hierarchy of directories that exist for a web application or when included in the Web application archive file.. The `plugin.xml` file must reside in the root directory when the `plugin.xml` file is placed in an Enterprise JavaBeans Java archive (JAR) file or shared library JAR file. The extension registry service includes the `plugin.xml` file as the participating components are loaded and started on the application server.

Usage notes

- Is this file read-only?

No

- Is this file updated by a product component?

???

- If so, what triggers its update?

Rational Application Developer updates the `web.xml` file when you assemble web components into a web module, or when you modify the properties of the web components or the web module.

- How and when are the contents of this file used?

WebSphere Application Server functions use information in this file during the configuration and deployment phases of web application development.

- The manifest markup definitions below make use of various naming tokens and identifiers. To eliminate ambiguity, the following are productions rules for these naming conventions. In general, all identifiers are case-sensitive.

SimpleToken := sequence of characters from ('a-z','A-Z','0-9')

ComposedToken := SimpleToken | (SimpleToken '.' ComposedToken)

PlugInId := ComposedToken

PlugInPrereq := PlugInId

ExtensionId := SimpleToken

ExtensionPointId := SimpleToken

ExtensionPointReference := ExtensionPointId | (PlugInId '.' ExtensionPointId)

Sample file entry

The entire plug-in manifest DTD is as follows. XML Schema is not used to define the manifest since the current Eclipse tooling for plug-in's requires a DTD. The XML DTD construction rule `element*` means zero or more occurrences of the element; `element?` means zero or one occurrence of the element; and `element+` means one or more occurrences of the element.

```
<?xml encoding="US-ASCII"?>

<!ELEMENT plugin (requires?, extension-point*, extension*)>
<!ATTLIST plugin
  name CDATA #IMPLIED
  id CDATA #REQUIRED
  version CDATA #REQUIRED
  provider-name CDATA #IMPLIED
>
<!ELEMENT requires (import+)>
<!ELEMENT import EMPTY>
<!ATTLIST import
  plugin CDATA #REQUIRED
  version CDATA #IMPLIED
  match (exact | compatible | greaterOrEqual) #IMPLIED
>
<!ELEMENT extension-point EMPTY>
<!ATTLIST extension-point
  name CDATA #IMPLIED
  id CDATA #REQUIRED
  schema CDATA #IMPLIED
>
<!ELEMENT extension ANY>
<!ATTLIST extension
  point CDATA #REQUIRED
  id CDATA #IMPLIED
  name CDATA #IMPLIED
>
```

WebSphere Application Server differences

The `plugin.xml` file closely follows the `plugin.xml` file provided for the Eclipse workbench. However it diverges within the following elements.

The `plugin` element

The `plugin` element provided in this manifest does not contain class attributes. The class attribute is unnecessary since the plug-in mechanism does not require the plug-in developer to extend or use any specific classes as is required by the Eclipse workbench. Also, the `plugin` element does not contain a runtime element since standards such as J2EE that already define the location of runtime libraries for the applications.

The `import` element

The `requires` element does not contain export attribute since J2EE modules are encouraged to be self-contained to improve manageability. In addition to eliminating the export attribute, the `match` attribute has an option for a greater than or equal to match for versions (`greaterOrEqual`).

The `extension-point` element

The `extension-point` element has the `name` attribute as optional since it has no real use in this J2EE implementation.

you can find details regarding the plug-in manifest in the Eclipse documentation, under Platform Plug-In Developer Guide>Other reference information>Plug-in manifest.

The following is an example of how adding a link to an existing page can be accomplished by an extension point. The plug-in manifest of this plug-in declares an extension point (`linkExtensionPoint`) and an extension to this extension point (`linkExtension`). The plug-in declaring the extension point does not need to be the plug-in that implements the extension point. Another plug-in can also define an extension to the link extension point in its plug-in manifest by including the contents of the `<extension>` and `</extension>` tags in its manifest.

```
<?xml version="1.0"?>
<!--the plugin id is derived from the vendor domain name -->
<plugin
  id="com.ibm.ws.console.core"
  version="1.0.0"
  provider-name="IBM WebSphere">

  <!--declaration of prerequisite plugins-->
  <requires>
    <import plugin="com.ibm.data" version="2.0.1" match="compatible"/>
    <import plugin="com.ibm.resources" version="3.0" match="exact"/>
  </requires>

  <!--declaration of link extension point -->
  <extension-point
    id="linkExtensionPoint"
    schema="/schemas/linkSchema.xsd"/>

  <!--declaration of an extension to the link extension point -->
  <extension
    point="com.ibm.ws.console.core.linkExtensionPoint"
    id="linkExtension">

    <link
      label="Example.displayName"
      actionView="com.ibm.ws.console.servermanagement.forwardCmd.do?
        forwardName=example.config.view&
        lastPage=ApplicationServer.config.view">
    </link>
  </extension>
</plugin>
```

Contexts and Dependency Injection (CDI)

Learn about Contexts and Dependency Injection (CDI).

Developing applications that use Contexts and Dependency Injection (CDI)

Use this task to provide a summary of the WebSphere Application Server extensions that you can use to develop servlets.

About this task

Several WebSphere Application Server extensions are provided for enhancing your servlets. This task provides a summary of the extensions that you can use.

Procedure

1. Review the supported specifications.
Create Java™ components, referring to the CDI specifications from Sun Microsystems. Place a beans.xml file in the WEB-INF directory of the WAR module, or META-INF directory of a JAR file, so the container identifies it as a bean deployment archive.
2. Use your favorite integrated development environment (IDE), or a text editor, to develop or migrate code artifacts that meet the specifications.
3. Test the code artifacts.

What to do next

Assemble your code artifacts into a web module using assembly tools as a prerequisite to deploying the code to the application server.

Contexts and Dependency Injection (CDI)

Contexts and Dependency Injection for the Java EE platform (CDI) is a JSR 299 implementation that is based on Apache OpenWebBeans.

CDI is activated in an application by the presence of a beans.xml file inside that module, as defined by the JSR 299 specification. You can find the beans.xml file in the WEB-INF directory of a web archive (WAR) or META-INF directory of other types of archives. When activated, the container provides services such as:

- Context management
- Type-safe dependency injection: A CDI-managed bean is instantiated and injected as needed.
- Decorators, which implement one or more bean interfaces and can contain business logic. Decorators are disabled by default. You can have multiple decorators per bean and order is defined by the beans.xml file.
- Interceptor bindings. Interceptors, which are enabled manually in the beans.xml file, are bound using an interceptor binding type.
- Event model
- Integration into JavaServer Faces (JSF) and JavaServer Pages (JSP) files using the Expression Language (EL)

The specification-related API classes for JSR 299 and JSR 330 and IBM modified implementation classes that are based on Apache OpenWebBeans are packaged with the application server runtime environment.

Although the WebSphere Application Server CDI implementation is based on Apache OpenWebBeans, there are some changes and additions on top of OpenWebBeans to support integration with the server runtime:

- Integration with other Java Platform, Enterprise Edition (Java EE) containers in WebSphere Application Server that support injectable components.
- ScannerService implementation that uses the WebSphere Application Server byte code scanner.

- Direct use of WebSphere Application Server Enterprise JavaBeans (EJB) metadata for determining EJB types.
- Automatic registration of Servlet Listeners, Filters, Interceptors for CDI applications so these no longer must be added by each application.
- WebSphere Application Server-specific implementations of many OpenWebBeans Service Programming Interfaces (SPI), such as ResourceInjectionService, TransactionService, failover service, and so on.

Important: Container-managed transactions and security are not provided by CDI.

Contexts and Dependency Injection custom properties:

WebSphere Application Server Contexts and Dependency Injection (CDI) implementation is based on OpenWebBeans, which is configurable through the openwebbeans.properties file.

To specify CDI custom properties, place the openwebbeans.properties file inside the META-INF/openwebbeans directory of your application. Properties that are not listed below, such as those that control the lifecycle and services, should remain at the default value for the application server. See the following list of some of the available CDI custom properties:

org.apache.webbeans.conversation.Conversation.periodicDelay:

Specifies a delay in milliseconds. Use the conversation periodic delay custom property to search for and delete unused conversations.

Value	Default
integer	15000

org.apache.webbeans.application.jsp:

Specifies that an application is a full JavaServer Pages (JSP) application. Specify true if you want to add the JSP ELResolver class to the application.

Value	Default
true	true

org.apache.webbeans.useOwbSpecificXmlConfig:

Specify true if you want to use OpenWebBeans-specific beans.xml files for the application. The default value is false, which is the portable specification beans.xml format.

Value	Default
true	false

org.apache.webbeans.fieldInjection.useOwbSpecificInjection:

Specify true if you want to use OpenWebBeans-specific injection for the application. The default value is false, which is the portable specification behavior.

Value	Default
true	false

org.apache.webbeans.application.useJSF2Extensions:

Specify true to enable JavaServerFaces (JSF) 2.0-based CDI extensions.

Value	Default
true	false

org.apache.webbeans.application.supportsConversation:

Specify true to support conversation scopes in the application.

Value	Default
true	true

CDI integration with JavaServer Faces:

Contexts and Dependency Injection (CDI) primarily integrates with JavaServer Faces (JSF) through the Expression Language (EL). It enables CDI beans to be exposed through the unified EL-to-JSF components. It also provides a built-in context for conversation scope that is active during standard JSF life cycle phases.

As part of the WebSphere Application Server integration with CDI containers, several JSF components are automatically registered for CDI applications, including:

- EL Resolver
- Phase Listener
- View Handler
- Application Factory

Only the default JSF implementation (based on MyFaces) is supported for use with CDI.

Contexts and Dependency Injection (CDI) integration with EJB container:

The CDI specification enhances the EJB component model with contextual life cycle management.

Relationship of the CDI to the EJB specification

Note: The EJB specification defines a programming model for application components that access transactional resources in a multi-user environment. Concerns, such as role-based security, transaction demarcation, concurrency, and scalability are specified declaratively using annotations and XML deployment descriptors that are enforced by the EJB container at run time. EJB components might be stateful, but are not by nature, contextual.

The following session bean instances are obtained using dependency injection:

- Contextual
- Bound to a life cycle context
- Available to other instances that launch in that context
- Container creates an instance when needed
- Container destroys an instance when context ends

The WebSphere Application Server CDI container performs dependency injection on all session and message-driven bean instances, even instances that are not contextual instances. WebSphere Application Server CDI supports injection of CDI beans inside enterprise beans and vice versa.

Usage

Note: Use the following best practices when injecting enterprise beans:

- Use the `@Inject` method for contextual injection of local session beans.
- Use the `@EJB` method for remote session beans

See the following examples of using the `@EJB` method in CDI:

Define producers making the EJB available for non-contextual injection:

```
@Produces @EJB PaymentService paymentService;
```

Consume the injected types in other CDI beans:

```
@Inject PaymentService myPaymentService
```

Practical considerations

You can define CDI-style interceptors with interceptor bindings and decorators enterprise beans. Interceptors are declared using `@Interceptors` methods or in `ejb-jar.xml` files, which are called before interceptors and are declared using interceptor bindings. Interceptors are called before decorators.

WebSphere Application Server supports failover (activation and passivation) of CDI beans and enterprise beans, along with their interceptors and decorators. EJB failover support with CDI only works for stateful session beans and requires the same configuration as stateful session bean failover. See the stateful session bean failover for the EJB container topic for more information. Configure EJB failover with web HTTP session failover. See the "Configuring for database session persistence" and the "Configuring memory-to-memory replication for the peer-to-peer mode (default memory-to-memory replication)" topics for more information. Except for abstract decorators, failover services are based on current WebSphere Application Server failover providers. Web session failover and EJB stateful session bean failover and configured separately.

When a contextual (`@Injected`) instance of an EJB container is destroyed as a result of going out of scope, and if the underlying EJB container was not already removed by direct invocation of a `remove` method by the application, the WebSphere Application Server CDI container removes the stateful session bean.

The WebSphere Application Server CDI container removes the stateful session bean when:

- You use the `@Inject` method to create a contextual injection instance and that instance in an EJB container is destroyed as a result of going out of scope.
- The underlying EJB container was not already removed by direct invocation of a `remove` method by the application.

You must also consider the scope and state propagation of CDI beans. The request and application scope CDI beans maintain state in their respective contexts across the web and EJB containers. For instance, a request-scoped CDI bean injected in a servlet holds its state when a business method on stateful session enterprise bean accesses the same request-scoped bean.

Developing servlet applications using asynchronous request dispatcher

Developing servlet applications using asynchronous request dispatcher

Web modules can dispatch requests concurrently on separate threads. Requests can be dispatched by the server or client.

Before you begin

For additional information about the `AsyncRequestDispatcherConfig` and the `AsyncRequestDispatcher` interfaces, review the `com.ibm.websphere.webcontainer.async` package in the application programming interfaces (API) documentation. The generated API documentation is available in the information center table of contents from the path `Reference > APIs - Application Programming Interfaces`.

Review the asynchronous request dispatcher application (ARD) design considerations topic before completing the following steps.

About this task

Concurrent dispatching can improve servlet response time. If operations are dependant on each other, do not enable asynchronous request dispatching, therefore, select Disabled. Concurrent dispatching might result in errors when operations are dependant. Select Server side to enable the server to aggregate requests dispatched concurrently. Select Client side to enable the client to aggregate requests dispatched concurrently.

Procedure

1. Logically separate resource intensive operations.
2. Develop servlets that use an asynchronous request dispatcher to include these operations.
3. Enable asynchronous request dispatching on an application server.
4. Deploy the application in an application server that has asynchronous request dispatching enabled.
5. Select an aggregation type for the application that needs ARD.
6. Optional: Configure the `AsyncRequestDispatcherWorkManager` work manager that is used for the request dispatch threads.
7. Restart the application server.

What to do next

Restart the modified applications if already installed or start newly installed applications to enable ARD on each application.

Assembling web applications

Assembling web applications

Assemble a web module to contain servlets, JavaServer Pages (JSP) files, and related code artifacts. (Group enterprise beans, client code, and resource adapter code in separate modules). After assembling a web module, you can install it as a stand-alone application or combine it with other modules into an enterprise application.

Before you begin

This topic assumes that you have created and unit tested Servlets and JavaServer Pages (JSP) files and other web components that you want to assemble in an enterprise application and deploy onto an application server.

About this task

Use an assembly tool to assemble a web module in any of the following ways:

- Import an existing web module (WAR file).
- Create a new web module.
- Copy code artifacts (such as servlets) from one web module into a new web module.

Although you can input various properties for web archives, available properties are specific to the Servlet, JSP, and Java Platform, Enterprise Edition (Java EE) specification level.

Procedure

1. Start an assembly tool.
2. If you have not done so already, configure the assembly tool for work on Java EE modules. Ensure that **J2EE** and **Web** capabilities are enabled.
3. Migrate WAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an assembly tool. To migrate files, import your WAR files to the assembly tool.
4. Create a new web module.
5. Copy code artifacts (such as servlets) from one web module into a new web module.

Results

A web project is migrated or created. Files for the Web project are shown in the Project Explorer view under **Enterprise Applications** and **Web Projects**.

What to do next

You can now deploy your web project to an application server.

web.xml file

The web.xml file provides configuration and deployment information for the web components that comprise a web application.

The Java Servlet specification defines the web.xml deployment descriptor file in terms of an XML schema document. For backwards compatibility, any web.xml file that is written to Servlet 2.2 or above that worked in previous versions of WebSphere Application Server are supported by the web container.

If you use Rational Application Developer Version 6 to create your portlets, you must remove the following reference to the std-portlet.tld from the web.xml file:

```
<taglib id="PortletTLD">
  <taglib-uri>http://java.sun.com/portlet</taglib-uri>
  <taglib-location>/WEB-INF/tld/std-portlet.tld</taglib-location>
</taglib>
```

Location

The web.xml file must reside in the WEB-INF directory under the context of the hierarchy of directories that exist for a web application.

For example, if the application is client.war, then the web.xml file is placed in the *profile_root/installedApps/cellName/client.ear/client.war/WEB-INF* directory (in a default installation), where the edition is either base or WebSphere Application Server, Network Deployment, depending on which edition you are using.

Usage notes

- Is this file read-only?

No

- Is this file updated by a product component?

This file is updated by the assembly tool.

- If so, what triggers its update?

The assembly tool updates the web.xml file when you assemble web components into a web module, or when you modify the properties of the web components or the web module.

- How and when are the contents of this file used?

WebSphere Application Server functions use information in this file during the configuration and deployment phases of web application development.

Sample file entry

Note: The web.xml file does not represent the entire configuration that is available for the web application. There are other servlets filters, and listeners that can be defined using programmatic configurations, annotations, and web fragments.

Note: Marking the web application metadata complete will prevent annotations and web fragments from being able to configure components.

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_9" version="3.0" xmlns="http://java.sun.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://java.sun.com/xml/ns/javaee
    http://java.sun.com/xml/ns/javaee/web-app_3_0.xsd">

```

```

    <url-pattern>/ServletErrorPage</url-pattern>
  </servlet-mapping>
</servlet-mapping>
  <servlet-name>IncludedServlet</servlet-name>
  <url-pattern>/IncludedServlet</url-pattern>
</servlet-mapping>
</servlet-mapping>
  <servlet-name>ForwardedServlet</servlet-name>
  <url-pattern>/ForwardedServlet</url-pattern>
</servlet-mapping>
</servlet-mapping>
  <welcome-file-list>
  <welcome-file>hello.welcome</welcome-file>
</welcome-file-list>
<error-page>
  <exception-type>java.lang.ArrayIndexOutOfBoundsException</exception-type>
  <location>/ServletErrorPage</location>
</error-page>
<error-page>
  <error-code>404</error-code>
  <location>/error404.html</location>
</error-page>
</web-app>

```

Note: For each `<error-page>` declaration, select either `<exception-type>` or `<error-code>`, but not both. The `<location>` tag is required.

File serving

In file serving, web applications can serve static file types, such as HTML. File-serving attributes are used by the servlet that implements file-serving behavior.

The file-serving behavior is implemented by setting the `fileservingenabled` property to true when configuring the web module.

Example attributes:

bufferSize

Sets buffer size that is used for serving static files.

extendedDocumentRoot

Enables you to configure an application with one or more directory paths from which you can serve static files and Java ServerPages (JSP) files. You can use this attribute when an application requires access to files that exist outside of the application web application archive (WAR) directory. For example, if several applications require access to a set of common files, you can place the common files in a directory to which you can link each application as an extended document root directory.

Use this attribute in addition to the `contextRoot` attribute.

You can also use this attribute to define a WebSphere variable on multiple nodes to the appropriate directory.

Example:

```

<fileServingAttributes xmi:id="FileServingAttribute_1" name="extendedDocumentRoot"
  value="{MY_CUSTOM_VARIABLE}"/>

```

where `MY_CUSTOM_VARIABLE` is the WebSphere variable that you want to define on multiple nodes.

For more information, see JSP engine configuration parameters.

file.serving.patterns.allow

Specifies that only files matching the specified pattern are served.

file.serving.patterns.deny

Specifies that files that match the specified file pattern are denied

Configuring JavaServer Faces implementation

Configuring JavaServer Faces implementation

Use this task to specify which JavaServer Faces implementation to use. You can use Apache MyFaces 2.0 or the SUN Reference Implementation 1.2 of JSF, or your own implementation.

Before you begin

Ensure that your application is configured for JavaServer Faces (JSF) using the specific `web.xml` context parameters for the implementation that you have chosen.

Attention: The JSF implementation is a server-wide configuration setting. Thus, if you have multiple applications which require different JSF implementations, you must separate the applications into different application servers or clusters, and specify the implementation by following the steps in this topic for each application server or cluster. Alternatively, you can use an isolated shared library, as described for third-party JSF implementations, as follows.

About this task

Note: The Application Server JSF engine determines if the SUN Reference Implementation (RI) 1.2 or Apache MyFaces 2.0 is used from the Application Server run time. If either is used, the correct listener class is registered with the web container. You do not need to add the `com.sun.faces.ConfigureListener` or the `org.apache.myfaces.StartupConfigureListener` to your `web.xml` file.

Be Aware: If you want to use a third-party JSF implementation that is not shipped with the product, then:

- Keep the configuration set to MyFaces.
- Add the third-party listener to the `web.xml` file that is required.
- Add the third-party implementation Java archive (JAR) files to the application as an isolated shared library and associate it with your application.

You can also configure the JSF implementation on the Provide JSP reloading options for web modules panel for application installation and update wizards.

Procedure

Configure the server or cluster to use the JSF implementation that you want. You can do this task using the administrative console or the wsadmin tool.

- In the administrative console panel, click **Applications > Application Types > WebSphere enterprise applications > *application_name* > JSP and JSF options**

Select one of the following implementations:

- Sun Reference Implementation 1.2 - Select this option to use the Sun Reference Implementation 1.2 JSF implementation.
- MyFaces 2.0 - Select this option to use the MyFaces 2.0 JSF implementation. This option is the default JSF implementation.

- Using the wsadmin tool:

- An example of setting a single server to use the Sun RI 1.2 JSF implementation:

```
wsadmin>set server [$AdminConfig list ApplicationServer *server1*]
server1(cells/myNode01Cell/nodes/myNode01/servers/server1|server.xml#ApplicationServer_1183122130078)
wsadmin>$AdminConfig modify $server {{jsfProvider SunRi1.2}}
```

```
wsadmin>$AdminConfig save
```

- An example of setting a cluster to use the MyFaces 2.0 JSF implementation:

```

wsadmin>set cluster [$AdminConfig list ServerCluster]
cluster1(cells/myNode01Cell/nodes/myNode01/clusters/cluster1|cluster.xml#ServerCluster_1173916133721)
wsadmin>$AdminConfig modify $cluster {{jsfProvider MyFaces}}

wsadmin>$AdminConfig save

```

Results

Note: Your application server or cluster has now been configured with the JSF implementation you specified. Any application that uses JSF technology uses that implementation, unless it is associated with an isolated shared library that contains a different implementation.

What to do next

Configure JSF engine parameters as necessary.

Deploying JavaServer Pages and JavaServer Faces files

JSP class loading settings

You can configure a JavaServer Pages (JSP) class to be loaded by either the JSP engine's class loader or by the web module's class loader.

By default, a JSP class is loaded by a unique instance of the JSP engine's class loader. The JSP engine's class loader enables reloading at runtime of a JSP class when the JSP source or one of its dependents is modified. This allows you to reload a single JSP class when necessary, without affecting any other loaded JSP classes.

JSP classes are loaded by the web module's class loader under either of the following scenarios.

1. The JSP engine configuration parameter `useFullPackageNames` is set to `true`, and the JSP file is configured as a servlet in the `web.xml` file using the `<servlet-class>` scenario in the table below.
2. The JSP engine configuration parameters `useFullPackageNames` and `disableJspRuntimeCompilation` are both set to `true`. In this case, you do not need to configure a JSP file does as a servlet in the `web.xml` file.

Configuring JSP files as Servlets

You can configure a JSP file as a servlet in the `web.xml` file. There are two ways to do this. They are described in the table below.

Before you configure a JSP file as a servlet, consider the following.

1. Reloading capability - If runtime reloading of JavaServer Pages files is desired, requests for JavaServer Pages files must be handled by the JSP engine. The `<servlet-class>` scenario in the table below disables runtime JSP file reloading, while the `<jsp-file>` scenario is compatible with reloading.
2. Reducing the number of class loaders - If you do not require runtime reloading of modified JSP pages and you want to reduce the number of class loader instances, then you can use the `<servlet-class>` scenario in the table below. Similarly, scenario 2 in section 1 above can be used without having to configure a JSP file as a servlet.

Table 130. Example: Configure a JSP file as a servlet in the web.xml file.. Configure a JSP file as a servlet

Scenario	Example	compatible with runtime reloading	multiple class loaders used?	useFullPackageNames

Table 130. Example: Configure a JSP file as a servlet in the web.xml file. (continued). Configure a JSP file as a servlet

<jsp-file>	<servlet> <servlet-name>jspOne</servlet-name> <jsp-file>jspOne.jsp</jsp-file> </servlet>	Yes	Yes	Can be true or false
<servlet-class>	<servlet> <servlet-name>jspTwo</servlet-name> <servlet-class>_ibmjsp.jspTwo</servlet-class> </servlet>	No	No	Must be true

The JSP batch compiler tool helps you configure JavaServer Pages files as servlets. When useFullPackageNames is true, the JSP batch compiler generates <servlet> and <servlet-mapping> elements for each JSP file that it successfully translates and compiles. The elements are written to a web.xml fragment file named generated_web.xml which is located in the binaries WEB-INF directory of a web module processed by the JSP file batch compiler (this directory is located within the deployed application's ear file). You can copy and paste all or some of these elements into the web.xml file to configure JavaServer Pages files as servlets.

Take note of the location of the web.xml that is used by the application server. The application specific configuration is obtained from either the application binaries (the application's ear file) or from the configuration repository. If an application is deployed into WebSphere Application Server with the flag Use Binary Configuration set to true, then the WEB-INF/web.xml file is looked for in a web module's binaries directory, not in the configuration repository. Below are examples of these two locations.

- An example of a configuration repository directory is *profile_root/config/cells/cellName/applications/enterpriseAppName/deployments/deployedName/webModuleName*
- An example of an application binaries directory is: *profile_root/installedApps/nodeName/EnterpriseAppName/WebModuleName/*

If the JSP batch compiler is executed on a pre-deployed application then the web.xml file is in the web module's WEB-INF directory.

JavaServer Pages (JSP) runtime reloading settings

JavaServer Pages files can be translated and compiled at run time when the JSP file or its dependencies are modified. This is known as JSP reloading.

Note: Use an assembly tool, such as Rational Application Developer, to modify IBM extension and binding files. You can convert extension and binding files within modules from XMI to XML using the IBM Bindings and Extensions Conversion Tool for Multi-Platforms.

JSP reloading is enabled through the **reloadEnabled** JSP engine parameter in the WEB-INF/ibm-web-ext.xmi or WEB-INF/ibm-web-ext.xml file.

ibm-web-ext.xmi example:

```
<jspAttributes xmi:id="JSPAttribute_1" name="reloadEnabled" value="true"/>
```

ibm-web-ext.xml example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
  xmlns="http://websphere.ibm.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
  version="1.0">
```

```

<jsp-attribute name="trackDependencies" value="true" />
<jsp-attribute name="disableJspRuntimeCompilation" value="true" />
<jsp-attribute name="reloadEnabled" value="true"/>

<reload-interval value="5"/>
<auto-encode-requests value="false"/>
<auto-encode-responses value="false"/>
<enable-directory-browsing value="false"/>
<enable-file-serving value="false"/>
<pre-compile-jsp value="false"/>
<enable-reloading value="true"/>
<enable-serving-servlets-by-class-name value="false" />
</web-ext>

```

Note: For IBM extension and binding files, the .xmi or .xml file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named `ibm-*-ext.xmi` or `ibm-*-bnd.xmi` where `*` is the type of extension or binding file such as `app`, `application`, `ejb-jar`, or `web`. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be `.xmi`.
- For an application or module that uses Java EE 5 or later, the file extension must be `.xml`. If `.xmi` files are included with the application or module, the product ignores the `.xmi` files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the `.xmi` file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the `.xmi` file extensions.

The following table contains suggested reload settings for production and development environments.

Table 131. Suggested reload settings for production and development environments.. Reload settings

Configuration Attribute	Settings	
	Production Environment	Development Environment
<code>reloadEnabled</code>	false	true
<code>reloadInterval</code>	n/a (ignored if <code>reloadEnabled</code> is false)	approximately 5 seconds
<code>trackDependencies</code>	n/a (ignored if <code>reloadEnabled</code> is false)	true Alternatively, set this to false to improve response time if dependencies are not changing
<code>disableJspRuntimeCompilation</code>	true - Alternatively, set this to false if JSP files are not pre-compiled and therefore need to be compiled on the first request.	false

The default for the **reloadEnabled** parameter is true. If the **reloadEnabled** parameter is set to true, a JSP file is reloaded at run time if the JSP file and its class file do not have the same timestamp. In addition, if **trackDependencies** is set to true then the JSP file is reloaded if the timestamp of any of its dependencies has changed since the JSP class file was last generated. If the **reloadEnabled** parameter is set to false, a JSP file is still compiled if necessary on the first request to it unless the parameter **disableJspRuntimeCompilation** is true. For example, when **disableJspRuntimeCompilation** is false and **reloadEnabled** is false, a JSP file is compiled on the first request if the class file is outdated. It would not compile on subsequent requests, even if the JSP source file is modified or the class file is deleted,, unless **reloadEnabled** is true.

Reload interval

The reload interval is set through the **reloadInterval** JSP engine parameter.

ibm-web-ext.xmi example:

```
<jspAttributes xmi:id="JSPAttribute_1" name="reloadInterval" value="5"/>
```

ibm-web-ext.xml example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
  xmlns="http://websphere.ibm.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
  version="1.0">

  <jsp-attribute name="trackDependencies" value="true" />
  <jsp-attribute name="disableJspRuntimeCompilation" value="true" />
  <jsp-attribute name="reloadInterval" value="5"/>

  <reload-interval value="5"/>
  <auto-encode-requests value="false"/>
  <auto-encode-responses value="false"/>
  <enable-directory-browsing value="false"/>
  <enable-file-serving value="false"/>
  <pre-compile-jsp value="false"/>
  <enable-reloading value="true"/>
  <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

If reloading is enabled, the **reloadInterval** parameter value determines the delay between checks to see if a JSP file is outdated. For example, if **reloadInterval** is 5, the JSP engine checks to see if a JSP file is outdated only when the last such check was done more than five seconds prior to the current request for the JSP file. Once the **reloadInterval** is exceeded, reload checking is performed and the reload interval timer is reset to 0 for that JSP file. The larger the **reloadInterval**, the less frequently the JSP engine checks for the need to reload a JSP file.

Dependency tracking

Dependency tracking is set through the **trackDependencies** JSP engine parameter.

ibm-web-ext.xml example:

```
<jspAttributes xmi:id="JSPAttribute_1" name="trackDependencies" value="true"/>
```

ibm-web-ext.xml example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
  xmlns="http://websphere.ibm.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
  version="1.0">

  <jsp-attribute name="trackDependencies" value="true" />
  <jsp-attribute name="disableJspRuntimeCompilation" value="true" />
  <jsp-attribute name="reloadInterval" value="5"/>

  <reload-interval value="5"/>
  <auto-encode-requests value="false"/>
  <auto-encode-responses value="false"/>
  <enable-directory-browsing value="false"/>
  <enable-file-serving value="false"/>
  <pre-compile-jsp value="false"/>
  <enable-reloading value="true"/>
  <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

If reloading is enabled, the **trackDependencies** parameter value determines whether the JSP engine tracks modifications to the requested JSP file dependencies as well as to the JSP file itself. The three types of dependencies tracked by the JSP engine are:

- files statically included in the JSP file
- tag files that are referenced in the JSP file (excluding tag files that are in JAR files)
- TLDs that are referenced in the JSP file (excluding TLDs that are in JAR files)

Dependency tracking information is always included in the generated class file even if **trackDependencies** is false. The information is not used by the JSP engine or batch compiler unless the **trackDependencies** parameter is true. This means that you can enable dependency tracking without having to recompile JSP files.

For example, the `toplevel.jsp` file statically includes the `footer.jspf` file. When the `toplevel.jsp` file is compiled, the path to the `footer.jspf` file and its timestamp are stored in the `toplevel.jsp`'s class file. As a result, the `footer.jspf` file is modified and the `toplevel.jsp` file is requested. Now that the reload interval for the `toplevel.jsp` file has been exceeded, the JSP engine compares the timestamp stored in the class file with the `footer.jspf` file timestamp on disk. Because the timestamps are different, the `toplevel.jsp` file is compiled, picking up the modification to the `footer.jspf` file. In order for dependency tracking to work, the **trackDependencies** value must be set to true at the time a JSP file is requested at run time or is processed by the batch compiler.

Disabling compilation

Disabling of run time compilation of JavaServer Pages is set via the `disableJspRuntimeCompilation` JSP engine parameter.

ibm-web-ext.xmi example:

```
<jspAttributes xmi:id="JSPAttribute_1" name="disableJspRuntimeCompilation" value="true"/>
```

ibm-web-ext.xml example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
  xmlns="http://websphere.ibm.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
  version="1.0">

  <jsp-attribute name="trackDependencies" value="true" />
  <jsp-attribute name="disableJspRuntimeCompilation" value="true" />
  <jsp-attribute name="reloadInterval" value="5"/>

  <reload-interval value="5"/>
  <auto-encode-requests value="false"/>
  <auto-encode-responses value="false"/>
  <enable-directory-browsing value="false"/>
  <enable-file-serving value="false"/>
  <pre-compile-jsp value="false"/>
  <enable-reloading value="true"/>
  <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

If the **disableJspRuntimeCompilation** parameter is set to true, the JSP engine at run time does not translate and compile JSP files; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order for the class files to be loaded. With this option set to true, an application can be installed without JSP source, but must have precompiled class files. There is a web container custom property of the same name that can be used to determine the behavior of all web modules installed in a server. If both the web container custom property and the JSP engine option are set, the JSP engine option takes precedence. Setting the **disableJspRuntimeCompilation** parameter to true automatically sets **reloadEnabled** to false.

Reload processing sequence

The processing sequence pertaining to JSP file reloading when **trackDependencies** is false is shown in Figure 1.

Figure 1. Reload processing sequence when **trackDependencies** is false.

When **trackDependencies** is true, the JSP engine does additional file system processing to determine if any of a JSP file's dependencies have changed since the JSP file was last translated and compiled. Figure 2 shows the additional processes that are performed on the 'No' path of flow chart labeled "is JSP class file outdated?". You can see that the path taken when `disableJspRuntimeCompilation` is true is the most efficient path.

Figure 2. Additional reload processing performed when `trackDependencies` is true.

JSP and JSF option settings

Use this panel to configure the class reloading of web modules such as JavaServer Pages (JSP) files and to select a JSF implementation to use with this application.

To view this administrative console panel, click **Applications > Application Types > WebSphere enterprise applications > application_name > JSP and JSF options**. This panel is the same as the **Provide JSP reloading options for web modules** panel on the application installation and update wizards.

The following note applies to the files with a `.xmi` extension in this topic:

Note: For IBM extension and binding files, the `.xmi` or `.xml` file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named `ibm-*-ext.xmi` or `ibm-*-bnd.xmi` where `*` is the type of extension or binding file such as `app`, `application`, `ejb-jar`, or `web`. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be `.xmi`.
- For an application or module that uses Java EE 5 or later, the file extension must be `.xml`. If `.xmi` files are included with the application or module, the product ignores the `.xmi` files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the `.xmi` file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the `.xmi` extensions.

Web module

Specifies the name of a web module in the installed or deployed application.

URI

Specifies the location of the module that is relative to the root of the application (EAR file).

JSP enable class reloading

Specifies whether to enable class reloading when JSP files are updated.

A web container reloads JSP files only when the IBM extension reloadEnabled in the jspAttributes of the `ibm-web-ext.xmi` file is set to true.

Java Platform, Enterprise Edition 5 (Java EE 5) applications IBM extension files are in `.xml` file format. For applications versions earlier than Java EE 5, they are in the `.xmi` file format.

JSP reload interval in seconds

Specifies the number of seconds to scan the application file system for updated JSP files. The default is the value of the reloading interval attribute in the IBM extension (META-INF/ibm-web-ext.xmi) file of the web module.

To enable reloading, specify a value greater than zero (for example, 1 to 2147483647). The default reload interval is 5. To disable reloading, specify zero (0). The range is from 0 to 2147483647.

The reloading interval attribute takes effect only if class reloading is enabled.

Java EE 5 applications IBM extension files are in `.xml` file format. For applications versions earlier than Java EE 5, they are in the `.xmi` file format.

Sun Reference Implementation 1.2

Select this option to use the Sun Reference Implementation 1.2 JSF implementation.

If you change the JSF implementation that you are using for your application, you must delete any previously compiled JSP files. If you precompiled your application, you must recompile. If you did not precompile, but have already requested JSP files from this application, you must delete the JSP files from the temp directory of your profile.

You can set the JSF engine configuration parameter, `com.ibm.ws.jsf.JSF_IMPL_CHECK`, to true to automatically mark the JSP files to recompile at application startup.

MyFaces 2.0

Select this option to use the MyFaces JSF implementation. This is the default JSF implementation.

If you change the JSF implementation that you are using for your application, you must delete any previously compiled JSP files. If you precompiled your application, you must recompile. If you did not precompile, but have already requested JSP files from this application, you must delete the JSP files from the temp directory of your profile.

You can set the JSF engine configuration parameter, `com.ibm.ws.jsf.JSF_IMPL_CHECK`, to true to automatically mark the JSP files to recompile at application startup.

In a mixed-version cell, a V7 node uses MyFaces 1.2 if the MyFaces selection is toggled, while a V8 node uses MyFaces 2.0. For WebSphere Application Server versions before V7 (for example, V6.1 and earlier), this toggle is ineffective because JSF implementation switching was not supported before V7.

JSP run time compilation settings

By default, the JavaServer Pages (JSP) engine translates a requested JSP file, compiles the `.java` file, and loads the compiled servlet into the run time environment. You can change the JSP engine default behavior by indicating that a JSP file must not be translated or compiled at run time, even when a `.class` file does not exist.

If run time compilation is disabled, you must precompile the JSP files, which provides the following advantages:

- Reduces compilation related disk operations.
- Minimizes disk storage requirements necessary for handling temporary .java files generated during a run time compilation.
- Allows you to not include the JSP source files in the application.
- Allows verification that a JSP file compiled successfully before deploying and installing the application in the product

You can disable run time JSP file compilation on a global or an individual web application basis:

- To disable the translation and compilation of JSP files for all Web applications, in the administrative console, click **Servers > Server Types > WebSphere application servers > server_name**. Then, in the Container Settings section, click **Web container settings > Web container > Custom properties**.

If the `disableJspRuntimeCompilation` property appears in the list of defined custom properties, but is set to `false`, click the property name, and then set the property to `true`.

If this property is not included in the list of defined custom properties, click **New**, and then specify `disableJspRuntimeCompilation` in the **Name** field and `true` in the **Value** field.

Valid settings for this property are `true` or `false`. When this property is set to `true`, translation and compilation of the JSP files is disabled at run time for all web applications.

- To disable the translation and compilation of JSP files for a specific web application, set the JSP engine initialization parameter `disableJspRuntimeCompilation` to `true`. This setting, if enabled, determines the run time behavior of the JSP engine and overrides the web container custom property setting.

Set this parameter through the **JavaServer Pages attribute assembly settings** page when assembling applications.

Valid values for this setting are `true` or `false`. If this parameter is set to `true`, then, for that specific web application, translation and compilation of the JSP files is disabled at run time, and the JSP engine only loads precompiled files.

- If neither the web container custom property nor the JSP parameter is set, the first request for a JSP file results in the translation and compilation of the JSP file when the `.class` file does not exist or is outdated. Subsequent requests for the file also result in translations and compilations, but only if the following conditions are met:
 - Translations are required because the `.class` file is outdated.
 - Reloading is enabled for the web module.
 - Reload interval is exceeded.

If you disable run time compilation and a request arrives for a JSP file that does not have a matching `.class` file, the JSP engine returns the following 404 error to the browser:

```
Error 404: SRVE0200E: Servlet [org.apache.jsp._jsp1]: Could not find required servlet class - _jsp1.class
```

In this case, an exception is written to the System Out (SYSOUT) and First Failure Data Capture (FFDC) logs. .

If a JSP file has a matching `.class` file but that file is out of date, the JSP engine still loads the `.class` file into memory.

Provide options to compile JavaServer Pages settings

Use this page to specify options to be used by the JavaServer Pages (JSP) compiler.

This administrative console page is a step in the application installation and update wizards. To view this page, you must select **Precompile JavaServer Pages files** on the **Select installations options** page. Thus, to view this page, click **Applications > New Application > New Enterprise Application > application_path > Next > Detailed - Show me all installation options and parameters > Next > Next or Continue > Precompile JavaServer Pages files > Next > Step: Provide options to compile JSPs**.

You can specify the JSP compiler options on this page only when installing or updating an application that contains web modules. After the application is installed, you must edit the JSP engine configuration parameters of a web module `WEB-INF/ibm-web-ext.xmi` file to change its JSP compiler options.

Note: For IBM extension and binding files, the `.xmi` or `.xml` file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named `ibm-*-ext.xmi` or `ibm-*-bnd.xmi` where `*` is the type of extension or binding file such as `app`, `application`, `ejb-jar`, or `web`. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be `.xmi`.
- For an application or module that uses Java EE 5 or later, the file extension must be `.xml`. If `.xmi` files are included with the application or module, the product ignores the `.xmi` files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the `.xmi` file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the `.xmi` file extensions.

Web module

Specifies the name of a module within the application.

URI

Specifies the location of the module relative to the root of the application (EAR file).

JSP class path

Specifies a temporary class path for the JSP compiler to use when compiling JSP files during application installation. This class path is not saved when the application installation is complete and is not used when the application is running. This class path is used only to identify resources outside of the application which are necessary for JSP compilation and which will be identified by other means (such as shared libraries) after the application is installed. In network deployment configurations, this class path is specific to the deployment manager machine.

To specify that multiple web modules use the same class path:

1. In the list of web modules, select the **Select** check box beside each web module that you want to use a particular class path.
2. Expand **Apply Multiple Mappings**.
3. Specify the desired class path.
4. Click **Apply**.

Use full package names

Specifies whether the JSP engine generates and loads JSP classes using full package names.

When full package names are used, precompiled JSP class files can be configured as servlets in the `web.xml` file, without having to use the `jsp-file` attribute. When full package names are not used, all JSP classes are generated in the same package, which has the benefit of smaller file-system paths.

When the options `useFullPackageNames` and `disableJspRuntimeCompilation` are both `true`, a single class loader is used to load all JSP classes, even if the JSP files are not configured as servlets in the `web.xml` file.

This option is the same as the `useFullPackageNames` JSP engine parameter.

JDK source level

Specifies the source level at which the Java compiler compiles JSP Java sources. Valid values are 13, 14, and 15. The default value is 13 for pre-Java EE 5 web modules, which specifies source level 1.3 and 15 for Java EE 5 and later web modules.

Disable JSP runtime compilation

Specifies whether a JSP file should never be translated or compiled at run time, even when a `.class` file does not exist.

When this option is set to `true`, the JSP engine does not translate and compile JSP files at run time; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order to load class files. You can install an application without JSP source, but the application must have precompiled class files.

For a single web application class loader to load all JSP classes, this compiler option and the **Use full package names** option both must be set to `true`.

This option is the same as the `disableJspRuntimeCompilation` JSP engine parameter.

Developing session management in servlets

About this task

This information, combined with the coding example `SessionSample.java`, provides a programming model for implementing sessions in your own servlets.

Procedure

1. Get the `HttpSession` object.

To obtain a session, use the `getSession` method of the `javax.servlet.http.HttpServletRequest` object in the Java Servlet 3.0 API.

When you first obtain the `HttpSession` object, the Session Management facility uses one of three ways to establish tracking of the session: cookies, URL rewriting, or Secure Sockets Layer (SSL) information.

Note: Session tracking using the SSL ID is deprecated in WebSphere Application Server version 7.0. You can configure session tracking to use cookies or modify the application to use URL rewriting

Assume the Session Management facility uses cookies. In such a case, the Session Management facility creates a unique session ID and typically sends it back to the browser as a *cookie*. Each subsequent request from this user (at the same browser) passes the cookie containing the session ID, and the Session Management facility uses this ID to find the user's existing `HttpSession` object.

In Step 1 of the code sample, the `Boolean(create)` is set to `true` so that the `HttpSession` object is created if it does not already exist. (With the Servlet 2.3 API and later, the `javax.servlet.http.HttpServletRequest.getSession()` method with no boolean defaults to `true` and creates a session if one does not already exist for this user.)

2. Store and retrieve user-defined data in the session.

After a session is established, you can add and retrieve user-defined data to the session. The `HttpSession` object has methods similar to those in `java.util.Dictionary` for adding, retrieving, and removing arbitrary Java objects.

In Step 2 of the code sample, the servlet reads an integer object from the `HttpSession`, increments it, and writes it back. You can use any name to identify values in the `HttpSession` object. The code sample uses the name `sessiontest.counter`.

Because the `HttpSession` object is shared among servlets that the user might access, consider adopting a site-wide naming convention to avoid conflicts.

3. (Optional) Output an HTML response page containing data from the HttpSession object.
4. Provide feedback to the user that an action has taken place during the session. You may want to pass HTML code to the client browser indicating that an action has occurred. For example, in step 3 of the code sample, the servlet generates a web page that is returned to the user and displays the value of the sessiontest.counter each time the user visits that web page during the session.
5. (Optional) Notify Listeners. Objects stored in a session that implement the javax.servlet.http.HttpSessionBindingListener interface are notified when the session is preparing to end and become invalidated. This notice enables you to perform post-session processing, including permanently saving the data changes made during the session to a database.
6. End the session. You can end a session:
 - Automatically with the Session Management facility if a session is inactive for a specified time. The administrators provide a way to specify the amount of time after which to invalidate a session.
 - By coding the servlet to call the invalidate() method on the session object.

Example

```
import java.io.*;
import java.util.*;
import javax.servlet.*;
import javax.servlet.http.*;

public class SessionSample extends HttpServlet {
    public void doGet (HttpServletRequest request, HttpServletResponse response)
        throws ServletException, IOException {

        // Step 1: Get the Session object

        boolean create = true;
        HttpSession session = request.getSession(create);

        // Step 2: Get the session data value

        Integer ival = (Integer)
            session.getAttribute ("sessiontest.counter");
        if (ival == null) ival = new Integer (1);
        else ival = new Integer (ival.intValue () + 1);
        session.setAttribute ("sessiontest.counter", ival);

        // Step 3: Output the page

        response.setContentType("text/html");
        PrintWriter out = response.getWriter();
        out.println("<html>");
        out.println("<head><title>Session Tracking Test</title></head>");
        out.println("<body>");
        out.println("<h1>Session Tracking Test</h1>");
        out.println ("You have hit this page " + ival + " times" + "<br>");
        out.println ("Your " + request.getHeader("Cookie"));
        out.println("</body></html>");
    }
}
```

Assembling so that session data can be shared

By default, the Session Management facility supports session scoping by web module in accordance with the Servlet 2.3 and later API specification. Only servlets in the same web module can access the data associated with a particular session. However, you can use the IBMApplicationSession object or the IBM extension, shared session context, to share data outside of the web module scope.

About this task

Attention: The `IBMApplicationSession` object is the recommended method for sharing session attributes. The IBM extension, shared session context, is deprecated.

The `IBMApplicationSession` object is a parent session object that can be retrieved by a web module's session and can share session attributes across all of the web modules in a business-level application. The default scope of the business-level application is the enterprise application. The shared session context option extends the scope of the session attributes as well. Using the shared session context extension, there is only one session object for the entire business-level application or for the default enterprise application.

If you are using a shared session for a business-level application, then the class files for all objects placed in the session must exist in an isolated shared library and be common among all applications.

The benefit to using the `IBMApplicationSession` method is that each web module can maintain its own session as well as have a reference to the shared session.

If you're migrating an application from a previous version of the product, the `IBMApplicationSession` method requires a change to the application logic of the application.

Restriction: To use a shared session, you must install all applications within a business-level application on a given server. You cannot split up the enterprise application by servers. For example, you cannot use this option when one enterprise application in "BLA1" is installed on one server and a second enterprise application also in "BLA1" is installed on a different server. In such split installations, applications might share session attributes across web modules using distributed sessions, but session data integrity is lost when concurrent access to a session is made in different web modules. It also severely restricts use of some Session Management features, like `TIME_BASED_WRITES`.

For enterprise applications on which this shared session context extension is enabled, the Session Management configuration on the web module inside the enterprise application is ignored. Then Session Management configuration defined on enterprise application is used if Session Management is overwritten at the enterprise application level. Otherwise, the Session Management configuration on the web container is used. If using multiple enterprise applications within a business-level application, the session management configuration must be common among all applications and web modules within this business-level application.

Servlet API Behavior

Note: `HttpSession` listeners defined in all the web modules inside the business-level application or enterprise application are invoked for session events. The order of listener invocation is not guaranteed.

Complete the following to share session data across the business-level application.

Procedure

1. Complete the following to share session data using the `IBMApplicationSession` object within the application code.
 - a. Retrieve the session object

```
HttpSession session = request.getSession();
```
 - b. Cast this object to an `IBMSession` object and call the `getIBMApplicationSession` method.

```
IBMApplicationSession appSession = ((IBMSession)session).getIBMApplicationSession();
```
 - c. Use the `appSession` like a normal session object.
2. Do the following to share session data using the Shared session context extension.

- a. Start an assembly tool.
- b. In the assembly tool, right-click the application (EAR file) that you want to share and click **Open With > Deployment Descriptor Editor**.
- c. In the application deployment descriptor editor of the assembly tool, select **Shared session context** under **WebSphere Extensions**. Make sure the class definition of attributes put into session are available to all web modules in the enterprise application. The shared session context does not fully meet the requirements of the specifications.
- d. Save the application (EAR) file. In the assembly tool, after you close the application deployment descriptor editor, confirm that you want to save changes made to the application.

Chapter 32. Developing web services

This page provides a starting point for finding information about web services.

Web services are self-contained, modular applications that can be described, published, located, and invoked over a network. They implement a services oriented architecture (SOA), which supports the connecting or sharing of resources and data in a very flexible and standardized manner. Services are described and organized to support their dynamic, automated discovery and reuse.

Using JAXB for XML data binding

Java Architecture for XML Binding (JAXB) is a Java technology that provides an easy and convenient way to map Java classes and XML schema for simplified web services development. JAXB provides the `xjc` schema compiler, the `schemagen` schema generator and a runtime framework to support marshalling and unmarshalling of XML documents to and from Java objects.

About this task

JAXB is an XML-to-Java binding technology that enables transformation between schema and Java objects and between XML instance documents and Java object instances. JAXB technology consists of a runtime API and accompanying tools that simplify access to XML documents. You can use JAXB APIs and tools to establish mappings between Java classes and XML schema. An XML schema defines the data elements and structure of an XML document. JAXB technology provides tooling to enable you to convert your XML documents to and from Java objects. Data stored in an XML document is accessible without the need to understand the XML data structure.

JAXB is the default data binding technology used by the Java API for XML Web Services (JAX-WS) tooling and implementation within this product. You can develop JAXB objects to use within your JAX-WS applications. You can also use JAXB independently of the JAX-WS programming model as a convenient way to leverage the XML data binding technology to manipulate XML within your Java applications.

Note: This version of the application server supports the JAXB 2.2 specification. JAX-WS 2.2 requires JAXB 2.2 for data binding. JAXB 2.2 provides minor enhancements to its annotations for improved schema generation and better integration with JAX-WS.

Note: The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

JAXB provides the `xjc` schema compiler tool, the `schemagen` schema generator tool, and a runtime framework. The `xjc` schema compiler tool enables you to start with an XML schema definition (XSD) to create a set of JavaBeans that map to the elements and types defined in the XSD schema. You can also start with a set of JavaBeans and use the `schemagen` schema generator tool to create the XML schema. After using either the schema compiler or the schema generator command-line tools, you can convert your XML documents both to and from Java objects and use the resulting Java classes to assemble a web services application.

In addition to using the tools from the command-line, you can invoke these JAXB tools from within the Ant build environments. Use the `com.sun.tools.xjc.XJCTask` Ant task from within the Ant build environment to invoke the `xjc` schema compiler tool. Use the `com.sun.tools.xjc.SchemaGenTask` Ant task from within the Ant build environment to invoke the `schemagen` schema generator tool. These Ant tasks require that the `com.ibm.jaxb.tools.jar` and the `com.ibm.jaxws.tools.jar` files be in the classpath.

JAXB annotated classes and artifacts contain all the information that the JAXB runtime API needs to process XML instance documents. The JAXB runtime API enables marshaling of JAXB objects to XML files and unmarshaling the XML document back to JAXB class instances. The JAXB binding package, `javax.xml.bind`, defines the abstract classes and interfaces that are used directly with content classes. In addition the package defines the marshal and unmarshal APIs.

You can optionally use JAXB binding customizations to override the default generated type mappings. You can customize JAXB bindings using inline annotations in the source schema, or by using an external bindings customization file to pass your customizations to the JAXB binding compiler, `xjc`, to control the Java type mappings. Alternatively, you can add Java annotations to existing Java classes to pass to the schema generator, `schemagen`, to control the schema or XML type mappings. See the JAXB specification for information regarding binding customization options and Java annotations.

Using JAXB, you can manipulate data objects in the following ways:

Procedure

- Generate an XML schema from a Java class. Use the schema generator `schemagen` command to generate an XML schema from Java classes.
- Generate Java classes from an XML schema. Use the schema compiler `xjc` command to create a set of JAXB-annotated Java classes from an XML schema.
- Marshal and unmarshal XML documents. After the mapping between XML schema and Java classes exists, use the JAXB binding runtime to convert XML instance documents to and from Java objects.

Results

You now have JAXB objects that your Java application can use to manipulate XML data.

Using JAXB schemagen tooling to generate an XML schema file from a Java class

Use Java Architecture for XML Binding (JAXB) `schemagen` tooling to generate an XML schema file from Java classes.

Before you begin

Identify the Java classes or a set of Java objects to map to an XML schema file.

About this task

Use JAXB APIs and tools to establish mappings between Java classes and XML schema. XML schema documents describe the data elements and relationships in an XML document. After a data mapping or binding exists, you can convert XML documents to and from Java objects. You can now access data stored in an XML document without the need to understand the data structure.

To develop web services using a bottom-up development approach starting from existing JavaBeans or enterprise beans, use the `wsgen` tool to generate the artifacts for Java API for XML-Based Web Services (JAX-WS) applications. After the Java artifacts for your application are generated, you can create an XML schema document from an existing Java application that represents the data elements of a Java application by using the JAXB schema generator, `schemagen` command-line tool. The JAXB schema generator processes either Java source files or class files. Java class annotations provide the capability to customize the default mappings from existing Java classes to the generated schema components. The XML schema file along with the annotated Java class files contain all the necessary information that the JAXB runtime requires to parse the XML documents for marshaling and unmarshaling.

You can create an XML schema document from an existing Java application that represents the data elements of a Java application by using the JAXB schema generator, `schemagen` command-line tool. The JAXB schema generator processes either Java source files or class files. Java class annotations provide the capability to customize the default mappings from existing Java classes to the generated schema components. The XML schema file along with the annotated Java class files contain all the necessary information that the JAXB runtime requires to parse the XML documents for marshaling and unmarshaling.

Note: The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are located in the `app_server_root\bin\` directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the `app_server_root\bin\` directory.

Note: This product supports the JAXB 2.2 specification. JAX-WS 2.2 requires JAXB 2.2 for data binding.

JAXB provides compilation support to enable you to configure the `schemagen` schema generator so that it does not automatically generate a new schema. This is helpful if you are using a common schema such as the World Wide Web Consortium (W3C), XML Schema, Web Services Description Language (WSDL), or WS-Addressing and you do not want a new schema generated for a particular package that is referenced. The location attribute on the `@XmlSchema` annotation causes the `schemagen` generator to refer to the URI of the existing schema instead of generating a new one.

In addition to using the `schemagen` tool from the command-line, you can invoke this JAXB tool from within the Ant build environments. Use the `com.sun.tools.jxc.SchemaGenTask` Ant task from within the Ant build environment to invoke the `schemagen` schema generator tool. To function properly, this Ant task requires that you invoke Ant using the `ws_ant` script.

Note: When running the `schemagen` tool, the schema generator does not correctly read the `@XmlSchema` annotations from the package-info class file to derive targetNamespaces. Instead of using the `@XMLSchema` annotation, use one of the following methods:

- Provide a package-info.java file with the `@XmlSchema`; for example:

```
schemagen sample.Address sample\package-info.java
```

- Use the `@XmlType` annotation namespace attribute to specify a namespace; for example:

```
@XmlType(namespace="http://myNameSpace")
```

Procedure

1. Locate the Java source files or Java class files to use in generating an XML schema file. Ensure that all classes referenced by your Java class files are contained in the classpath or are provided to the tool using the `-classpath/-cp` options.
2. Use the JAXB schema generator, `schemagen` command to generate an XML schema. The schema generator is located in the `app_server_root\bin\` directory.

```
app_server_root/bin/schemagen myObj1.java myObj2.java
```

The parameters, `myObj1.java` and `myObj2.java`, are the names of the Java files containing the data objects. If `myObj1.java` or `myObj2.java` refer to Java classes that are not passed into the `schemagen`

command, you must use the `-cp` option to provide the classpath location for these Java classes. Read about the `schemagen` command to learn more about this command and additional options that you can specify.

3. (Optional) Use JAXB program annotations defined in the `javax.xml.bind.annotations` package to customize the JAXB XML schema mappings.
4. (Optional) Configure the `location` property on the `@XmlSchema` annotation to indicate to the schema compiler to use an existing schema rather than generating a new one. For example,

```
@XmlSchema(namespace="foo")
package foo;
@XmlType
class Foo {
  @XmlElement Bar zot;
}
@XmlSchema(namespace="bar",
  location="http://example.org/test.xsd")
package bar;
@XmlType
class Bar {
  ...
}
<xs:schema targetNamespace="foo">
<xs:import namespace="bar"
  schemaLocation="http://example.org/test.xsd"/>
<xs:complexType name="foo">
<xs:sequence>
<xs:element name="zot" type="bar:Bar" xmlns:bar="bar"/>
</xs:sequence>
</xs:complexType>
```

the `location="http://example.org/test.xsd"` indicates the location on the existing schema to the `schemagen` tool and a new schema is not generated.

Results

Now that you have generated an XML schema file from Java classes, you are ready to marshal and unmarshal the Java objects as XML instance documents.

Note: The `schemagen` command does not differentiate the XML namespace between multiple `@XMLType` annotations that have the same `@XMLType` name defined within different Java packages. When this scenario occurs, the following error is produced:

```
Error: Two classes have the same XML type name ...
Use @XmlType.name and @XmlType.namespace to assign different names to them...
```

This error indicates you have class names or `@XMLType.name` values that have the same name, but exist within different Java packages. To prevent this error, add the `@XMLType.namespace` class to the existing `@XMLType` annotation to differentiate between the XML types.

Example

The following example illustrates how JAXB tooling can generate an XML schema file from an existing Java class, `Bookdata.java`.

1. Copy the following `Bookdata.java` file to a temporary directory.

```
package generated;

import javax.xml.bind.annotation.XmlAccessType;
import javax.xml.bind.annotation.XmlAccessorType;
import javax.xml.bind.annotation.XmlAttribute;
import javax.xml.bind.annotation.XmlElement;
import javax.xml.bind.annotation.XmlType;
import javax.xml.datatype.XMLGregorianCalendar;

@XmlAccessorType(XmlAccessType.FIELD)
@XmlType(name = "bookdata", propOrder = {
    "author",
    "title",
    "genre",
    "price",
    "publishDate",
})
```

```

    "description"
  })
}
public class Bookdata {

    @XmlElement(required = true)
    protected String author;
    @XmlElement(required = true)
    protected String title;
    @XmlElement(required = true)
    protected String genre;
    protected float price;
    @XmlElement(name = "publish_date", required = true)
    protected XMLGregorianCalendar publishDate;
    @XmlElement(required = true)
    protected String description;
    @XmlAttribute
    protected String id;

    public String getAuthor() {
        return author;
    }
    public void setAuthor(String value) {
        this.author = value;
    }
    public String getTitle() {
        return title;
    }

    public void setTitle(String value) {
        this.title = value;
    }

    public String getGenre() {
        return genre;
    }

    public void setGenre(String value) {
        this.genre = value;
    }

    public float getPrice() {
        return price;
    }

    public void setPrice(float value) {
        this.price = value;
    }

    public XMLGregorianCalendar getPublishDate() {
        return publishDate;
    }

    public void setPublishDate(XMLGregorianCalendar value) {
        this.publishDate = value;
    }

    public String getDescription() {
        return description;
    }

    public void setDescription(String value) {
        this.description = value;
    }

    public String getId() {
        return id;
    }

    public void setId(String value) {
        this.id = value;
    }
}

```

2. Open a command prompt.
3. Run the schemagen schema generator tool from the directory where you copied the Bookdata.java file.

app_server_root/bin/schemagen Bookdata.java

4. The XML schema file, schema1.xsd is generated:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<xs:schema version="1.0" xmlns:xs="http://www.w3.org/2001/XMLSchema">

  <xs:complexType name="bookdata">
    <xs:sequence>
      <xs:element name="author" type="xs:string"/>
      <xs:element name="title" type="xs:string"/>
      <xs:element name="genre" type="xs:string"/>
      <xs:element name="price" type="xs:float"/>
      <xs:element name="publish_date" type="xs:anySimpleType"/>
      <xs:element name="description" type="xs:string"/>
    </xs:sequence>
    <xs:attribute name="id" type="xs:string"/>
  </xs:complexType>
</xs:schema>
```

Refer to the JAXB Reference implementation documentation for additional information about the **schemagen** command.

Using JAXB xjc tooling to generate JAXB classes from an XML schema file

Use Java Architecture for XML Binding (JAXB) xjc tooling to compile an XML schema file into fully annotated Java classes.

Before you begin

Develop or obtain an XML schema file.

About this task

Use JAXB APIs and tools to establish mappings between an XML schema and Java classes. XML schemas describe the data elements and relationships in an XML document. After a data mapping or binding exists, you can convert XML documents to and from Java objects. You can now access data stored in an XML document without the need to understand the data structure.

To develop web services using a top-down development approach starting with an existing Web Services Description Language (WSDL) file, use the `wsimport` tool to generate the artifacts for your Java API for XML-Based Web Services (JAX-WS) applications when starting with a WSDL file. After the Java artifacts for your application are generated, you can generate fully annotated Java classes from an XML schema file by using the JAXB schema compiler, `xjc` command-line tool. The resulting annotated Java classes contain all the necessary information that the JAXB runtime requires to parse the XML for marshaling and unmarshaling. You can use the resulting JAXB classes within Java API for XML Web Services (JAX-WS) applications or other Java applications for processing XML data.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are located in the `app_server_root\bin\` directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the `app_server_root\bin\` directory.

Note: This product supports the JAXB 2.2 specification. JAX-WS 2.2 requires JAXB 2.2 for data binding.

In addition to using the `xjc` tool from the command-line, you can invoke this JAXB tool from within the Ant build environments. Use the `com.sun.tools.xjc.XJCTask` Ant task from within the Ant build environment to invoke the `xjc` schema compiler tool. To function properly, this Ant task requires that you invoke Ant using the `ws_ant` script.

Note: If you are using the `xjc` Ant task, you must use the `destDir` parameter to specify the destination directory instead of the `target` option. Specifying the `target` option when using the `xjc` Ant task causes an error.

Procedure

1. Use the JAXB schema compiler, `xjc` command to generate JAXB-annotated Java classes. The schema compiler is located in the `app_server_root\bin\` directory. The schema compiler produces a set of packages containing Java source files and JAXB property files depending on the binding options used for compilation.
2. (Optional) Use custom binding declarations to change the default JAXB mappings. Define binding declarations either in the XML schema file or in a separate bindings file. You can pass custom binding files by using the `-b` option with the `xjc` command.
3. Compile the generated JAXB objects. To compile generated artifacts, add the Thin Client for JAX-WS with WebSphere Application Server to the classpath.

Results

Now that you have generated JAXB objects, you can write Java applications using the generated JAXB objects and manipulate the XML content through the generated JAXB classes.

Example

The following example illustrates how JAXB tooling can generate Java classes when starting with an existing XML schema file.

1. Copy the following `bookSchema.xsd` schema file to a temporary directory.

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema">
  <xsd:element name="CatalogData">
    <xsd:complexType >
      <xsd:sequence>
        <xsd:element name="books" type="bookdata" minOccurs="0"
          maxOccurs="unbounded"/>
      </xsd:sequence>
    </xsd:complexType>
  </xsd:element>
  <xsd:complexType name="bookdata">
    <xsd:sequence>
      <xsd:element name="author" type="xsd:string"/>
      <xsd:element name="title" type="xsd:string"/>
      <xsd:element name="genre" type="xsd:string"/>
      <xsd:element name="price" type="xsd:float"/>
      <xsd:element name="publish_date" type="xsd:dateTime"/>
      <xsd:element name="description" type="xsd:string"/>
    </xsd:sequence>
    <xsd:attribute name="id" type="xsd:string"/>
  </xsd:complexType>
</xsd:schema>
```

2. Open a command prompt.
3. Run the JAXB schema compiler, `xjc` command from the directory where the schema file is located. The `xjc` schema compiler tool is located in the `app_server_root\bin\` directory.

Running the `xjc` command generates the following JAXB Java files:

```
generated\Bookdata.java
generated\CatalogData.java
generated\ObjectFactory.java
```

4. Use the generated JAXB objects within a Java application to manipulate XML content through the generated JAXB classes.

Refer to the JAXB Reference implementation documentation for additional information about the xjc command.

Using the JAXB runtime to marshal and unmarshal XML documents

Use the Java Architecture for XML Binding (JAXB) run time to manipulate XML instance documents.

Before you begin

Use JAXB to generate Java classes from an XML schema with the schema compiler, xjc command or to generate an XML schema from a Java class with the schema generator, schemagen command.

About this task

Use JAXB APIs and tools to establish mappings between an XML schema and Java classes. After data bindings exist, use the JAXB binding runtime API to convert XML instance documents to and from Java objects. Data stored in an XML document is accessible without the need to understand the data structure. JAXB annotated classes and artifacts contains all the information that the JAXB runtime API needs to process XML instance documents. The JAXB runtime API enables marshaling of JAXB objects to XML and unmarshaling the XML document back to JAXB class instances.

Procedure

- Marshal JAXB objects to XML instance documents.

Use the JAXB runtime API to marshal or convert JAXB object instances into an XML instance document.

1. Instantiate your JAXB classes.
2. Invoke the JAXB marshaller.

This example demonstrates how to instantiate the generated JAXB objects within an application and use the JAXBContext class and the JAXB runtime marshaller APIs to marshal the JAXB objects into XML instances.

```
JAXBContext jc = JAXBContext.newInstance("myPackageName");
//Create marshaller
Marshaller m = jc.createMarshaller();
//Marshal object into file.
m.marshal(myJAXBObject, myOutputStream);
```

The JAXB Reference Implementation introduces additional vendor specific marshaller properties such as namespace prefix mapping, indentation, and character escaping control that are not defined by the JAXB specification. Use these properties to specify additional controls of the marshaling process. These properties operate with the JAXB Reference Implementation only and might not with other JAXB providers. Additional information regarding the vendor specific properties is located in the Java Architecture for XML Binding JAXB RI Vendor Extensions Runtime Properties specification.

- Unmarshal XML files to JAXB objects.

Use the JAXB runtime API to unmarshal or convert an XML instance document to JAXB object instances.

1. Obtain an existing XML instance document.
2. Invoke the JAXB unmarshaller.

This example demonstrates a program that reads an XML document and unmarshals or converts the XML document into JAXB object instances. Use the JAXBContext class and JAXB runtime Unmarshaller APIs to unmarshal the XML document.

```
JAXBContext jc = JAXBContext.newInstance("myPackageName");
//Create unmarshaller
Unmarshaller um = jc.createUnmarshaller();
//Unmarshal XML contents of the file myDoc.xml into your Java
object instance.
MyJAXBObject myJAXBObject = (MyJAXBObject)
um.unmarshal(new java.io.FileInputStream( "myDoc.xml" ));
```

Results

You can now marshal JAXB Java classes, and unmarshal XML data using the JAXB binding framework. Refer to the JAXB Reference implementation documentation for additional information about the marshal and unmarshal runtime APIs

Note: If Java 2 Security is enabled, wrap your `JAXBContext.newInstance()`, `Unmarshaller.unmarshal()` and, `Marshaller.marshal()` method calls within a `AccessController.doPrivileged` method to avoid a security exception.

xjc command for JAXB applications

Use the Java Architecture for XML Binding (JAXB) tools to generate Java classes from an XML schema with the xjc schema compiler tool.

JAXB is an XML-to-Java binding technology that enables transformation between schema and Java objects and between XML instance documents and Java object instances. JAXB technology consists of a runtime API and accompanying tools that simplify access to XML documents. You can use JAXB APIs and tools to establish mappings between Java classes and XML schema. An XML schema defines the data elements and structure of an XML document. JAXB technology provides a runtime environment to enable you to convert your XML documents to and from Java objects. Data stored in an XML document is accessible without the need to understand the XML data structure.

You can generate fully annotated Java classes from an XML schema file by using the JAXB schema compiler, xjc command-line tool. Use the xjc schema compiler tool to start with an XML schema definition (XSD) to create a set of JavaBeans that map to the elements and types defined in the XSD schema. Once the mapping between XML schema and Java classes exists, XML instance documents can be converted to and from Java objects through the use of the JAXB binding runtime API. The resulting annotated Java classes contains all the necessary information that the JAXB runtime requires to parse the XML for marshaling and unmarshaling. You can use the resulting JAXB classes within Java API for XML Web Services (JAX-WS) applications or in your non-JAX-WS Java applications for processing XML data.

Note: The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are located in the `app_server_root\bin\` directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the `app_server_root\bin\` directory.

In addition to using the xjc tool from the command line, you can invoke this JAXB tool from within the Ant build environments. Use the `com.sun.tools.xjc.XJCTask` Ant task from within the Ant build environment to invoke the xjc schema compiler tool. To function properly, this Ant task requires that you invoke Ant using the `ws_ant` script.

Note: If you are using the xjc Ant task, you must use the `destdir` parameter to specify the destination directory instead of the `target` option. Specifying the `target` option when using the xjc Ant task causes an error.

Syntax

The command-line syntax is:

```
app_server_root/bin/xjc [options] <schema_file/URL/directory_or_jar> ...[-b<binding_information>] ...
```

If a directory is specified, all schema files in the directory are compiled.

Parameters

The schema file/URL JAR file name or location of the directory is the only parameter that is required. The following parameters are optional for the xjc command:

-b <file_name or directory>

Specifies the external JAX-WS or JAXB binding files. You can specify multiple JAX-WS and JAXB binding files by using the `-b` option; however, each file must be specified with its own `-b` option. If a directory is specified, `**/*.xjb` is searched.

-catalog <file_name>

Specifies the catalog file to resolve external entity references. It supports the TR9401, XCatalog, and the OASIS XML Catalog formats.

-classpath <path>

Specifies the location of the class files.

-d <directory>

Specifies where to place the generated output files.

-dtd

Specifies to treat the input as XML Document Type Definition (DTD). This option is unsupported and experimental.

-extension

Specifies whether to enable custom extensions for functionality not specified by the JAXB specification. Use of the extensions can result in applications that are not portable or do not interoperate with other implementations.

-help

Displays the help menu.

-httpproxy <[user[:password]@]<proxyhost>:<proxyport>>

Specifies an HTTP or HTTPs proxy.

-httpproxyfile <file_name>

This parameter is similar to the `-httpproxy` parameter, but takes the argument in a file to protect the password.

-no-header

Specifies to suppress the generation of a file header with a timestamp.

-npa

Specifies to suppress the generation of the `**/package-info.java` package level annotation.

-nv

Specifies to not perform a strict validation of the input schemas.

-p <package_name>

Specifies a target package.

- quiet**
Specifies to suppress the output from the xjc tool.
- relaxng**
Specifies to treat the input as REgular LAnguage for XML Next Generation (RELAX NG). This option is unsupported and experimental.
- readOnly**
Specifies that the generated files are in read-only mode.
- relaxng-compact**
Specifies to treat the input as REgular LAnguage for XML Next Generation (RELAX NG) compact syntax. This option is unsupported and experimental.
- target <version>**
Specifies to generate output to conform to the specified level of the JAX-WS specification. Specify 2.0 or 2.1 for the tool to generate compliant code for the JAXB 2.0 or JAX-WS 2.1 specification respectively. Specify 2.1 for the tool to generate compliant code for the JAXB 2.1 specification. The default target version is 2.2 and generates compliant code for the JAXB 2.2 specification.
- verbose**
Specifies to output messages about what the compiler is doing.
- version**
Prints the version information. If you specify this option, only the version information is output and typical command processing does not occur.
- wsdl**
Specifies to treat the input as a Web Services Description Language (WSDL) file and compile schemas inside the WSDL. This option is unsupported and experimental.
- xml schema**
Specifies to treat the input as a World Wide Web Consortium (W3C) XML schema. This value is the default.

schemagen command for JAXB applications

Use the schema generator tool, `schemagen`, to generate an XML schema using Java Architecture for XML Binding (JAXB).

Use JAXB APIs and tools to establish mappings between an XML schema and Java classes. XML schemas describe the data elements and relationships in an XML document. After a data mapping or binding exists, you can convert XML documents to and from Java objects. You can now access data stored in an XML document without the need to understand the data structure.

You can generate a schema file from Java classes using the `schemagen` schema generator tool to create the XML schema. After the mapping between XML schema and Java classes exists, XML instance documents can be converted to and from Java objects through the use of the JAXB binding runtime API. The resulting Java classes contain all the necessary information that the JAXB run time requires to parse the XML for marshaling and unmarshaling. You can use the JAXB classes within Java API for XML Web Services (JAX-WS) applications or in your non-JAX-WS Java applications for processing XML data.

Note: The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are located in the `app_server_root\bin\` directory. Similar tooling is provided by

the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root\bin* directory.

Note: When running the schemagen tool to process JavaBeans, the schema generator will not automatically process the @XmlSchema annotations from existing package-info.class files to derive targetNamespaces. To assure that the schemagen tool processes namespace values correctly, use one of the following methods:

- Explicitly specify the package-info.java source file in the schemagen invocation; for example:

```
schemagen sample.Address sample\package-info.java
```

- Use the @XmlType annotation namespace attribute within your JavaBeans to specify a namespace; for example:

```
@XmlType(namespace="http://myNameSpace")  
public class Address {...}
```

In addition to using the schemagen tool from the command line, you can invoke this JAXB tool from within the Ant build environments. Use the `com.sun.tools.jxc.SchemaGenTask` Ant task from within the Ant build environment to invoke the schemagen schema generator tool. To function properly, this Ant task requires that you invoke Ant using the `ws_ant` script.

Syntax

The command-line syntax is:

```
app_server_root/bin/schemagen [options] <java_files>
```

Parameters

The following parameters are optional for the schemagen command:

-classpath <path>

Specifies the location of the Java source or class files.

-cp <path>

Specifies the location of the Java source or class files.

-d <path>

Specifies where to place the processor and the generated Java class files.

-episode<file_name>

Specifies to generate an episode file for separate compilation.

-encoding <encoding>

Specifies to use encoding when invoking the -apt or -javac tool. This property is applicable for JAXB 2.2 and later.

-help

Displays the help menu.

-version

Prints the version information. If you specify this option, only the version information is output and typical command processing does not occur.

Developing JAX-WS web services (bottom up)

Setting up a development environment for web services

The application server provides command-line tools to develop web services clients and implementations that are based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. You must set up your development environment before you start developing web services.

Before you begin

Before you can set up a web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information on installing the application server, read about installing your application server environment.

About this task

Set up a web services development environment by completing the following actions.

Procedure

Set up the environment.

Run the `setupCmdLine` script on the Qshell command line from the `./profile_root/bin` directory.

Results

You have set up an environment so that you can develop Web services.

What to do next

Implement web services applications. See the task overview for implementing web services applications information to learn about how to develop and implement a Java EE web service.

Developing JAX-WS web services with annotations

Java API for XML-Based Web Services (JAX-WS) supports two different service endpoint implementations types, the standard web service endpoint interface and a new Provider interface to enable services to work at the XML message level. By using annotations on the service endpoint implementation or client, you can define the service endpoint as a web service.

Before you begin

Set up a development environment for web services.

About this task

This task is a required step to develop JAX-WS web services.

JAX-WS technology supports the implementation of web services based on both the standard service endpoint interface and a new Provider interface. JAX-WS endpoints are like the endpoint implementations in the Java API for XML-based RPC (JAX-RPC) specification. Unlike JAX-RPC, the requirement for a service endpoint interface (SEI) is optional for JAX-WS web services. JAX-WS services that do not have an associated SEI are regarded as having an implicit SEI; whereas services that have an associated SEI are regarded as having an explicit SEI. The service endpoint interfaces required by JAX-WS are also more generic than the service endpoint interfaces required by JAX-RPC. With JAX-WS, the SEI is not required to extend the `java.rmi.Remote` interface as required by the JAX-RPC specification.

The JAX-WS programming model also uses support for annotating Java classes with metadata to define a service endpoint implementation as a web service and define how a client can access the web service. JAX-WS supports annotations based on the Metadata Facility for the Java Programming Language (JSR 175) specification, the Web Services Metadata for the Java Platform (JSR 181) specification and annotations defined by the JAX-WS 2.0 (JSR 224) specification, which includes Java Architecture for XML Binding (JAXB) annotations. Using annotations, the service endpoint implementation can independently describe the web service without requiring a WSDL file. Annotations can provide all the WSDL information necessary to configure your service endpoint implementation or web services client. You can specify annotations on the service endpoint interface used by the client and the server, or on the server-side service implementation class.

For details regarding the supported standards and specifications, see the web services specifications and API documentation.

When developing a JAX-WS web service starting from existing Java classes, known as the bottom-up approach, you must annotate the class with either the `@WebService` (`javax.jws.WebService`) annotation or `@WebServiceProvider` (`javax.xml.ws.Provider`) annotation to initially define the class as a web service. The `@WebService` annotation defines the service as an SEI-based endpoint, while the `@WebServiceProvider` annotation defines the service as a Provider-based endpoint.

Develop SEI-based JAX-WS web services

For an SEI-based endpoint, the service endpoint interface (SEI), whether it is a Java class or a Java interface, declares the business methods provided by a particular web service. The only methods that a web services client can invoke on a JAX-WS endpoint are the business methods that are defined in the explicit or implicit SEI.

All SEI-based endpoints are required to have the `@WebService` annotation included on the implementation class. If the service implementation uses an explicit SEI, then that interface must be referenced by the `endpointInterface` attribute on the `@WebService` annotation. If the service implementation does not use an explicit SEI, then the service is described implicitly by the implementation class and is an implicit SEI.

Develop JAX-WS web services using the Provider interface

The JAX-WS programming model introduces the Provider interface for Provider endpoints, `javax.xml.ws.Provider`, as the dynamic alternative to SEI-based endpoints. The Provider interface supports a more messaging-oriented approach to web services. With the Provider interface, you can create a Java class that implements a simple interface to produce a generic service implementation class. The Provider interface defines one method, the `invoke` method, which uses generics to control both the input and output types when working with various messages or message payloads. All Provider endpoints must be annotated with the `@WebServiceProvider` (`javax.xml.ws.WebServiceProvider`) annotation. A service implementation cannot specify the `@WebService` annotation if it implements the `javax.xml.ws.Provider` interface.

Note: Starting with WebSphere Application Server Version 7.0 and later, Java EE 5 application modules (web application modules version 2.5 or above, or EJB modules version 3.0 or above) are scanned for annotations to identify JAX-WS services and clients. However, pre-Java EE 5 application modules (web application modules version 2.4 or before, or EJB modules version 2.1 or before) are not scanned for JAX-WS annotations, by default, for performance considerations. In the Version 6.1 Feature Pack for Web Services, the default behavior is to scan pre-Java EE 5 web application modules to identify JAX-WS services and to scan pre-Java EE 5 web application modules and EJB modules for service clients during application installation. Because the default behavior for WebSphere Application Server Version 7.0 and later is to not scan pre-Java EE 5 modules for annotations during application installation or server startup, to preserve backward compatibility with the feature pack from previous releases, you must configure either the `UseWSFEP61ScanPolicy` property in the META-INF/MANIFEST.MF of a web application archive (WAR) file or EJB module or define the Java virtual machine custom property,

com.ibm.websphere.webservices.UseWSFEP61ScanPolicy, on servers to request scanning during application installation and server startup. To learn more about annotations scanning, see the JAX-WS annotations information.

Procedure

1. Determine if you want to define your web services using SEI endpoints or the Provider interface. If you prefer a high-level Java-centric abstraction that hide the details of converting between Java objects and their XML representation, consider using SEI-based endpoints to develop your web services. However, if you prefer that your web service operate more at the XML message level, consider using Provider-based endpoints.
2. Annotate the service endpoints.

a. Annotate the SEI-based endpoint with the `javax.jws.WebService` annotation.

- For an SEI-based endpoint, annotate the implementation class with the `javax.jws.WebService` annotation. You can choose to explicitly reference a service endpoint interface by defining the `@WebService.endpointInterface` attribute, which specifies this endpoint is an explicit SEI. In this case, the Java interface that is referenced must also contain the `javax.jws.WebService` annotation. If the `endpointInterface` attribute is not defined or is empty, the implementation bean is considered an implicit SEI. You can add the `@WebMethod` annotation to methods of a service endpoint interface to customize the Java-to-WSDL mappings. All public methods are considered exposed methods regardless of whether the `@WebMethod` annotation is specified. It is incorrect to have an `@WebMethod` annotation on a service endpoint interface that contains the `exclude` attribute.
- If you use an implicit SEI, you can apply more granular control on how the methods are exposed through selective use of the `@WebMethod` annotation. For a more detailed explanation, see the exposing methods in SEI-based JAX-WS web services information.

b. Annotate the Provider-based endpoint with the `javax.xml.ws.WebServiceProvider` annotation.

- For a Provider-based endpoint, annotate the implementation class with the `javax.xml.ws.WebServiceProvider` annotation. This annotation must be specified only on a class that implements a strongly typed `javax.xml.ws.Provider` interface class such as `Provider<Source>` or `Provider<SOAPMessage>`, in contrast to a class that is unbounded, such as `Provider<T>`. A strongly typed class is one that is associated with a specific input and output Java type, such as `Source` or `SOAPMessage`, for example.

```
@WebServiceProvider(  
    serviceName="StringProviderService",  
    wsdlLocation="META-INF/echostring.wsdl",  
    targetNamespace="http://stringprovider.sample.test.org")
```

- (optional) According the JAX-WS 2.2 specification, if you are defining a Provider-based endpoint so that the Provider implementation returns a null value, no response is needed. If the `javax.xml.ws.WebServiceProvider` annotation does not specify a WSDL, and the `Provider` `invoke()` method returns a null value, the default behavior of the JAX-WS runtime environment is to return a response that consists of a `SOAPEnvelope` that contains an empty `SOAPBody`. You can set the JVM property, `jaxws.provider.interpretNullAsOneway`, to true if you want the JAX-WS runtime environment to interpret this scenario as a request-only operation and not return a response.

3. Understand and apply best practices for exposing methods as operations in SEI-based JAX-WS web services.

Because of ambiguity across multiple web services specifications regarding which methods are exposed as web services operations for SEI-based endpoints, you can ensure consistent behavior by following best practices, regardless of the JAX-WS implementation that you use.

Results

You have defined the service endpoint implementation that represents the web services application. See the JAX-WS annotations documentation to learn more about the supported JAX-WS annotations.

Example

Sample JavaBeans service endpoint implementation and interface

The following example illustrates a simple explicit JavaBeans service endpoint implementation and the associated service endpoint interface:

```
/** This is an excerpt from the service implementation file, EchoServicePortTypeImpl.java.
package com.ibm.was.wssample.echo;
import java.io.ByteArrayInputStream;
import java.io.ByteArrayOutputStream;

import javax.xml.bind.JAXBContext;
import javax.xml.bind.Marshaller;
import javax.xml.bind.Unmarshaller;
import javax.xml.transform.stream.StreamSource;

@javax.jws.WebService(serviceName = "EchoService", endpointInterface =
"com.ibm.was.wssample.echo.EchoServicePortType", targetNamespace="http://com.ibm.was.wssample/echo/",
portName="EchoServicePort")
public class EchoServicePortTypeImpl implements EchoServicePortType {

    public EchoServicePortTypeImpl() {
    }

    public String echo(String obj) {
        String str;
        ....
        str = obj;
        ....

        return str;
    }
}

/** This is a sample EchoServicePortType.java service interface. */

import javax.jws.WebMethod;
import javax.jws.WebService;
import javax.xml.ws.*;

@WebService(name = "EchoServicePortType", targetNamespace = "http://com.ibm.was.wssample/echo/",
wsdlLocation="WEB-INF/wsdl/Echo.wsdl")
public interface EchoServicePortType {

    /** ...the method process ...*/
    @WebMethod
}

```

Sample Provider endpoint implementation

The following example illustrates a simple Provider service endpoint interface for a Java class:

```
package javax.xml.ws.provider.source;

import javax.xml.ws.Provider;
import javax.xml.ws.WebServiceProvider;
import javax.xml.transform.Source;

@WebServiceProvider()
public class SourceProvider implements Provider<Source> {

    public Source echo(Source data) {
        return data;
    }
}

```

In the Provider implementation example, the `javax.xml.transform.Source` type is specified in the generic `<Source>` method. The generic `<Source>` method specifies that both the input and output types are Source objects.

What to do next

Develop Java artifacts for JAX-WS applications from JavaBeans. To learn more, see the generating Java artifacts for JAX-WS applications information.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root

The default installation root directory for the Application Client for IBM WebSphere Application Server is the /QIBM/ProdData/WebSphere/AppClient/V8/client directory.

app_client_user_data_root

The default Application Client for IBM WebSphere Application Server user data root is the /QIBM/UserData/WebSphere/AppClient/V8/client directory.

app_client_profile_root

The default Application Client for IBM WebSphere Application Server profile root is the /QIBM/UserData/WebSphere/AppClient/V8/client/profiles/*profile_name* directory.

app_server_root

The default installation root directory for WebSphere Application Server - Express is the /QIBM/ProdData/WebSphere/AppServer/V8/Express directory.

java_home

Table 132. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32-bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit
64-bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit

plugins_profile_root

The default Web Server Plug-ins profile root is the /QIBM/UserData/WebSphere/Plugins/V8/webserver/profiles/*profile_name* directory.

plugins_root

The default installation root directory for Web Server Plug-ins is the /QIBM/ProdData/WebSphere/Plugins/V8/webserver directory.

plugins_user_data_root

The default Web Server Plug-ins user data root is the /QIBM/UserData/WebSphere/Plugins/V8/webserver directory.

product_library

product_lib

This is the product library for the installed product. The product library for each Version 8.0 installation on the system contains the program and service program objects (similar to .exe, .dll, .so objects) for the installed product. The product library name is QWAS8x (where x is A, B, C, and so on). The product library for the first WebSphere Application Server Version 8.0 product installed

on the system is QWAS8A. The *app_server_root/properties/product.properties* file contains the value for the product library of the installation, *was.install.library*, and is located under the *app_server_root* directory.

profile_root

The default directory for a profile named *profile_name* for WebSphere Application Server - Express is the */QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/profile_name* directory.

shared_product_library

The shared product library, which contains all of the objects shared by all installations on the system, is QWAS8. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root

The default user data directory for WebSphere Application Server - Express is the */QIBM/UserData/WebSphere/AppServer/V8/Express* directory.

The profiles and profileRegistry subdirectories are created under this directory when you install the product.

web_server_root

The default web server path is */www/web_server_name*.

Exposing methods in SEI-based JAX-WS web services

You can use the `@WebService` and `@WebMethod` annotations on a service endpoint implementation to specify Java methods that you want to expose as Java API for XML-Based Web Services (JAX-WS) web services.

Before you begin

JAX-WS technology enables the implementation of web services based on both the standard service endpoint interface and a Provider interface. When developing a JAX-WS web service starting from existing Java classes, known as the bottom-up approach, you must annotate the class with either the `@WebService` or `@WebServiceProvider` annotation to initially define the class as a web service.

Using the Provider interface is the dynamic approach to defining your JAX-WS services. To use the Provider interface, your class must implement the `javax.xml.ws.Provider` interface, and contain the `@WebServiceProvider` annotation. The Provider interface has one method, the `invoke` method, which uses generics in the Java programming language to control both the input and output types when working with various messages or message payloads.

In contrast, this topic describes how you can use Java annotations to describe your web services using the service endpoint interface (SEI) approach.

About this task

To initially define a web service, annotate the Java class with the `@WebService` annotation. You can also selectively annotate individual methods with the `@WebMethod` annotation to control their exposure as web services operations.

Because of ambiguities across multiple web services specifications regarding how methods are exposed as operations, use the following guidelines to help ensure consistent behavior regardless of the JAX-WS implementation that you use.

- To define a basic web service, annotate the implementation class with the `@WebService` annotation.
- To define your web services using an explicit SEI, explicitly reference a Java interface class using the `endpointInterface` attribute of the `@WebService` annotation.

- Provide a reference to a WSDL file in the `wSDLLocation` attribute of the `@WebService` annotation. By specifying a pre-defined WSDL file, performance is improved. Also, discrepancies between the WSDL file and the annotations are reported to you by the runtime environment.
- When you use an explicit SEI, all public methods in the SEI and inherited classes are always exposed. You only need to add `@WebMethod` annotations if you want to further customize the methods that are already exposed.
- Providing a reference in the `@WebService` annotation to an explicit SEI or to an existing WSDL file helps to remove possible ambiguities when exposing methods.
- If you do not use an explicit SEI, follow these rules to ensure that your methods are exposed consistently:
 - Add an `@WebService` annotation to your implementation class and all its superclasses that contain methods that you want to expose. Adding an `@WebService` annotation to a class exposes all public methods in that class that are not static or final.
 - If you want more granular control to expose only certain methods, use the `@WebMethod` annotation on selected methods. To ensure that a method is exposed, annotate it with the `@WebMethod` annotation. If you want to make sure that a method is not exposed, annotate it with the `@WebMethod(exclude=true)` annotation.

Note:

Behavior change for exposing methods that are not annotated:

The behavior of JAX-WS has changed regarding exposing methods as web services operations. This complies with recent clarifications to JAX-WS specifications.

Applications without an explicit SEI or WSDL that are migrated from prior versions might have additional operations exposed as shown below. You can set a property so the JAX-WS runtime environment uses the legacy behavior. You might need this when migrating applications without a WSDL or an SEI so that additional methods are not exposed.

```
@WebService
public class Foo {
    @WebMethod
    public void a() {} // exposed now, exposed before
    public void b() {} // exposed now, not exposed before
}
```

Using the new interpretation, public methods in an implementation class and its superclasses are only exposed under the following conditions:

- The containing class has an `@WebService` annotation.
- The method does not have an `@WebMethod(exclude=true)` annotation.

Using the legacy interpretation, a method in an implementation class and its superclasses are only exposed under the following conditions:

- The containing class has an `@WebService` annotation.
- The method has no `@WebMethod` annotations AND no other methods have `@WebMethod` annotations.
- The method has an `@WebMethod` or `@WebMethod(exclude=false)` annotation.

To specify that the JAX-WS runtime environment use the legacy `@WebMethod` behavior, configure the `jaxws.runtime.legacyWebMethod=true` property. You can configure this property as a Java Virtual Machine (JVM) system property or as a property in the `META-INF/MANIFEST.MF` file of a web application archive (WAR) file. By default, this property is set to `false` and the application server uses the new behavior.

You might encounter a `WSWS7054E` error message if all of the following conditions are true:

- Your web service application consists of unannotated methods.
- The methods are not meant to be mapped to a web service operation.
- Your application does not reference an SEI nor package a WSDL file.

The error message contains information that is similar to the following text:

```
javax.xml.ws.WebServiceException: WSWS7054E:  
The Web Services Description Language (WSDL) file could not be generated for the XXXX Web service implementation  
class because of the following error: javax.xml.ws.WebServiceException: Unable to create JAXBContext
```

The JAX-WS tooling complies with the JAX-WS specification with respect to `@WebMethod` mapping principles. This change might affect applications that have been dependent on previously non-compliant default behavior. If your applications package and reference WSDL or an SEI and have ALL methods correctly annotated with the `@WebMethod` exclude flag in the SEI implementation, then this change does not affect you. However, if you are affected, add explicit annotations to your methods to ensure that they are excluded in WSDL generation. For example: `@WebMethod(exclude=true)` Also, you can package a WSDL with your application to eliminate the need for the run time to generate a WSDL on your behalf.

Behavior change for exposing static and final methods:

Static or final methods in a service without an explicit SEI are no longer exposed as web services operations. To expose them, package the WSDL with the application and set `jaxws.runtime.legacyWebMethod=true`.

Procedure

1. Identify the methods that you want to expose as web services operations.
2. Review the rules for exposing methods as operations on classes annotated with the `@WebService` annotation.
3. Use the best practices for applying the `@WebMethod` and `@WebService` annotations in applications without SEIs to appropriately expose methods as operations within your web services.

Results

You have used the `@WebMethod` annotation to specify which methods to expose as web services operations.

Note:

If you have upgraded your application server environment and you are experiencing problems, review the following troubleshooting information.

Client errors indicate a mismatch between the WSDL file and portType when using a JAX-WS tooling version 2.1.6 or higher environment

You might receive a client-side error message like the following message:

```
javax.xml.ws.WebServiceException: The Endpoint validation failed to validate due to the following errors:  
:: Invalid Endpoint Interface ::  
:: The number of operations in the WSDL portType does not match the number of methods in the SEI or web service  
implementation class. wsdl operations = [...] dispatch operations = [....]
```

To correct this problem, you must regenerate client artifacts to match the WSDL file.

Note: Be sure to regenerate your client side artifacts any time you receive an updated WSDL file.

Clients that perform a ?WSDL operation on web services have non-dispatchable operations

After performing a ?WSDL operation, you might receive a WSDL file that contains more operations than the JAX-WS runtime environment can dispatch. If the client tries to invoke any of the non-dispatchable operations, the client receives an error like the following message:

```
The endpoint reference (EPR) for the Operation not found is http://localhost:9086/example/BeanImpl2Service and the WSA  
Action = <WSA_action_from_server>. If this EPR was previously reachable, contact the server administrator.
```

Clients must only access the operations that the web service intends to expose. You can correct this problem in one of the following ways:

- Modify the `@WebMethod` annotations in the web services application so that the resulting WSDL file exposes the correct set of operations.
- Set the `jaxws.runtime.legacyWebMethod` property to `false` to ensure that all operations in the WSDL are dispatched.

What to do next

Develop Java artifacts for JAX-WS applications from JavaBeans.

JAX-WS annotations

Java API for XML-Based Web Services (JAX-WS) relies on the use of annotations to specify metadata associated with web services implementations and to simplify the development of web services. Annotations describe how a server-side service implementation is accessed as a web service or how a client-side Java class accesses web services.

The JAX-WS programming standard introduces support for annotating Java classes with metadata that is used to define a service endpoint application as a web service and how a client can access the web service. JAX-WS supports the use of annotations based on the Metadata Facility for the Java Programming Language (Java Specification Request (JSR) 175) specification, the Web Services Metadata for the Java Platform (JSR 181) specification and annotations defined by the JAX-WS 2.0 and later (JSR 224) specification which includes JAXB annotations. Using annotations from the JSR 181 standard, you can simply annotate the service implementation class or the service interface and now the application is enabled as a web service. Using annotations within the Java source simplifies development and deployment of web services by defining some of the additional information that is typically obtained from deployment descriptor files, WSDL files, or mapping metadata from XML and WSDL into the source artifacts.

Use annotations to configure bindings, handler chains, set names of portType, service and other WSDL parameters. Annotations are used in mapping Java to WSDL and schema, and at runtime to control how the JAX-WS runtime processes and responds to web service invocations.

For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

Note:

Starting with WebSphere Application Server Version 7.0 and later, Java EE 5 application modules (Web application modules version 2.5 or above, or EJB modules version 3.0 or above) are scanned for annotations to identify JAX-WS services and clients. However, pre-Java EE 5 application modules (web application modules version 2.4 or before, or EJB modules version 2.1 or before) are not scanned for JAX-WS annotations, by default, for performance considerations.

In the Version 6.1 Feature Pack for Web Services, the default behavior is to scan pre-Java Platform, Enterprise Edition (Java EE) 5 web application modules to identify JAX-WS services and to scan pre-Java EE 5 web application modules and EJB modules for service clients during application installation. Because the default behavior for WebSphere Application Server Version 7.0 and later is to not scan pre-Java EE 5 modules for annotations during application installation or server startup, to preserve backward compatibility with the feature pack from previous releases, you must configure one of the following properties:

- You can set the `UseSFEP61ScanPolicy` property in the META-INF/MANIFEST.MF of a WAR file or EJB module to `true`. For example:

```
Manifest-Version: 1.0
UseSFEP61ScanPolicy: true
```

When this property is set to `true` in the `META-INF/MANIFEST.MF` file of the module, the module is scanned for JAX-WS annotations regardless of the Java EE version of the module. The default value is `false` and when the default value is in effect, JAX-WS annotations are only supported in modules whose version is Java EE 5 or later.

- You can set the `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` custom Java virtual machine (JVM) property using the administrative console. See the JVM custom properties documentation for the correct navigation path to use. To request annotation scanning in all modules regardless of their Java EE version, set the custom property `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` to `true`. You must change the setting on each server that requires a change in the default behavior.

If the property is set within the `META-INF/MANIFEST.MF` file of the module, this setting takes precedence over the server's custom JVM property. When using either property, you must establish the desired annotation scanning behavior before the application is installed. You cannot dynamically change the scanning behavior once an application is installed. If changes to the behavior are required after your application is installed, you must first uninstall the application, specify the desired scanning behavior using the appropriate property and then install the application again. When federating nodes that have the `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` set to `true` in the configuration of the servers contained within the node, this property does not affect the deployment manager. You must set the property to `true` on the deployment manager before the node is federated to preserve the behavior as it was on the node before federation.

Annotations supported by JAX-WS are listed in the table below. The target for annotations is applicable for these Java objects:

- types such as a Java class, enum or interface
- methods
- fields representing local instance variables within a Java class
- parameters within a Java method

Table 133. Web services Metadata Annotations (JSR 181). Describes the supported web services metadata annotations and their associated properties.

Annotation class	Annotation	Properties
<p>javax.jws.WebService</p>	<p>The @WebService annotation marks a Java class as implementing a Web service or marks a service endpoint interface (SEI) as implementing a web service interface.</p> <p>Important:</p> <ul style="list-style-type: none"> A Java class that implements a web service must specify either the <code>@WebService</code> or <code>@WebServiceProvider</code> annotation. Both annotations cannot be present. <p>This annotation is applicable on a client or server SEI or a server endpoint implementation class.</p> <ul style="list-style-type: none"> If the annotation references an SEI through the <code>endpointInterface</code> attribute, the SEI must also be annotated with the <code>@WebService</code> annotation. See the exposing methods in SEI-based JAX-WS web services information to learn about best practices for using the <code>@WebService</code> and <code>@WebMethod</code> annotations on a service endpoint implementation to specify Java methods that you want to expose as JAX-WS web services. 	<ul style="list-style-type: none"> Annotation target: Type Properties: <ul style="list-style-type: none"> name The name of the <code>wsdl:portType</code>. The default value is the unqualified name of the Java class or interface. (String) targetNamespace Specifies the XML namespace of the WSDL and XML elements generated from the web service. The default value is the namespace mapped from the package name containing the web service. (String) serviceName Specifies the service name of the web service: <code>wsdl:service</code>. The default value is the simple name of the Java class + <code>Service</code>. (String) endpointInterface Specifies the qualified name of the service endpoint interface that defines the services' abstract web service contract. If specified, the service endpoint interface is used to determine the abstract WSDL contract. (String) portName The <code>wsdl:portName</code>. The default value is <code>WebService.name + Port</code>. (String) wsdlLocation Specifies the web address of the WSDL document defining the web service. The web address is either relative or absolute. (String)
<p>javax.jws.WebMethod</p>	<p>The @WebMethod annotation denotes a method that is a web service operation.</p> <p>Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.</p>	<ul style="list-style-type: none"> Annotation target: Method Properties: <ul style="list-style-type: none"> operationName Specifies the name of the <code>wsdl:operation</code> matching this method. The default value is the name of Java method. (String) action Defines the action for this operation. For SOAP bindings, this value determines the value of the SOAPAction header. The default value is the name of Java method. (String) exclude Specifies whether to exclude a method from the web service. The default value is <code>false</code>. (Boolean)

Table 133. Web services Metadata Annotations (JSR 181) (continued). Describes the supported web services metadata annotations and their associated properties.

Annotation class	Annotation	Properties
<p>javax.jws.Oneway</p>	<p>The @Oneway annotation denotes a method as a web service one-way operation that only has an input message and no output message.</p> <p>Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.</p>	<ul style="list-style-type: none"> • Annotation target: Method • There are no properties on the Oneway annotation.
<p>javax.jws.WebParam</p>	<p>The @WebParam annotation customizes the mapping of an individual parameter to a web service message part and XML element.</p> <p>Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.</p>	<ul style="list-style-type: none"> • Annotation target: Parameter • Properties: <ul style="list-style-type: none"> - name <p>The name of the parameter. If the operation is remote procedure call (RPC) style and the <code>partName</code> attribute is not specified, then this is the name of the <code>wsdl:part</code> attribute representing the parameter. If the operation is document style or the parameter maps to a header, then <code>-name</code> is the local name of the XML element representing the parameter. This attribute is required if the operation is document style, the parameter style is BARE, and the mode is OUT or INOUT. (String)</p> - partName <p>Defines the name of <code>wsdl:part</code> attribute representing this parameter. This is only used if the operation is RPC style, or the operation is document style and the parameter style is BARE. (String)</p> - targetNamespace <p>Specifies the XML namespace of the XML element for the parameter. Applies only for document bindings when the attribute maps to an XML element. The default value is the <code>targetNamespace</code> for the web service. (String)</p> - mode <p>The value represents the direction the parameter flows for this method. Valid values are IN, INOUT, and OUT. (String)</p> - header <p>Specifies whether the parameter is in a message header rather than a message body. The default value is <code>false</code>. (Boolean)</p>

Annotation class	Annotation	Properties
javax.xml.ws.RespectBinding	<p>The @RespectBinding annotation specifies whether the JAX-WS implementation must use the contents of the wsdl:binding for an endpoint.</p> <p>When this annotation is specified, a check is performed to ensure all required WSDL extensibility elements with the enabled attribute set to true are supported.</p> <p>Apply this annotation to methods on a server endpoint implementation class.</p>	<ul style="list-style-type: none"> • Annotation target: Method • Properties: <ul style="list-style-type: none"> - enabled Specifies whether the wsdl:binding must be used or not. The default value is true. (Boolean)
javax.xml.ws.ServiceMode	<p>The @ServiceMode annotation specifies whether a service provider needs to have access to an entire protocol message or just the message payload.</p> <p>Important:</p> <ul style="list-style-type: none"> • The @ServiceMode annotation is only supported on classes that are annotated with the @WebServiceProvider annotation. 	<ul style="list-style-type: none"> • Annotation target: Type • Properties: <ul style="list-style-type: none"> - value Indicates whether the provider class accepts the payload of the message, PAYLOAD or the entire message MESSAGE. The default value is PAYLOAD. (String)
javax.xml.ws.soap.Addressing	<p>The @Addressing annotation specifies that this service wants to enable WS-Addressing support.</p> <p>Apply this annotation to methods on a server endpoint implementation class.</p>	<ul style="list-style-type: none"> • Annotation target: Type • Properties: <ul style="list-style-type: none"> - enabled Specifies if WS-Addressing is enabled or not. The default value is true. (Boolean) - required Specifies that WS-Addressing headers must be present on incoming messages. The default value is false. (Boolean) - responses Specifies the message exchange pattern to use. The default value is Responses.ALL. This property is applicable for JAX-WS 2.2 and later. (String)

Table 134. JAX-WS Annotations (JSR 224) (continued). Describes the supported JAX-WS annotations and their associated properties.

Annotation class	Annotation	Properties
<p>javax.xml.ws.soap.MTOM</p>	<p>The @MTOM annotation specifies whether binary content in the body of a SOAP message is sent using MTOM.</p> <p>Apply this annotation to a service endpoint implementation class.</p>	<ul style="list-style-type: none"> • Annotation target: Class • Properties: <ul style="list-style-type: none"> - enabled Specifies if MTOM is enabled for the JAX-WS endpoint. The default value is <code>true</code>. (Boolean) - threshold Specifies the minimum size for messages that are sent using MTOM. When the message size is less than this specified integer, the message is inlined in the XML document as base64 or hexBinary data. (integer)
<p>javax.xml.ws.WebFault</p>	<p>The @WebFault annotation maps WSDL faults to Java exceptions. It is used to capture the name of the fault during the serialization of the JAXB type that is generated from a global element referenced by a WSDL fault message. It can also be used to customize the mapping of service specific exceptions to WSDL faults.</p> <p>This annotation can only be applied to a fault implementation class on the client or server.</p>	<ul style="list-style-type: none"> • Annotation target: Type • Properties: <ul style="list-style-type: none"> - name Specifies the local name of the XML element that represents the corresponding fault in the WSDL file. The actual value must be specified. (String) - targetNamespace Specifies the namespace of the XML element that represents the corresponding fault in the WSDL file. (String) - faultBean Specifies the name of the fault bean class. (String) - messageName Specifies the name of the wsdl:message attribute that represents the corresponding fault in the WSDL file. This property is applicable for JAX-WS 2.2 and later. (String)

Table 134. JAX-WS Annotations (JSR 224) (continued). Describes the supported JAX-WS annotations and their associated properties.

Annotation class	Annotation	Properties
<p>javax.xml.ws.WebServiceProvider</p>	<p>The @WebServiceProvider annotation denotes that a class satisfies requirements for a JAX-WS Provider implementation class.</p> <p>Important:</p> <ul style="list-style-type: none"> • A Java class that implements a web service must specify either the <code>@WebService</code> or <code>@WebServiceProvider</code> annotation. Both annotations cannot be present. • The <code>@WebServiceProvider</code> annotation is only supported on the service implementation class. <p>Any class with the <code>@WebServiceProvider</code> annotation must implement the <code>javax.xml.ws.Provider</code> interface.</p>	<ul style="list-style-type: none"> • Annotation target: Type • Properties: <ul style="list-style-type: none"> - targetNamespace Specifies the XML namespace of the WSDL and XML elements generated from the web service. The default value is the namespace mapped from the package name containing the web service. (String) - serviceName Specifies the service name of the web service: <code>wsdl:service</code>. The default value is the simple name of the Java class + <code>Service</code>. (String) - portName The <code>wsdl:portName</code>. The default value is the name of the class + <code>Port</code>. (String) - wsdlLocation The web address of the WSDL document defining the web service. This attribute is required. (String)

Table 134. JAX-WS Annotations (JSR 224) (continued). Describes the supported JAX-WS annotations and their associated properties.

Annotation class	Annotation	Properties
<p>javax.xml.ws.WebServiceRef</p>	<p>The @WebServiceRef annotation defines a reference to a web service invoked by the client.</p> <p>Important:</p> <ul style="list-style-type: none"> The @WebServiceRef annotation can be used to inject instances of JAX-WS services and ports. The @WebServiceRef annotation is only supported in certain class types. Examples are JAX-WS endpoint implementation classes, JAX-WS handler classes, Enterprise JavaBeans classes, and servlet classes. This annotation is supported in the same class types as the @Resource annotation. See the Java Platform, Enterprise Edition (Java EE) 5 specification for a complete list of supported class types. 	<ul style="list-style-type: none"> Annotation target: Type, Field or Method Properties: <ul style="list-style-type: none"> - name Specifies the JNDI name of the resource. The field name is the default for field annotations. The JavaBeans property name that corresponds to the method is the default for method annotations. You must specify a value for class annotations as there is no default. (String) - type Indicates the Java type of the resource. The field type is the default for field annotations. The type of the JavaBeans property is the default for method annotations. You must specify a value for class annotations as there is no default. (Class) - mappedName Specifies the name to map this resource to. (String) - value Indicates the value of the service class and it is a type that extends <code>javax.xml.ws.Service</code>. This attribute is required when the type of the reference is a service endpoint interface. (Class) - wsdlLocation The web address of the WSDL document defining the web service. This attribute is required. (String) - lookup Specifies the JNDI lookup name for the target web service. This property is applicable for JAX-WS 2.2 and later. (String)
<p>javax.xml.ws.WebServiceRefs</p>	<p>The @WebServiceRefs annotation associates multiple @WebServiceRef annotations with a specific class.</p> <p>Important:</p> <ul style="list-style-type: none"> The @WebServiceRef annotation is only supported in certain class types. Examples are JAX-WS endpoint implementation classes, JAX-WS handler classes, Enterprise JavaBeans classes, and servlet classes. This attribute is required.</p>
<p>javax.annotation.PostConstruct</p>	<p>The @PostConstruct annotation marks a method that needs to run after dependency injection is performed on the class.</p> <p>Apply this annotation to a JAX-WS application handler, a server endpoint implementation class.</p>	<ul style="list-style-type: none"> • Annotation target: Method
<p>javax.annotation.PreDestroy</p>	<p>The @PreDestroy annotation marks a method that must be run when the instance is in the process of being removed by the container.</p> <p>Apply this annotation to a JAX-WS application handler or a server endpoint implementation class.</p>	<ul style="list-style-type: none"> • Annotation target: Method

Table 136. IBM proprietary annotations. Describes the supported IBM proprietary annotations and their associated properties.

Annotation class	Annotation	Properties
<p>com.ibm.websphere.wsaddressing. Jaxws21. SubmissionAddressing</p>	<p>The @SubmissionAddressing annotation specifies that this service wants to enable WS-Addressing support for the 2004/08 WS-Addressing specification.</p> <p>This annotation is part of the IBM implementation of the JAX-WS 2.1 specification.</p> <p>Apply this annotation to methods on a server endpoint implementation class.</p>	<ul style="list-style-type: none"> • Annotation target: Type • Properties: <ul style="list-style-type: none"> - enabled Specifies if WS-Addressing is enabled or not. The default value is true. (Boolean) - required Specifies that WS-Addressing headers must be present on incoming messages. The default value is false. (Boolean)

Generating Java artifacts for JAX-WS applications

Use Java API for XML-Based Web Services (JAX-WS) tools to generate the necessary JAX-WS and Java Architecture for XML Binding (JAXB) Java artifacts that are needed for JAX-WS web services applications when starting from JavaBeans or enterprise beans components.

Before you begin

To develop a Java API for XML-Based Web Services (JAX-WS) web service application, you must first develop a service endpoint interface (SEI) implementation that explicitly or implicitly describes the SEI.

About this task

When using a bottom-up approach to develop JAX-WS web services, use the `wsgen` command-line tool on the existing service endpoint implementation. The `wsgen` tool processes a compiled service endpoint implementation class as input and generates the following portable artifacts:

- Java Architecture for XML Binding (JAXB) classes that are required to marshal and unmarshal the message contents.
- a Web Services Description Language (WSDL) file if the optional `-wsdl` argument is specified.

Note: The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are located in the `app_server_root\bin\` directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the `app_server_root\bin\` directory.

You are not required to develop a WSDL file when developing JAX-WS Web services using the bottom-up approach of starting with JavaBeans. The use of annotations provides all of the WSDL information necessary to configure the service endpoint or the client. The application server supports WSDL 1.1 documents that comply with Web Services-Interoperability (WS-I) Basic Profile 1.1 specifications and are either Document/Literal style documents or RPC/Literal style documents. Additionally, WSDL documents with bindings that declare a `USE` attribute of value `LITERAL` are supported while the value, `ENCODED`, is not supported. For WSDL documents that implement a Document/Literal wrapped pattern, a root element is declared in the XML schema and is used as an operation wrapper for a message flow. Separate wrapper element definitions exist for both the request and the response.

To ensure the `wsgen` command does not miss inherited methods on a service endpoint implementation bean, you must either add the `@WebService` annotation to the desired superclass or you can override the inherited method in the implementation class with a call to the superclass method.

Although a WSDL file is typically optional when developing a JAX-WS service implementation bean, it is required if your JAX-WS endpoints are exposed using the SOAP over JMS transport and you are publishing your WSDL file. If you are developing an enterprise JavaBeans service implementation bean that is invoked using the SOAP over JMS transport, and you want to publish the WSDL so that the

published WSDL file contains the fully resolved JMS endpoint URL, then have wsgen tool generate the WSDL file by specifying the `-wsdl` argument. In this scenario, you must package the WSDL file with your web service application.

In addition to using the tools from the command-line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsGen` Ant task from within the Ant build environment to invoke the wsgen tool. To function properly, this Ant task requires that you invoke Ant using the `ws_ant` script.

Procedure

1. Locate your service endpoint implementation class file.
2. Run the wsgen command to generate the portable artifacts. The wsgen tool is located in the `app_server_root/bin/` directory.

```
app_server_root/bin/ wsgen [options] service_implementation_class
```

(Optional) Use the following options with the wsgen command:

- Use the **-verbose** option to see a list of generated files along with additional informational messages.
- Use the **-keep** option to keep generated Java files.
- Use the **-wsdl** option to generate a WSDL file. If you are developing a service implementation bean that will be invoked using the HTTP transport, then the WSDL file generated by the wsgen command-line tool during this step is optional. However, if you are developing a service implementation bean that will be invoked using the SOAP over JMS transport, then the WSDL file generated by the wsgen tool during this step is required in subsequent developing JAX-WS applications steps, so it is not optional.

Read about wsgen to learn more about this command and additional options that you can specify.

Results

You have the required Java artifacts to create a JAX-WS web service.

Note: The wsgen command does not differentiate the XML namespace between multiple XMLType annotations that have the same `@XMLType` name defined within different Java packages. When this scenario occurs, the following error is produced:

```
Error: Two classes have the same XML type name ....  
Use @XMLType.name and @XMLType.namespace to assign different names to them...
```

This error indicates that you have classes or `@XMLType.name` values that have the same name, but exist within different Java packages. To prevent this error, add the `@XML.Type.namespace` class to the existing `@XMLType` annotation to differentiate between the XML types.

With JAX-WS applications, the wsgen command-line tool might not locate shared class files. You can specify the location of these class files using the `com.ibm.websphere.webservices.wsdl_generation_extra_classpath` custom property. For more information, see the documentation about the Java virtual machine custom properties.

Example

The following example demonstrates how to use the wsgen command to process the service endpoint implementation class to generate JAX-WS artifacts. This example EchoService service implementation class uses an explicit JavaBeans service endpoint.

1. Copy the sample `EchoServicePortTypeImpl` service implementation class file and the associated `EchoServicePortType` service interface class file into a directory. The directory must contain a directory tree structure that corresponds to the `com.ibm.was.wssample.echo` package name for the class file.

```

/* This is a sample EchoServicePortTypeImpl.java file.  */
package com.ibm.was.wssample.echo;

@javax.jws.WebService(serviceName = "EchoService", endpointInterface =
"com.ibm.was.wssample.echo.EchoServicePortType",
targetNamespace="http://com/ibm/was/wssample/echo/",
portName="EchoServicePort")

public class EchoServicePortTypeImpl implements EchoServicePortType {

    public EchoServicePortTypeImpl() {
    }

    public String invoke(String obj) {
        System.out.println(">> JAXB Provider Service:
Request received.\n");
        String str = "Failed";
        if (obj != null) {
            try {
                str = obj;
            } catch (Exception e) {
                e.printStackTrace();
            }
        }
        return str;
    }
}

```

```

/* This is a sample EchoServicePortType.java file.  */
package com.ibm.was.wssample.echo;

```

```

import javax.jws.WebMethod;
import javax.jws.WebParam;
import javax.jws.WebResult;
import javax.jws.WebService;
import javax.xml.ws.RequestWrapper;
import javax.xml.ws.ResponseWrapper;

```

```

@WebService(name = "EchoServicePortType", targetNamespace =
"http://com/ibm/was/wssample/echo/",
wsdlLocation="WEB-INF/wsdl/Echo.wsdl")

```

```

public interface EchoServicePortType {

```

```

    /**
     *
     * @param arg0
     * @return
     * returns java.lang.String
     */
    @WebMethod
    @WebResult(name = "response", targetNamespace =
"http://com/ibm/was/wssample/echo/")
    @RequestWrapper(localName = "invoke", targetNamespace =
"http://com/ibm/was/wssample/echo/",
        className = "com.ibm.was.wssample.echo.Invoke")
    @ResponseWrapper(localName = "echoStringResponse",
        targetNamespace = "http://com/ibm/was/wssample/echo/",
        className = "com.ibm.was.wssample.echo.EchoStringResponse")
    public String invoke(
        @WebParam(name = "arg0", targetNamespace =
"http://com/ibm/was/wssample/echo/")
        String arg0);
}

```

2. Run the `wsgen` command from the `app_server_root\bin\` directory. The `-cp` option specifies the location of the service implementation class file. The `-s` option specifies the directory for the generated source files. The `-d` option specifies the directory for the generated output files. When using the `-s` or `-d` options, you must first create the directory for the generated output files.

After generating the Java artifacts using the `wsgen` command, the following files are generated:

```

/generated_source/com/ibm/was/wssample/echo/EchoStringResponse.java
/generated_source/com/ibm/was/wssample/echo/Invoke.java
/generated_artifacts/EchoService.wsdl
/generated_artifacts/EchoService_schema1.xsd
/generated_artifacts/com/ibm/was/wssample/echo/EchoStringResponse.class
/generated_artifacts/com/ibm/was/wssample/echo/Invoke.class

```

The `EchoStringResponse.java` and `Invoke.java` files are the generated Java class files. The compiled versions of the generated Java files are `EchoStringResponse.class` and `Invoke.class` files. The

EchoService.wsdl and EchoService_schema1.xsd files are generated because the -wsdl option was specified.

What to do next

Complete the implementation of your JAX-WS web service application.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root

The default installation root directory for the Application Client for IBM WebSphere Application Server is the /QIBM/ProdData/WebSphere/AppClient/V8/client directory.

app_client_user_data_root

The default Application Client for IBM WebSphere Application Server user data root is the /QIBM/UserData/WebSphere/AppClient/V8/client directory.

app_client_profile_root

The default Application Client for IBM WebSphere Application Server profile root is the /QIBM/UserData/WebSphere/AppClient/V8/client/profiles/*profile_name* directory.

app_server_root

The default installation root directory for WebSphere Application Server - Express is the /QIBM/ProdData/WebSphere/AppServer/V8/Express directory.

java_home

Table 137. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32-bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit
64-bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit

plugins_profile_root

The default Web Server Plug-ins profile root is the /QIBM/UserData/WebSphere/Plugins/V8/webserver/profiles/*profile_name* directory.

plugins_root

The default installation root directory for Web Server Plug-ins is the /QIBM/ProdData/WebSphere/Plugins/V8/webserver directory.

plugins_user_data_root

The default Web Server Plug-ins user data root is the /QIBM/UserData/WebSphere/Plugins/V8/webserver directory.

product_library

product_lib

This is the product library for the installed product. The product library for each Version 8.0 installation on the system contains the program and service program objects (similar to .exe, .dll, .so objects) for the installed product. The product library name is QWAS8x (where x is A, B, C, and so on). The product library for the first WebSphere Application Server Version 8.0 product installed

on the system is QWAS8A. The *app_server_root/properties/product.properties* file contains the value for the product library of the installation, *was.install.library*, and is located under the *app_server_root* directory.

profile_root

The default directory for a profile named *profile_name* for WebSphere Application Server - Express is the */QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/profile_name* directory.

shared_product_library

The shared product library, which contains all of the objects shared by all installations on the system, is QWAS8. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root

The default user data directory for WebSphere Application Server - Express is the */QIBM/UserData/WebSphere/AppServer/V8/Express* directory.

The profiles and profileRegistry subdirectories are created under this directory when you install the product.

web_server_root

The default web server path is */www/web_server_name*.

wsgen command for JAX-WS applications

The *wsgen* command-line tool generates the necessary artifacts required for Java API for XML Web Services (JAX-WS) applications when starting from Java code. The generated artifacts are Java 5 compliant, making them portable across different Java versions and platforms.

When using a bottoms-up approach to develop JAX-WS web services and you are starting from a service endpoint implementation, use the *wsgen* tool to generate the required JAX-WS artifacts.

Note: The *wsimport*, *wsgen*, *schemagen* and *xjc* command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The *wsimport*, *wsgen*, *schemagen* and *xjc* command-line tools are located in the *app_server_root\bin* directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root\bin* directory.

The *wsgen* tool accepts a properly annotated service endpoint implementation using the *@WebService* annotation as input and generates the following artifacts:

- any additional Java Architecture for XML Binding (JAXB) classes that are required to marshal and unmarshal the message contents.
- a WSDL file if the optional *-wsdl* argument is specified. The *wsgen* tool does not automatically generate the WSDL file.

When using JAX-WS V2.2 tools, *java.lang.RuntimeException* and *java.rmi.RemoteException* references and their subclasses are no longer mapped in the WSDL file. This behavior change complies with the JAX-WS V2.1 specification conformance rule that is described in section 3.7 of the specification. This

conformance rule specifies that the `java.lang.RuntimeException` and `java.rmi.RemoteException` classes and their subclasses cannot be treated as service-specific exceptions and mapped in the WSDL file.

In addition to using the tools from the command line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsGen` Ant task from within the Ant build environment to invoke the `wsgen` tool. To function properly, this Ant task requires that you invoke Ant using the `ws_ant` script.

Note: The `wsgen` command does not differentiate the XML namespace between multiple `XMLType` annotations that have the same `@XMLType` name defined within different Java packages. When this scenario occurs, the following error is produced:

```
Error: Two classes have the same XML type name ....
Use @XMLType.name and @XMLType.namespace to assign different names to them...
```

This error indicates you have class names or `@XMLType.name` values that have the same name, but exist within different Java packages. To prevent this error, add the `@XML.Type.namespace` class to the existing `@XMLType` annotation to differentiate between the XML types.

With JAX-WS applications, the `wsgen` command-line tool might not locate shared class files. You can specify the location of these class files using the `com.ibm.websphere.webservices.wsd_generation_extra_classpath` custom property. For more information, see the documentation about the Java virtual machine custom properties.

Syntax

The command-line syntax is:

```
app_server_root/bin/wsgen [options] service_implementation_class
```

Parameters

The `service_implementation_class` name is the only parameter that is required. The following parameters are optional for the `wsgen` command:

-classpath <path>

Specifies the location of the service implementation class.

-cp <path>

Specifies the location of the service implementation class. This parameter is the same as `-classpath <path>`.

-d <directory>

Specifies where to place the generated output files.

-extension

Specifies whether to enable custom extensions for functionality not specified by the JAX-WS specification. Use of the extensions can result in applications that are not portable or do not interoperate with other implementations.

-help

Displays the help menu.

-keep

Specifies whether to keep the generated source files.

-r <directory>

This parameter is only used with the `-wsdl` parameter. Specifies where to place the generated WSDL file.

-s <directory>

Specifies the directory to place the generated source files.

-verbose

Specifies to output messages about what the compiler is doing.

-version

Prints the version information. If you specify this option, only the version information is output and normal command processing does not occur.

-wsdl [:protocol]

By default, the wsgen tool does not generate a WSDL file. This optional parameter causes wsgen to generate a WSDL file and is typically only used to enable a developer to review a WSDL file before the endpoint is deployed. The protocol is optional and specifies the protocol used in the wsdl:binding. Valid values for protocol are soap 1.1 and Xsoap 1.2. The default value is soap 1.1. The Xsoap 1.2 value is not standard and is only used with the *-extension* option.

-servicename <name>

This parameter is only used with the -wsdl option. Specifies a wsdl:service name to be generated in the WSDL file. For example,

```
-service name "{http://mynamespace/}MyService"
```

-portname

This parameter is only used with the -wsdl option. Specifies a wsdl:port name to be generated in the WSDL file. For example,

```
-portname "{http://mynamespace/}MyPort"
```

Mapping between Java language, WSDL and XML for JAX-WS applications

Data for Java API for XML Web Services (JAX-WS) applications flows as extensible Markup Language (XML). JAX-WS applications use mappings to describe the data conversion between the Java language and extensible Markup Language (XML) technologies, including XML Schema, Web Services Description Language (WSDL) and SOAP that are supported by the application server.

For web services based on the JAX-WS programming model, mappings between the Java language and XML are specified by the JAX-WS specification and the Java Architecture for XML Binding (JAXB) specification for data bindings. JAX-WS leverages the JAXB API and tools as the binding technology for mappings between Java objects and XML documents. JAX-WS tooling relies on JAXB tooling for default data binding for two-way mappings between Java objects and XML documents.

The JAX-WS specification describes the mapping between Web Services Description Language (WSDL) files and the Java language. The supported mappings include WSDL-to-Java mappings and Java-to-WSDL mappings. WSDL 1.1 is required by the JAX-WS 2.0 specification. You can use annotations to customize the mapping from Java artifacts to their associated WSDL components. Refer to the JAX-WS specification for details describing the WSDL-to-Java mappings and Java-to-WSDL mappings.

Data binding mappings used by the JAX-WS programming model are described by the JAXB specification. Refer to the JAXB specification for details that describe the JAXB mappings for the Java representation of XML content, including the default and custom bindings between XML schema to Java representations.

Enabling MTOM for JAX-WS web services

With Java API for XML-Based Web Services (JAX-WS), you can send binary attachments such as images or files along with web services requests. JAX-WS adds support for optimized transmission of binary data as specified by the SOAP Message Transmission Optimization Mechanism (MTOM) specification.

About this task

JAX-WS supports the use of SOAP Message Transmission Optimized Mechanism (MTOM) for sending binary attachment data. By enabling MTOM, you can send and receive binary data optimally without incurring the cost of data encoding needed to embed the binary data in an XML document.

The application server supports sending attachments using MTOM only for JAX-WS applications. This product also provides the ability to provide attachments with Web Services Security SOAP messages by using the new MTOM and XOP standards.

JAX-WS applications can send binary data as base64 or hexBinary encoded data contained within the XML document. However, to take advantage of the optimizations provided by MTOM, enable MTOM to send binary base64 data as attachments contained outside the XML document. MTOM optimization is not enabled by default. JAX-WS applications require separate configuration of both the client and the server artifacts to enable MTOM support.

Procedure

1. Develop Java artifacts for your JAX-WS application that includes an XML schema or Web Services Description Language (WSDL) file that represents your web services application data that includes a binary attachment.
 - a. If you are starting with a WSDL file, develop Java artifacts from a WSDL file by using the `wsimport` command to generate the required JAX-WS portable artifacts.
 - b. If you are starting with JavaBeans components, develop Java artifacts for JAX-WS applications and optionally generate a WSDL file using the `wsgen` command. The XML schema or WSDL file includes a `xsd:base64Binary` or `xsd:hexBinary` element definition for the binary data.
 - c. You can also include the `mime:expectedContentTypes` attribute on the element to affect the mapping by JAXB.

2. Enable MTOM on your endpoint implementation class using one of the following methods:

- Use the `@MTOM` annotation on the endpoint.

To enable MTOM on an endpoint, use the `@MTOM` (`javax.xml.ws.soap.MTOM`) annotation on the endpoint. The `@MTOM` annotation has two parameters, `enabled` and `threshold`. The `enabled` parameter has a boolean value and indicates if MTOM is enabled for the JAX-WS endpoint. The `threshold` parameter has an integer value, that must be greater than or equal to zero. When MTOM is enabled, any binary data whose size, in bytes, exceeds the threshold value is XML-binary Optimized Packaging (XOP) encoded or sent as an attachment. When the message size is less than the threshold value, the message is inlined in the XML document as either base64 or hexBinary data.

The following example snippet illustrates adding the `@MTOM` annotation so that MTOM is enabled for the JAX-WS `MyServiceImpl` endpoint and specifies a threshold value of 2048 bytes:

```
@MTOM(enabled=true, threshold=2048)
@WebService
public class MyServiceImpl {
    ...
}
```

Additionally, you can use the `@BindingType` (`javax.xml.ws.BindingType`) annotation on an endpoint implementation class to specify that the endpoint supports one of the MTOM binding types so that the response messages are MTOM-enabled. The `javax.xml.ws.SOAPBinding` class defines two different constants, `SOAP11HTTP_MTOM_BINDING` and `SOAP12HTTP_MTOM_BINDING` that you can use for the value of the `@BindingType` annotation; for example:

```
// This example is for SOAP version 1.1.
@BindingType(value = SOAPBinding.SOAP11HTTP_MTOM_BINDING)
@WebService
public class MyServiceImpl {
    ...
}

// This example is for SOAP version 1.2.
@BindingType(value = SOAPBinding.SOAP12HTTP_MTOM_BINDING)
@WebService
public class MyServiceImpl {
    ...
}
```

The presence and value of an `@MTOM` annotation overrides the value of the `@BindingType` annotation. For example, if the `@BindingType` indicates MTOM is enabled, but an `@MTOM` annotation is present with an `enabled` value of `false`, then MTOM is not enabled.

- Use the `<enable-mtom>` and `<mtom-threshold>` deployment descriptor elements.

You can use the `<enable-mtom>` and `<mtom-threshold>` elements within the `<port-component>` element in the `webservices.xml` deployment descriptor as an alternative to using the `@MTOM` annotation on the service endpoint implementation class; for example:

```
<port-component>
  <port-component-name>MyPort1</port-component-name>
  <enable-mtom>true</enable-mtom>
  <mtom-threshold>2048</mtom-threshold>
  <service-impl-bean>
    <servlet-link>MyPort1ImplBean</servlet-link>
  </service-impl-bean>
</port-component>
```

Note: The deployment descriptor elements take precedence over the corresponding attributes in the MTOM annotation. For example, if the `enabled` attribute is set to `true` in the annotation, but the `<enable-mtom>` element is set to `false` in the `webservices.xml` file, MTOM is not enabled for the corresponding endpoint.

3. Enable MTOM on your client to optimize the binary messages that are sent from the client to the server. Use one of the following methods to enable MTOM on your client:

- Enable MTOM on a Dispatch client.

The following examples use SOAP version 1.1.

The first method uses `SOAPBinding.setMTOMEnabled()`; for example:

```
SOAPBinding binding = (SOAPBinding)dispatch.getBinding();
binding.setMTOMEnabled(true);
```

The second method uses `Service.addPort`; for example:

```
Service svc = Service.create(serviceName);
svc.addPort(portName, SOAPBinding.SOAP11HTTP_MTOM_BINDING, endpointUrl);
```

The third method uses `MTOMFeature`; for example:

```
MTOMFeature mtom = new MTOMFeature(true, 2048);
Service svc = Service.create(serviceName);
svc.addPort(portName, SOAPBinding.SOAP11_HTTP_BINDING, endpointUrl);
Dispatch<Source> dsp = svc.createDispatch(portName, Source.class, Service.Mode.PAYLOAD, mtom);
```

- Enable MTOM on a Dynamic Proxy client.

```
// Create a BindingProvider bp from a proxy port.
Service svc = Service.create(serviceName);
MtomSample proxy = svc.getPort(portName, MtomSample.class);
BindingProvider bp = (BindingProvider) proxy;

//Enable MTOM using the SOAPBinding.
MtomSample proxy = svc.getPort(portName, MtomSample.class);
BindingProvider bp = (BindingProvider) proxy;
SOAPBinding binding = (SOAPBinding) bp.getBinding();
binding.setMTOMEnabled(true);

//Or, you can enable MTOM with the MTOMFeature.
MTOMFeature mtom = new MTOMFeature();
MtomSample proxy = svc.getPort(portName, MtomSample.class, mtom);
```

- Enable MTOM on your client using the `@MTOM` annotation; for example:

```
public class MyClientApplication {

  // Enable MTOM for a port-component-ref resource injection.
  @MTOM(enabled=true, threshold=1024)
  @WebServiceRef(MyService.class)
  private MyPortType myPort;
  ...
}
```

- Enable MTOM on your client using deployment descriptor elements within a `port-component-ref` element; for example:

```
<service-ref>
  <service-ref-name>service/MyPortComponentRef</service-ref-name>
  <service-interface>com.example.MyService</service-ref-interface>
  <port-component-ref>
    <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
    <enable-mtom>true</enable-mtom>
    <mtom-threshold>1024</mtom-threshold>
  </port-component-ref>
</service-ref>
```

Note: The deployment descriptor elements take precedence over the corresponding attributes in the MTOM annotation. For example, if the `enabled` attribute is set to `true` in the annotation, but

the `<enable-mtom>` element is set to `false` in the deployment descriptor entry for the service-ref of the client, MTOM is not enabled for that service reference.

Results

You have developed a JAX-WS web services server and client application that optimally sends and receives binary data using MTOM.

Example

The following example illustrates enabling MTOM support on both the web services client and server endpoint when starting with an WSDL file.

1. Locate the WSDL file containing an `xsd:base64Binary` element. The following example is a portion of a WSDL file that contains an `xsd:base64Binary` element.

```
<types>
.....
<xs:complexType name="ImageDepot">
  <xs:sequence>
    <xs:element name="imageData"
      type="xs:base64Binary"
      xmime:expectedContentTypes="image/jpeg"/>
  </xs:sequence>
</xs:complexType>
.....
</types>
```

2. Run the **wsimport** command from the `app_server_root\bin\` directory against the WSDL file to generate a set of JAX-WS portable artifacts.

Depending on the `expectedContentTypes` value contained in the WSDL file, the JAXB artifacts generated are in the Java type as described in the following table:

Table 138. Mapping of MIME type and Java type. Describes the mapping between MIME types and Java types.

MIME Type	Java Type
image/gif	java.awt.Image
image/jpeg	java.awt.Image
text/plain	java.lang.String
text/xml	javax.xml.transform.Source
application/xml	javax.xml.transform.Source
/	javax.activation.DataHandler

3. Use the JAXB artifacts in the same manner as in any other JAX-WS application. Use these beans to send binary data from both the Dispatch and the Dynamic Proxy client APIs.
4. Enable MTOM on a Dispatch client.

```
//Create the Dispatch instance.
JAXBContext jbc = JAXBContext.newInstance("org.apache.axis2.jaxws.sample.mtom");
Dispatch<Object> dispatch = svc.createDispatch(portName, jbc, Service.Mode.PAYLOAD);

//Enable MTOM.
SOAPBinding binding = (SOAPBinding) dispatch.getBinding();
binding.setMTOMEnabled(true);
```

5. Enable MTOM on a Dynamic Proxy client.

```
//Create the Dynamic Proxy instance.
Service svc = Service.create(serviceName);
MtomSample proxy = svc.getPort(portName, MtomSample.class);

//Enable MTOM.
BindingProvider bp = (BindingProvider) proxy;
SOAPBinding binding = (SOAPBinding) bp.getBinding();
binding.setMTOMEnabled(true);
```

Now that you have enabled the JAX-WS client for MTOM, messages sent to the server have MTOM enabled. However, for the server to respond back to the client using MTOM, you must enable MTOM on the endpoint.

6. Enable MTOM on the endpoint implementation class.

```

@MTOM(enabled, threshold=4096)
@WebService (endpointInterface="org.apache.axis2.jaxws.sample.mtom.MtomSample")

public class MtomSampleService implements MtomSample {
    ....
}

```

The `jaxax.xml.ws.SOAPBinding` class has a static member for each of the supported binding types. Include either the `SOAP11HTTP_MTOM_BINDING` or the `SOAP12HTTP_MTOM_BINDING` as the value for the `@BindingType` annotation. This value enables all server responses to have MTOM enabled.

When you enable MTOM on the server and the client, the binary data that represents the attachment is included as a Multipurpose Internet Mail Extensions (MIME) attachment to the SOAP message. Without MTOM, the same data is encoded in the format that describes the XML schema, either base64 or hexadecimal encoding, and included inline in the XML document.

This example illustrates an MTOM enabled SOAP version 1.1 message with an attachment. The type and content-type attributes both have the value, `application/xop+xml`, which indicates that the message was successfully optimized using XML-binary Optimized packaging (XOP) when MTOM was enabled. This example demonstrates how the optimized message looks on the wire with MTOM enabled.

```

... other transport headers ...
Content-Type: multipart/related; boundary=MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812;
type="application/xop+xml"; start="
<0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org"; start-info="text/xml"; charset=UTF-8

--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: application/xop+xml; charset=UTF-8; type="text/xml";
content-transfer-encoding: binary
content-id:
    <0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org>

<?xml version="1.0" encoding="UTF-8"?>
    <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
        <soapenv:Header/>
        <soapenv:Body>
            <sendImage xmlns="http://org.apache.axis2/jaxws/sample/mtom">
                <input>
                    <imageData>
                        <xop:Include xmlns:xop="http://www.w3.org/2004/08/xop/include"
href="cid:1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org"/>
                    </imageData>
                </input>
            </sendImage>
        </soapenv:Body>
    </soapenv:Envelope>
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: text/plain
content-transfer-encoding: binary
content-id:
    <1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org>

... binary data goes here ...
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812--

```

In contrast, this example demonstrates a SOAP version 1.1 message on the wire without MTOM enabled. The binary data is included in the body of the SOAP message, and the SOAP message is not optimized.

```

... other transport headers ...
Content-Type: text/xml; charset=UTF-8

<?xml version="1.0" encoding="UTF-8"?>
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
    <soapenv:Header/>
    <soapenv:Body>
        <sendImage xmlns="http://org.apache.axis2/jaxws/sample/mtom">
            <input>
                <imageData>R01GAD1 ... more base64 encoded data ... KTJk8giAAA7</imageData>
            </input>
        </sendImage>
    </soapenv:Body>
</soapenv:Envelope>

```

For additional information, refer to the Samples section of the Information Center which includes a sample that demonstrates the use of MTOM with JAX-WS web services.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root

The default installation root directory for the Application Client for IBM WebSphere Application Server is the `/QIBM/ProdData/WebSphere/AppClient/V8/client` directory.

app_client_user_data_root

The default Application Client for IBM WebSphere Application Server user data root is the `/QIBM/UserData/WebSphere/AppClient/V8/client` directory.

app_client_profile_root

The default Application Client for IBM WebSphere Application Server profile root is the `/QIBM/UserData/WebSphere/AppClient/V8/client/profiles/profile_name` directory.

app_server_root

The default installation root directory for WebSphere Application Server - Express is the `/QIBM/ProdData/WebSphere/AppServer/V8/Express` directory.

java_home

Table 139. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32-bit IBM Technology for Java	<code>/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit</code>
64-bit IBM Technology for Java	<code>/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit</code>

plugins_profile_root

The default Web Server Plug-ins profile root is the `/QIBM/UserData/WebSphere/Plugins/V8/webserver/profiles/profile_name` directory.

plugins_root

The default installation root directory for Web Server Plug-ins is the `/QIBM/ProdData/WebSphere/Plugins/V8/webserver` directory.

plugins_user_data_root

The default Web Server Plug-ins user data root is the `/QIBM/UserData/WebSphere/Plugins/V8/webserver` directory.

product_library

product_lib

This is the product library for the installed product. The product library for each Version 8.0 installation on the system contains the program and service program objects (similar to `.exe`, `.dll`, `.so` objects) for the installed product. The product library name is `QWAS8x` (where `x` is A, B, C, and so on). The product library for the first WebSphere Application Server Version 8.0 product installed on the system is `QWAS8A`. The `app_server_root/properties/product.properties` file contains the value for the product library of the installation, `was.install.library`, and is located under the `app_server_root` directory.

profile_root

The default directory for a profile named *profile_name* for WebSphere Application Server - Express is the `/QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/profile_name` directory.

shared_product_library

The shared product library, which contains all of the objects shared by all installations on the system, is QWAS8. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root

The default user data directory for WebSphere Application Server - Express is the /QIBM/UserData/WebSphere/AppServer/V8/Express directory.

The profiles and profileRegistry subdirectories are created under this directory when you install the product.

web_server_root

The default web server path is /www/web_server_name.

Enforcing adherence to WSDL bindings in JAX-WS web services

Java API for XML-Based Web Services (JAX-WS) Version 2.1 introduced the concept of *features* as a way to programmatically control specific functions and behaviors. The `RespectBindingFeature` is one of the supported standard features. You can use the `RespectBindingFeature` to control whether a JAX-WS implementation is required to respect the contents of a Web Services Description Language (WSDL) binding that is associated with an endpoint.

About this task

While WSDL documents are often used during the development process, the actual enforcement of the use of the WSDL document specifications, when they are provided, at run time has not been well defined in versions of the JAX-WS specification previous to Version 2.1. The JAX-WS Version 2.1 specification added the feature, `RespectBindingFeature`, to clarify the impact of the `wsdl:binding` in a JAX-WS runtime environment.

Enabling the feature, `RespectBindingFeature`, causes the JAX-WS runtime environment to inspect the `wsdl:binding` for an endpoint at run time to ensure that the binding of service endpoint interface (SEI) parameters and return values is respected. Additionally, this feature ensures that all required `wsdl:binding` extensions are either understood and used by the runtime environment, or the extensions have been explicitly disabled by the application. Your JAX-WS application can disable a specific `wsdl:binding` extension that has a defined `WebServiceFeature` interface by using the appropriate annotation that is associated with that feature, using an API that accepts the `javax.xml.ws.WebServiceFeature` interface, or configuring the deployment descriptors.

When the `RespectBindingFeature` feature is not enabled, which is the default, the runtime environment can choose whether any part of the `wsdl:binding` is enforced.

Procedure

1. Develop Java artifacts for your JAX-WS application that includes a Web Services Description Language (WSDL) file that represents your web services application.
 - a. If you are starting with a WSDL file, develop Java artifacts from a WSDL file by using the `wsimport` command to generate the required JAX-WS portable artifacts.
 - b. If you are starting with JavaBeans components, develop Java artifacts for JAX-WS applications and generate a WSDL file using the `wsgen` command.
2. If you want to enable `RespectBindingFeature` on your endpoint implementation class, use one of the following methods:
 - Use the `@RespectBinding` annotation on the endpoint.

To enable `RespectBinding` on an endpoint, use the `@RespectBinding` (`javax.xml.ws.RespectBinding`) annotation on the endpoint. The `@RespectBinding` annotation has only one parameter, `enabled`.

This parameter is optional. The enabled parameter has a Boolean value and indicates if `RespectBindingFeature` is enabled for the JAX-WS endpoint.

The following example snippet illustrates adding the `@RespectBinding` annotation for the JAX-WS `MyServiceImpl` endpoint:

```
@RespectBinding(enabled=true)
@WebService
public class MyServiceImpl {
    ...
}
```

- Use the `<respect-binding>` deployment descriptor element. You can use the `<respect-binding>` element within the `<port-component>` element in the `webservices.xml` deployment descriptor as an alternative to using the `@RespectBinding` annotation on the service endpoint implementation class; for example:

```
<port-component>
  <port-component-name>MyPort1</port-component-name>
  <respect-binding>
    <enabled>true</enabled>
  </respect-binding>
  <service-impl-bean>
    <servlet-link>MyPort1ImplBean</servlet-link>
  </service-impl-bean>
</port-component>
```

3. If you want to enable `RespectBindingFeature` on your client, use one of the following methods:

- Enable `RespectBindingFeature` on a dispatch client; for example:

```
RespectBindingFeature respectBinding = new RespectBindingFeature();
Service svc = Service.create(serviceName);
svc.addPort(portName, SOAPBinding.SOAP11_HTTP_BINDING, endpointUrl);
Dispatch<Source> dsp = svc.createDispatch(portName, Source.class, Service.Mode.PAYLOAD, respectBinding);
```

- Enable `RespectBindingFeature` on a dynamic proxy client; for example:

```
// Create a dynamic proxy with RespectBinding enabled.
Service svc = Service.create(serviceName);
RespectBindingFeature respectBinding = new RespectBindingFeature();
RespectBindingSample proxy = svc.getPort(portName, RespectBindingSample.class, respectBinding);
```

- Enable `RespectBindingFeature` on your client using the `@RespectBinding` annotation; for example:

```
public class MyClientApplication {

    // Enable RespectBinding for a port-component-ref resource injection.
    @RespectBinding(enabled=true)
    @WebServiceRef(MyService.class)
    private MyPortType myPort;

    ...
}
```

- Enable `RespectBindingFeature` on your client using deployment descriptor elements within a `port-component-ref` element; for example:

```
<service-ref>
  <service-ref-name>service/MyPortComponentRef</service-ref-name>
  <service-interface>com.example.MyService</service-ref-interface>
  <port-component-ref>
    <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
    <respect-binding>
      <enabled>true</enabled>
    </respect-binding>
  </port-component-ref>
</service-ref>
```

Results

By implementing the feature, `RespectBindingFeature`, you have specified to enforce adherence of the contents of a WSDL binding that is associated with an endpoint for your JAX-WS application.

Developing a `webservices.xml` deployment descriptor for JAX-WS applications

Deployment descriptors are standard text files, formatted using XML and packaged in a web services application. You can optionally use the `webservices.xml` deployment descriptor to augment or override application metadata specified in annotations within Java API for XML-Based Web Services (JAX-WS) web services.

About this task

Similar to Java API for XML-based RPC (JAX-RPC) Web services, you can use deployment descriptors to describe JAX-WS web services. For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

A JAX-WS web service requires that you annotate your Java class with the `javax.jws.WebService` annotation or the `javax.jws.WebServiceProvider` annotation for Provider endpoints. You can use server-side deployment descriptors to override corresponding attributes of the annotation or to enhance information in annotations. There is a defined relationship between the deployment descriptor elements and the `@WebService` and `@WebServiceProvider` annotations. Refer to section 5.3 in the Web Services for Java Platform, Enterprise Edition (Java EE) specification, Version 1.2 for detailed information regarding the deployment descriptor elements and the mapping to the `@WebService` and `@WebServiceProvider` annotation attributes. There are also elements in the `webservice.xml` deployment descriptor that map to other annotations. For example, the deployment descriptor element `<protocol-binding>` maps to the `@BindingType` annotation, and the deployment descriptor element `<enable-mtom>` maps to the `@MTOM` annotation. For more information regarding the web services deployment descriptor elements, see section 7.1 in the Web Services for Java Platform, Enterprise Edition (Java EE) specification.

Procedure

Use assembly tools to generate the `webservice.xml` deployment descriptor.

Results

You have deployment descriptor templates that you can use to override JAX-WS annotation attributes or specify attributes that are not defined by the annotation.

Example

In the following example, the service implementation class for a JAX-WS web service includes the `@WebService` annotation:

```
@WebService(wsdlLocation="http://myhost.com/location/of/the/wsdl/ExampleService.wsdl")
```

The associated `webservices.xml` deployment descriptor specifies a different filename for the WSDL document as follows:

```
<webservices>
<webservice-description>
<webservice-description-name>ExampleService</webservice-description-name>
<wsdl-file>META-INF/wsdl/ExampleService.wsdl</wsdl-file>
...
</webservice-description>
</webservices>
```

The value that is specified in the deployment descriptor, `META-INF/wsdl/ExampleService.wsdl`, overrides the annotation value.

What to do next

Configure the `webservice.xml` deployment descriptor. After you configure the deployment descriptors, you must assemble the Web services application for deployment.

Directory conventions

References in product information to `app_server_root`, `profile_root`, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root

The default installation root directory for the Application Client for IBM WebSphere Application Server is the /QIBM/ProdData/WebSphere/AppClient/V8/client directory.

app_client_user_data_root

The default Application Client for IBM WebSphere Application Server user data root is the /QIBM/UserData/WebSphere/AppClient/V8/client directory.

app_client_profile_root

The default Application Client for IBM WebSphere Application Server profile root is the /QIBM/UserData/WebSphere/AppClient/V8/client/profiles/*profile_name* directory.

app_server_root

The default installation root directory for WebSphere Application Server - Express is the /QIBM/ProdData/WebSphere/AppServer/V8/Express directory.

java_home

Table 140. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32-bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit
64-bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit

plugins_profile_root

The default Web Server Plug-ins profile root is the /QIBM/UserData/WebSphere/Plugins/V8/webserver/profiles/*profile_name* directory.

plugins_root

The default installation root directory for Web Server Plug-ins is the /QIBM/ProdData/WebSphere/Plugins/V8/webserver directory.

plugins_user_data_root

The default Web Server Plug-ins user data root is the /QIBM/UserData/WebSphere/Plugins/V8/webserver directory.

product_library

product_lib

This is the product library for the installed product. The product library for each Version 8.0 installation on the system contains the program and service program objects (similar to .exe, .dll, .so objects) for the installed product. The product library name is QWAS8x (where x is A, B, C, and so on). The product library for the first WebSphere Application Server Version 8.0 product installed on the system is QWAS8A. The *app_server_root*/properties/product.properties file contains the value for the product library of the installation, was.install.library, and is located under the *app_server_root* directory.

profile_root

The default directory for a profile named *profile_name* for WebSphere Application Server - Express is the /QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/*profile_name* directory.

shared_product_library

The shared product library, which contains all of the objects shared by all installations on the system, is QWAS8. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root

The default user data directory for WebSphere Application Server - Express is the /QIBM/UserData/WebSphere/AppServer/V8/Express directory.

The profiles and profileRegistry subdirectories are created under this directory when you install the product.

web_server_root

The default web server path is /www/*web_server_name*.

Completing the JavaBeans implementation for JAX-WS applications

After you have developed the Java artifacts necessary to develop a Java API for XML-Based Web Services (JAX-WS) web service, you must complete the JavaBeans implementation to assemble a web application archive (WAR) file. The resulting WAR file contains the JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Generate Java artifacts for JAX-WS applications and optionally generate a WSDL file using the `wsgen` command-line tool. You can also optionally use deployment descriptors to augment or override binding information contained in annotations for JAX-WS web services.

About this task

For JAX-WS applications, complete the JavaBeans implementation by writing your business application.

Procedure

1. Write the JavaBeans implementation. The JavaBeans implementation is not generated by JAX-WS tooling.
2. Compile all the Java classes.

Results

You have now written your JavaBeans implementation to complete your web service application.

What to do next

After completing the JavaBeans implementation, assemble your web services application.

Completing the EJB implementation for JAX-WS applications

After you have developed the Java artifacts necessary to develop a Java API for XML-Based Web Services (JAX-WS) web service, you must complete the Enterprise JavaBeans (EJB) implementation to assemble a Java archive (JAR) file. The resulting JAR file contains the Enterprise JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Generate Java artifacts for JAX-WS applications and optionally generate a WSDL file using the `wsgen` command-line tool. You can also optionally use deployment descriptors to augment or override binding information contained in annotations for JAX-WS web services.

About this task

For JAX-WS applications, complete the enterprise beans implementation by writing your business application.

Procedure

1. Write the enterprise beans implementation. The enterprise beans implementation is not generated by JAX-WS tooling.
2. Compile all the Java classes.

Results

You have now written your enterprise beans implementation to complete your web service application.

What to do next

After completing the enterprise beans implementation, assemble your web services application.

Developing JAX-WS web services with WSDL files (top down)

Setting up a development environment for web services

The application server provides command-line tools to develop web services clients and implementations that are based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. You must set up your development environment before you start developing web services.

Before you begin

Before you can set up a web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information on installing the application server, read about installing your application server environment.

About this task

Set up a web services development environment by completing the following actions.

Procedure

Set up the environment.

Run the `setupCmdLine` script on the Qshell command line from the `./profile_root/bin` directory.

Results

You have set up an environment so that you can develop Web services.

What to do next

Implement web services applications. See the task overview for implementing web services applications information to learn about how to develop and implement a Java EE web service.

Generating Java artifacts for JAX-WS applications from a WSDL file

Use JAX-WS tools to generate the Java artifacts that are needed to develop JAX-WS web services when starting with a Web Services Description Language (WSDL) file.

Before you begin

When using a top-down development approach to developing Java API for XML-Based Web Services (JAX-WS) web services by starting with a Web Services Description Language (WSDL) file, you must obtain the Uniform Resource Locator (URL) of the WSDL file.

If the WSDL file is a local file, the URL looks like this example: `file:/path/file_name.wsdl`.

You can also specify local files using the absolute or relative file system path.

About this task

You can use the JAX-WS tool, `wsimport`, to process a WSDL file and generate portable Java artifacts that are used to create a web service. The portable Java artifacts created using the `wsimport` tool are:

- Service endpoint interface (SEI)
- Service class
- Exception class that is mapped from the `wsdl:fault` class (if any)
- Java Architecture for XML Binding (JAXB) generated type values which are Java classes mapped from XML schema types

Note: The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are located in the `app_server_root\bin\` directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the `app_server_root\bin\` directory.

In addition to using the tools from the command-line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsImport` Ant task from within the Ant build environment to invoke the `wsimport` tool. To function properly, this Ant task requires that you invoke Ant using the `ws_ant` script.

Procedure

Run the `wsimport` command to generate the portable client artifacts. The `wsimport` tool is located in the `app_server_root\bin\` directory.

```
app_server_root/bin/wsimport wsdl_URL
```

(Optional) Use the following options with the `wsimport` command:

- Use the **-verbose** option to see a list of generated files when you run the command.
- Use the **-keep** option to keep generated Java files.
- Use the **-wsdlLocation** option to specify the location of the WSDL file.

Note: A best practice for ensuring that you produce a JAX-WS web services client enterprise archive (EAR) file that is portable to other systems is to package the WSDL document within the application module such as a web services client Java archive (JAR) file or a web application archive (WAR) file. You can specify a relative URI for the location of your WSDL file by using the `-wsdlLocation` annotation attribute. For example, if your `MyService.wsdl` file is located in the `META-INF/wsdl/` directory, then run the `wsimport` tool and use the `-wsdlLocation` option to specify

the value to be used for the location of the WSDL file. This ensures that the generated artifacts contain the correct `-wsdllocation` information needed when the application is loaded into the administrative console; for example:

```
wsimport -keep -wsdllocation=META-INF/wsdl/MyService.wsdl
```

- Use the **-b** option if you are using WSDL or schema customizations to specify external binding files that contain your customizations.

You can customize the bindings in your WSDL file to enable asynchronous mappings or attachments. To generate asynchronous interfaces, add the client-side only customization `enableAsyncMapping` binding declaration to the `wsdl:definitions` element or in an external binding file that is defined in the WSDL file. Use the `enableMIMEContent` binding declaration in your custom client or server binding file to enable or disable the default `mime:content` mapping rules. For additional information on custom binding declarations, see chapter 8 the JAX-WS specification.

Read about the `wsimport` command to learn more about this command and additional options that you can specify.

Results

You have the required Java artifacts to create a JAX-WS web service. To learn more about the usage, syntax, and parameters for the `wsimport` command, see the `wsimport` command for JAX-WS applications documentation.

Example

The following example illustrates how the `wsimport` command is used to process the sample Ping WSDL file to generate portable artifacts.

1. Copy the following `ping.wsdl` WSDL file to a temporary directory.

```
<?xml version="1.0" encoding="UTF-8"?>
<!--
 * This program can be used, run, copied, modified and distributed
 * without royalty for the purpose of developing, using, marketing, or distributing.
-->
<wsdl:definitions xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
 xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
 xmlns:tns="http://com.ibm/was/wssample/sei/ping/"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema" name="PingService"
 targetNamespace="http://com.ibm/was/wssample/sei/ping/">
  <wsdl:types>
    <xsd:schema
      targetNamespace="http://com.ibm/was/wssample/sei/ping/"
      xmlns:xsd="http://www.w3.org/2001/XMLSchema">

      <xsd:element name="pingStringInput">
        <xsd:complexType>
          <xsd:sequence>
            <xsd:element name="pingInput" type="xsd:string" />
          </xsd:sequence>
        </xsd:complexType>
      </xsd:element>
    </xsd:schema>
  </wsdl:types>
  <wsdl:message name="pingOperationRequest">
    <wsdl:part element="tns:pingStringInput" name="parameter" />
  </wsdl:message>
  <wsdl:portType name="PingServicePortType">
    <wsdl:operation name="pingOperation">
      <wsdl:input message="tns:pingOperationRequest" />

    </wsdl:operation>
  </wsdl:portType>
  <wsdl:binding name="PingSOAP" type="tns:PingServicePortType">
    <soap:binding style="document"
      transport="http://schemas.xmlsoap.org/soap/http" />
    <wsdl:operation name="pingOperation">
      <soap:operation soapAction="pingOperation" style="document" />
    </wsdl:operation>
  </wsdl:binding>
</wsdl:definitions>
```

```

    <soap:body use="literal" />
  </wsdl:input>
</wsdl:operation>
</wsdl:binding>
<wsdl:service name="PingService">
  <wsdl:port binding="tns:PingSOAP" name="PingServicePort">
    <soap:address
      location="http://localhost:9080/WSSampleSei/PingService" />
  </wsdl:port>
</wsdl:service>
</wsdl:definitions>

```

2. Run the `wsimport` command from the `app_server_root\bin\` directory.

```
app_server_root/bin/wsimport -keep -verbose ping.wsdl
```

After generating the template files using the `wsimport` command, the following files are generated:

```

com\ibm\was\wssample\sei\ping\ObjectFactory.java
com\ibm\was\wssample\sei\ping\package-info.java
com\ibm\was\wssample\sei\ping\PingServicePortType.java
com\ibm\was\wssample\sei\ping\PingStringInput.java
com\ibm\was\wssample\sei\ping\PingService.java

```

The `ObjectFactory.java` file contains factory methods for each Java content interface and Java element interface generated in the associated ping package. The `package-info.java` file takes the `targetNamespace` value and creates the directory structure. The `PingServicePortType.java` file is the generated service endpoint interface (SEI) class that contains the ping method definition. The `PingStringInput.java` file contains the JAXB generated type values which are Java classes mapped from XML schema types. The `PingService.java` file is the generated service provider class file that is used by the JAX-WS client.

What to do next

Complete the implementation of your web service application by completing the JavaBeans or enterprise beans implementation.

wsimport command for JAX-WS applications

The `wsimport` command-line tool processes an existing Web Services Description Language (WSDL) file and generates the required artifacts for developing Java API for XML-Based Web Services (JAX-WS) web service applications. The generated artifacts are Java 5 compliant, making them portable across different Java versions and platforms.

The `wsimport` command-line tool supports the top-down approach to developing JAX-WS web services. When you start with an existing WSDL file, use the `wsimport` command-line tool to generate the required JAX-WS artifacts.

Note: The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are located in the `app_server_root\bin\` directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the `app_server_root\bin\` directory.

The wsimport tool reads an existing WSDL file and generates the following artifacts:

- Service Endpoint Interface (SEI) - The SEI is the annotated Java representation of the WSDL file for the web service. This interface is used for implementing JavaBeans endpoints or creating dynamic proxy client instances.
- `javax.xml.ws.Service` extension class - This is a generated class that extends the `javax.xml.ws.Service` class. This class is used to configure and create both dynamic proxy and dispatch instances.
- required data beans, including any Java Architecture for XML Binding (JAXB) beans that are required to model the web service data.

You can package the generated artifacts in a web application archive (WAR) file with the WSDL file and schema documents along with the endpoint implementation to be deployed.

Note: To correctly use the wsimport tool, you must adhere to the following requirements:

- You must define all your services within the main WSDL file. Services that are defined within an imported WSDL file are not processed by the wsimport tool.
- If you run the wsimport tool on a WSDL file that implements a Document or Literal style pattern, the `complexType` elements that define the input and output types must be composed of unique names to prevent naming conflicts in the parameter list for the operation..
- If you run the wsimport tool and pass a `?wsdl` Uniform Resource Identifier (URI) as a parameter for a WSDL file, ensure that you are using the actual resolved WSDL URI. The wsimport tool correctly resolves the `?wsdl` URI, but other relative URIs that are referenced might not resolve correctly.

In addition to using the tools from the command line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsImport` Ant task from within the Ant build environment to invoke the wsimport tool. To function properly, this Ant task requires that you invoke Ant using the `ws_ant` script.

Syntax

The command-line syntax is:

```
app_server_root/bin/wsimport [options] WSDL_URI
```

Parameters

The `WSDL_URI` is the only parameter that is required. The following parameters are optional for the wsimport command:

-b <path>

Specifies the external JAX-WS or JAXB binding files. You can specify multiple JAX-WS and JAXB binding files by using the `-b` option; however, each file must be specified with its own `-b` option.

-B <jaxbOption>

Specifies to pass this option to the JAXB schema compiler.

-catalog

Specifies the catalog file to resolve external entity references. It supports the TR9401, XCatalog, and the OASIS XML Catalog formats

-d <directory>

Specifies where to place the generated output files.

-extension

Specifies whether to accept custom extensions for functionality that are not specified by the JAX-WS specification. The use of custom extensions can result in applications that are not portable or do not interoperate with other implementations.

- help**
Displays the help menu.
- httpproxy:<host>:<port>**
Specifies an HTTP proxy. The default port value is 8080.
- keep**
Specifies whether to keep the generated source files.
- p <package_name>**
Specifies a target package with this command-line option and overrides any WSDL file and schema binding customization for the package name and the default package name algorithm defined in the JAX-WS specification.
- quiet**
Specifies to suppress the wsimport output.
- s <directory>**
Specifies the directory to place the generated source files.
- target <version>>**
Specifies to generate code that is compliant with a specific JAX-WS specification level. Specify version 2.0 or 2.1 to generate code that is compliant with the JAX-WS 2.0 or JAX-WS 2.1 specification respectively. Specifying version 2.1 indicates to generate code that is compliant with the JAX-WS 2.1 specification. The default value is version 2.2 and generates compliant code for the JAXB 2.2 specification.
- verbose**
Specifies to output messages about what the compiler is doing.
- version**
Prints the version information. If you specify this option, only the version information is included in the output and normal command processing does not occur.
- wsdlLocation**
Specifies the `@WebServiceClient.wsdlLocation` value.

Note: The wsimport tool does not set the `@WebService.wsdlLocation` value either by default or when the `-wsdlLocation` attribute is specified. The wsimport command-line tool updates the `@WebServiceClient.wsdlLocation` annotation only. You can manually update the `@WebService.wsdlLocation` annotation with a relative URL that specifies the location of the Web Services Description Language (WSDL) file. If the `@WebService.wsdlLocation` annotation is present on an endpoint implementation class, then the value must be a relative URL and the WSDL document that it references must be packaged with the application.

Note: If you specify an HTTPS URL for the `-wsdlLocation` parameter, the wsimport tool generates a service class with a no-argument constructor that is not valid. Avoid using the no-argument service constructor to instantiate your service. Instead, pass the HTTPS URL to one of the service class constructors that takes a WSDL URL for an argument; for example:

```
MyService("https://example.ibm.com/My?wsdl");
```

Enabling MTOM for JAX-WS web services

With Java API for XML-Based Web Services (JAX-WS), you can send binary attachments such as images or files along with web services requests. JAX-WS adds support for optimized transmission of binary data as specified by the SOAP Message Transmission Optimization Mechanism (MTOM) specification.

About this task

JAX-WS supports the use of SOAP Message Transmission Optimized Mechanism (MTOM) for sending binary attachment data. By enabling MTOM, you can send and receive binary data optimally without incurring the cost of data encoding needed to embed the binary data in an XML document.

The application server supports sending attachments using MTOM only for JAX-WS applications. This product also provides the ability to provide attachments with Web Services Security SOAP messages by using the new MTOM and XOP standards.

JAX-WS applications can send binary data as base64 or hexBinary encoded data contained within the XML document. However, to take advantage of the optimizations provided by MTOM, enable MTOM to send binary base64 data as attachments contained outside the XML document. MTOM optimization is not enabled by default. JAX-WS applications require separate configuration of both the client and the server artifacts to enable MTOM support.

Procedure

1. Develop Java artifacts for your JAX-WS application that includes an XML schema or Web Services Description Language (WSDL) file that represents your web services application data that includes a binary attachment.
 - a. If you are starting with a WSDL file, develop Java artifacts from a WSDL file by using the `wsimport` command to generate the required JAX-WS portable artifacts.
 - b. If you are starting with JavaBeans components, develop Java artifacts for JAX-WS applications and optionally generate a WSDL file using the `wsgen` command. The XML schema or WSDL file includes a `xsd:base64Binary` or `xsd:hexBinary` element definition for the binary data.
 - c. You can also include the `xmime:expectedContentTypes` attribute on the element to affect the mapping by JAXB.
2. Enable MTOM on your endpoint implementation class using one of the following methods:
 - Use the `@MTOM` annotation on the endpoint.

To enable MTOM on an endpoint, use the `@MTOM` (`javax.xml.ws.soap.MTOM`) annotation on the endpoint. The `@MTOM` annotation has two parameters, `enabled` and `threshold`. The `enabled` parameter has a boolean value and indicates if MTOM is enabled for the JAX-WS endpoint. The `threshold` parameter has an integer value, that must be greater than or equal to zero. When MTOM is enabled, any binary data whose size, in bytes, exceeds the threshold value is XML-binary Optimized Packaging (XOP) encoded or sent as an attachment. When the message size is less than the threshold value, the message is inlined in the XML document as either base64 or hexBinary data.

The following example snippet illustrates adding the `@MTOM` annotation so that MTOM is enabled for the JAX-WS `MyServiceImpl` endpoint and specifies a threshold value of 2048 bytes:

```
@MTOM(enabled=true, threshold=2048)
@WebService
public class MyServiceImpl {
    ...
}
```

Additionally, you can use the `@BindingType` (`javax.xml.ws.BindingType`) annotation on an endpoint implementation class to specify that the endpoint supports one of the MTOM binding types so that the response messages are MTOM-enabled. The `javax.xml.ws.SOAPBinding` class defines two different constants, `SOAP11HTTP_MTOM_BINDING` and `SOAP12HTTP_MTOM_BINDING` that you can use for the value of the `@BindingType` annotation; for example:

```
// This example is for SOAP version 1.1.
@BindingType(value = SOAPBinding.SOAP11HTTP_MTOM_BINDING)
@WebService
public class MyServiceImpl {
    ...
}
```

```
// This example is for SOAP version 1.2.
@BindingType(value = SOAPBinding.SOAP12HTTP_MTOM_BINDING)
@WebService
public class MyServiceImpl {
    ...
}
```

The presence and value of an `@MTOM` annotation overrides the value of the `@BindingType` annotation. For example, if the `@BindingType` indicates MTOM is enabled, but an `@MTOM` annotation is present with an enabled value of `false`, then MTOM is not enabled.

- Use the `<enable-mtom>` and `<mtom-threshold>` deployment descriptor elements. You can use the `<enable-mtom>` and `<mtom-threshold>` elements within the `<port-component>` element in the `webservices.xml` deployment descriptor as an alternative to using the `@MTOM` annotation on the service endpoint implementation class; for example:

```
<port-component>
  <port-component-name>MyPort1</port-component-name>
  <enable-mtom>true</enable-mtom>
  <mtom-threshold>2048</mtom-threshold>
  <service-impl-bean>
    <servlet-link>MyPort1ImplBean</servlet-link>
  </service-impl-bean>
</port-component>
```

Note: The deployment descriptor elements take precedence over the corresponding attributes in the MTOM annotation. For example, if the `enabled` attribute is set to `true` in the annotation, but the `<enable-mtom>` element is set to `false` in the `webservices.xml` file, MTOM is not enabled for the corresponding endpoint.

3. Enable MTOM on your client to optimize the binary messages that are sent from the client to the server. Use one of the following methods to enable MTOM on your client:

- Enable MTOM on a Dispatch client.

The following examples use SOAP version 1.1.

The first method uses `SOAPBinding.setMTOMEnabled()`; for example:

```
SOAPBinding binding = (SOAPBinding)dispatch.getBinding();
binding.setMTOMEnabled(true);
```

The second method uses `Service.addPort`; for example:

```
Service svc = Service.create(serviceName);
svc.addPort(portName, SOAPBinding.SOAP11HTTP_MTOM_BINDING, endpointUrl);
```

The third method uses `MTOMFeature`; for example:

```
MTOMFeature mtom = new MTOMFeature(true, 2048);
Service svc = Service.create(serviceName);
svc.addPort(portName, SOAPBinding.SOAP11HTTP_BINDING, endpointUrl);
Dispatch<Source> dsp = svc.createDispatch(portName, Source.class, Service.Mode.PAYLOAD, mtom);
```

- Enable MTOM on a Dynamic Proxy client.

```
// Create a BindingProvider bp from a proxy port.
Service svc = Service.create(serviceName);
MtomSample proxy = svc.getPort(portName, MtomSample.class);
BindingProvider bp = (BindingProvider) proxy;

//Enable MTOM using the SOAPBinding.
MtomSample proxy = svc.getPort(portName, MtomSample.class);
BindingProvider bp = (BindingProvider) proxy;
SOAPBinding binding = (SOAPBinding) bp.getBinding();
binding.setMTOMEnabled(true);

//Or, you can enable MTOM with the MTOMFeature.
MTOMFeature mtom = new MTOMFeature();
MtomSample proxy = svc.getPort(portName, MtomSample.class, mtom);
```

- Enable MTOM on your client using the `@MTOM` annotation; for example:

```
public class MyClientApplication {
    // Enable MTOM for a port-component-ref resource injection.
    @MTOM(enabled=true, threshold=1024)
    @WebServiceRef(MyService.class)
    private MyPortType myPort;
    ...
}
```

- Enable MTOM on your client using deployment descriptor elements within a `port-component-ref` element; for example:

```

<service-ref>
  <service-ref-name>service/MyPortComponentRef</service-ref-name>
  <service-interface>com.example.MyService</service-ref-interface>
  <port-component-ref>
    <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
    <enable-mtom>true</enable-mtom>
    <mtom-threshold>1024</mtom-threshold>
  </port-component-ref>
</service-ref>

```

Note: The deployment descriptor elements take precedence over the corresponding attributes in the MTOM annotation. For example, if the enabled attribute is set to true in the annotation, but the <enable-mtom> element is set to false in the deployment descriptor entry for the service-ref of the client, MTOM is not enabled for that service reference.

Results

You have developed a JAX-WS web services server and client application that optimally sends and receives binary data using MTOM.

Example

The following example illustrates enabling MTOM support on both the web services client and server endpoint when starting with an WSDL file.

1. Locate the WSDL file containing an `xsd:base64Binary` element. The following example is a portion of a WSDL file that contains an `xsd:base64Binary` element.

```

<types>
  .....
  <xs:complexType name="ImageDepot">
    <xs:sequence>
      <xs:element name="imageData"
        type="xs:base64Binary"
        mimeType:expectedContentTypes="image/jpeg"/>
    </xs:sequence>
  </xs:complexType>
  .....
</types>

```

2. Run the **wsimport** command from the `app_server_root\bin\` directory against the WSDL file to generate a set of JAX-WS portable artifacts.

Depending on the `expectedContentTypes` value contained in the WSDL file, the JAXB artifacts generated are in the Java type as described in the following table:

Table 141. Mapping of MIME type and Java type. Describes the mapping between MIME types and Java types.

MIME Type	Java Type
image/gif	java.awt.Image
image/jpeg	java.awt.Image
text/plain	java.lang.String
text/xml	javax.xml.transform.Source
application/xml	javax.xml.transform.Source
/	javax.activation.DataHandler

3. Use the JAXB artifacts in the same manner as in any other JAX-WS application. Use these beans to send binary data from both the Dispatch and the Dynamic Proxy client APIs.
4. Enable MTOM on a Dispatch client.

```

//Create the Dispatch instance.
JAXBContext jbc = JAXBContext.newInstance("org.apache.axis2.jaxws.sample.mtom");
Dispatch<Object> dispatch = svc.createDispatch(portName, jbc, Service.Mode.PAYLOAD);

```

```

//Enable MTOM.
SOAPBinding binding = (SOAPBinding) dispatch.getBinding();
binding.setMTOMEnabled(true);

```

5. Enable MTOM on a Dynamic Proxy client.

```

//Create the Dynamic Proxy instance.
Service svc = Service.create(serviceName);
MtomSample proxy = svc.getPort(portName, MtomSample.class);

```

```
//Enable MTOM.
    BindingProvider bp = (BindingProvider) proxy;
    SOAPBinding binding = (SOAPBinding) bp.getBinding();
    binding.setMTOMEnabled(true);
```

Now that you have enabled the JAX-WS client for MTOM, messages sent to the server have MTOM enabled. However, for the server to respond back to the client using MTOM, you must enable MTOM on the endpoint.

6. Enable MTOM on the endpoint implementation class.

```
@MTOM(enabled, threshold=4096)
@WebService (endpointInterface="org.apache.axis2.jaxws.sample.mtom.MtomSample")

public class MtomSampleService implements MtomSample {
    ....
}
```

The `jaxax.xml.ws.SOAPBinding` class has a static member for each of the supported binding types. Include either the `SOAP11HTTP_MTOM_BINDING` or the `SOAP12HTTP_MTOM_BINDING` as the value for the `@BindingType` annotation. This value enables all server responses to have MTOM enabled.

When you enable MTOM on the server and the client, the binary data that represents the attachment is included as a Multipurpose Internet Mail Extensions (MIME) attachment to the SOAP message. Without MTOM, the same data is encoded in the format that describes the XML schema, either base64 or hexadecimal encoding, and included inline in the XML document.

This example illustrates an MTOM enabled SOAP version 1.1 message with an attachment. The type and content-type attributes both have the value, `application/xop+xml`, which indicates that the message was successfully optimized using XML-binary Optimized packaging (XOP) when MTOM was enabled. This example demonstrates how the optimized message looks on the wire with MTOM enabled.

```
... other transport headers ...
Content-Type: multipart/related; boundary=MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812;

<?xml version="1.0" encoding="UTF-8"?>
    <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
        <soapenv:Header/>
        <soapenv:Body>
            <sendImage xmlns="http://org.apache.axis2/jaxws/sample/mtom">
                <input>
                    <imageData>
                        <xop:Include xmlns:xop="http://www.w3.org/2004/08/xop/include"
href="cid:1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org"/>
                    </imageData>
                </input>
            </sendImage>
        </soapenv:Body>
    </soapenv:Envelope>
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: text/plain
content-transfer-encoding: binary
content-id:
    <1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org>

... binary data goes here ...
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812--
```

In contrast, this example demonstrates a SOAP version 1.1 message on the wire without MTOM enabled. The binary data is included in the body of the SOAP message, and the SOAP message is not optimized.

```
... other transport headers ...
Content-Type: text/xml; charset=UTF-8

<?xml version="1.0" encoding="UTF-8"?>
    <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
        <soapenv:Header/>
        <soapenv:Body>
            <sendImage xmlns="http://org.apache.axis2/jaxws/sample/mtom">
```

```

<input>
  <imageData>R01GAD1 ... more base64 encoded data ... KTJk8giAAA7</imageData>
</input>
</sendImage>
</soapenv:Body>
</soapenv:Envelope>

```

For additional information, refer to the Samples section of the Information Center which includes a sample that demonstrates the use of MTOM with JAX-WS web services.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root

The default installation root directory for the Application Client for IBM WebSphere Application Server is the /QIBM/ProdData/WebSphere/AppClient/V8/client directory.

app_client_user_data_root

The default Application Client for IBM WebSphere Application Server user data root is the /QIBM/UserData/WebSphere/AppClient/V8/client directory.

app_client_profile_root

The default Application Client for IBM WebSphere Application Server profile root is the /QIBM/UserData/WebSphere/AppClient/V8/client/profiles/*profile_name* directory.

app_server_root

The default installation root directory for WebSphere Application Server - Express is the /QIBM/ProdData/WebSphere/AppServer/V8/Express directory.

java_home

Table 142. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32-bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit
64-bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit

plugins_profile_root

The default Web Server Plug-ins profile root is the /QIBM/UserData/WebSphere/Plugins/V8/webserver/profiles/*profile_name* directory.

plugins_root

The default installation root directory for Web Server Plug-ins is the /QIBM/ProdData/WebSphere/Plugins/V8/webserver directory.

plugins_user_data_root

The default Web Server Plug-ins user data root is the /QIBM/UserData/WebSphere/Plugins/V8/webserver directory.

product_library

product_lib

This is the product library for the installed product. The product library for each Version 8.0 installation on the system contains the program and service program objects (similar to .exe, .dll, .so objects) for the installed product. The product library name is QWAS8x (where x is A, B, C, and

so on). The product library for the first WebSphere Application Server Version 8.0 product installed on the system is QWAS8A. The *app_server_root/properties/product.properties* file contains the value for the product library of the installation, *was.install.library*, and is located under the *app_server_root* directory.

profile_root

The default directory for a profile named *profile_name* for WebSphere Application Server - Express is the */QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/profile_name* directory.

shared_product_library

The shared product library, which contains all of the objects shared by all installations on the system, is QWAS8. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root

The default user data directory for WebSphere Application Server - Express is the */QIBM/UserData/WebSphere/AppServer/V8/Express* directory.

The profiles and profileRegistry subdirectories are created under this directory when you install the product.

web_server_root

The default web server path is */www/web_server_name*.

Enforcing adherence to WSDL bindings in JAX-WS web services

Java API for XML-Based Web Services (JAX-WS) Version 2.1 introduced the concept of *features* as a way to programmatically control specific functions and behaviors. The *RespectBindingFeature* is one of the supported standard features. You can use the *RespectBindingFeature* to control whether a JAX-WS implementation is required to respect the contents of a Web Services Description Language (WSDL) binding that is associated with an endpoint.

About this task

While WSDL documents are often used during the development process, the actual enforcement of the use of the WSDL document specifications, when they are provided, at run time has not been well defined in versions of the JAX-WS specification previous to Version 2.1. The JAX-WS Version 2.1 specification added the feature, *RespectBindingFeature*, to clarify the impact of the *wsdl:binding* in a JAX-WS runtime environment.

Enabling the feature, *RespectBindingFeature*, causes the JAX-WS runtime environment to inspect the *wsdl:binding* for an endpoint at run time to ensure that the binding of service endpoint interface (SEI) parameters and return values is respected. Additionally, this feature ensures that all required *wsdl:binding* extensions are either understood and used by the runtime environment, or the extensions have been explicitly disabled by the application. Your JAX-WS application can disable a specific *wsdl:binding* extension that has a defined *WebServiceFeature* interface by using the appropriate annotation that is associated with that feature, using an API that accepts the *javax.xml.ws.WebServiceFeature* interface, or configuring the deployment descriptors.

When the *RespectBindingFeature* feature is not enabled, which is the default, the runtime environment can choose whether any part of the *wsdl:binding* is enforced.

Procedure

1. Develop Java artifacts for your JAX-WS application that includes a Web Services Description Language (WSDL) file that represents your web services application.
 - a. If you are starting with a WSDL file, develop Java artifacts from a WSDL file by using the *wsimport* command to generate the required JAX-WS portable artifacts.

- b. If you are starting with JavaBeans components, develop Java artifacts for JAX-WS applications and generate a WSDL file using the `wsgen` command.
2. If you want to enable `RespectBindingFeature` on your endpoint implementation class, use one of the following methods:

- Use the `@RespectBinding` annotation on the endpoint.

To enable `RespectBinding` on an endpoint, use the `@RespectBinding` (`javax.xml.ws.RespectBinding`) annotation on the endpoint. The `@RespectBinding` annotation has only one parameter, `enabled`. This parameter is optional. The `enabled` parameter has a Boolean value and indicates if `RespectBindingFeature` is enabled for the JAX-WS endpoint.

The following example snippet illustrates adding the `@RespectBinding` annotation for the JAX-WS `MyServiceImpl` endpoint:

```
@RespectBinding(enabled=true)
@WebService
public class MyServiceImpl {
    ...
}
```

- Use the `<respect-binding>` deployment descriptor element.

You can use the `<respect-binding>` element within the `<port-component>` element in the `webservices.xml` deployment descriptor as an alternative to using the `@RespectBinding` annotation on the service endpoint implementation class; for example:

```
<port-component>
  <port-component-name>MyPort1</port-component-name>
  <respect-binding>
    <enabled>true</enabled>
  </respect-binding>
  <service-impl-bean>
    <servlet-link>MyPort1ImplBean</servlet-link>
  </service-impl-bean>
</port-component>
```

3. If you want to enable `RespectBindingFeature` on your client, use one of the following methods:

- Enable `RespectBindingFeature` on a dispatch client; for example:

```
RespectBindingFeature respectBinding = new RespectBindingFeature();
Service svc = Service.create(serviceName);
svc.addPort(portName, SOAPBinding.SOAP11_HTTP_BINDING, endpointUrl);
Dispatch<Source> dsp = svc.createDispatch(portName, Source.class, Service.Mode.PAYLOAD, respectBinding);
```

- Enable `RespectBindingFeature` on a dynamic proxy client; for example:

```
// Create a dynamic proxy with RespectBinding enabled.
Service svc = Service.create(serviceName);
RespectBindingFeature respectBinding = new RespectBindingFeature();
RespectBindingSample proxy = svc.getPort(portName, RespectBindingSample.class, respectBinding);
```

- Enable `RespectBindingFeature` on your client using the `@RespectBinding` annotation; for example:

```
public class MyClientApplication {
    ...
    // Enable RespectBinding for a port-component-ref resource injection.
    @RespectBinding(enabled=true)
    @WebServiceRef(MyService.class)
    private MyPortType myPort;
    ...
}
```

- Enable `RespectBindingFeature` on your client using deployment descriptor elements within a `port-component-ref` element; for example:

```
<service-ref>
  <service-ref-name>service/MyPortComponentRef</service-ref-name>
  <service-interface>com.example.MyService</service-ref-interface>
  <port-component-ref>
    <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
    <respect-binding>
      <enabled>true</enabled>
    </respect-binding>
  </port-component-ref>
</service-ref>
```

Results

By implementing the feature, `RespectBindingFeature`, you have specified to enforce adherence of the contents of a WSDL binding that is associated with an endpoint for your JAX-WS application.

Developing a webservices.xml deployment descriptor for JAX-WS applications

Deployment descriptors are standard text files, formatted using XML and packaged in a web services application. You can optionally use the `webservices.xml` deployment descriptor to augment or override application metadata specified in annotations within Java API for XML-Based Web Services (JAX-WS) web services.

About this task

Similar to Java API for XML-based RPC (JAX-RPC) Web services, you can use deployment descriptors to describe JAX-WS web services. For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

A JAX-WS web service requires that you annotate your Java class with the `javax.jws.WebService` annotation or the `javax.jws.WebServiceProvider` annotation for Provider endpoints. You can use server-side deployment descriptors to override corresponding attributes of the annotation or to enhance information in annotations. There is a defined relationship between the deployment descriptor elements and the `@WebService` and `@WebServiceProvider` annotations. Refer to section 5.3 in the Web Services for Java Platform, Enterprise Edition (Java EE) specification, Version 1.2 for detailed information regarding the deployment descriptor elements and the mapping to the `@WebService` and `@WebServiceProvider` annotation attributes. There are also elements in the `webservice.xml` deployment descriptor that map to other annotations. For example, the deployment descriptor element `<protocol-binding>` maps to the `@BindingType` annotation, and the deployment descriptor element `<enable-mtom>` maps to the `@MTOM` annotation. For more information regarding the web services deployment descriptor elements, see section 7.1 in the Web Services for Java Platform, Enterprise Edition (Java EE) specification.

Procedure

Use assembly tools to generate the `webservice.xml` deployment descriptor.

Results

You have deployment descriptor templates that you can use to override JAX-WS annotation attributes or specify attributes that are not defined by the annotation.

Example

In the following example, the service implementation class for a JAX-WS web service includes the `@WebService` annotation:

```
@WebService(wsdlLocation="http://myhost.com/location/of/the/wsdl/ExampleService.wsdl")
```

The associated `webservices.xml` deployment descriptor specifies a different filename for the WSDL document as follows:

```
<webservices>
<webservice-description>
<webservice-description-name>ExampleService</webservice-description-name>
<wsdl-file>META-INF/wsdl/ExampleService.wsdl</wsdl-file>
...
</webservice-description>
</webservices>
```

The value that is specified in the deployment descriptor, `META-INF/wsdl/ExampleService.wsdl`, overrides the annotation value.

What to do next

Configure the `webservice.xml` deployment descriptor. After you configure the deployment descriptors, you must assemble the Web services application for deployment.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root

The default installation root directory for the Application Client for IBM WebSphere Application Server is the `/QIBM/ProdData/WebSphere/AppClient/V8/client` directory.

app_client_user_data_root

The default Application Client for IBM WebSphere Application Server user data root is the `/QIBM/UserData/WebSphere/AppClient/V8/client` directory.

app_client_profile_root

The default Application Client for IBM WebSphere Application Server profile root is the `/QIBM/UserData/WebSphere/AppClient/V8/client/profiles/profile_name` directory.

app_server_root

The default installation root directory for WebSphere Application Server - Express is the `/QIBM/ProdData/WebSphere/AppServer/V8/Express` directory.

java_home

Table 143. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32-bit IBM Technology for Java	<code>/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit</code>
64-bit IBM Technology for Java	<code>/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit</code>

plugins_profile_root

The default Web Server Plug-ins profile root is the `/QIBM/UserData/WebSphere/Plugins/V8/webserver/profiles/profile_name` directory.

plugins_root

The default installation root directory for Web Server Plug-ins is the `/QIBM/ProdData/WebSphere/Plugins/V8/webserver` directory.

plugins_user_data_root

The default Web Server Plug-ins user data root is the `/QIBM/UserData/WebSphere/Plugins/V8/webserver` directory.

product_library

product_lib

This is the product library for the installed product. The product library for each Version 8.0 installation on the system contains the program and service program objects (similar to `.exe`, `.dll`, `.so` objects) for the installed product. The product library name is `QWAS8x` (where `x` is A, B, C, and so on). The product library for the first WebSphere Application Server Version 8.0 product installed

on the system is QWAS8A. The *app_server_root/properties/product.properties* file contains the value for the product library of the installation, *was.install.library*, and is located under the *app_server_root* directory.

profile_root

The default directory for a profile named *profile_name* for WebSphere Application Server - Express is the */QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/profile_name* directory.

shared_product_library

The shared product library, which contains all of the objects shared by all installations on the system, is QWAS8. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root

The default user data directory for WebSphere Application Server - Express is the */QIBM/UserData/WebSphere/AppServer/V8/Express* directory.

The profiles and profileRegistry subdirectories are created under this directory when you install the product.

web_server_root

The default web server path is */www/web_server_name*.

Completing the JavaBeans implementation for JAX-WS applications

After you have developed the Java artifacts necessary to develop a Java API for XML-Based Web Services (JAX-WS) web service, you must complete the JavaBeans implementation to assemble a web application archive (WAR) file. The resulting WAR file contains the JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Generate Java artifacts for JAX-WS applications and optionally generate a WSDL file using the *wsgen* command-line tool. You can also optionally use deployment descriptors to augment or override binding information contained in annotations for JAX-WS web services.

About this task

For JAX-WS applications, complete the JavaBeans implementation by writing your business application.

Procedure

1. Write the JavaBeans implementation. The JavaBeans implementation is not generated by JAX-WS tooling.
2. Compile all the Java classes.

Results

You have now written your JavaBeans implementation to complete your web service application.

What to do next

After completing the JavaBeans implementation, assemble your web services application.

Completing the EJB implementation for JAX-WS applications

After you have developed the Java artifacts necessary to develop a Java API for XML-Based Web Services (JAX-WS) web service, you must complete the Enterprise JavaBeans (EJB) implementation to assemble a Java archive (JAR) file. The resulting JAR file contains the Enterprise JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Generate Java artifacts for JAX-WS applications and optionally generate a WSDL file using the **wsgen** command-line tool. You can also optionally use deployment descriptors to augment or override binding information contained in annotations for JAX-WS web services.

About this task

For JAX-WS applications, complete the enterprise beans implementation by writing your business application.

Procedure

1. Write the enterprise beans implementation. The enterprise beans implementation is not generated by JAX-WS tooling.
2. Compile all the Java classes.

Results

You have now written your enterprise beans implementation to complete your web service application.

What to do next

After completing the enterprise beans implementation, assemble your web services application.

Developing JAX-WS clients

Developing a JAX-WS client from a WSDL file

Java API for XML-Based Web Services (JAX-WS) tooling supports generating Java artifacts you need to develop static JAX-WS web services clients when starting with a Web Services Description Language (WSDL) file.

Before you begin

When you use a top-down development approach to developing JAX-WS web services by starting with a WSDL file, you must obtain the Uniform Resource Locator (URL) for the WSDL file.

If the WSDL file is a local file, the URL looks like this example: `file:/path/file_name.wsdl`.

You can also specify local files using the absolute or relative file system path.

About this task

The static client programming model for JAX-WS is called the dynamic proxy client. The dynamic proxy client invokes a web service based on a service endpoint interface that is provided. After you create the proxy, the client application can invoke methods on the proxy just like a standard implementation of those interfaces. For JAX-WS web service clients using the dynamic proxy programming model, use the JAX-WS tool, `wsimport`, to process a WSDL file and generate portable Java artifacts that are used to create a web service client. Create the following portable Java artifacts using the `wsimport` tool:

- Service endpoint interface (SEI)
- Service class
- Exception class that is mapped from the `wsdl:fault` class (if any)
- Java Architecture for XML Binding (JAXB) generated type values which are Java classes mapped from XML schema types

Note: The `wimport`, `wsgen`, `schemagen` and `xjc` command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The `wimport`, `wsgen`, `schemagen` and `xjc` command-line tools are located in the `app_server_root\bin\` directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the `app_server_root\bin\` directory.

In addition to using the tools from the command-line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsImport` Ant task from within the Ant build environment to invoke the `wimport` tool. To function properly, this Ant task requires that you invoke Ant using the `ws_ant` script.

Procedure

Run the `wimport` command to generate the portable client artifacts. The `wimport` tool is located in the `app_server_root\bin\` directory.

```
app_server_root/bin/wimport wsdl_URL
```

(Optional) Use the following options with the `wimport` command:

- Use the **-verbose** option to see a list of generated files when you run the command.
- Use the **-keep** option to keep generated Java files.
- Use the **-wsdlLocation** option to specify the location of the WSDL file.

Note: A best practice for ensuring that you produce a JAX-WS web services client enterprise archive (EAR) file that is portable to other systems is to package the WSDL document within the application module such as a web services client Java archive (JAR) file or a web application archive (WAR) file. You can specify a relative URI for the location of your WSDL file by using the `-wsdllocation` annotation attribute. For example, if your `MyService.wsdl` file is located in the `META-INF/wsdl/` directory, then run the `wimport` tool and use the `-wsdllocation` option to specify the value to be used for the location of the WSDL file. This ensures that the generated artifacts contain the correct `-wsdllocation` information needed when the application is loaded into the administrative console; for example:

```
wimport -keep -wsdllocation /META-INF/wsdl/MyService.wsdl
```

- Use the **-b** option if you are using WSDL or schema customizations to specify external binding files that contain your customizations.

You can customize the bindings in your WSDL file to enable asynchronous mappings or attachment files. To generate asynchronous interfaces, add the client-side only customization `enableAsyncMapping` binding declaration to the `wsdl:definitions` element or in an external binding file that is defined in the WSDL file. Use the `enableMIMEContent` binding declaration in your custom client or server binding file to enable or disable the default `mime:content` mapping rules. For additional information on custom binding declarations, see chapter 8 the JAX-WS specification.

Read about the `wimport` command to learn more about this command and additional options that you can specify.

Results

You have the generated Java artifacts to create a JAX-WS client that can invoke JAX-WS web services. To learn more about the usage, syntax, and parameters for the `wsimport` command, see the `wsimport` command for JAX-WS applications documentation.

Example

The following example illustrates how the `wsimport` command is used to process the sample `ping.wsdl` file to generate portable artifacts.

1. Copy the following `ping.wsdl` file to a temporary directory.

```
<?xml version="1.0" encoding="UTF-8"?>
<!--
 * This program can be used, run, copied, modified and distributed
 * without royalty for the purpose of developing, using, marketing, or distributing.
-->
<wsdl:definitions xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
 xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
 xmlns:tns="http://com.ibm/was/wssample/sei/ping/"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema" name="PingService"
 targetNamespace="http://com.ibm/was/wssample/sei/ping/"
 <wsdl:types>
 <xsd:schema
  targetNamespace="http://com.ibm/was/wssample/sei/ping/"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema">

 <xsd:element name="pingStringInput">
  <xsd:complexType>
  <xsd:sequence>
    <xsd:element name="pingInput" type="xsd:string" />
  </xsd:sequence>
  </xsd:complexType>
 </xsd:element>
 </xsd:schema>
 </wsdl:types>
 <wsdl:message name="pingOperationRequest">
 <wsdl:part element="tns:pingStringInput" name="parameter" />
 </wsdl:message>
 <wsdl:portType name="PingServicePortType">
 <wsdl:operation name="pingOperation">
  <wsdl:input message="tns:pingOperationRequest" />

 </wsdl:operation>
 </wsdl:portType>
 <wsdl:binding name="PingSOAP" type="tns:PingServicePortType">
 <soap:binding style="document"
  transport="http://schemas.xmlsoap.org/soap/http" />
 <wsdl:operation name="pingOperation">
 <soap:operation soapAction="pingOperation" style="document" />
 <wsdl:input>
  <soap:body use="literal" />
 </wsdl:input>
 </wsdl:operation>
 </wsdl:binding>
 <wsdl:service name="PingService">
 <wsdl:port binding="tns:PingSOAP" name="PingServicePort">
 <soap:address
  location="http://localhost:9080/WSSampleSei/PingService" />
 </wsdl:port>
 </wsdl:service>
 </wsdl:definitions>
```

2. Run the `wsimport` command from the `app_server_root\bin` directory.

```
app_server_root/bin/wsimport -keep -verbose ping.wsdl
```

After generating the template files from the `wsimport` command, the following files are generated:

```
com\ibm\was\wssample\sei\ping\ObjectFactory.java
com\ibm\was\wssample\sei\ping\package-info.java
com\ibm\was\wssample\sei\ping\PingServicePortType.java
com\ibm\was\wssample\sei\ping\PingService.java
com\ibm\was\wssample\sei\ping\PingStringInput.java
```

The `ObjectFactory.java`, `PingService.java`, and `PingServicePortType.java` files are the generated Java class files to use when you package the Java artifacts with your client implementation inside a Java archive (JAR) or a web application archive (WAR) file.

What to do next

Complete the client implementation.

Developing deployment descriptors for a JAX-WS client

Deployment descriptors are standard text files, formatted using XML and packaged in a web services application. You can optionally use the Web Services for Java Platform, Enterprise Edition (Java EE) specification (JSR 109) service reference deployment descriptor to augment or override application metadata specified in annotations within Java API for XML-Based Web Services (JAX-WS) web services client.

Before you begin

You must first generate the web services client artifacts from a Web Services Description Language (WSDL) file using the `wsimport` command.

About this task

You can add `service-ref` entries within the `application-client.xml`, `web.xml`, or `ejb-jar.xml` Java EE deployment descriptors. A `service-ref` entry represents a reference to a web service that is used by a Java EE component in Web, Enterprise JavaBeans (EJB) or application client containers. A `service-ref` entry has a JNDI name that is used to lookup the service. Specifying the `service-ref` entry enables the client applications to locate the service using a JNDI lookup and you can also use these service references for resource injection.

For each `service-ref` entry found in one of the deployment descriptors, the corresponding service object is bound into the JNDI namespace and the port information is included, if specified. The JAX-WS client can now perform a JNDI lookup to retrieve either a JAX-WS service or port instance.

When defining a `service-ref` that represents a JAX-WS service, use the `javax.xml.ws.Service` subclass that is generated by the `wsimport` tool as the `service-interface` value. This is the class that contains the `@WebServiceClient` annotation. When defining a `service-ref` that represents a JAX-WS port, the `service-interface` value is still the `javax.xml.ws.Service` subclass generated by the `wsimport` tool, and the `service-ref-type` value specifies the service endpoint interface (SEI) class used by the port. The SEI class is also generated by `wsimport`, and it is annotated with the `@WebService` annotation.

Procedure

1. Define the `service-ref` entry in your `application-client.xml`, `web.xml`, or `ejb-jar.xml` deployment descriptors.

For example, suppose a web application archive (WAR) file contains a `WEB-INF/web.xml` deployment descriptor that includes the following `service-ref` entries:

```
<service-ref>
  <service-ref-name>service/ExampleService</service-ref-name>
  <service-interface>com.ibm.sample.ExampleService</service-interface>
</service-ref>

<service-ref>
  <service-ref-name>service/ExamplePort</service-ref-name>
  <service-interface>com.ibm.sample.ExampleService</service-interface>
  <service-ref-type>com.ibm.sample.ExamplePort</service-ref-type>
</service-ref>

<service-ref>
  <service-ref-name>service/ExamplePortInjected</service-ref-name>
  <service-interface>com.ibm.sample.ExampleService</service-interface>
  <service-ref-type>com.ibm.sample.ExamplePort</service-ref-type>
</service-ref>
```

```

<injection-target>
  <injection-target-class>com.ibm.sample.J2EEClient</injection-target-class>
  <injection-target-name>injectedPort</injection-target-name>
</injection-target>
</service-ref>

```

In this example, `com.ibm.sample.ExampleService` is a generated JAX-WS service class and this class must be a subclass of `javax.xml.ws.Service`. Additionally, the `ExampleService.getPort()` method returns an instance of `com.ibm.sample.ExamplePort`.

2. Use the deployment descriptors within your web services client application to customize your application. The following code fragments are examples of how your client application can use the `service-ref` entries within the WAR module:

```

import javax.xml.ws.Service;
import com.ibm.sample.ExampleService;
import com.ibm.sample.ExamplePort;

// Create an InitialContext object for doing JNDI lookups.
InitialContext ic = new InitialContext();

// Client obtains an instance of the generic service class using JNDI.
Service genericService =
(Service) ic.lookup("java:comp/env/service/ExampleService");

// Client obtains an instance of the generated service class using JNDI.
ExampleService exampleService =
(ExampleService) ic.lookup("java:comp/env/service/ExampleService");

// Client obtains an instance of the port using JNDI.
ExamplePort examplePort =
(ExamplePort) ic.lookup("java:comp/env/service/ExamplePort");

// The container injects an instance of ExamplePort based on the client deployment descriptor
private ExamplePort injectedPort;

```

Results

You can now use the service references that were defined in the deployment descriptor within your client application. Additionally, you can use deployment descriptors to augment or override information specified by `@WebServiceRef` or `@Resource` annotations.

Note:

The `<lookup-name>` deployment descriptor element is new in Java EE 6, and is used to indirectly refer to an already-defined service reference. When the `<lookup-name>` element is used, only the `<service-ref-name>` element may also be specified, and no other child elements of `<service-ref>` may be defined.

The following example shows a `service-ref` entry within a `WEB-INF/web.xml` file which defines a reference to a JAX-WS service, as well as a `service-ref` entry within the same `web.xml` file which defines an indirect reference to the first `service-ref`:

```

<service-ref>
  <service-ref-name>service/ExampleService</service-ref-name>
  <service-interface>com.ibm.sample.ExampleService</service-interface>
  <service-ref-type>com.ibm.sample.ExampleServicePortType</service-ref-type>
  <wsdl-file>WEB-INF/wsdl/ExampleService.wsdl</wsdl-file>
</service-ref>

<service-ref>
  <service-ref-name>service/ExampleService2</service-ref>
  <lookup-name>java:comp/env/service/ExampleService</lookup-name>
</service-ref>

```

Assuming the above `service-refs` are defined in the `WEB-INF/web.xml` file, the client application could perform a JNDI lookup using the name `java:comp/env/service/ExampleService2`, and the result would be a reference to the `ExampleService` service defined in the WSDL document `WEB-INF/wsdl/ExampleService.wsdl`, as defined in the first `service-ref`.

What to do next

Complete the client implementation by writing your client application code that is used to invoke the web service.

Developing a dynamic client using JAX-WS APIs

Java API for XML-Based Web Services (JAX-WS) provides support for the dynamic invocation of service endpoint operations.

About this task

JAX-WS provides a new dynamic Dispatch client API that is more generic and offers more flexibility than the existing Java API for XML-based RPC (JAX-RPC)-based Dynamic Invocation Interface (DII). The Dispatch client interface, `javax.xml.ws.Dispatch`, is an XML messaging oriented client that is intended for advanced XML developers who prefer to work at the XML level using XML constructs. To write a Dispatch client, you must have expertise with the Dispatch client APIs, the supported object types, and knowledge of the message representations for the associated Web Services Description Language (WSDL) file.

The Dispatch API can send data in either `PAYLOAD` or `MESSAGE` mode. When using the `PAYLOAD` mode, the Dispatch client is only responsible for providing the contents of the `<soap:Body>` and JAX-WS includes the input payload in a `<soap:Envelope>` element. When using the `MESSAGE` mode, the Dispatch client is responsible for providing the entire SOAP envelope.

The Dispatch client API requires application clients to construct messages or payloads as XML and requires a detailed knowledge of the message or message payload. The Dispatch client can use HTTP bindings when using Source objects, Java Architecture for XML Binding (JAXB) objects, or data source objects. The Dispatch client supports the following types of objects:

- `javax.xml.transform.Source`: Use Source objects to enable clients to use XML APIs directly. You can use Source objects with SOAP and HTTP bindings.
- JAXB objects: Use JAXB objects so that clients can use JAXB objects that are generated from an XML schema to create and manipulate XML with JAX-WS applications. JAXB objects can only be used with SOAP and HTTP bindings.
- `javax.xml.soap.SOAPMessage`: Use SOAPMessage objects so that clients can work with SOAP messages. You can only use SOAPMessage objects with SOAP version 1.1 or SOAP version 1.2 bindings.
- `javax.activation.DataSource`: Use DataSource objects so that clients can work with Multipurpose Internet Mail Extension (MIME) messages. Use DataSource only with HTTP bindings.

The Dispatch API uses the concept of generics that are introduced in Java SE Runtime Environment (JRE) 6. For each of the `invoke()` methods on the Dispatch interface, generics are used to determine the return type.

Procedure

1. Determine if you want your dynamic client to send data in `PAYLOAD` or `MESSAGE` mode.
2. Create a service instance and add at least one port to it. The port carries the protocol binding and service endpoint address information.
3. Create a `Dispatch<T>` object using either the `Service.Mode.PAYLOAD` method or the `Service.Mode.MESSAGE` method.
4. Configure the request context properties on the `javax.xml.ws.BindingProvider` interface. Use the request context to specify additional properties such as enabling HTTP authentication or specifying the endpoint address.
5. Optional: Set the `jaxws.response.throwExceptionIfSOAPFault` property on the RequestContext option for the Dispatch API to `Boolean.TRUE` if you do not want the JAX-WS runtime to throw a `SOAPFaultException`.

The following example illustrates how to specify this property on the RequestContext option for the Dispatch API

```
Dispatch<OMElement> dispatch = service.createDispatch(  
portName, OMElement.class, Mode.MESSAGE);  
BindingProvider bp = (BindingProvider)dispatch;  
bp.getRequestContext().put(  
"jaxws.response.throwExceptionIfSOAPFault", Boolean.FALSE);
```

6. Compose the client request message for the dynamic client.
7. Invoke the service endpoint with the Dispatch client either synchronously or asynchronously.
8. Process the response message from the service.

Results

You have developed a dynamic JAX-WS client using the Dispatch API. Refer to Chapter 4, section 3 of the JAX-WS 2.0 specification for more information on using a Dispatch client.

Note: JAX-WS dynamic ports, which are those added using the service method `addPort`, might have additional memory requirements starting in WebSphere Application Server Version 8.0. In previous releases, a single instance of a dynamic port could be shared across multiple service instances. In version 8, dynamic ports are now scoped to the instance of the service that added them. If a JAX-WS client has multiple service instances which refer to a dynamic port of the same name, those instances are no longer shared. This can potentially increase the memory requirements for that client. The memory used by dynamic ports is released when the service instance goes out of scope. However, if you encounter issues related to increased memory usage, it is possible to revert the behavior so that dynamic ports are again shared across service instances. To do this, set the system property `jaxws.share.dynamic.ports.enable` to the value `true`. However, note that doing so can cause some other issues, such as having policy set attachments incorrectly applied across shared dynamic ports. If you set this flag to `true` and encounter some of these issues, then you should remove the flag setting.

In previous releases, if a SOAP Action was not provided by the Dispatch client application, the correct SOAP Action was not sent on the outbound message. Instead, the SOAP action was set to an anonymous operation. Starting in WebSphere Application Server Version 8, if the SOAP Action is not provided by the Dispatch client application, the JAX-WS runtime environment parses the outgoing message. It determines the operation being invoked and uses that information to determine the appropriate value for the SOAP Action. The operation resolution of the outbound message is based on the SOAP Body and the message encoding, for example, Doc/Lit/Bare, Doc/Lit/Wrapped. Since this parsing can be expensive, a property can be set. To always disable the parsing, set the property at the System level. To disable parsing on a per-message basis, set the property on the JAX-WS Request Message Context. The property is defined as a constant `org.apache.axis2.jaxws.Constants.DISPATCH_CLIENT_OUTBOUND_RESOLUTION` with a String value of `jaxws.dispatch.outbound.operation.resolution.enable`. The default value of the property is null which is interpreted as the String `true`, which enables the outbound operation resolution. Setting the property to `false` disables the outbound operation resolution. If parsing is disabled, then the SOAP Action in the outbound message is set to an anonymous operation as in previous releases. If the client provides a SOAP Action through the JAX-WS `javax.xml.ws.BindingProvider` properties, `SOAPACTION_USE_PROPERTY` and `SOAPACTION_URI_PROPERTY`, then that SOAP Action is used. Therefore, parsing of the outbound message does not occur regardless of the setting of the property. Setting a SOAP Action explicitly by the client is considered a best practice, particularly for performance on the service-provider. This practice prevents the inbound message from being parsed, to be routed to the correct endpoint operation.

Example

The following example illustrates the steps to create a Dispatch client and invoke a sample EchoService service endpoint.

```

String endpointUrl = ...;

QName serviceName = new QName("http://com/ibm/was/wssample/echo/",
    "EchoService");
QName portName = new QName("http://com/ibm/was/wssample/echo/",
    "EchoServicePort");

/** Create a service and add at least one port to it. */
Service service = Service.create(serviceName);
service.addPort(portName, SOAPBinding.SOAP11HTTP_BINDING, endpointUrl);

/** Create a Dispatch instance from a service.*/
Dispatch<SOAPMessage> dispatch = service.createDispatch(portName,
    SOAPMessage.class, Service.Mode.MESSAGE);

/** Create SOAPMessage request. */
// compose a request message
MessageFactory mf = MessageFactory.newInstance(SOAPConstants.SOAP_1_1_PROTOCOL);

// Create a message. This example works with the SOAPPART.
SOAPMessage request = mf.createMessage();
SOAPPart part = request.getSOAPPart();

// Obtain the SOAPEnvelope and header and body elements.
SOAPEnvelope env = part.getEnvelope();
SOAPHeader header = env.getHeader();
SOAPBody body = env.getBody();

// Construct the message payload.
SOAPElement operation = body.addChildElement("invoke", "ns1",
    "http://com/ibm/was/wssample/echo/");
SOAPElement value = operation.addChildElement("arg0");
value.addTextNode("ping");
request.saveChanges();

/** Invoke the service endpoint. */
SOAPMessage response = dispatch.invoke(request);

/** Process the response. */

```

Invoking JAX-WS web services asynchronously

Java API for XML-Based Web Services (JAX-WS) provides support for invoking web services using an asynchronous client invocation. JAX-WS provides support for both a callback and polling model when calling web services asynchronously. Both the callback model and the polling model are available on the Dispatch client and the Dynamic Proxy client.

Before you begin

Develop a JAX-WS Dynamic Proxy or Dispatch client. When developing Dynamic Proxy clients, after you generate the portable client artifacts from a Web Services Description Language (WSDL) file using the **wsimport** command, the generated service endpoint interface (SEI) does not have asynchronous methods included in the interface. Use JAX-WS bindings to add the asynchronous callback or polling methods on the interface for the Dynamic Proxy client. To enable asynchronous mappings, you can add the `jaxws:enableAsyncMapping` binding declaration to the WSDL file. For more information on adding binding customizations to generate an asynchronous interface, see chapter 8 of the JAX-WS specification.

Note: When you run the `wsimport` tool and enable asynchronous invocation through the use of the JAX-WS `enableAsyncMapping` binding declaration, ensure that the corresponding response message your WSDL file does not contain parts. When a response message does not contain parts, the request acts as a two-way request, but the actual response that is sent back is empty. The `wsimport` tool does not correctly handle a void response. To avoid this scenario, you can remove the output message from the operation which makes your operation a one-way operation or you can add a `<wsdl:part>` to your message. For more information on the usage, syntax and parameters for the `wsimport` tool, see the `wsimport` command for JAX-WS applications documentation.

About this task

An asynchronous invocation of a web service sends a request to the service endpoint and then immediately returns control to the client program without waiting for the response to return from the

service. JAX-WS asynchronous web service clients consume web services using either the callback approach or the polling approach. Using a polling model, a client can issue a request and receive a response object that is polled to determine if the server has responded. When the server responds, the actual response is retrieved. Using the callback model, the client provides a callback handler to accept and process the inbound response object. The `handleResponse()` method of the handler is called when the result is available. Both the polling and callback models enable the client to focus on continuing to process work without waiting for a response to return, while providing for a more dynamic and efficient model to invoke web services. Polling invocations are valid from Enterprise JavaBeans (EJB) clients or Java Platform, Enterprise Edition (Java EE) application clients. Callback invocations are valid only from Java EE application clients.

Using the callback asynchronous invocation model

To implement an asynchronous invocation that uses the callback model, the client provides an `AsyncHandler` callback handler to accept and process the inbound response object. The client callback handler implements the `javax.xml.ws.AsyncHandler` interface, which contains the application code that is run when an asynchronous response is received from the server. The `javax.xml.ws.AsyncHandler` interface contains the `handleResponse(javax.xml.ws.Response)` method that is called after the run time has received and processed the asynchronous response from the server. The response is delivered to the callback handler in the form of a `javax.xml.ws.Response` object. The response object returns the response content when the `get()` method is called. Additionally, if an error was received, then an exception is returned to the client during that call. The response method is then invoked according to the threading model used by the executor method, `java.util.concurrent.Executor` on the client's `javax.xml.ws.Service` instance that was used to create the Dynamic Proxy or Dispatch client instance. The executor is used to invoke any asynchronous callbacks registered by the application. Use the `setExecutor` and `getExecutor` methods to modify and retrieve the executor configured for your service.

Using the polling asynchronous invocation model

Using the polling model, a client can issue a request and receive a response object that can subsequently be polled to determine if the server has responded. When the server responds, the actual response can then be retrieved. The response object returns the response content when the `get()` method is called. The client receives an object of type `javax.xml.ws.Response` from the `invokeAsync` method. That `Response` object is used to monitor the status of the request to the server, determine when the operation has completed, and to retrieve the response results.

Using an asynchronous message exchange

By default, asynchronous client invocations do not have asynchronous behavior of the message exchange pattern on the wire. The programming model is asynchronous; however, the exchange of request or response messages with the server is not asynchronous. To use an asynchronous message exchange, the `com.ibm.websphere.webservices.use.async.mep` property must be set on the client request context with a boolean value of `true`. When this property is enabled, the messages exchanged between the client and server are different from messages exchanged synchronously. With an asynchronous exchange, the request and response messages have WS-Addressing headers added that provide additional routing information for the messages. Another major difference between asynchronous and synchronous message exchange is that the response is delivered to an asynchronous listener that then delivers that response back to the client. For asynchronous exchanges, there is no timeout that is sent to notify the client to stop listening for a response. To force the client to stop waiting for a response, issue a `Response.cancel()` method on the object returned from a polling invocation or a `Future.cancel()` method on the object returned from a callback invocation. The cancel response does not affect the server when processing a request.

Procedure

1. Determine if you want to implement the callback method or the polling method for the client to asynchronously invoke the web service.
2. (Optional) Configure the client request context. Add the

`com.ibm.websphere.webservices.use.async.mep`

property to the request context to enable asynchronous messaging for the web services client. Using this property requires that the service endpoint supports WS-Addressing which is supported by default for the application server. The following example demonstrates how to set this property:

```
Map<String, Object> rc = ((BindingProvider) port).getRequestContext();
rc.put("com.ibm.websphere.webservices.use.async.mep", Boolean.TRUE);
```

3. To implement the asynchronous callback method, perform the following steps.
 - a. Find the asynchronous callback method on the SEI or `javax.xml.ws.Dispatch` interface. For an SEI, the method name ends in *Async* and has one more parameter than the synchronous method of type `javax.xml.ws.AsyncHandler`. The `invokeAsync(Object, AsyncHandler)` method is the one that is used on the Dispatch interface.
 - b. (Optional) Add the `service.setExecutor` methods to the client application. Adding the executor methods gives the client control of the scheduling methods for processing the response. You can also choose to use the `java.concurrent.Executors` class factory to obtain packaged executors or implement your own executor class. See the JAX-WS specification for more information on using executor class methods with your client.
 - c. Implement the `javax.xml.ws.AsyncHandler` interface. The `javax.xml.ws.AsyncHandler` interface only has the `handleResponse(javax.xml.ws.Response)` method. The method must contain the logic for processing the response or possibly an exception. The method is called after the client run time has received and processed the asynchronous response from the server.
 - d. Invoke the asynchronous callback method with the parameter data and the callback handler.
 - e. The `handleResponse(Response)` method is invoked on the callback object when the response is available. The `Response.get()` method is called within this method to deliver the response.
4. To implement the polling method,
 - a. Find the asynchronous polling method on the SEI or `javax.xml.ws.Dispatch` interface. For an SEI, the method name ends in *Async* and has a return type of `javax.xml.ws.Response`. The `invokeAsync(Object)` method is used on the Dispatch interface.
 - b. Invoke the asynchronous polling method with the parameter data.
 - c. The client receives the object type, `javax.xml.ws.Response`, that is used to monitor the status of the request to the server. The `isDone()` method indicates whether the invocation has completed. When the `isDone()` method returns a value of `true`, call the `get()` method to retrieve the response object.
5. Use the `cancel()` method for the callback or polling method if the client needs to stop waiting for a response from the service. If the `cancel()` method is invoked by the client, the endpoint continues to process the request. However, the wait and response processing for the client is stopped.

Results

You have enabled your JAX-WS web service client to asynchronously invoke and consume web services. See the JAX-WS specification for additional information regarding the asynchronous client APIs.

Example

The following example illustrates a web service interface with methods for asynchronous requests from the client.

```
@WebService
public interface CreditRatingService {
    // Synchronous operation.
    Score getCreditScore(Customer customer);
    // Asynchronous operation with polling.
    Response<Score> getCreditScoreAsync(Customer customer);
    // Asynchronous operation with callback.
    Future<?> getQuoteAsync(Customer customer,
        AsyncHandler<Score> handler);
}
```

Using the callback method

The callback method requires a callback handler that is shown in the following example. When

using the callback procedure, after a request is made, the callback handler is responsible for handling the response. The response value is a response or possibly an exception. The `Future<?>` method represents the result of an asynchronous computation and is checked to see if the computation is complete. When you want the application to find out if the request is completed, invoke the `Future.isDone()` method. Note that the `Future.get()` method does not provide a meaningful response and is not similar to the `Response.get()` method.

```
CreditRatingService svc = ...;

Future<?> invocation = svc.getCreditScoreAsync(customerTom,
    new AsyncHandler<Score>() {
        public void handleResponse (
            Response<Score> response)
        {
            score = response.get();
            // process the request...
        }
    }
);
```

Using the polling method

The following example illustrates an asynchronous polling client:

```
CreditRatingService svc = ...;
Response<Score> response = svc.getCreditScoreAsync(customerTom);

while (!response.isDone()) {
    // Do something while we wait.
}

score = response.get();
```

Implementing extensions to JAX-WS web services clients

WebSphere Application Server provides extensions to web services clients using the Java API for XML-based Web Services (JAX-WS) programming model.

About this task

You can customize web services by using the following extensions to the JAX-WS client programming model.

Procedure

- Set the **JAXWS_OUTBOUND_SOAP_HEADERS** and **JAXWS_INBOUND_SOAP_HEADERS** properties on the request context of the Dispatch or Proxy object to enable a JAX-WS web services client to send or retrieve implicit SOAP headers.

An implicit SOAP header is a SOAP header that is not explicitly defined in the WSDL file. An implicit SOAP header file fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the WSDL file, but the message definition is not referenced by a portType within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

To learn how to modify your client code to send or retrieve transport headers, see the information on sending implicit SOAP headers with JAX-WS or receiving implicit SOAP headers with JAX-WS.

- Set the **REQUEST_TRANSPORT_PROPERTIES** and **RESPONSE_TRANSPORT_PROPERTIES** properties to enable a web services client to send or retrieve transport headers.

Set the properties on the BindingProvider instance.

By modifying your client code to send or retrieve transport headers, you can send or receive specific information within the transport headers of outgoing requests or incoming responses from the server. For requests or responses that use the HTTP transport, the information is sent or retrieved in an HTTP header. Similarly, for a request or response that uses the Java Message Service (JMS) transport, the information is sent or retrieved in a JMS message property.

To learn how to modify your client code to send or retrieve transport headers, see the information on sending transport headers with JAX-WS or retrieving transport headers with JAX-WS.

To learn how to enable a web services client to send or retrieve transport headers, see the transport header properties best practices information.

Example: Using JAX-WS properties to manipulate SOAP headers in a JAX-WS handler

WebSphere Application Server provides extensions to the Java API for XML-Based Web Services (JAX-WS) and Web Services for Java Platform, Enterprise Edition (Java EE) client programming models, including the `jaxws.binding.soap.headers.outbound` and `jaxws.binding.soap.headers.inbound` properties. This example shows how to use these two properties to manipulate SOAP headers in a JAX-WS handler.

The following programming example illustrates how to set two request SOAP headers and retrieve one response SOAP header within a JAX-WS handler context:

```
1 //Create the hashmaps for the outbound soap headers
2 Map<QName, List<String>> outboundHeaders=messageContext.get("jaxws.binding.soap.headers.outbound");
3
4 //Add "AtmUuid1" and "AtmUuid2" to the outbound map
5 List<String> list1 = new ArrayList<String>();
6 list1.add("<AtmUuid1 xmlns=\"com.rotbank.security\"><uuid>ROTB-0A01254385FCA09</uuid></AtmUuid1>");
7 List<String> list2 = new ArrayList<String>();
8 list2.add("<AtmUuid2 xmlns=\"com.rotbank.security\"><uuid>ROTB-0A01254385FCA09</uuid></AtmUuid2>");
9 outboundHeaders.put(new QName("com.rotbank.security", "AtmUuid1"), list1);
10 outboundHeaders.put(new QName("com.rotbank.security", "AtmUuid2"), list2);
11 // Set the outbound map on the MessageContext object, which is passed into the JAX-WS handler method
12 messageContext.put("jaxws.binding.soap.headers.outbound", outboundHeaders);
```

On line 2, retrieve the outbound SOAP header map from the `MessageContext` parameter, which is passed into the JAX-WS handler method.

On lines 5-10, the `AtmUuid1` and `AtmUuid2` headers elements are added to the outbound map.

On line 12, the outbound map is set on the JAX-WS handler context, which causes the `AtmUuid1` and `AtmUuid2` headers to be added to the request message. This code is not necessary because the `outboundHeaders` map is a live map.

JAX-WS handler methods might also retrieve specific headers from the map and remove headers or entire lists of headers, if desired.

Sending implicit SOAP headers with JAX-WS

You can enable an existing Java API for XML-Based Web Services (JAX-WS) web services client to send values in implicit SOAP headers. By modifying your client code to send implicit SOAP headers, you can send specific information within an outgoing web service request.

Before you begin

To complete this task, you need a web services client that you can enable to send implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a `portType` element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

Using JAX-WS, there is no restriction on types of headers that you can manipulate.

About this task

The client application sets properties on the Dispatch or Proxy object to send and receive implicit SOAP headers.

Procedure

1. Create a `java.util.HashMap<QName, List<String>>` object.
2. Add an entry to the `HashMap` object for each implicit SOAP header that the client wants to send. The `HashMap` entry key is the `QName` of the SOAP header. The `HashMap` entry value is a `List<String>` object, and each `String` is the XML text of the entire SOAP header element. By using `List<String>` object, you can add multiple SOAP header elements that each have the same `QName` object.
3. Set the `HashMap` object as a property on the request context of the Dispatch or Proxy object. The property name is `com.ibm.wsspi.websvcs.Constants.JAXWS_OUTBOUND_SOAP_HEADERS`. The value of the property is the `HashMap`.
4. Issue the remote method calls using the Dispatch or Proxy object. The headers within the `HashMap` object are sent in the outgoing message.

A `WebServiceException` error can occur if any of the following are true:

- The `HashMap` object contains a key that is not a `QName` object or if the `HashMap` object contains a value that is not a `List<String>` object.
- The `String` representing an SOAP header is not a compliant XML message.
- The `HashMap` contains a key that represents a SOAP header that is declared protected by the owning component.

Results

You have a JAX-WS web services client that is configured to send implicit SOAP headers.

Example

The following programming example illustrates how to set two request SOAP headers and retrieve one response SOAP header within a JAX-WS web services request and response context:

```
1 //Create the hashmaps for the outbound soap headers
2 Map<QName, List<String>> outboundHeaders=new HashMap<QName, List<String>>();
3
4 //Add "AtmUuid1" and "AtmUuid2" to the outbound map
5 List<String> list1 = new ArrayList<String>();
6 list1.add("<AtmUuid1 xmlns=\"com.rotbank.security\">uuid>ROTB-0A01254385FCA09</uuid></AtmUuid1>");
7 List<String> list2 = new ArrayList<String>();
8 list2.add("<AtmUuid2 xmlns=\"com.rotbank.security\">uuid>ROTB-0A01254385FCA09</uuid></AtmUuid2>");
9 outboundHeaders.put(new QName("com.rotbank.security", "AtmUuid1"), list1);
10 outboundHeaders.put(new QName("com.rotbank.security", "AtmUuid2"), list2);
11 // Set the outbound map on the request context
12 dispatch.getRequestContext().put("jaxws.binding.soap.headers.outbound");
13 // Invoke the remote operation
14 dispatch.invoke(param1);
15 // Get the inbound header map from the response context
16 Map<QName,List<String>> inboundMap = dispatch.getResponseContext().get("jaxws.binding.soap.headers.outbound");
17 List<String> serverUuidList = inboundMap.get(new QName("com.rotbank.security","ServerUuid"));
18 String text = serverUuidList.get(0);
19 //Note: text now equals a XML object that contains a SOAP header:
20 //<y:ServerUuid xmlns:y=\"com.rotbank.security\"><:uuid>ROTB-0A03519322FSA01
21 //</y:uuid></y:ServerUuid.>");
22
```

On line 2, create the outbound SOAP header map.

On lines 5-10, the `AtmUuid1` and `AtmUuid2` headers elements are added to the outbound map.

On line 12, the outbound map is set on the request context, which causes the `AtmUuid1` and `AtmUuid2` headers to be added to the request message when the operation is invoked.

On line 14, invoke the remote operation.

On line 15, obtain the outbound header map.

On lines 17-18, the ServerUid header is retrieved from the response Map. The Map accesses the SOAP header from the response message.

Receiving implicit SOAP headers with JAX-WS

You can enable an existing Java API for XML-Based Web Services (JAX-WS) web services client to receive values from implicit SOAP headers. By modifying your client code to receive implicit SOAP headers, you can receive specific information within an incoming web service response.

Before you begin

To complete this task, you need a web services client that you can enable to receive implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a portType element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

Using JAX-WS, there is no restriction on types of headers that you can manipulate.

About this task

The client application sets properties on the Dispatch or Proxy object to send and receive implicit SOAP headers.

Procedure

1. Issue a remote method call with the Dispatch or Proxy object.
2. Using the property name, `com.ibm.wsspi.websvcs.Constants.JAXWS_INBOUND_SOAP_HEADERS`, retrieve the `Map<QName, List<String>>` from the `ResponseContext` of the Dispatch or Proxy object.
3. From the `Map<QName, List<String>>` value, retrieve a `List<String>` using the `QName` of the SOAP header. If the `List<String>` value is present, that value contains zero or more `String` objects that contain the XML text of the SOAP headers for the corresponding `QName`.

Results

You have a JAX-WS web services client that can receive values from implicit SOAP headers.

Transport header properties best practices

You can set the `REQUEST_TRANSPORT_PROPERTIES` property and `RESPONSE_TRANSPORT_PROPERTIES` property on a Java API for XML-based RPC (JAX-RPC) client Stub, a Call instance, or a Java API for XML-Based Web services (JAX-WS) `BindingProvider`'s `RequestContext` instance to enable a web services client to send or retrieve transport headers.

Note: Use these best practices to enable a Web services client to send or retrieve transport headers.

REQUEST_TRANSPORT_PROPERTIES best practices

Transport headers that require multiple values

Some transport headers such as the HTTP Cookie header and the Cookie2 header contain multiple embedded values. For headers that contain multiple values, the header value must be written in the following way:

- Each name=value pair embedded within the header value must be separated by a semi-colon (;).
- Each *name* and its value must be separated by an equal (=) sign.

The following is an example of how the header value must be written:

```
name1=value1;name2=value2;name3=value3
```

Map values

The values contained in the user's Map might be parsed before being added to the outgoing request if the outgoing request already contains a header identifier that matches one in the Map. For certain transport headers that contain multiple embedded values, the header values in the Map are parsed into individual name=value components. A semi-colon (;) separates the components, for example, name1=value1;name2=value2. Each name=value is appended to the outgoing header unless:

- **The outgoing request header contains a *name* value.**

In this case, the name=value from the Map is silently ignored, preventing a client from overwriting or modifying values for the *name* value that are already set in the outgoing request header by either the server or the web services engine.

- **The user's header value contains multiple *name* values.**

When the user's header value contains multiple *name* values, the first occurrence of the *name* value is used and the others are silently ignored. For example, if the user's header value contains name1=value1;name2=value2;name1=value3, where there are two occurrences of name1, the first value, name1=value1, is used. The other value, name1=value3, is silently ignored.

RESPONSE_TRANSPORT_PROPERTIES best practices

Map values

Only the Map keys are used; the Map values are ignored. The values are filled in this Map by retrieving the transport headers, which correspond to the Map keys from the incoming response message. An empty Map causes all of the transport headers and the associated values to be retrieved from the incoming response message.

HTTP headers that are processed under special consideration

The following are HTTP headers that are given special consideration when sending and retrieving HTTP responses and requests.

The values in these headers can be set in a variety of ways. For example, some header values are sent based on settings in a deployment descriptor or binding file. In these cases, the value set through REQUEST_TRANSPORT_PROPERTIES overrides the values set any other way.

Table 144. HTTP request and response header values. Values to specify for HTTP headers when sending and retrieving HTTP responses and requests.

Header	Send request	Retrieve response
Transfer-encoding	<ul style="list-style-type: none"> • The transfer-encoding header is ignored for HTTP 1.0. • When using HTTP 1.1, the transfer-encoding header is set to chunked if the value is chunked. 	There is no special processing.

Table 144. HTTP request and response header values (continued). Values to specify for HTTP headers when sending and retrieving HTTP responses and requests.

Connection	<ul style="list-style-type: none"> The connection header is ignored for HTTP 1.0. When using HTTP 1.1, the following values are set: <ul style="list-style-type: none"> The connection header is set to "close" if the value is set to "close". The connection header is set to "keep-alive" if the value is set to "keep-alive". All other value settings are ignored. 	There is no special processing.
Expect	<ul style="list-style-type: none"> The expect header is ignored for HTTP 1.0. When using HTTP 1.1, the following values are set: <ul style="list-style-type: none"> The connection header is set to "100-continue" if the value is set to "100-continue". All other value settings are ignored. 	There is no special processing.
Host	Ignored	There is no special processing.
Content-type	Ignored	There is no special processing.
SOAPAction	Ignored	There is no special processing.
Content-length	Ignored	There is no special processing.
Cookie The following is a String constant: com.ibm.websphere.webservices.Constants.HTTP_HEADER_COOKIE	The value is sent on the header if it is structured correctly. See the information in this article for Header value format and Map values.	There is no special processing.
Cookie2 The following is a String constant: com.ibm.websphere.webservices.Constants.HTTP_HEADER_COOKIE2	See the information in the "Cookie" entry.	There is no special processing.
Set-cookie The following is a String constant: com.ibm.websphere.webservices.Constants.HTTP_HEADER_SET_COOKIE	There is no special processing.	If the property MAINTAIN_SESSION is set to true, the entire value is saved into SessionContext.CONTEXT_PROPERTY and is sent on subsequent requests in the Cookie header. See the Cookie entry in this table for more information.
Set-cookie2 The following is a String constant: com.ibm.websphere.webservices.Constants.HTTP_HEADER_SET_COOKIE2	There is no special processing.	If the property MAINTAIN_SESSION is set to true, the entire value is saved into SessionContext.CONTEXT_PROPERTY and is sent on subsequent requests in the Cookie header. See the Cookie entry in this table for more information.

Example client code

The following is an example of how you can code a web services client to send and retrieve transport header values:

```
public class MyApplicationClass {
    // Inject an instance of the service's port-type.
    @WebServiceRef(EchoService.class)
    private EchoPortType port;

    // This method will invoke the web service operation and send and receive transport headers.
    public void invokeService() {

        // Set up the Map that will contain the request headers.
        Map<String, Object> requestHeaders = new HashMap<String, Object>();
        requestHeaders.put("Cookie", "ClientAuthenticationToken=FFEEBCC");
        requestHeaders.put("MyHeaderFlag", new Boolean(true));

        // Set the Map as a property on the RequestContext.
        BindingProvider bp = (BindingProvider) port;
```

```

bp.getRequestContext().put(com.ibm.websphere.webservices.Constants.REQUEST_TRANSPORT_PROPERTIES, requestHeaders);

// Set up the Map to retrieve transport headers from the response message.
Map<String, Object>responseHeaders = new HashMap<String, Object>();
responseHeaders.put("Set-Cookie", null);
responseHeaders.put("MyHeaderFlag", null);

// Invoke the web services operation.
String result = port.echoString("Hello, world!");

// Retrieve the headers from the response.
String cookieValue = responseHeaders.get("Set-Cookie");
String headerFlag = responseHeaders.get("MyHeaderFlag");
}
}

```

Sending transport headers with JAX-WS

You can enable an existing Java API for XML-Based Web Services (JAX-WS) web services client to send application-defined information along with your web services requests by using transport headers. In addition, you can enable a JAX-WS Web services endpoint to send application-defined information along with the Web services response message by using transport headers.

Before you begin

You need a JAX-WS web services client that you can enable to send transport headers.

Sending transport headers is supported in JAX-WS Web services clients, and is supported for the HTTP and JMS transports. The web services client must call the JAX-WS APIs directly and not through any intermediary layers, such as a gateway function.

About this task

When using the JAX-WS programming model, the client must set a property on the BindingProvider's RequestContext object to send values in transport headers with the Web services request message. After you set the property, the values are set in all the requests for subsequent remote method invocations against the BindingProvider object until the associated property is set to null or the BindingProvider object is discarded.

To send values in the transport headers on outbound requests from a JAX-WS Web services client application, modify the client code as follows:

Procedure

1. Create a java.util.Map object that contains the transport headers.
2. Add an entry to the Map object for each transport header that you want the client to send.
 - a. Set the Map entry key to a string that exactly matches the transport header identifier. You can define the header identifier with a reserved header name, such as Cookie in the case of HTTP, or the header identifier can be user-defined, such as MyTransportHeader. Certain header identifiers are processed in a unique manner, but no other checks are made as to the header identifier value. To learn more about the HTTP header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as HTTP_HEADER_SET_COOKIE in the com.ibm.websphere.webservices.Constants class.
 - b. Set the Map entry value to the value of the transport header. The type of this value can be one of the following data types:
 - java.lang.String
 - java.lang.Integer
 - java.lang.Short
 - java.lang.Long
 - java.lang.Float
 - java.lang.Double

- java.lang.Byte
- java.lang.Boolean

Note: When using transport headers with HTTP, all non-String header values are converted to java.lang.String before being set on the HTTP message.

3. Set the Map object on the BindingProvider's RequestContext using the com.ibm.websphere.webservices.Constants.REQUEST_TRANSPORT_PROPERTIES property. When the REQUEST_TRANSPORT_PROPERTIES property value is set, that Map is used on subsequent invocations to set the header values in the outgoing requests. If the REQUEST_TRANSPORT_PROPERTIES property value is set to null, no transport properties are sent in outgoing requests. To learn more about these properties, see the transport header properties documentation.

4. Issue remote method calls against the BindingProvider instance. The headers and the associated values from the Map are added to the outgoing request for each method invocation. If the invocation uses HTTP, then the transport headers are sent as HTTP headers within the HTTP request. If the invocation uses JMS, then the transport headers are sent as JMS message properties.

If the Constants.REQUEST_TRANSPORT_PROPERTIES property is not set correctly, you might experience API usage errors that result in a WebServiceException error. The following requirements must be met, or the process fails:

- a. The Constants.REQUEST_TRANSPORT_PROPERTIES property value that is set on the BindingProvider's RequestContext must be a java.util.Map object or null.
- b. Each key in the Map must be a java.util.String data type.
- c. Each value in the Map must be one of the following data types:
 - java.lang.String
 - java.lang.Integer
 - java.lang.Short
 - java.lang.Long
 - java.lang.Float
 - java.lang.Double
 - java.lang.Byte
 - java.lang.Boolean

Results

You have a JAX-WS web services client that is configured to send transport headers in Web services request messages.

Example

Here is a short programming example that illustrates how request transport headers are sent by a JAX-WS Web services client application:

```
public class MyApplicationClass {
    // Inject an instance of the service's port-type.
    @WebServiceRef(EchoService.class)
    private EchoPortType port;

    // This method will invoke the web service operation and send transport headers on the request.
    public void invokeService() {

        // Set up the Map that will contain the request headers.
        Map<String, Object> requestHeaders = new HashMap<String, Object>();
        requestHeaders.put("MyHeader1", "This is a string value");
        requestHeaders.put("MyHeader2", new Integer(33));
        requestHeaders.put("MyHeader3", new Boolean(true));

        // Set the Map as a property on the RequestContext.
```

```

BindingProvider bp = (BindingProvider) port;
bp.getRequestContext().put(com.ibm.websphere.webservices.Constants.REQUEST_TRANSPORT_PROPERTIES, requestHeaders);

// Invoke the web services operation.
String result = port.echoString("Hello, world!");
}
}

```

Sending response transport headers from a JAX-WS endpoint: Before you begin

You need a JAX-WS Web services endpoint implementation class that you can enable to send transport headers.

Sending response transport headers from a JAX-WS endpoint is similar to sending request transport headers from a JAX-WS client. It is supported for the HTTP and JMS transports.

About this task

When using the JAX-WS programming model, the endpoint implement class must set a property on the `MessageContext` to send values in transport headers with the Web services response message.

Procedure

1. Create a `java.util.Map` object that contains the transport headers.
2. Add an entry (key and value) to the `Map` object for each transport header that you want to send in the response message. This is similar to the procedure for the client above.
3. Retrieve the `MessageContext` (instance of `javax.xml.ws.handler.MessageContext`) associated with the invocation of the endpoint.
4. Set the `Map` object on the `MessageContext` using the `com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES` property.

Results

You have a JAX-WS Web services endpoint implementation class that is configured to send transport headers in Web services response messages.

Example

Here is a short programming example that illustrates how response transport headers are sent by a JAX-WS Web services endpoint implementation class:

```

@WebService
public class EchoServiceImpl implements EchoServicePortType {

    // Inject an instance of WebServiceContext so we can retrieve
    // the MessageContext for each invocation of this endpoint.
    @Resource
    WebServiceContext ctxt;

    /**
     * Default constructor.
     */
    public EchoServiceImpl() {
        ....
    }

    public String echoString(String input) {
        String result = "Echo result: " + input;

        // Retrieve the MessageContext from the injected WebServiceContext.
        MessageContext mc = ctxt.getMessageContext();

        // Send some headers back in the response message.
        Map<String, Object> responseHeaders = new HashMap<String, Object>();
    }
}

```

```

responseHeaders.put("MyHeader1", "This is a string response value");
responseHeaders.put("MyHeader2", new Integer(33));
responseHeaders.put("MyHeader3", new Boolean(false));

// Set the response header Map on the MessageContext.
mc.put(com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES, responseHeaders);

return result;
}
}

```

Retrieving transport headers with JAX-WS

You can enable a Java API for XML-Based Web Services (JAX-WS) web services client to retrieve values from transport headers. For a request that uses HTTP, the transport headers are retrieved from HTTP headers found in the HTTP response message. For a request that uses Java Message Service (JMS), the transport headers are retrieved from the JMS message properties found on the JMS response message.

Before you begin

You need a JAX-WS web services client that you can enable to retrieve transport headers.

Retrieving transport headers is supported only by Web services clients, and is supported for the HTTP and JMS transports. The web services client must call the JAX-WS APIs directly and not through any intermediary layers, such as a gateway function.

About this task

When using the JAX-WS programming model, the client must set a property on the BindingProvider's RequestContext object to retrieve values from the transport headers. After you set the property, values are read from responses for the subsequent method invocations against that BindingProvider object until the associated property is set to null or the BindingProvider object is discarded.

To retrieve values from the transport headers on inbound responses, modify the client code as follows:

Procedure

1. Create a `java.util.Map` object that will hold the transport headers retrieved from the response message. To retrieve all the transport headers from a response message, leave this Map empty.
2. (Optional) Add an entry to the Map for each header that you want to retrieve from the incoming response message.
 - a. Set the Map entry key to a string that exactly matches the transport header identifier. You can specify the header identifier with a reserved header name, such as `Cookie` in the case of HTTP, or the header identifier can be user-defined, such as `MyTransportHeader`. Certain header identifiers are processed in a unique manner, but no other checks are made to confirm the header identifier value. To learn more about the HTTP header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as `HTTP_HEADER_SET_COOKIE` in the `com.ibm.websphere.webservices.Constants` class. The Map entry value is ignored and does not need to be set. An empty Map, for example, one that is non-null, but does not contain any keys, causes all the transport headers in the response to be retrieved.
3. Set the Map object on the BindingProvider's RequestContext using the `com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES` property. When the Map is set, the `RESPONSE_TRANSPORT_PROPERTIES` property is used in subsequent invocations to retrieve the headers from the responses. If you set the property to null, no headers are retrieved from the response. To learn more about these properties, see the transport header properties documentation.
4. Invoke remote method calls against the BindingProvider instance. The values from the specified transport headers are retrieved from the response message and placed in the Map.

If the property is not set correctly, you might experience API usage errors that result in a `WebServiceException` error. The following requirements must be met, or the process fails:

- The `Constants.RESPONSE_TRANSPORT_PROPERTIES` property value that is set on the `BindingProvider`'s `RequestContext` instance must be either null or an instance of `java.util.Map`.
- All the `Map` keys must be of the `java.lang.String` data type, and the keys must not be null.
- The `Map` may be empty, which means that it contains no entries at all. In this case, all the transport headers will be retrieved from the response message.

Results

You have a JAX-WS web service that can receive transport headers from incoming response messages.

Example

Here is a short programming example that illustrates how response transport headers are retrieved by a JAX-WS Web services client application:

```
public class MyApplicationClass {
    // Inject an instance of the service's port-type.
    @WebServiceRef(EchoService.class)
    private EchoPortType port;

    // This method will invoke the web service operation and retrieve transport headers on the request.
    public void invokeService() {

        // Set up the Map to retrieve our response headers.
        Map<String, Object> responseHeaders = new HashMap<String, Object>;
        responseHeaders.put("MyHeader1", null);
        responseHeaders.put("MyHeader2", null);
        responseHeaders.put("MyHeader3", null);

        // Set the Map as a property on the RequestContext.
        BindingProvider bp = (BindingProvider) port;
        bp.getRequestContext().put(com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES, responseHeaders);

        // Invoke the web services operation.
        String result = port.echoString("Hello, world!");

        // Now retrieve our response headers.
        Object header1 = responseHeaders.get("MyHeader1");
        Object header2 = responseHeaders.get("MyHeader2");
        Object header3 = responseHeaders.get("MyHeader3");
    }
}
```

Developing JAX-RPC web services

Setting up a development environment for web services

The application server provides command-line tools to develop web services clients and implementations that are based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. You must set up your development environment before you start developing web services.

Before you begin

Before you can set up a web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information on installing the application server, read about installing your application server environment.

About this task

Set up a web services development environment by completing the following actions.

Procedure

Set up the environment.

Run the `setupCmdLine` script on the Qshell command line from the `./profile_root/bin` directory.

Results

You have set up an environment so that you can develop Web services.

What to do next

Implement web services applications. See the task overview for implementing web services applications information to learn about how to develop and implement a Java EE web service.

Developing a service endpoint interface from JavaBeans for JAX-RPC applications

You must develop a service endpoint interface if you are developing a JAX-RPC web service from a JavaBeans implementation.

Before you begin

You need to set up a development environment for web services and access an existing Java bean web application archive (WAR) file. See the setting up a development environment for web services information.

About this task

This task is a required step in developing a JAX-RPC Web service from a Java bean.

The service endpoint interface defines the methods for particular Java API for XML-based RPC (JAX-RPC) web services. The JavaBeans implementation must implement methods with the same signature as the methods on the service endpoint interface. A number of restrictions apply on which types to use as parameters and results of service endpoint interface methods. These restrictions are documented in the JAX-RPC specification.

You can also create a service endpoint interface by using assembly tools.

Develop a service endpoint interface for a JavaBeans implementation by following the actions listed:

Procedure

1. Create a Java interface that contains the methods to include in the service endpoint interface. If you start with an existing Java interface, remove any methods that do not conform to the JAX-RPC specification.
2. Compile the interface.
Use the name of the service endpoint interface class in the `javac` command for the class to compile. Ensure the `j2ee.jar` file is in your class path to compile the interface. The JAR file is located in the `app_server_root/dev/JavaEE` directory path.

Results

You have developed a service endpoint interface that you can use to develop web services.

Example

The following example depicts the AddressBook interface:

```
package addr;
public interface AddressBook {
    /**
     * Retrieve an entry from the AddressBook.
     *
     * @param name the name of the entry to look up.
     * @return the AddressBook entry matching name or null if none.
     * @throws java.rmi.RemoteException if communications failure.
     */
    public addr.Address getAddressFromName(java.lang.String name);
}
```

Use the AddressBook interface to create the service endpoint interface:

1. Make a copy of the AddressBook.java interface and name it AddressBook_SEI.java. Use this copy as a template for the service endpoint interface.
2. Compile the interface.

What to do next

Continue to gather the artifacts that are required to develop a web service, including the Web Services Description Language (WSDL) file. You need to develop a WSDL file because it is the engine of a web service. Without a WSDL file, you do not have a web service. See the developing a WSDL file for JAX-RPC applications information.

Developing a service endpoint interface from enterprise beans for JAX-RPC applications

You can develop a service endpoint interface from an Enterprise JavaBeans (EJB) for JAX-RPC web services.

Before you begin

Set up a development environment for web services. To learn more, see the setting up a development environment for web services information.

Set up a development environment for web services.

This task is a required step in developing a Java API for XML-based RPC (JAX-RPC) web service from an enterprise bean.

The service endpoint interface defines the web services methods. The enterprise beans that implements the web service must implement methods having the same signature as the methods of the service endpoint interface. A number of restrictions exist on which types to use as parameters and results of service endpoint interface methods. These restrictions are documented in the Java API for XML-based remote procedure call (JAX-RPC) specification. See the web services specifications and API documentation to review the JAX-RPC specification along with a complete list of the supported standards and specifications.

The easiest method for creating the service endpoint interface for an EJB web service implementation is from the EJB remote interface.

You can also create a service endpoint interface by using assembly tools..

About this task

Develop a service endpoint interface by following the steps provided in this task section.

Procedure

1. Create a Java interface that contains the methods that you want to include in the service endpoint interface. If you start with an existing Java interface, remove any methods that do not conform to the JAX-RPC specification.
2. Compile the interface.
Use the name of the service endpoint interface class in the `javac` command for the class to compile.
Ensure that the `j2ee.jar` file is in your CLASSPATH to compile the interface. The JAR file is located in the `app_server_root/dev/JavaEE` directory path.

Results

You have a service endpoint interface that you can use to develop a web service.

Example

This example uses the EJB remote interface, `AddressBook_RI`, to create a service endpoint interface for an EJB implementation that is used as a web service. The following code example illustrates the `AddressBook_RI` remote interface.

```
package addr;
public interface AddressBook_RI extends javax.ejb.EJBObject {
    /**
     * Retrieve an entry from the AddressBook.
     *
     * @param name the name of the entry to look up.
     * @return the AddressBook entry matching name or null if none.
     * @throws java.rmi.RemoteException if communications failure.
     */
    public addr.Address getAddressFromName(java.lang.String name)
        throws java.rmi.RemoteException;
}
```

Use the following steps to create the service endpoint interface with the `AddressBook_RI` remote interface:

1. Locate a remote interface that has already been created, like the `AddressBook_RI.java` remote interface.
2. Make a copy of the `AddressBook.java` remote interface and use it as a template for the service endpoint interface.
3. Compile the `AddressBook.java` service endpoint interface.

What to do next

Continue gathering the artifacts that are required to develop a web service, including the Web Services Description Language (WSDL) file. You need to develop a WSDL file because it is the engine of a web service; without a WSDL file, you have no web service.

Developing a WSDL file for JAX-RPC applications

You can develop a Web Services Description Language (WSDL) file to describe the characteristics of your Java API for XML-based RPC (JAX-RPC) web services application including where the service resides and how to invoke the service using an XML format.

Before you begin

Depending on your development path, develop a service endpoint interface from a JavaBeans implementation or develop a service endpoint interface from an enterprise bean implementation.

About this task

You need a WSDL file to use web services. You can develop your own WSDL file or get one from a web services provider through email, downloading, or through a Uniform Resource Locator (URL). This documentation assumes you are creating your own.

Develop a WSDL file by following the actions listed:

Procedure

1. Run the Start Qshell (**STRQSH**) command to start the Qshell.
2. Update the CLASSPATH environment variable to include the location of the service endpoint interface class and other referenced classes, for example:

```
export -s CLASSPATH=/myapp/myclass.class:/myapp/myjar.jar
```

3. Run the Java2WSDL *seiInterface* command. A WSDL file named *seiInterface.wsdl* is created.
 - Move the WSDL file to the META-INF/wsdl subdirectory if you are using Enterprise JavaBeans (EJB).
 - Move the WSDL file to the WEB-INF/wsdl subdirectory if you are using JavaBeans.
4. Edit the generated WSDL file and inspect the part names. The WSDL parts have names like `arg_0_0`. Modify the WSDL file to use the actual names of the Java parameters.
5. (Optional) Use the Java2WSDL command tool to generate the correct part names of WSDL file. You can automatically generate and set the correct part names by using the Java2WSDL command tool. Generating and setting the part names is done by providing additional information to the Java2WSDL command tool in the form of a Java implementation class that implements the same methods as the service endpoint interface and is compiled with debug information turned on. Parameter names are stored in the `.class` file with the debug information. If your implementation class is compiled with debug on, you can use the Java2WSDL `-implClass seiImpl seiInterface` command to generate a WSDL file with the proper part names.

Results

A WSDL file that defines the web services described by the service endpoint interface.

Example

This example uses the JAR file name `AddressBook.jar` that contains a class named `AddressBook.class` class file.

You must add the `AddressBook.jar` file to your CLASSPATH to create the WSDL file. The JAR file contains an EJB implementation class that is compiled with debugging information turned on. Run the `Java2WSDL -implClass addr.AddressBookBean addr.AddressBook` command to create the file, `AddressBook.wsdl`.

What to do next

Depending on your development path, develop web services deployment descriptor templates for JavaBeans or develop web services deployment descriptor templates for an enterprise beans implementation.

Java2WSDL command for JAX-RPC applications

The Java2WSDL command-line tool maps Java classes to a WSDL file for Java API for XML-based RPC (JAX-RPC) applications.

The Java2WSDL command maps a Java class to a Web Services Description Language (WSDL) file by following the Java API for XML-based Remote Procedure Call (JAX-RPC) 1.1 specification.

The Java2WSDL command accepts a Java class as input and produces a WSDL file that represents the input class. If a file exists at the output location, it is overwritten. The WSDL file that is generated by the Java2WSDL command contains WSDL and XML schema constructs that are automatically derived from the input class. You can override these default values with command-line arguments.

The Java2WSDL command is protocol independent; when you run the Java2WSDL command, you can specify command-line options that generate both SOAP and non-SOAP protocol bindings in the WSDL file. For each binding that can be generated, the **Java2WSDL** command has a binding generator to generate the WSDL for that binding.

Command line syntax and arguments

The command line syntax is:

```
Java2WSDL [argument...] class
```

The following command-line arguments are supported:

Required arguments

- *class*

Represents the fully qualified name of one of the following Java classes:

- Stateless session Enterprise JavaBeans (EJB) remote interface that extends the `javax.ejb.EJBObject` class
- Service endpoint interface that extends the `java.rmi.Remote` class
- Java beans

The Java2WSDL command locates the class in the CLASSPATH variable.

Important arguments

- `-location` *location*

Provides the published location or the Uniform Resource Locator (URL) of the service. If this information is not provided, a warning is issued that indicates that the final published location is not determined yet. The service location is typically overridden when the web service is deployed.

The name after the last backslash is the name of the service port, unless the name is overridden by the `-serviceName` argument. The service port address location attribute is assigned the specified value. Multiple endpoint addresses can be specified. Using the `-location` option is recommended only if a single binding type is required. If multiple binding types are requested, protocol binding-specific location properties are passed over the command line using the `-x` flag.

- `-output` *wsdl-uri*

Indicates the path and file name of the output WSDL file. If not specified, the default `class.wsdl` file is written into the current directory.

- `-input` *wsdl-uri*

Specifies the input WSDL file that is used to build an output WSDL file. Information from an existing WSDL file, is specified in this option and is used with the input Java class to generate the output.

- `-bindingTypes`

Specifies the list of binding types write to the output WSDL file. Each binding generator in the Java2WSDL command supports specific binding types. The valid binding type values are `http` (SOAP over HTTP), `jms` (SOAP over JMS) and `ejb` (local or remote EJB invocation). For example, the following command can be used to generate SOAP over HTTP, EJB bindings for the `my.pkg.MySEI` Service Endpoint Interface and the `my.pkg.MyEJBClass` implementation class :

```
java2wsdl -bindingTypes http,ejb -implClass my.pkg.MyEJBClass my.pkg.MySEI
```

The following command is an example of using the `-bindingTypes` option to generate SOAP over HTTP and SOAP over JMS bindings:

```
java2wsdl -bindingTypes http,jms -implClass my.pkg.MyEJBClass my.pkg.MySEI
```

- `-style` `RPC` | `DOCUMENT`

Specifies the WSDL style to use in the generated WSDL file. To learn more, see the Mapping between Java language, WSDL and XML for JAX-RPC applications information. This argument is used with the `-use` argument.

If RPC is specified with `-use ENCODED`, a `style=rpc/use=encoded` WSDL file is generated. If RPC is specified with the `-use LITERAL` option, a `style=rpc/use=literal` WSDL file is generated. If DOCUMENT is specified with the `-use LITERAL` option, a `style=document/use=literal` WSDL file is generated.

- `-use LITERAL | ENCODED`

Specifies which style and use combinations are generated into the WSDL file when used with the `-style` argument. The combinations are `rpc` and `encoded`, `rpc` and `literal`, or `doc` and `literal`. This setting applies to all SOAP bindings. To learn more, see the Mapping between Java language, WSDL and XML for JAX-RPC applications information.

- `-transport http | jms`

Generates SOAP bindings for either HTTP (default) or JMS. If JMS is specified, the characters `jms` are appended to the WSDL file name to prevent overwriting an existing WSDL file for another transport. The transport option can be specified only once.

This option is deprecated. The `-bindingTypes` option replaces the `-transport` option, so that you can generate bindings that are non-SOAP specific.

- `-portTypeName name`

Specifies the name to use for the `portType` element. If not specified, the binding name is the port type name.

- `-bindingName name`

Specifies the name to use for the binding element. If not specified, the binding name is the port type name.

- `-serviceName name`

Specifies the name of the service element.

- `-servicePortName name`

Specifies the name of the service. If not specified, the service name is derived from the `-location` argument.

- `-namespace targetNamespace`

Indicates the target namespace for the WSDL file being generated. To learn about the algorithm that is used to obtain the default namespace, see the Mapping between Java language, WSDL and XML for JAX-RPC applications information.

- `-PkgtoNS package namespace`

Specifies the mapping of a Java package to a namespace. If a package does not have a namespace, the `Java2WSDL` command generates a namespace name. You can repeat the `-PkgtoNS` argument to specify mappings for multiple packages.

- `-extraClasses classes`

Specifies other classes that are represented in the WSDL file.

- `-implClass impl-class`

The `Java2WSDL` command uses method parameter names to construct the WSDL file message part names. The command automatically obtains the message names from the debug information in the class. If the class is compiled without debug information, or if the class is an interface, the method parameter names are not available. In this case, you can use the `-implClass` argument to provide an alternative class from which to obtain method parameter names. The `impl-class` does not need to implement the class if the class is an interface, but it must implement the same methods as the class.

- `-verbose`

Displays verbose messages.

- `-help`

Displays the help message.

- `-helpX`

Displays the help message for extended options and for various options that are supported by binding generators.

Other arguments

- `-wrapped` *boolean*

Specifies whether to generate the WSDL file according to wrapped rules. This option is valid if use is literal only. The option defaults to true.

- `-stopClasses` *parent* [, *parent*]

The Java2WSDL command searches inherited classes and interfaces to construct the list of methods for WSDL file operations if the `-all` argument is specified.

The Java2WSDL command searches inherited classes and interfaces when generating extended complexTypes. The search stops when a class or an interface is found within a package that begins with `java` or `javax`. You can use the `-stopClasses` argument to define additional classes that cause the search to stop.

- `-methods` *argument*

Specifies a list of method names from the Service Endpoint Interface that must be exposed in the output WSDL file. The list is separated by spaces or commas.

- `-soapAction`

Valid arguments are:

- DEFAULT

Sets the soapAction field according to the deployment information.

- NONE

Sets the soapAction field to double quotes ("").

- OPERATION

Sets the soapAction field to the operation name.

- `-outputImpl` *impl-wsdl*

Specifies if you want an interface and implementation WSDL file emitted.

- `-locationImport` *location-uri*

Specifies the location of the interface WSDL file if you use the `-outputImpl` argument.

- `-namespaceImpl` *namespace*

Specifies the target namespace for the implementation WSDL file, if you use the `-outputImpl` argument.

- `-MIMEStyle` *<style>*

Specifies the Multipurpose Internet Mail Extensions (MIME)- type used to map to Web Services-Interoperability (WS-I) SOAP with attachments reference (`wsa:swaRef`) for the binding element.

<style> can be one of the following:

- WSDL11 (default): Exclusively map MIME types using WSDL 1.1 standards. If the MIME type cannot map to WSDL 1.1 standards, the command fails.

- AXIS: Map MIME types using AXIS standards, for example image becomes `axis:image`.

- `swaRef`: Map MIME types using WSDL 1.1 standards with two caveats:

- `DataHandler` maps to the `wsa:swaRef` element instead of an application and octet-stream

- If mapping is illegal through WSDL 1.1, map to the `wsa:swaRef` element

- `-propertiesFile` *argument*

Sets existing options, such as `-extraClasses`, with a properties file instead of with a command line. The following example illustrates the use of this argument:

```
extraClasses=com.ibm.Class1, com.sun.Class2,org.apache.Class3
```

- `-voidReturn`

Valid arguments are:

- ONEWAY

Methods with void returns are one-way. This argument is the default for a JMS transport.

– TWOWAY

Methods with void returns are two-way. This argument is the default for an HTTP transport.

- -debug

Displays debug messages.

- -property or -x

You can use the -x option to pass command-line options to various binding generators. Use the -x option multiple times on the command line to specify a set of property values to pass to each binding generator method called by the Java2WSDL command. You can also use a single -x option to specify multiple properties by separating them with a comma, for example:

```
java2wsdl -x prop1=value1 -x prop2=value2
```

is equivalent to:

```
java2wsdl -x prop1=value1,prop2=value2
```

The -x option provides flexibility to specify each command-line option for each binding generator individually, if required. The value specified in the -x option overrides the value that is specified in the equivalent command-line option if both are specified.

Mapping between Java language, WSDL and XML for JAX-RPC applications

Data for Java API for XML-based Remote Procedure Call (JAX-RPC) applications flows as extensible Markup Language (XML). JAX-RPC applications use mappings to describe the data conversion between the Java language and extensible Markup Language (XML) technologies, including XML Schema, Web Services Description Language (WSDL) and SOAP that are supported by the application server.

For JAX-RPC applications, most of the mappings between the Java language and XML are specified by the JAX-RPC specification. Some mappings that are optional or unspecified in JAX-RPC are also supported. Review the JAX-RPC specification for a complete list of APIs. For a complete list of the supported standards and specifications, see the web services specifications and API documentation.

Notational conventions

Table 145. Namespace conventions. Describes the namespace prefixes and the corresponding namespace used in namespace conventions.

Namespace prefix	Namespace
xsd	http://www.w3.org/2001/XMLSchema
xsi	http://www.w3.org/2001/XMLSchema-instance
soapenc	http://schemas.xmlsoap.org/soap/encoding/
wSDL	http://schemas.xmlsoap.org/wSDL/
wSDLsoap	http://schemas.xmlsoap.org/wSDL/soap/
ns	user-defined namespace
apache	http://xml.apache.org/xml-soap
wasws	http://websphere.ibm.com/webservices/

Detailed mapping information

The following sections identify the supported mappings, including:

- Java-to-WSDL mapping
- WSDL-to-Java mapping
- Mapping between WSDL and SOAP messages

Java-to-WSDL mapping

This section summarizes the Java-to-WSDL mapping rules. The Java-to-WSDL mapping rules are used by the Java2WSDL command for *bottom-up processing*. In bottom-up processing, an existing Java service implementation is used to create a WSDL file defining the web service. The generated WSDL file can require additional manual editing for the following reasons:

- Not all Java classes and constructs have mappings to WSDL files. For example, Java classes that do not comply with the Java bean specification rules might not map to a WSDL construct.
- Some Java classes and constructs have multiple mappings to a WSDL file. For example, a `java.lang.String` class can map to either an `xsd:string` or `soapenc:string` construct. The Java2WSDL command chooses one of these mappings, but you must edit the WSDL file if a different mapping is required.
- Multiple ways exist to generate WSDL constructs. For example, you can generate the `wsdl:part` in `wsdl:message` with a `type` or `element` attribute. The Java2WSDL command makes an informed choice based on the `-style` and `-use` option settings.
- The WSDL file describes the instance data elements sent in the SOAP message. If you want to modify the names or format used in the message, the WSDL file must be edited. For example, the Java2WSDL command maps a Java bean property as an XML element. In some circumstances, you might want to change the WSDL file to map the Java bean property as an XML attribute.
- The WSDL file requires editing if header or attachment support is desired.
- The WSDL file requires editing if a multipart WSDL file, using the `wsdl:import` construct, is desired.

For simple services, the generated WSDL file is sufficient. For complicated services, the generated WSDL file is a good starting point. Read about the Java2WSDL command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

General issues

- **Package to namespace mapping**

The JAX-RPC specification does not indicate the default mapping of Java package names to XML namespaces. The JAX-RPC specification does specify that each Java package must map to a single XML namespace. Likewise, each XML namespace must map to a single Java package. A default mapping algorithm is provided that constructs the namespace by reversing the names of the Java package and adding an `http://` prefix. For example, a package named, `com.ibm.webservice`, is mapped to the XML namespace `http://webservice.ibm.com`.

You can override the default mapping between XML namespaces and Java package names by using the `-NStoPkg` and `-PkgtoNS` options of the `WSDL2Java` and `Java2WSDL` commands.

- **Identifier mapping**

Java identifiers are mapped directly to WSDL and XML identifiers.

Java bean property names are mapped to XML identifiers. For example, a Java bean, with `getInfo` and `setInfo` methods, maps to an XML construct with the name, `info`.

The service endpoint interface method parameter names, if available, are mapped directly to the WSDL and XML identifiers. See the information for the `WSDL2Java` command `-implClass` option to learn more.

- **WSDL construction summary**

Table 146. Mapping of Java to WSDL or an XML construct. Describes the mapping from a Java construct to the related WSDL and XML construct.

Java construct	WSDL and XML construct
Service endpoint interface	<code>wsdl:portType</code>
Method	<code>wsdl:operation</code>
Parameters	<code>wsdl:input</code> , <code>wsdl:message</code> , <code>wsdl:part</code>
Return	<code>wsdl:output</code> , <code>wsdl:message</code> , <code>wsdl:part</code>
Throws	<code>wsdl:fault</code> , <code>wsdl:message</code> , <code>wsdl:part</code>
Primitive types	<code>xsd</code> and <code>soapenc</code> simple types
Java beans	<code>xsd:complexType</code>

Table 146. Mapping of Java to WSDL or an XML construct (continued). Describes the mapping from a Java construct to the related WSDL and XML construct.

Java bean properties	Nested xsd:elements of xsd:complexType
Arrays	JAX-RPC defined xsd:complexType or xsd:element with a maxOccurs="unbounded" attribute
User defined exceptions	xsd:complexType

- **Binding and service construction**

A wsdl:binding that conforms to the generated wsdl:portType is generated. A wsdl:service containing a port that references the generated wsdl:binding is generated. The names of the binding and service are controlled by the Java2WSDL command.

- **Style and use**

Use the -style and -use options to generate different kinds of WSDL files. The four supported combinations are:

- -style DOCUMENT -use LITERAL
- -style RPC -use LITERAL
- -style DOCUMENT -use LITERAL -wrapped false
- -style RPC -use ENCODED

The following is a brief description of each combination.

- **DOCUMENT LITERAL**

The Java2WSDL command generates a Web Services - Interoperability (WS-I) specification compliant document-literal WSDL file. The wsdl:binding is generated with embedded style="document" and use="literal" attributes. An xsd:element is generated for each service endpoint interface method to describe the request message. A similar xsd:element is generated for each service endpoint interface method to describe the response message.

- **RPC LITERAL**

The Java2WSDL command generates a WS-I compliant rpc-literal WSDL file. The wsdl:binding is generated with embedded style="rpc" and use="literal" attributes. The wsdl:message constructs are generated for the inputs and outputs of each service endpoint interface method. The parameters of the method are described by the part elements within the wsdl:message constructs.

- **DOCUMENT LITERAL not wrapped**

The Java2WSDL command generates a document-literal WSDL file according to the JAX-RPC specification. This WSDL file is not compliant with .NET. The main difference between DOCUMENT LITERAL and DOCUMENT LITERAL not wrapped is the use of wsdl:message constructs to define the request and response messages.

- **RPC ENCODED**

The Java2WSDL command generates an rpc-encoded WSDL file according to the JAX-RPC specification. This WSDL file is not compliant with the WS-I specification. The wsdl:binding is generated with embedded style="rpc" and use="encoded" attributes. Certain soapenc mappings are used to represent types and arrays.

Mapping of standard XML types from Java types

Many Java types map directly to standard XML types. For example, a java.lang.String maps to an xsd:string. These mappings are described in the JAX-RPC specification.

Generation of wsdl:types

Java types that cannot be mapped directly to standard XML types are generated in the wsdl:types section. A Java class that matches the Java bean pattern is mapped to an xsd:complexType. Review the JAX-RPC specification for a description of all the mapping rules. The following example illustrates the mapping for a sample base and derived Java classes.

Java:

```
public abstract class Base {
    public Base() {}
    public int a;           // mapped
    private int b;         // mapped via setter/getter
    private int c;         // not mapped
    private int[] d;       // mapped via indexed setter/getter
}
```

```

public int getB() { return b;}           // map property b
public void setB(int b) {this.b = b;}

public int[] getD() { return d;}        // map indexed property d
public void setD(int[] d) {this.d = d;}
public int getD(int index) { return d[index];}
public void setB(int index, int value) {this.d[index] = value;}

public void someMethod() {...}         // not mapped
}

public class Derived extends Base {
    public int x;                       // mapped
    private int y;                      // not mapped
}

```

Mapped to:

```

<xsd:complexType name="Base" abstract="true">
  <xsd:sequence>
    <xsd:element name="a" type="xsd:int"/>
    <xsd:element name="b" type="xsd:int"/>
    <xsd:element name="d" minOccurs="0" maxOccurs="unbounded" type="xsd:int"/>
  </xsd:sequence>
</xsd:complexType>

<xsd:complexType name="Derived">
  <xsd:complexContent>
    <xsd:extension base="ns:Base">
      <xsd:sequence>
        <xsd:element name="x" type="xsd:int"/>
      </xsd:sequence>
    </xsd:extension>
  </xsd:complexContent>
</xsd:complexType>

```

- **Unsupported classes**

If a class cannot be mapped to an XML type, the Java2WSDL command issues a message and an xsd:anyType reference is generated in the WSDL file. In these situations, modify the web service implementation to use the JAX-RPC compliant classes.

WSDL-to-Java mapping

The WSDL2Java command generates Java classes using information described in the WSDL file.

General issues

- **Mapping of a namespace to a package**

JAX-RPC does not specify the mapping of XML namespaces to Java package names. JAX-RPC does specify that each Java package map to a single XML namespace. Likewise, each XML namespace must map to a single Java package. A default mapping algorithm omits any protocol from the XML namespace and reverses the names. For example, an XML namespace `http://websphere.ibm.com` becomes a Java package with the name `com.ibm.websphere`.

The default mapping of an XML namespace to a Java package disregards the context-root. If two namespaces are the same up to the first slash, they map to the same Java package. For example, the XML namespaces `http://websphere.ibm.com/foo` and `http://websphere.ibm.com/bar` map to the `com.ibm.websphere` Java package. You can override the default mapping between XML namespaces and Java package names by using the `-NStoPkg` and `-PkgtoNS` options of the WSDL2Java and Java2WSDL commands.

Identifier mapping

XML names are much richer than Java identifiers. They can include characters that are not permitted in Java identifiers. See Appendix 20 of the JAX-RPC specification for the rules to map an XML name to a Java identifier.

- **Java construction summary**

The following table summarizes the XML to Java construction. See the JAX-RPC specification for a description of these mappings.

Table 147. Mapping of a WSDL or an XML construct to Java. Describes the mapping between constructions for XML and Java.

WSDL and XML construction	Java construction
xsd:complexType	Java bean class, Java exception class, or Java array
nested xsd:element/xsd:attribute	Java bean property
xsd:simpleType (enumeration)	JAX-RPC enumeration class
wsdl:message The method parameter signature typically is determined by the wsdl:message.	Service endpoint interface method signature
wsdl:portType	Service endpoint interface
wsdl:operation	Service endpoint interface method
wsdl:binding	Stub
wsdl:service	Service interface
wsdl:port	Port accessor method in Service interface

- **Mapping standard XML types**

- **JAX-RPC simple XML types mapping**

Many XML types are mapped directly to Java types. See the JAX-RPC specification for a description of these mappings.

- **Mapping the XML types defined in the wsdl:types section**

The WSDL2Java command generates Java types for the XML schema constructs that are defined in the wsdl:types section. The XML schema language is broader than the required or optional subset defined in the JAX-RPC specification. The WSDL2Java command supports the required mappings and most of the optional mappings, as well as some XML schema mappings that are not included in the JAX-RPC specification. The WSDL2Java command ignores some constructs that it does not support. For example, the command does not support the default attribute. If an xsd:element is defined with the default attribute, the default attribute is ignored. In some cases, the command maps unsupported constructs to the Java interface, javax.xml.soap.SOAPElement.

The standard Java bean mapping is defined in section 4.2.3 of the JAX-RPC specification. The xsd:complexType defines the type. The nested xsd:elements within the xsd:sequence or xsd:all groups are mapped to Java bean properties. For example:

XML:

```
<xsd:complexType name="Sample">
  <xsd:sequence>
    <xsd:element name="a" type="xsd:string"/>
    <xsd:element name="b" maxOccurs="unbounded" type="xsd:string"/>
  </xsd:sequence>
</xsd:complexType>
```

Java:

```
public class Sample {
    // ..
    public Sample() {}

    // Bean Property a
    public String getA() {...}
    public void setA(String value) {...}

    // Indexed Bean Property b
    public String[] getB() {...}
    public String getB(int index) {...}
    public void setB(String[] values) {...}
    public void setB(int index, String value) {...}
}
```

- **Mapping of the wsdl:portType construct**

The wsdl:portType construct is mapped to the service endpoint interface. The name of the wsdl:portType construct is mapped to the name of the class of the service endpoint interface.

- **Mapping of the wsdl:operation construct**

A wsdl:operation construct within a wsdl:portType is mapped to a method of the service endpoint interface. The name of the wsdl:operation is mapped to the name of the method. The wsdl:operation

contains `wsdl:input` and `wsdl:output` elements that reference the request and response `wsdl:message` constructs using the message attribute. The `wsdl:operation` can contain a `wsdl:fault` element that references a `wsdl:message` describing the fault. These faults are mapped to Java classes that extend the exception, `java.lang.Exception` as discussed in section 4.3.6 of the JAX-RPC specification.

- Effect of document literal wrapped format

If the WSDL file uses the document literal wrapped format, the method parameters are mapped from the wrapper `xsd:element`. The document literal wrapped and literal format is automatically detected by the `WSDL2Java` command. The following criteria must be met:

- The WSDL file must have `style="document"` in its `wsdl:binding` construct.
- The input and output constructs of the operations within the `wsdl:binding` must contain `soap:body` elements that contain `use="literal"`.
- The `wsdl:message` referenced by the `wsdl:operation` input construct must have a single part.
- The part must use the element attribute to reference an `xsd:element`.
- The referenced `xsd:element`, or wrapper element, must have the same name as the `wsdl:operation`.
- The wrapper element must not contain any `xsd:attributes`.

In such cases, each parameter name is mapped from a nested `xsd:element` contained within wrapper element. The type of the parameter is mapped from the type of the nested `xsd:element`. For example:

WSDL:

```
<xsd:element name="myMethod">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="param1" type="xsd:string"/>
      <xsd:element name="param2" type="xsd:int"/>
    </xsd:sequence>
  </xsd:complexType>
</xsd:element>
...
<wsdl:message name="response"/>
  <part name="parameters" element="ns:myMethod"/>
</wsdl:message name="response"/>

<wsdl:message name="response"/>
...
<wsdl:operation name="myMethod">
  <input name="input" message="request"/>
  <output name="output" message="response"/>
</wsdl:operation>
```

Java:

```
void myMethod(String param1, int param2) ...
```

- Parameter mapping

If the document and literal wrapped format is not detected, the parameter mapping follows the normal JAX-RPC mapping rules set in section 4.3.4 of the JAX-RPC specification.

Each parameter is defined by a `wsdl:message` part referenced from the input and output elements.

- A `wsdl:part` in the request `wsdl:message` is mapped to an input parameter.
- A `wsdl:part` in the response `wsdl:message` is mapped to the return value. If multiple `wsdl:parts` exist in the response message, they are mapped to output parameters.
 - A Holder class is generated for each output parameter, as discussed in section 4.3.5 of the JAX-RPC specification.
- A `wsdl:part` that is both the request and response `wsdl:message` is mapped to an inout parameter.
 - A Holder class is generated for each inout parameter, as discussed in section 4.3.5 of the JAX-RPC specification.
 - The `wsdl:operation parameterOrder` attribute defines the order of the parameters.

XML:

```
<wsdl:message name="request">
  <part name="param1" type="xsd:string"/>
  <part name="param2" type="xsd:int"/>
</wsdl:message name="response"/>
```

```

<wsdl:message name="response"/>
...
<wsdl:operation name="myMethod" parameterOrder="param1, param2">
  <input name="input" message="request"/>
  <output name="output" message="response"/>
</wsdl:operation>

```

Java:

```
void myMethod(String param1, int param2) ...
```

– **Mapping of wsdl:binding**

The WSDL2Java command uses the wsdl:binding information to generate an implementation-specific client-side stub. WebSphere Application Server uses the wsdl:binding information on the server side to properly deserialize the request, invoke the web service, and serialize the response. The information in the wsdl:binding does not affect the generation of the service endpoint interface, except when the document and literal wrapped format is used, or when MIME attachments are present.

- **MIME attachments**

For a WSDL 1.1-compliant WSDL file, the part of an operation message, that is defined in the binding as a MIME attachment, becomes a parameter of the type of the attachment regardless of the part declared. For example:

XML:

```

<wsdl:types>
<schema ...>
  <complexType name="ArrayOfBinary">
    <restriction base="soapenc:Array">
      <attribute ref="soapenc:arrayType" wsdl:arrayType="xsd:binary[]" />
    </restriction>
  </complexType>
</schema>
</wsdl:types>

```

```

<wsdl:message name="request">
  <part name="param1" type="ns:ArrayOfBinary"/>
</wsdl:message name="response"/>

```

```

<wsdl:message name="response"/>
...

```

```

<wsdl:operation name="myMethod">
  <input name="input" message="request"/>
  <output name="output" message="response"/>
</wsdl:operation>
...

```

```

<binding ...
<wsdl:operation name="myMethod">
  <input>
    <mime:multipartRelated>
      <mime:part>
        <mime:content part="param1" type="image/jpeg"/>
      </mime:part>
    </mime:multipartRelated>
  </input>
  ...
</wsdl:operation>

```

Java:

```
void myMethod(java.awt.Image param1) ...
```

The JAX-RPC specification requires support for the following MIME types:

Table 148. Mapping of MIME type and Java type. Describes the mapping between MIME types and Java types.

MIME type	Java type
image/gif	java.awt.Image
image/jpeg	java.awt.Image
text/plain	java.lang.String
multipart/*	javax.mail.internet.MimeMultipart
text/xml	javax.xml.transform.Source
application/xml	javax.xml.transform.Source

– **Mapping of wsdl:service**

The `wsdl:service` element is mapped to a generated service interface. The generated service interface contains methods to access each of the ports in the `wsdl:service` element. The generated service interface is discussed in sections 4.3.9, 4.3.10, and 4.3.11 of the JAX-RPC specification.

In addition, the `wsdl:service` element is mapped to the implementation-specific `ServiceLocator` class, which is an implementation of the generated service interface.

Read about the `WSDL2Java` command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

Mapping between WSDL and SOAP messages

The WSDL file defines the format of the SOAP message that are transmitted through network connections. The `WSDL2Java` command and the WebSphere Application Server runtime use the information in the WSDL file to ensure that the SOAP message is properly serialized and deserialized.

DOCUMENT versus RPC, LITERAL versus ENCODED

If a `wsdl:binding` element indicates that a message is sent using an RPC format, the SOAP message contains an element defining the operation. If a `wsdl:binding` element indicates that the message is sent using a document format, the SOAP message does not contain the operation element.

If the `wsdl:part` element is defined using the `type` attribute, the name and type of the part are used in the message. If the `wsdl:part` element is defined using the `element` attribute, the name and type of the element are used in the message. The `element` attribute is not supported by the JAX-RPC specification when `use="encoded"`.

If a `wsdl:binding` element indicates that a message is encoded, the values in the message are sent with `xsi:type` information. If a `wsdl:binding` element indicates that a message is literal, the values in the message are typically not sent with `xsi:type` information. For example:

DOCUMENT/LITERAL

WSDL:

```
<xsd:element name="c" type="xsd:int"/>
<xsd:element name="method">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="a" type="xsd:string"/>
      <xsd:element ref="ns:c"/>
    </xsd:sequence>
  </xsd:complexType>
</xsd:element>
...
<wsdl:message name="request">
  <part name="parameters" element="ns:method"/>
</wsdl:message>
...
<wsdl:operation name="method">
  <input message="request"/>
  ...
  ...
```

Message:

```
<soap:body>
  <ns:method>
    <a>ABC</a>
    <c>123</c>
  </ns:method>
</soap:body>
```

RPC/ENCODED

WSDL:

```
<xsd:element name="c" type="xsd:int"/>
...
<wsdl:message name="request">
  <part name="a" type="xsd:string"/>
  <part name="b" element="ns:c"/>
</wsdl:message>
...
<wsdl:operation name="method">
  <input message="request"/>
  ...
  ...
```

```
Message:
<soap:body>
  <ns:method>
    <a xsi:type="xsd:string">ABC</a>
    <element attribute is not permitted in rpc/encoded mode>
  </ns:method>
</soap:body>
```

DOCUMENT/LITERAL not wrapped

```
WSDL:
<xsd:element name="c" type="xsd:int"/>
```

```
...
<wsdl:message name="request">
  <part name="a" type="xsd:string"/>
  <part name="b" element="ns:c"/>
</wsdl:message>
...
<wsdl:operation name="method">
  <input message="request"/>
```

...

```
Message:
<soap:body>
  <a>ABC</a>
  <c>123</a>
</soap:body>
```

Developing JAX-RPC web services deployment descriptor templates for a JavaBeans implementation

Deployment descriptors are standard text files, formatted using XML and packaged in a web services application. Deployment descriptors are required to deploy Java API for XML-based RPC (JAX-RPC) web services that are developed using Web Services for Java Platform, Enterprise Edition (Java EE) technology.

Before you begin

Develop a Web Services Description Language (WSDL) file.

You need a WSDL file to use web services. You can develop your own WSDL file or get one from a web services provider through email, downloading, or through a Uniform Resource Locator (URL). This documentation assumes you are creating your own. See the developing a WSDL file for JAX-RPC applications information.

About this task

Completing this task creates the deployment descriptors used to describe how to map the service implementation to a JavaBeans component for Java API for XML-based RPC (JAX-RPC) applications.

To develop the deployment descriptor templates from a WSDL file, you must obtain the web address of the WSDL file.

If the WSDL file is a local file and you are running on the Windows platform, the web address looks like this example: `file:drive:\path\file_name.wsdl`. If you are using the Linux or Unix platform, the Web address looks like this example: `file:/path/file_name.wsdl`. You can also specify local files using the absolute or relative file system path.

When the web service is a JavaBeans implementation in a web module, the `webservices.xml`, `ibm-webservices-bnd.xmi` and `ibm-webservices.ext.xmi` deployment descriptors and the JAX-RPC mapping file are generated in the WEB-INF subdirectory.

Procedure

Run the **WSDL2Java -verbose -role develop-server -container web -genJava no wsdlURL** command to generate the server deployment descriptor templates and mapping file into the WEB-INF subdirectory. If the **-verbose** option is specified, a list of all the generated files is displayed when the command runs.

Results

You have deployment descriptor templates that are required to implement or use JAX-RPC web services.

Example

The following example uses a WSDL file named AddressBookJ2WB.wsdl:

Generate the template files:

```
WSDL2Java -verbose -role develop-server -container web -genJava no AddressBookJ2WB.wsdl
```

The deployment descriptor templates and mapping file are generated into the WEB-INF subdirectory:

```
Parsing XML file: AddressBookJ2WB.wsdl
Generating: WEB-INF\webservices.xml
Generating: WEB-INF\ibm-webservices-bnd.xml
Generating: WEB-INF\ibm-webservices-ext.xml
Generating: WEB-INF\AddressBookJ2WB_mapping.xml
```

What to do next

Now, you need to configure the deployment descriptors so that WebSphere Application Server can process the incoming web services. After you configure the deployment descriptors, you must assemble the web services application for deployment.

WSDL2Java command for JAX-RPC applications:

Run the WSDL2Java command-line tool against the WSDL file to create Java APIs and deployment descriptor templates.

A Web Services Description Language (WSDL) file describes a Web service. The Java API for XML-based Remote Procedure Call (JAX-RPC) 1.1 specification defines a Java API mapping that interacts with the web service. The Web Services for Java Platform, Enterprise Edition (Java EE) specification defines deployment descriptors that deploy a web service in a Java EE environment. The WSDL2Java command is run against the WSDL file to create Java APIs and deployment descriptor templates according to these specifications.

Note: It is a best practice to use absolute namespaces within your WSDL or schema. By default, the WSDL2Java tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. However, if you have an established WSDL or schema that relies on relative namespaces, under specific conditions you can use the allowRelativeNamespace property to disable the relative namespace restrictions in the WSDL2Java tool. For additional information, see the property description.

You can convert any relative namespaces to absolute namespaces. The following is an example of a relative namespace:

```
targetNamespace="MyReINamespace"
```

. You can change the relative namespace in this example to an absolute namespace by adding the protocol and base URI information:

```
targetNamespace="http://www.sample.com/MyReINamespace"
```

.

Command-line syntax

The command-line syntax is:

```
WSDL2Java [arguments] WSDL-URI
```

Required arguments

- WSDL-URI

Specifies the location of the input WSDL file using a Universal Resource Identifier (URI). You can also use a regular file path if the WSDL file is on the local file system.

Important arguments

- `-role Java EE role`

Specifies the Java EE development role that identifies which files to generate. Valid arguments include:

- client

A combination of the `develop-client` and `deploy-client` arguments.

- `deploy-client`

Generates binding files for client deployment.

- `deploy-server`

Generates binding files for server deployment.

- `develop-client` (default)

Generates files for client development.

- `develop-server`

Generates files for server development.

- `server`

A combination of the `develop-server` and `deploy-server` arguments.

- `-container Java EE-container`

Indicates the Java EE container to use. Valid arguments include:

- client

Indicates client container.

- `ejb`

Indicates an Enterprise JavaBeans (EJB) container.

- `none`

Indicates no container.

- `web`

Indicates a web container.

For client roles (see the `-role` option), the default argument is `none`. For server roles, the container must be `ejb` or `web`. The same container option must be used for both development and deployment.

- `-output directory`

Sets the root directory for emitted files.

- `-inputMappingFile mapping file`

Specifies the file name of the Web Services for Java EE mapping file.

- `-introspect`

Uses existing Java beans with a new web service API.

In some scenarios, it is good to use existing Java classes instead of generating new classes. The `-introspect` option directs the `WSDL2Java` command to examine existing Java classes when generating classes. The existing classes are validated against the JAX-RPC specification. For example:

Suppose you have an existing Java bean

```
public class Bean {  
    public Date x;  
}
```

The WSDL file defines *x* as `xsd:dateTime`. Without the `-introspect` option, the `WSDL2Java` command generates a Java bean that is similar to the following example:

```
public class Bean {
    private Calendar x;
    public void setx(Calendar value) (x=value;)
    public Calendar getX() { return x;}
}
```

The `WSDL2Java` command uses the `-introspect` option to examine the original Java bean and to generate classes that are compatible with existing Java beans.

- `-classpath paths`

Defines an alternative class path to search for Java classes.

- `-noDataBinding`

Disables the binding of XML types to Java types. Instead, each XML type is mapped to a `javax.xml.soap.SOAPElement` interface defined by the SOAP with Attachments API for Java (SAAJ) specification.

The Java API for XML Web Services (JAX-WS) programming model supports SAAJ 1.2 and 1.3.

The JAX-RPC programming model supports SAAJ 1.2.

The Java programming models define Java mappings for a subset of XML types. Several XML types cannot be mapped to Java beans or primitives. In this situation, the `WSDL2Java` command maps the type to an SAAJ `SOAPElement`. A SAAJ `SOAPElement` is a generic representation of the element in the message. The methods on the `SOAPElement` can be used to examine the element and its children.

In some scenarios, it might be more appropriate to use the generic `SOAPElement` mapping exclusively. To learn more about the use of `SOAPElement`, see the information on SOAP with Attachments API for Java interface and custom data binders for JAX-RPC applications.

For a complete list of the supported standards and specifications, see the web services specifications and API documentation.

- `-help`

Displays a help message and exits.

- `-helpX`

Displays a help message for extended options. The options include:

- `-verbose`

Displays processing information, including the names of the generated files.

- `-NStoPkg namespace=package`

By default, package names are automatically derived from the namespace strings in the WSDL file. For example, if the namespace is of the form `http://x.y.com` or `urn:x.y.com`, the corresponding package is `com.y.x`.

You can provide your own mapping by using the `-NStoPkg` argument, which you can repeat as often as necessary, once for each unique namespace mapping. For example, if a namespace in the WSDL file is called `urn:AddressFetcher2`, and you want files generated from the objects in this namespace to reside in the `samples.addr` package, provide the `-NStoPkg "http://urn:AddressFetcher2/"=samples.addr` argument to the `WSDL2Java` command.

- `-timeout seconds`

Specifies how long the `WSDL2Java` command waits, in seconds, for the WSDL-URI to respond before giving up. The default is 45 seconds; `-1` disables the timeout.

- `-genResolver`

Generates an absolute-import resolver class. The purpose of this class is to record the contents of the imported WSDL files that are used by the WSDL URI. This class is used by the run time and can also be used for future `WSDL2Java` command runs. This flexibility is desirable when the imported WSDL files are remote and possibly inaccessible. When an import resolver is used, the possibility that a remote WSDL file has different contents at run time that it did during development is eliminated. The generated class is named `_AbsoluteImportResolver.java`. Compile and package this class with the other Java classes that are generated by the `WSDL2Java` command.

- `-useResolver resolver-class`

Specifies an absolute-import resolver class to use during parsing. This class must be created during a previous run of the WSDL2Java command that uses the -genResolver option. The class must be available in the CLASSPATH variable.

- -deployScope *argument*

Indicates how to deploy the server implementation. Valid arguments include:

- Application
Uses one instance of the implementation class for all requests.
- Request
Creates a new instance of the implementation class for each request.
- Session
Creates a new instance of the implementation class for each session.

Other arguments

- -user *id*
Specifies the login user name to access the WSDL URI.
- -password *password*
Specifies the login user password to access the WSDL URI.
- -all
Generates Java files for all types, even those that are not referenced.
- -allowRelativeNamespace *true or false*
Specifies whether to disable the relative namespace restrictions. If you specify -allowRelativeNamespace=true, the relative namespace restrictions are disabled.

Note: Only use this property if you have an established WSDL file or schema that relies on a relative namespaces and you are seeking to interoperate with a defined set of vendors that permit the use of relative namespaces.

- -debug
Prints debugging information.
- -genJava *argument*
Generates Java files. Valid arguments include:
 - IfNotExists, default
 - Overwrite
 - No
- -javaSearch *argument*
The -javaSearch option is used with the -genJava option. If the -genJava IfNotExists, use the -javaSearch option to determine how file existence is detected.
 - File (default): Looks for a file in the output directory
 - Classpath: Looks for a class in the CLASSPATH variable
 - Both: Looks for a file in the output directory or in a class in the CLASSPATH variable
- -genXML *argument*
Generates the .xml and .xmi files. Valid arguments are:
 - IfNotExists, default
 - Overwrite
 - No
- -genImplSer *true or false*
Indicates that each generated Java bean implements the java.io.Serializable. The default is false.
- -genEquals *true or false*
Indicates that each generated Java bean have equals and hashCode methods. The default is false.
- -noWrappedOperations

Disables wrapped operations detection. Java beans for the request and response messages are generated.

- `-noWrappedArrays`
Disables wrapped array detection.
- `-fileNStoPkg file name`
Specifies the file of the namespace to package mappings. The default is `NStoPKG.properties`.
- `service wsdl service name`
Generates files for the installed WSDL service only.
- `-testCase`
Generates the template for a JUnit test case for testing web services. JUnit is a simple framework to write repeatable tests.

Developing JAX-RPC web services deployment descriptor templates for an enterprise bean implementation

You can develop deployment descriptor templates for an Enterprise JavaBeans (EJB) implementation that is enabled for Java API for XML-based RPC (JAX-RPC) web services.

Before you begin

You need to create a service endpoint interface and develop a Web Services Description Language (WSDL) file before you can develop the deployment descriptor templates because the service endpoint interface and the WSDL file are artifacts that are used to create the templates.

About this task

Completing this task creates deployment descriptor templates that describe how to map the service implementation to a Enterprise JavaBeans (EJB). This task is a required step in developing a web service from an enterprise bean.

To develop the deployment descriptor templates from a WSDL file, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use.

If the WSDL file is a local file, the URL looks like this example: `file:/path/file_name.wsdl`.

You can also specify local files using the absolute or relative file system path.

When the web service implementation contains an enterprise bean in an EJB module, the `webservices.xml`, `ibm-webservices-bnd.xmi` and `ibm-webservices-ext.xmi` deployment descriptors, and the Java API for XML-based remote procedure call (JAX-RPC) mapping file are generated in the `META-INF` subdirectory.

Procedure

Run the `WSDL2Java -verbose -role develop-server -container ejb -genJava no wsdlURL` command to generate the server deployment descriptor templates and mapping file into the `META-INF` subdirectory. If the `-verbose` option is specified, a list of all generated files displays when the command runs.

Results

You have deployment descriptor templates that are required to implement a web service.

Example

The following example uses the AddressBookJ2WE.wsdl WSDL file:

1. Generate the template files with the following command syntax:

```
WSDL2Java -verbose -role develop-server -container ejb -genJava no AddressBookJ2WE.wsdl
```

The deployment descriptor templates are generated into the META-INF subdirectory as follows:

```
Parsing XML file: AddressBookJ2WE.wsdl
Generating: META-INF\webservices.xml
Generating: META-INF\ibm-webservices-bnd.xmi
Generating: META-INF\ibm-webservices-ext.xmi
Generating: META-INF\AddressBookJ2WE_mapping.xml
```

What to do next

Continue to complete the steps that are necessary to develop a JAX-RPC web service from an enterprise bean. The next step is to complete the EJB implementation. When you complete the EJB implementation, you assemble an enterprise bean Java archive (JAR) file that contains the enterprise bean and supporting classes created from a WSDL file. To learn more, see the completing the EJB implementation for JAX-RPC applications information.

Completing the JavaBeans implementation for JAX-RPC applications

After you have developed the Java artifacts necessary to develop a Java API for XML-based RPC (JAX-RPC) web service, you must complete the JavaBeans implementation to assemble a Java archive (JAR) file or a web application archive (WAR) file based on your programming model. The resulting JAR file or WAR file contains the JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Develop web services deployment descriptor templates for a JavaBeans implementation using the WSDL2java command-line tool. You need to complete this step to create the deployment descriptor templates that are configured to map the service implementation to the JavaBeans implementation.

About this task

For JAX-RPC applications, complete the JavaBeans implementation by writing your business application.

Procedure

1. Edit the JavaBeans implementation template, *bindingImpl.java*. The *binding* is the name of the `<wsdl:binding>` element in the WSDL file. The JavaBeans implementation is generated by the WSDL2java command-line tool.
 - a. Complete the implementation of the methods in the template.
 - b. (Optional) Make changes if necessary.
 - c. (Optional) Change the class name if the binding name is not acceptable.
2. Compile all the Java classes.
3. Assemble a Web archive (WAR) file. Assemble all the Java classes into a WAR file using web module assembly tools. Include all of the classes generated from running the WSDL2java command tool for JAX-RPC web service applications when developing implementation templates and bindings from a WSDL file.

Results

You have now enabled the JavaBeans-based business application for JAX-RPC web services. You have a JAR file or a WAR file containing the JavaBeans implementation and supported classes created from the WSDL file.

What to do next

If you are developing a JAX-RPC web services application from JavaBeans, you need to configure the `webservices.xml` deployment descriptor and configure the `ibm-webservices-bnd.xmi` deployment descriptor so that the application server can process the incoming web services requests.

Completing the EJB implementation for JAX-RPC applications

After you have developed the Java artifacts necessary to develop a Java API for XML-based RPC (JAX-RPC) web service, you must complete the Enterprise JavaBeans (EJB) implementation to assemble a Java archive (JAR) file or a web application archive (WAR) file based on your programming model. The resulting JAR file or WAR file contains the Enterprise JavaBeans (EJB) implementation and the supported classes created from the tooling.

Before you begin

Develop EJB implementation templates and bindings from a WSDL file for JAX-RPC web services using the `wsdl2java` command-line tool. The deployment descriptor templates that are generated from a Web Services Description Language (WSDL) file are required to complete the EJB implementation in the web services development process.

About this task

For JAX-RPC applications, complete the enterprise beans implementation by writing your business application.

Procedure

1. Inspect the EJB remote interface template, `portType_RI.java`. If necessary, modify the template. The value `portType` is the name of the `<wsdl:portType>` element in the WSDL file.
2. Edit the `bindingImpl.java` EJB implementation template. Where `binding` is the name of the `<wsdl:binding>` element in the WSDL file.
3. Complete the implementation of the methods in the template.
4. (Optional) Make changes if necessary.
5. (Optional) Change the class name if the binding name is not acceptable.
6. Compile all the Java classes.
7. Assemble an EJB Java archive (JAR) file. Assemble all the Java classes into an enterprise bean JAR file using assembly tools. Include all of the classes generated from running the `WSDL2Java` command tool when developing implementation templates and bindings from a WSDL file.

Results

You have enabled an enterprise beans business application for JAX-RPC web services. You now have an enterprise bean JAR file containing an EJB and supporting classes created from web services artifacts.

What to do next

Now that you have gathered the required artifacts for developing a JAX-RPC web service with an enterprise bean, you need to, configure the `webservices.xml` deployment descriptor.

Configuring the webservices.xml deployment descriptor for JAX-RPC web services

You can configure the `webservices.xml` deployment descriptor with an assembly tool.

Before you begin

To configure the client deployment descriptor, read about the configuring the client deployment descriptor in the Rational Application Developer information.

Before you can configure the `ibm-webservices-bnd.xml` deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

About this task

For JAX-RPC web services, this task is one of the required steps in developing a web service. You need to configure the deployment descriptors so that the application server can process the incoming web services requests.

If you are developing a web service from JavaBeans, you can develop web services JavaBeans deployment descriptor templates from a Web Services Description Language (WSDL) file. Then, you complete the JavaBeans implementation. To learn more, read about developing JavaBeans deployment descriptor templates from a WSDL file and completing the JavaBeans implementation.

If you are developing a web service from an enterprise bean, you can develop web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file. Then, you complete the EJB implementation. To learn more, read about developing web services EJB deployment descriptor templates from a WSDL file and completing the EJB implementation.

When the JavaBeans implementation is complete, the web module web application archive (WAR) file is assembled. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. These archive files contain the `webservices.xml` deployment descriptor. The archive files must be assembled before you can configure the `webservices.xml` deployment descriptor.

The assembly tools provide a graphical interface for developing code artifacts, assembling the code artifacts into various archives (modules) and configuring compliant deployment descriptors for Java Platform, Enterprise Edition (Java EE).

Configure the `webservices.xml` deployment descriptor by following the steps provided in this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Results

You have a `webservices.xml` deployment descriptor that is configured.

What to do next

For JAX-RPC web services, you must configure the `ibm-webservices-bnd.xml` deployment descriptor. To learn more, see the configuring the `ibm-webservices-bnd.xml` deployment descriptor for JAX-RPC web services information.

Configuring the `webservices.xml` deployment descriptor for handler classes

You can use an assembly tool to configure the `webservices.xml` deployment descriptor for user-provided handler classes.

Before you begin

You can configure deployment descriptors with assembly tools provided with the application server.

A *handler class* is a class that is written to modify a SOAP message that represents a remote procedure call (RPC) request or response. Handlers can be associated with a web service or a web service client.

Similar to Java API for XML-based RPC (JAX-RPC) web services, you can use deployment descriptors to describe Java API for XML Web Services (JAX-WS) web services. For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

To complete this task, you need an enterprise archive (EAR) file for the applications that you want to configure. For some handler use, such as logging or tracing, only the server or client application require configuration. For other handler use, including sending information in the SOAP headers, the client and server applications must be configured with symmetrical handlers.

About this task

The modules in the EAR file contain the handler classes to configure. These classes implement the `javax.xml.rpc.handler.Handler` interface. For more information on writing handler classes, see chapter 6 of the Web Services for Java EE specification. See chapter 9 in the JAX-WS specification or chapter 12 in the JAX-RPC specification for additional information on the handler framework for your programming model. The application modules must contain the `webservices.xml` deployment descriptor. See the web services specifications and API information to review the JAX-RPC specification along with a complete list of the supported standards and specifications.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate

files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.

4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Configuring the `ibm-webservices-bnd.xml` deployment descriptor for JAX-RPC web services

Use assembly tools to configure the `ibm-webservices-bnd.xml` deployment descriptor. This file stores binding information that is associated with the endpoints defined with the `webservices.xml` deployment descriptor file.

Before you begin

Note: The `ibm-webservices-bnd.xml` deployment descriptor is for Java API for XML-based RPC (JAX-RPC) based web services application. It is not used for Java API for XML-Based Web Services (JAX-WS) enabled applications.

To configure the client deployment descriptor, read about the configuring the client deployment descriptor in the Rational Application Developer information.

Before you can configure the `ibm-webservices-bnd.xml` deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

About this task

This task is one of the steps in developing a web service. You need to configure the deployment descriptors so that WebSphere Application Server can process the incoming web services requests.

Depending on if you are developing a web service from JavaBeans or an enterprise bean:

- Develop web services JavaBeans deployment descriptor templates from a Web Services Description Language (WSDL) file.
- Develop web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file.

Then, complete the EJB implementation or complete the JavaBeans implementation. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. When the JavaBeans implementation is complete, the web module web application archive (WAR) file is assembled. These archive files contain the `webservices.xml` deployment descriptor. The archive files must be assembled before you can configure the `webservices.xml` deployment descriptor.

Configure the `webservices.xml` deployment descriptor by following the steps provided in this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Results

The `ibm-webservices-bnd.xml` deployment descriptor is configured for the web service implementation module.

What to do next

If you are developing a web service from JavaBeans, assemble a WAR file that is enabled for web services from Java code. See the assembling a WAR file that is enabled for web services from Java code information.

If you are developing a web service from an enterprise bean, assemble a JAR file that is enabled for web services from an enterprise bean. To learn more about assembling the artifacts that are required to enable the EJB module for web services into the JAR file, see the assembling a JAR file that is enabled for web services from an enterprise bean information.

JAX-RPC web services enabled module - deployment descriptor settings (ibm-webservices-bnd.xml file)

The `ibm-webservices-bnd.xml` file is a deployment descriptor for a Java API for XML-based RPC (JAX-RPC) web services-enabled web module or an Enterprise JavaBeans (EJB) module. This file contains information for the web services run time that is required by WebSphere Application Server.

The following user-defined assembly properties are supported:

- **wsDescNameLink**
Attribute of the `wsdescBindings` element that specifies the link to the corresponding `<webservice-description-name>` element in the `webservices.xml` file.
- **pc-name-link**
Attribute of the `pcBindings` element that specifies the link to the `<port-component-name>` element in the `webservices.xml` file.
- **scope**
Attribute of the `pcBindings` element that specifies when new instances of implementation beans are created. Possible values are `request`, `session`, and `application`.

You can change scope value for a deployed web service using the administrative console. Click **Enterprise Applications** > *application* > **Web modules** or **EJB modules** > *module* > **Web Services Implementation Scope**.

Bindings file examples

The following examples demonstrate the spelling and position of the various attributes. You cannot cut and paste these examples because they do not contain the required ID attributes. If you add elements to a binding file template generated by the WSDL2Java command, you must confirm that each element has an ID attribute with a unique string value. Review the template xmi files generated by the WSDL2Java command for examples of ID strings. Read about the WSDL2Java command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

```
<com.ibm.etools.webservice.wsbind:WSBinding xmi:version="2.0" xmlns:xmi="http://www.omg.org/XMI" xmlns:com.ibm.etools.webservice.wsbind="http://www.ibm.com/websphere/appserver/schemas/5.0.2/wsbind.xmi">
  <wsdescBindings wsDescNameLink="AddressBookService">
    <pcBindings pcNameLink="AddressBook" scope="Application"/>
  </wsdescBindings>
</com.ibm.etools.webservice.wsbind:WSBinding>
```

Developing JAX-RPC web services with WSDL files (top down)

Setting up a development environment for web services

The application server provides command-line tools to develop web services clients and implementations that are based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. You must set up your development environment before you start developing web services.

Before you begin

Before you can set up a web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information on installing the application server, read about installing your application server environment.

About this task

Set up a web services development environment by completing the following actions.

Procedure

Set up the environment.

Run the `setupCmdLine` script on the Qshell command line from the `./profile_root/bin` directory.

Results

You have set up an environment so that you can develop Web services.

What to do next

Implement web services applications. See the task overview for implementing web services applications information to learn about how to develop and implement a Java EE web service.

Developing Java artifacts for JAX-RPC applications from a WSDL file

You can develop Java artifacts from a Web Services Description Language (WSDL) file for JAX-RPC applications from a WSDL file by using the `WSDL2Java` command-line tool to create Java implementation templates and bindings.

Before you begin

To develop the JavaBeans implementation templates and bindings from a WSDL file, you must obtain the Uniform Resource Locator (URL) of the WSDL file.

If the WSDL file is a local file, the URL looks like this example: `file:/path/file_name.wsdl`.

You can also specify local files using the absolute or relative file system path.

Implementation templates are generated using the `-role develop-server` option of the `WSDL2Java` command. The `WSDL2Java` command also generates bindings and deployment descriptors.

About this task

Develop JavaBeans implementation templates and bindings from a WSDL file by issuing the proper command.

Note: It is a best practice to use absolute namespaces within your WSDL or schema. By default, the WSDL2Java tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. You can convert any relative namespaces to absolute namespaces. To learn more about the use of namespaces with the WSDL2Java tool, see the WSDL2Java command for JAX-RPC applications documentation.

Procedure

Run the `WSDL2Java -verbose -role develop-server -container web wsdURL` command. Since the `-verbose` option is specified, a list of all the generated files is displayed when the command runs.

Results

You have templates for the implementation and deployment descriptors required to implement a web service, as well as bindings files. These templates are partially filled with information from the WSDL file.

Example

The following example uses the `AddressBook` JavaBeans implementation and the `AddressBook.wsdl` WSDL file. After generating the template files from the `WSDL2Java -verbose -role develop-server -container web AddressBook.wsdl` command, the following files are generated:

```
Parsing XML file: file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file: AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookSoapBindingImpl.java..
WSWS3282I: Info: Generating WEB-INF\webservices.xml.
WSWS3282I: Info: Generating WEB-INF\ibm-webservices-bnd.xmi.
WSWS3282I: Info: Generating WEB-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating WEB-INF\ibm-webservices-ext.xmi.
```

The `AddressBookSOAPBindingImpl.java` file is the template for the implementation bean. It is named after the port in the WSDL file. Generally, this class is renamed to a more meaningful name.

What to do next

Complete the JavaBeans implementation for JAX-RPC applications.

Developing EJB implementation templates and bindings from a WSDL file for JAX-RPC web services

You can develop Enterprise JavaBeans (EJB) implementation deployment descriptor templates and bindings from a Web Services Description Language (WSDL) file for a JAX-RPC application.

Before you begin

To develop EJB implementation templates and bindings from a WSDL file for a Java API for XML-based RPC (JAX-RPC) web service, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use.

If the WSDL file is a local file, the URL looks like the following example: `file:/path/file_name.wsdl`.

You can also specify local files using the absolute or relative file system path.

About this task

This task is one a required step in developing a web service from an enterprise bean.

Implementation templates are generated using the `-role develop-server` option of the `WSDL2Java` command.

Templates are generated for an EJB implementation for the following components:

- enterprise bean
- EJB remote interface
- EJB Home

The `WSDL2Java` command also generates bindings and deployment descriptors.

Note: It is a best practice to use absolute namespaces within your WSDL or schema. By default, the `WSDL2Java` tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. You can convert any relative namespaces to absolute namespaces. To learn more about the use of namespaces with the `WSDL2Java` tool, see the `WSDL2Java` command for JAX-RPC applications documentation.

Procedure

Run the `WSDL2Java -verbose -role develop-server -container ejb wsdlURL` command. Because the verbose option is specified, a list of all the generated files is displayed when the command runs.

Results

You have templates for the implementation and deployment descriptors required to implement web services, as well as bindings files. These templates are partially completed with information from the WSDL file.

Example

The following example uses the enterprise bean `AddressBook` enterprise bean and the `AddressBook.wsdl` file. After generating the template files from the `WSDL2Java -verbose -role develop-server -container EJB AddressBook.wsdl` command, the following files are generated:

```
Parsing XML file: file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file: AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookSoapBindingImpl.java.
WSWS3282I: Info: Generating addr\AddressBook_RI.java.
WSWS3282I: Info: Generating addr\AddressBookHome.java.
WSWS3282I: Info: Generating META-INF\webservices.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservices-bnd.xmi.
WSWS3282I: Info: Generating META-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservices-ext.xmi.
```

What to do next

Complete the EJB implementation. When you complete the EJB implementation, an EJB Java archive (JAR) file that contains an EJB and supporting classes is created from a WSDL file.

Completing the JavaBeans implementation for JAX-RPC applications

After you have developed the Java artifacts necessary to develop a Java API for XML-based RPC (JAX-RPC) web service, you must complete the JavaBeans implementation to assemble a Java archive (JAR) file or a web application archive (WAR) file based on your programming model. The resulting JAR file or WAR file contains the JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Develop web services deployment descriptor templates for a JavaBeans implementation using the WSDL2java command-line tool. You need to complete this step to create the deployment descriptor templates that are configured to map the service implementation to the JavaBeans implementation.

About this task

For JAX-RPC applications, complete the JavaBeans implementation by writing your business application.

Procedure

1. Edit the JavaBeans implementation template, *bindingImpl.java*. The *binding* is the name of the `<wsdl:binding>` element in the WSDL file. The JavaBeans implementation is generated by the WSDL2java command-line tool.
 - a. Complete the implementation of the methods in the template.
 - b. (Optional) Make changes if necessary.
 - c. (Optional) Change the class name if the binding name is not acceptable.
2. Compile all the Java classes.
3. Assemble a Web archive (WAR) file. Assemble all the Java classes into a WAR file using web module assembly tools. Include all of the classes generated from running the WSDL2java command tool for JAX-RPC web service applications when developing implementation templates and bindings from a WSDL file.

Results

You have now enabled the JavaBeans-based business application for JAX-RPC web services. You have a JAR file or a WAR file containing the JavaBeans implementation and supported classes created from the WSDL file.

What to do next

If you are developing a JAX-RPC web services application from JavaBeans, you need to configure the `webservices.xml` deployment descriptor and configure the `ibm-webservices-bnd.xmi` deployment descriptor so that the application server can process the incoming web services requests.

Completing the EJB implementation for JAX-RPC applications

After you have developed the Java artifacts necessary to develop a Java API for XML-based RPC (JAX-RPC) web service, you must complete the Enterprise JavaBeans (EJB) implementation to assemble a Java archive (JAR) file or a web application archive (WAR) file based on your programming model. The resulting JAR file or WAR file contains the Enterprise JavaBeans (EJB) implementation and the supported classes created from the tooling.

Before you begin

Develop EJB implementation templates and bindings from a WSDL file for JAX-RPC web services using the `wsdl2java` command-line tool. The deployment descriptor templates that are generated from a Web

Services Description Language (WSDL) file are required to complete the EJB implementation in the web services development process.

About this task

For JAX-RPC applications, complete the enterprise beans implementation by writing your business application.

Procedure

1. Inspect the EJB remote interface template, *portType_RI.java*. If necessary, modify the template. The value *portType* is the name of the `<wsdl:portType>` element in the WSDL file.
2. Edit the *bindingImpl.java* EJB implementation template. Where *binding* is the name of the `<wsdl:binding>` element in the WSDL file.
3. Complete the implementation of the methods in the template.
4. (Optional) Make changes if necessary.
5. (Optional) Change the class name if the binding name is not acceptable.
6. Compile all the Java classes.
7. Assemble an EJB Java archive (JAR) file. Assemble all the Java classes into an enterprise bean JAR file using assembly tools. Include all of the classes generated from running the WSDL2Java command tool when developing implementation templates and bindings from a WSDL file.

Results

You have enabled an enterprise beans business application for JAX-RPC web services. You now have an enterprise bean JAR file containing an EJB and supporting classes created from web services artifacts.

What to do next

Now that you have gathered the required artifacts for developing a JAX-RPC web service with an enterprise bean, you need to, configure the `webservices.xml` deployment descriptor.

Configuring the `webservices.xml` deployment descriptor for JAX-RPC web services

You can configure the `webservices.xml` deployment descriptor with an assembly tool.

Before you begin

To configure the client deployment descriptor, read about the configuring the client deployment descriptor in the Rational Application Developer information.

Before you can configure the `ibm-webservices-bnd.xml` deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

About this task

For JAX-RPC web services, this task is one of the required steps in developing a web service. You need to configure the deployment descriptors so that the application server can process the incoming web services requests.

If you are developing a web service from JavaBeans, you can develop web services JavaBeans deployment descriptor templates from a Web Services Description Language (WSDL) file. Then, you complete the JavaBeans implementation. To learn more, read about developing JavaBeans deployment descriptor templates from a WSDL file and completing the JavaBeans implementation.

If you are developing a web service from an enterprise bean, you can develop web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file. Then, you complete the EJB implementation. To learn more, read about developing web services EJB deployment descriptor templates from a WSDL file and completing the EJB implementation.

When the JavaBeans implementation is complete, the web module web application archive (WAR) file is assembled. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. These archive files contain the `webservices.xml` deployment descriptor. The archive files must be assembled before you can configure the `webservices.xml` deployment descriptor.

The assembly tools provide a graphical interface for developing code artifacts, assembling the code artifacts into various archives (modules) and configuring compliant deployment descriptors for Java Platform, Enterprise Edition (Java EE).

Configure the `webservices.xml` deployment descriptor by following the steps provided in this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Results

You have a `webservices.xml` deployment descriptor that is configured.

What to do next

For JAX-RPC web services, you must configure the `ibm-webservices-bnd.xmi` deployment descriptor. To learn more, see the configuring the `ibm-webservices-bnd.xmi` deployment descriptor for JAX-RPC web services information.

Configuring the `webservices.xml` deployment descriptor for handler classes

You can use an assembly tool to configure the `webservices.xml` deployment descriptor for user-provided handler classes.

Before you begin

You can configure deployment descriptors with assembly tools provided with the application server.

A *handler class* is a class that is written to modify a SOAP message that represents a remote procedure call (RPC) request or response. Handlers can be associated with a web service or a web service client.

Similar to Java API for XML-based RPC (JAX-RPC) web services, you can use deployment descriptors to describe Java API for XML Web Services (JAX-WS) web services. For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of

the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

To complete this task, you need an enterprise archive (EAR) file for the applications that you want to configure. For some handler use, such as logging or tracing, only the server or client application require configuration. For other handler use, including sending information in the SOAP headers, the client and server applications must be configured with symmetrical handlers.

About this task

The modules in the EAR file contain the handler classes to configure. These classes implement the `javax.xml.rpc.handler.Handler` interface. For more information on writing handler classes, see chapter 6 of the Web Services for Java EE specification. See chapter 9 in the JAX-WS specification or chapter 12 in the JAX-RPC specification for additional information on the handler framework for your programming model. The application modules must contain the `webservices.xml` deployment descriptor. See the web services specifications and API information to review the JAX-RPC specification along with a complete list of the supported standards and specifications.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Configuring the `ibm-webservices-bnd.xml` deployment descriptor for JAX-RPC web services

Use assembly tools to configure the `ibm-webservices-bnd.xml` deployment descriptor. This file stores binding information that is associated with the endpoints defined with the `webservices.xml` deployment descriptor file.

Before you begin

Note: The `ibm-webservices-bnd.xml` deployment descriptor is for Java API for XML-based RPC (JAX-RPC) based web services application. It is not used for Java API for XML-Based Web Services (JAX-WS) enabled applications.

To configure the client deployment descriptor, read about the configuring the client deployment descriptor in the Rational Application Developer information.

Before you can configure the `ibm-webservices-bnd.xml` deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

About this task

This task is one of the steps in developing a web service. You need to configure the deployment descriptors so that WebSphere Application Server can process the incoming web services requests.

Depending on if you are developing a web service from JavaBeans or an enterprise bean:

- Develop web services JavaBeans deployment descriptor templates from a Web Services Description Language (WSDL) file.
- Develop web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file.

Then, complete the EJB implementation or complete the JavaBeans implementation. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. When the JavaBeans implementation is complete, the web module web application archive (WAR) file is assembled. These archive files contain the `webservices.xml` deployment descriptor. The archive files must be assembled before you can configure the `webservices.xml` deployment descriptor.

Configure the `webservices.xml` deployment descriptor by following the steps provided in this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Results

The `ibm-webservices-bnd.xmi` deployment descriptor is configured for the web service implementation module.

What to do next

If you are developing a web service from JavaBeans, assemble a WAR file that is enabled for web services from Java code. See the assembling a WAR file that is enabled for web services from Java code information.

If you are developing a web service from an enterprise bean, assemble a JAR file that is enabled for web services from an enterprise bean. To learn more about assembling the artifacts that are required to enable the EJB module for web services into the JAR file, see the assembling a JAR file that is enabled for web services from an enterprise bean information.

JAX-RPC web services enabled module - deployment descriptor settings (ibm-webservices-bnd.xmi file)

The `ibm-webservices-bnd.xmi` file is a deployment descriptor for a Java API for XML-based RPC (JAX-RPC) web services-enabled web module or an Enterprise JavaBeans (EJB) module. This file contains information for the web services run time that is required by WebSphere Application Server..

The following user-defined assembly properties are supported:

- `wsDescNameLink`

Attribute of the `wsdescBindings` element that specifies the link to the corresponding `<webservice-description-name>` element in the `webservices.xml` file.

- **pc-name-link**

Attribute of the `pcBindings` element that specifies the link to the `<port-component-name>` element in the `webservices.xml` file.

- **scope**

Attribute of the `pcBindings` element that specifies when new instances of implementation beans are created. Possible values are `request`, `session`, and `application`.

You can change scope value for a deployed web service using the administrative console. Click **Enterprise Applications** > *application* > **Web modules** or **EJB modules** > *module* > **Web Services Implementation Scope**.

Bindings file examples

The following examples demonstrate the spelling and position of the various attributes. You cannot cut and paste these examples because they do not contain the required ID attributes. If you add elements to a binding file template generated by the `WSDL2Java` command, you must confirm that each element has an ID attribute with a unique string value. Review the template xmi files generated by the `WSDL2Java` command for examples of ID strings. Read about the `WSDL2Java` command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

```
<com.ibm.etools.webservice.wsbind:WSBinding xmi:version="2.0" xmlns:xmi="http://www.omg.org/XMI" xmlns:com.ibm.etools.webservice.wsbind="http://www.ibm.com/websphere/appserver/schemas/5.0.2/wsbind.xmi">
  <wsdescBindings wsDescNameLink="AddressBookService">
    <pcBindings pcNameLink="AddressBook" scope="Application"/>
  </wsdescBindings>
</com.ibm.etools.webservice.wsbind:WSBinding>
```

Developing JAX-RPC web services clients

Developing client bindings from a WSDL file for a JAX-RPC Web services client

You can develop client bindings from a Web Services Description (WSDL) file for a JAX-RPC web services client.

Before you begin

To develop the client bindings from a WSDL file for JAX-RPC web service applications, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use. You need bindings and deployment descriptors in order for a client to use a web service.

If the WSDL file is a local file, the URL looks like the following example: `file:/path/file_name.wsdl`.

You can also specify local files using the absolute or relative file system path.

Client bindings are generated using the `-role develop-client` option in combination with the `-container` option of the `WSDL2Java` command. The `-container` option takes the following parameters:

- **-container client**

Generates bindings and deployment descriptors for a client residing in the application client container.

- **-container ejb**

Generates bindings and deployment descriptors for a client that is an enterprise bean in the Enterprise JavaBeans (EJB) module.

- **-container web**

Generates bindings and deployment descriptors for a client residing in the web container.

About this task

Develop client bindings from a WSDL file by running the appropriate command.

Note: It is a best practice to use absolute namespaces within your WSDL or schema. By default, the WSDL2Java tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. You can convert any relative namespaces to absolute namespaces. To learn more about the use of namespaces with the WSDL2Java tool, see the WSDL2Java command for JAX-RPC applications documentation.

Procedure

Run the `WSDL2Java -verbose -role develop-client -container type wsdlURL` command, where *type* is `ejb` for an enterprise EJB client, `web` for a JavaBeans client, or `client` for an application client.

You can use the following combinations in the command-line:

- `-container web`
- `-container ejb`
- `-container client`

Because the verbose option is specified, a list of all generated files is displayed when the command runs.

Results

You have the bindings and deployment descriptors needed by a client to use a web service.

Example

The following example uses the AddressBook enterprise bean the `AddressBook.wsdl` WSDL file. After generating the bindings from the `WSDL2Java -verbose -role develop-client -container client AddressBook.wsdl` command, the following files are generated:

```
Parsing XML file: file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file: AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookService.java.
WSWS3282I: Info: Generating META-INF\ibm-webservicesclient-bnd.xmi.
WSWS3282I: Info: Generating META-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservicesclient-ext.xmi.
```

What to do next

Complete the client implementation by writing your client application and then assembling the client artifacts.

Changing SOAP message encoding to support WSI-Basic Profile

Support for Universal Transformation Format (UTF)-16 encoding is required by the WS-I Basic Profile 1.0. WebSphere Application Server conforms to the WS-I Basic Profile 1.1. UTF-16 is a kind of unicode encoding scheme using 16-bit values to store Universal Character Set (UCS) characters. UTF-8 is the most common encoding that is used on the Internet and UTF-16 encoding is typically used for Java and Windows product applications. You can change the encoding in a SOAP message from UTF-8 to UTF-16.

Before you begin

To learn more about the requirements of the Web Services-Interoperability Basic Profile (WS-I), including UTF-16, see Web Services-Interoperability Basic Profile information.

About this task

Support for UTF-16 encoding is required by WS-I Basic Profile. The application server only supports UTF-8 and UTF-16 encoding of SOAP messages.

You can change the character encoding in one of two ways:

Procedure

- Use a property on the Stub for users to set.

This choice applies to the client only.

For a client, the encoding is specified in the SOAP request. The SOAP engine serializes the request and sends it to the web service engine. The web service engine receives the request and deserializes the message to Java objects, which are returned to you in a response.

When the web service engine on the server receives the serialized request, a raw message in the form of an input stream, is passed to the parser, which understands Byte Order Mark (BOM). BOM is mandatory for UTF-16 encoding and it can be used in UTF-8. The message is deserialized to a Java objects and a service invocation is made. For two-way invocation, the engine needs to serialize the message using a specific encoding and send it back to the caller. The following example shows you how to use a property on the Stub to change the character set:

```
javax.xml.rpc.Stub stub=service.getPort("MyPortType");
((javax.xml.rpc.Stub)stub).setProperty(com.ibm.wsspi.webservices.Constants.MESSAGE_CHARACTER_SET_ENCODING, "UTF-16");
stub.invokeMethod();
```

In this code example, `com.ibm.wsspi.webservices.Constants.MESSAGE_CHARACTER_SET_ENCODING = "com.ibm.wsspi.webservices.xmlcharset"`;

- Use a handler to change the character set through SOAP with Attachments API for Java (SAAJ).

If you are using a handler, the SOAP message is transformed to a SAAJ format from other possible forms, such as an input stream. In such cases as a `handleRequest` method on the client side and a `handleResponse` method on the server side, the web services engine transforms from a SAAJ format back to the stream with appropriate character encoding. This transformation or change is called a *roundtrip transformation*. The following is an example of how you can use a handler to specify the character encoding through SAAJ:

```
handleResponse(MessageContext mc) {
    SOAPMessageContext smc = (SOAPMessageContext) context;
    javax.xml.soap.SOAPMessage msg = smc.getMessage();
    msg.setProperty (javax.xml.soap.SOAPMessage.CHARACTER_SET_ENCODING, "UTF-16");
}
}
```

Results

You have modified the character encoding from UTF-8 to UTF-16 in the web service SOAP message.

Configuring the JAX-RPC web services client deployment descriptor with an assembly tool

You can configure JAX-RPC web services client deployment descriptor with an assembly tool.

Before you begin

You can configure deployment descriptors with assembly tools provided with WebSphere Application Server.

Also, you need an enterprise JavaBeans (EJB) Java archive (JAR) file, web application archive (WAR) file or an application client file that you can import into the assembly tool.

Assemble the client JAR file into an EAR file or assemble the client WAR file into an EAR file. To learn more, see the information on assembling a web services-enabled client JAR file into an EAR file or assembling a web services-enabled client WAR file into an EAR file.

About this task

Complete this task if you are developing a managed client that runs in the Java EE client container. This task is done after you assemble the EJB or web module.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) or Java Archive (JAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to assembly tools. To migrate files, import your WAR or JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Results

You have a client deployment descriptor that is configured.

What to do next

Test the web services client. See the testing web services-enabled clients information to learn more about how to test an unmanaged client Java archive (JAR) file and an unmanaged client application.

Configuring the JAX-RPC client deployment descriptor for handler classes

You can configure the JAX-RPC client deployment descriptor for user-provided handler classes.

Before you begin

You need an enterprise archive (EAR) file for the applications that you want to configure. For some handler use, such as logging or tracing, only the server or client application needs to be configured. For other handler use, including sending information in SOAP headers, the client and server applications must be configured with symmetrical handlers.

The modules in the EAR file should contain the handler classes to configure. These classes implement the `javax.xml.rpc.handler.Handler` interface. For more information on writing handler classes, see chapter 6 of the Web Services for Java Platform, Enterprise Edition (Java EE) specification and chapter 12 of the Java API for XML-based remote procedure call (JAX-RPC) specification. The application modules must contain the `webservices.xml` (for server) and the client deployment descriptors.

For a complete list of the supported standards and specifications, see the web services specifications and API documentation.

About this task

Configure a handler in the client deployment descriptor by following the steps provided:

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) or Java archive (JAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. Read about importing WAR or JAR files using an assembly tool in the Rational Application Developer information.
4. Configure the client deployment descriptor. Read about creating web services handlers in the Rational Application Developer information.

Results

You have a client deployment descriptor that is configured.

What to do next

Test the web services client. See the testing web services-enabled clients information to learn more about how to test an unmanaged client Java archive (JAR) file and an unmanaged client application.

Handler class properties with JAX-RPC

This article describes handler class properties using Java API for XML-based RPC (JAX-RPC).

You can configure the following handler class properties with assembly tools provided with WebSphere Application Server. See *Configuring the `webservices.xml` deployment descriptor for Handler classes* or *Configuring the client deployment descriptors for Handler classes* for instructions on how to configure the properties.

You can configure the following handler class properties with assembly tools provided with WebSphere Application Server. For instructions on how to configure the handler class properties, read about *configuring the `webservices.xml` deployment descriptor for handler classes* or *configuring the client deployment descriptors for handler classes*.

Description:

Standard Java Platform, Enterprise Edition (Java EE) technology descriptor field.

Display name:

Standard Java EE technology descriptor field.

Small icon:

Standard Java EE technology descriptor field.

Large icon:

Standard Java EE technology descriptor field.

Handler name:

The name of the handler. This name must be unique within the module.

Handler class:

The fully qualified name of the handler class. Initially, it is set by an assembly tool.

Initial parameters:

Property names and values available to the handler.

SOAP headers:

Qualified names (Qnames) of the SOAP headers that are processed by this handler.

See section 12.2.2 of the Java API for XML-based remote procedure call (JAX-RPC) specification, available through the web services specifications and APIs information, for more information about setting this property.

SOAP roles:

URIs containing the SOAP actor names for which the handler acts in the role.

See section 12.2.2 of the Java API for XML-based remote procedure call (JAX-RPC) specification, available through the web services specifications and APIs information, for more information about setting this property.

Example: Configuring handler classes for web services deployment descriptors

This scenario explains how to add a client and server handler class to a sample application, `WebServicesSamples.ear`. The handler classes display messages when given a request or response to handle.

The code for the client handler class is illustrated in the following example:

```
package samples;

public class ClientHandler implements javax.xml.rpc.handler.Handler {
    public ClientHandler() { }

    public boolean handleRequest(javax.xml.rpc.handler.MessageContext context) {
        System.out.println("ClientHandler: In handleRequest");
        return true; }

    public boolean handleResponse(javax.xml.rpc.handler.MessageContext context) {
        System.out.println("ClientHandler: In handleResponse");
        return true; }

    public boolean handleFault(javax.xml.rpc.handler.MessageContext context) {
        System.out.println("ClientHandler: In handleFault");
        return true; }

    public void init(javax.xml.rpc.handler.HandlerInfo config) {}

    public void destroy() {}

    public javax.xml.namespace.QName[] getHeaders() {
        return null; }
}
```

The code for the server handler class is illustrated in the following example:

```
package sample;
public class ServerHandler implements javax.xml.rpc.handler.Handler {
    public ServerHandler() { }
```

```

public boolean handleRequest(javax.xml.rpc.handler.MessageContext context) {
    System.out.println("ServerHandler: In handleRequest");
    return true; }

public boolean handleResponse(javax.xml.rpc.handler.MessageContext context) {
    System.out.println("ServerHandler: In handleResponse");
    return true; }

public boolean handleFault(javax.xml.rpc.handler.MessageContext context) {
    System.out.println("ServerHandler: In handleFault");
    return true; }

public void init(javax.xml.rpc.handler.HandlerInfo config) {}

public void destroy() {}

public javax.xml.namespace.QName[] getHeaders() {
    return null; }
}

```

1. Compile these classes using:
2. Open an assembly tool and import the two sample enterprise archive (EAR) files:
 -
 -
3. Import the compiled handler classes into the projects for the sample modules:
 - Import sample.ClientHandler into the **appClientModule** directory of the **AddressBookClient** project.
 - Import sample.ServerHandler into the **ejbModule** directory of the **AddressBookW2JE** project.
4. Configure the client deployment descriptor for handler classes.
This topic explains how to configure the client deployment descriptor for user-provided handler classes.
5. Configure the webservices.xml deployment descriptor for handler classes.
This topic explains how to configure the webservices.xml deployment descriptor for user-provided handler classes.
6. Save your changes and export the EAR files.
7. Uninstall the WebServicesSamples.ear application from your server if it is already installed.
8. Install the new WebServicesSamples.ear application.
9. Start the server.
10. Run the client:

```

launchClient ApplicationClients.ear -CCjar=AddressBookClient.jar

```

When the client runs, the console output looks like the following example. The messages from the handlers are shown in bold.

```

IBM WebSphere Application Server
J2EE Application Client Tool
Copyright IBM Corp., 1997-2003
WSDL0012I: Processing command line arguments.

Environment.
WSDL0035I: Initialization of the J2EE Application Client
Environment has completed.
WSDL0014I: Invoking the Application Client class
com.ibm.websphere.samples.webservices.addr.AddressBookClient
>> Querying address for 'Purdue Boilermaker' using port
AddressBookW2JE
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
    1 University Drive
    West Lafayette, IN 47907
    Phone: (765) 555-4900
>> Querying address for 'Purdue Boilermaker' using port
AddressBookJ2WE
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:

```

```

    2 University Drive
    West Lafayette, IN 47907
    Phone: (765) 555-4900
>> Querying address for 'Purdue Boilermaker' using port
AddressBookJ2WB
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
    3 University Drive
    West Lafayette, IN 47907
    Phone: (765) 555-4900
>> Querying address for 'Purdue Boilermaker' using port AddressBookW2JB
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
    4 University Drive
    West Lafayette, IN 47907
    Phone: (765) 555-4900

```

For the client, the handler class is configured for each service reference, not for each port. The AddressBook sample has four ports, but only one service reference, therefore the ClientHandler handles requests and responses on all ports.

When the server log file is examined, it contains the following data:

```

[9/24/03 16:39:22:661 CDT] 4deec1c6 WebGroup      I SRVE0180I:
[HTTP router for AddressBookW2JE.jar] [/AddressBookW2JE] [Servlet.LOG]:
AddressBook: init
[9/24/03 16:39:23:161 CDT] 4deec1c6 SystemOut    0 ServerHandler: In handleRequest
[9/24/03 16:39:23:211 CDT] 4deec1c6 SystemOut    0 ServerHandler: In handleResponse

```

Results

The deployment descriptors for handler classes are configured. Deployment descriptors are required so that so that WebSphere Application Server can process the incoming web services requests.

What to do next

Deploy the EAR file that has been configured and enabled for web services. Then you can test the application to make sure it runs within the WebSphere Application Server environment.

Configuring the JAX-RPC web services client bindings in the ibm-webservicesclient-bnd.xmi deployment descriptor

You can configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor file with assembly tools.

Before you begin

You can configure deployment descriptors with assembly tools provided with the application server.

You must configure the assembly tool before you can use it. Read about configuring the assembly tool in the Rational Application Developer documentation.

About this task

Now that you have assembled the client module, complete this step to configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor. Deployment descriptors are required so that so that WebSphere Application Server can process the incoming web services requests.

Configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor file with the following steps provided:

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.

2. Switch to the Java EE Perspective.
 - a. Click **Window > Open Perspective > Other > Java EE.**
3. Open the Project Explorer.
 - a. Click **Window > Show View > Other > Project Explorer.**
4. Locate the deployment descriptor file for the module. Hint: Deployment Descriptor: *<module>*
5. Double-click the deployment descriptor file to open the Deployment Descriptor editor.
 - a. Select the **WS Binding** tab at the bottom of the editor window to open the Web Services Client Bindings editor.
6. Verify the serviceRefLink element settings.
 - a. Open the **Web Services Client Bindings** editor.
 - b. Click the **Services References** tab.
 - c. Click **Add**.
 - d. Select the service references defined in the client deployment descriptor file from the list.
7. Verify the deployedWSDLFile element settings.
 - a. Open the **Web Services Client Bindings** editor.
 - b. Select the service reference.
 - c. Expand the **Service Reference Details** section.
 - d. Click **Browse** that is located to the right of the Deployed WSDL file field.
 - e. Select the new Web Services Description Language (WSDL) file.
 - f. Click **OK**.

You can also change the deployedWSDLFile element of a deployed web service using the administrative console. Click **Enterprise Applications > application > Web module or EJB module > module > Web services client bindings.**

8. Verify the defaultMappings element settings.
 - a. Open the **Web services client bindings** editor.
 - b. Click **Default mappings**.
 - c. Click **Add**.
 - d. Edit the entries in the newly added row to establish a mapping between a *portType* and a *port* in the WSDL file. Only one entry is supported for each *portType*.
 - e. Click **OK**.

You can also change the defaultMappings element of a deployed web service using the administrative console. Click **Enterprise Applications > application > Web module or EJB module > module > Web services client bindings.**

9. Access the web services client Port bindings editor through the **Port qualified name binding details** section at the bottom of the editor pane.
10. Verify the syncTimeout element settings.
 - a. Create a Port qualified name bindings for the port.
 - b. Open the **Web services client bindings** editor.
 - c. Confirm that a service reference is selected in either the **Component-scoped references** or the **Service references** section.
 - d. Expand the **Port qualified name binding** section.
 - e. Click **Add**. The **Add port qualified name binding** dialog opens.
 - f. Type the *namespace* of the WSDL file port you want to configure, in the **Port namespace link** field.
 - g. Type the *local_name* of the WSDL file port you want to configure in the **Port local name link** field. The name displayed in the **Port qualified name binding** list is the local name of the WSDL file port.

- h. Click **OK**.
 - a. Configure the `syncTimeout` property by locating the Synchronization timeout field and enter the desired value. The default is 300 seconds.
11. Verify the `basicAuth` element settings.
 - a. Locate the **HTTP basic authentication** field in the **Port qualified name binding details** section.
 - b. Type the desired value in the User ID and Password fields.
 - c. Click **OK**.
12. Verify the `sslConfig` element settings.
 - a. Locate the **SSL configuration** field in the **Port qualified name binding details** section.
 - b. Type the desired value in the **Name** field.
 - c. Click **OK**.
13. After editing the properties, type `ctrl-s` on your keyboard to save the changes.

Results

You have configured the `ibm-webservicesclient-bnd.xml` deployment descriptor. If you have configured all of the client deployment descriptors, test the web services client. If you have not configured all of the client deployment descriptors, complete the configurations and then test the web services client.

ibm-webservicesclient-bnd.xml assembly properties for JAX-RPC applications

The `ibm-webservicesclient-bnd.xml` deployment descriptor file contains information for the web services run time that is WebSphere product-specific. This deployment descriptor file is used with Java API for XML-based RPC (JAX-RPC) web services. This binding file is not applicable for Java API for XML-Based Web Services (JAX-WS) web services.

You can configure deployment descriptors with assembly tools provided with WebSphere Application Server. Read about configuring the JAX-RPC web services client bindings in the `ibm-webservicesclient-bnd.xml` deployment descriptor to learn more about configuring this deployment descriptor.

Assembly properties

The following user-definable assembly properties are supported:

- **componentNameLink**

An attribute of the `componentScopedRefs` element. When a web service is implemented by an Enterprise JavaBeans (EJB) implementation, each `<componentScopedRefs>` element contains assembly properties for an individual enterprise bean. The `componentNameLink` attribute of the `<componentScopedRefs>` element identifies the enterprise bean that the assembly properties apply to by specifying the `<ejb-name>`. This property is used only when the web service client is an enterprise bean.
- **serviceRefLink**

An attribute of the `serviceRefs` element. Specifies the link to the `<service-ref-name>` in the `<service-ref>` element in the client deployment descriptor. The client deployment descriptor is either `ejb-jar.xml`, `web.xml` or `application-client.xml`.
- **deployedWSDLFile**

An attribute of the `serviceRefs` element is optional. Permits an alternate Web Services Description Language (WSDL) file to use other than that specified in the `<wsdl-file>` element of the `<service-ref>` element in the client deployment descriptor. If an attribute is specified, the alternate WSDL file must be packaged in the same module and must be compatible with the development WSDL file. The `deployedWSDLFile` property supplies a new WSDL file containing a different endpoint web address than the original WSDL file.
- **defaultMappings** element

Identifies which port to use for a given portType when one is not selected by the client. This element has the following attributes: portTypeNamespace, portTypeLocalName, portNamespace, portLocalName. These attributes identify which wsdl:port is used for a wsdl:portType.

- **syncTimeout**

An attribute of the portQnameBindings element. Specifies how long, in seconds, to wait for a response from a synchronous call. The default is 300 seconds.

- **basicAuth**

An element of the portQnameBindings element. Authenticates a service client to the service endpoint, independent of the underlying transport that includes, HTTP, HTTPS, and Java Message Service (JMS). Set the user ID and password attributes as needed.

- **sslConfig**

An element of the portQnameBindings element. Specifies the Secure Sockets Layer (SSL) configuration of an HTTPS outbound request. The name attribute is the name of an SSL configuration entry or alias that is defined in the SSL configuration repertoire. This attribute is used only when the client is running in the WebSphere Application Server.

A bindings file example

The following example demonstrates the spelling and position of the various attributes. You cannot cut and paste these examples because they do not contain the required ID attributes. If you add elements to a binding file template generated by the WSDL2Java command, you must confirm that each element has an ID attribute whose value is a unique string. Review the template xmi files generated by the WSDL2Java command for examples of ID strings. Read about the WSDL2Java command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

```
<com.ibm.etools.webservice.wscbnd:ClientBinding xmi:version="2.0"
xmlns:xmi="http://www.omg.org/XMI" xmlns:com.ibm.etools.webservice.wscbnd=
"http://www.ibm.com/websphere/appserver/schemas/5.0.2/wscbnd.xmi">

  <componentScopedRefs componentNameLink="myComponent ref"/>

  <serviceRefs serviceRefLink="myService ref" deployedWSDLFile="META-INF/wsd1/alternate.wsd1">
    <defaultMappings portTypeLocalName="AddressBook" portTypeNamespace="http://www.com.ibm"
portLocalName="AddressBookPort" portNamespace="http://www.com.ibm"/>
    <portQnameBindings portQnameNamespaceLink="http://www.com.ibm"
portQnameLocalNameLink="AddressBookPort" syncTimeout="99">
      <basicAuth userid="myId" password="myPassword"/>
      <sslConfig name="mynode/DefaultSSLSettings"/>
    </portQnameBindings>
  </serviceRefs>
</com.ibm.etools.webservice.wscbnd:ClientBinding>
```

Implementing extensions to JAX-RPC web services clients

WebSphere Application Server provides extensions to web services clients using the Java API for XML-based RPC (JAX-RPC) programming model.

About this task

You can customize web services by using the following extensions to the JAX-RPC client programming model.

Procedure

- Set the **REQUEST_SOAP_HEADERS** and **RESPONSE_SOAP_HEADERS** properties in a JAX-RPC client Stub to enable a web services client to send or retrieve implicit SOAP headers.

An implicit SOAP header is a SOAP header that is not explicitly defined in the WSDL file. An implicit SOAP header file fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the WSDL file, but the message definition is not referenced by a portType within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

To learn how to modify your client code to send or retrieve transport headers, see the information on sending implicit SOAP headers with JAX-RPC or receiving implicit SOAP headers with JAX-RPC.

- Set the **REQUEST_TRANSPORT_PROPERTIES** and **RESPONSE_TRANSPORT_PROPERTIES** properties to enable a web services client to send or retrieve transport headers.

Set the properties on the Stub or Call object.

By modifying your client code to send or retrieve transport headers, you can send or receive specific information within the transport headers of outgoing requests or incoming responses from the server. For requests or responses that use the HTTP transport, the information is sent or retrieved in an HTTP header. Similarly, for a request or response that uses the Java Message Service (JMS) transport, the information is sent or retrieved in a JMS message property.

To learn how to modify your client code to send or retrieve transport headers, see the information on sending transport headers with JAX-RPC or retrieving transport headers with JAX-RPC.

To learn how to enable a Web services client to send or retrieve transport headers, see the transport header properties best practices information.

- Implement support for `javax.xml.rpc.ServiceFactory.loadService()` methods.

The `loadService` methods create an instance of the generated service implementation class in an implementation-specific manner. The `loadService` methods are new for JAX-RPC 1.1 and include three signatures:

- **public javax.xml.rpc.Service loadService (Class serviceInterface)**

As documented in the JAX-RPC specification, this method returns the generated service implementation for the service interface. See the web services specifications and API documentation to review the JAX-RPC specification.

- **public javax.xml.rpc.Service loadService (URL wsdlDocumentLocation, Class serviceInterface, Properties properties)**

This method behaves like the `loadService (Class serviceInterface)` because the following parameters are ignored:

- `wsdlDocumentLocation`
- `properties`

- **public javax.xml.rpc.Service loadService (URL wsdlDocumentLocation, QName serviceName, Properties properties)**

This method returns the generated service implementation for the specified service by using optional namespace-to-package mapping information.

- `wsdlDocumentLocation` - ignored
- `serviceName` - `QName` (namespace, localpart) of the service
- `properties` - If this parameter is non-null, it contains namespace-to-package mapping entries. Each Property entry key is a String corresponding to the namespace. Each Property entry value is a String corresponding to the Java package name.

If the `properties` argument contains an entry with a key (namespace) that matches the namespace portion of the `QName serviceName` argument, the entry value (`javaPackage`) is used as the package name when trying to locate the service implementation.

For more information on these methods, see the JAX-RPC specification.

- Implement the `CustomBinder` interface to provide concrete custom data binders for a specific XML schema type (**JAX-RPC applications only**).

Custom data binders are used to map XML schema types with Java objects. Custom data binders provide bindings for XML schema types that are not supported by the current Java API for XML-based Remote Call Procedure (JAX-RPC) specification. WebSphere Application Server provides an extension to the Web Services for Java Platform, Enterprise Edition (Java EE) programming model called the

CustomBinder interface that implements these custom bindings for a specific XML schema type. The CustomBinder interface has three properties, in addition to deserialize and serialize methods:

- QName for the XML schema type
- QName scope
- Java type

The custom data binder defines serialize and deserialize methods to convert between a Java object and a SOAPElement interface. A custom data binder is added to the runtime system and interacts with the web services runtime using a SOAPElement. They are added to the runtime by using custom binding providers. Read about the custom data binders and the custom binding provider to learn more. See the CustomBinder interface documentation to learn more about how you can implement this interface to provide concrete custom data binders for a specific XML schema type.

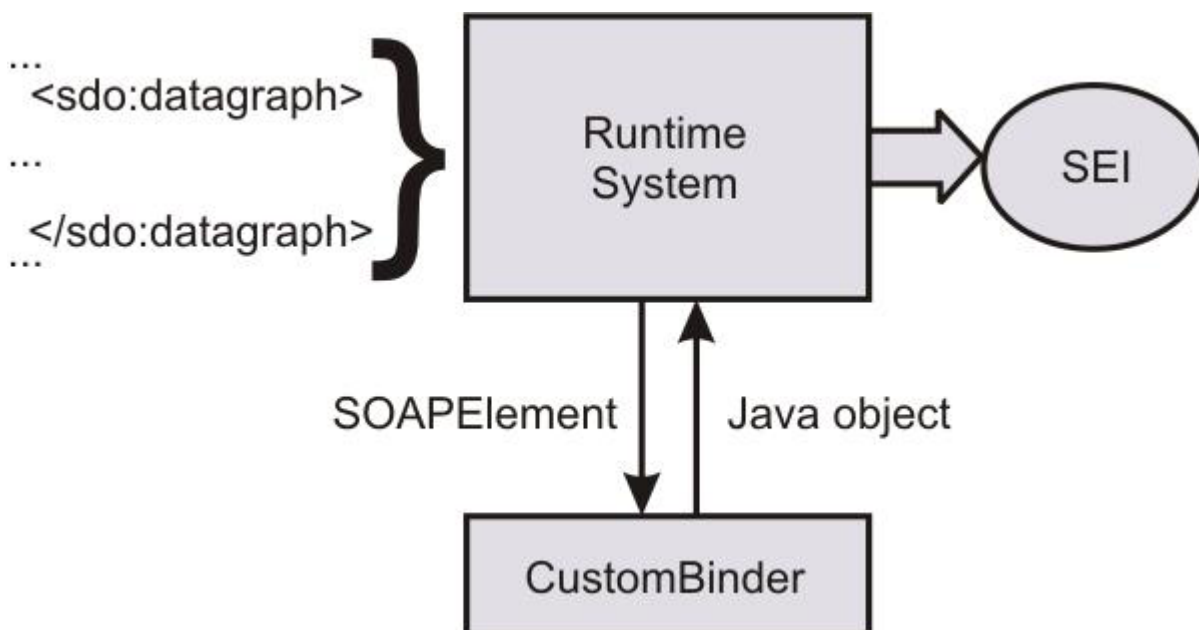

Custom data binders for JAX-RPC applications

A *custom data binder* is used to map XML schema types with Java objects. Custom data binders provide bindings for XML schema types that are not supported by the current Java API for XML-based Remote Call Procedure (JAX-RPC) specification.

The custom data binder defines serialize and deserialize methods to convert between a Java object and a SOAPElement interface. A custom data binder is added to the runtime system and interacts with the web services run time using a SOAPElement. Unlike conventional deserializers, custom data binders do not rely on the low-level parsing events from the run time to build the Java object, such as Simple API for XML (SAX). Instead, the run time builds the custom data binder by rendering the incoming SOAP message into a SOAPElement. The SOAPElement that contains the message is passed to the customer data binder. For example, if the incoming message contains a Service Data Object (SDO) datagraph, the runtime system processes as follows:

1. The runtime system recognizes the `<sdo:Datagraph>` code.
2. The run time queries the type mapping system to locate the custom data binder for the datagraph data, for example `SDOCustomBinder`.
3. A SOAPElement is created that represents the incoming SDO datagraph.
4. The run time passes the SOAPElement to the `SDOCustomBinder`.

Within the deserialized method, the `SDOCustomBinder` extracts the content from the SOAPElement and builds a concrete `DataGraph` object with a `commonj.sdo.DataGraph` type.

When a Java object is serialized, a similar process occurs. The run time locates a custom data binder and converts the Java object to a SOAPElement. The runtime serializes the SOAPElement to the raw message that is transported in the output stream.

The following is an example of an XML schema that is defined by the SDO specification:

```
<xsd:schema
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:sdo="commonj.sdo"
  targetNamespace="commonj.sdo">

  <xsd:element name="datagraph" type="sdo:DataGraphType"/>

  <xsd:complexType name="DataGraphType">
    <xsd:complexContent>
      <xsd:extension base="sdo:BaseDataGraphType">
        <xsd:sequence>
          <xsd:any minOccurs="0" maxOccurs="1"
            namespace="##other" processContents="lax"/>
        </xsd:sequence>
      </xsd:extension>
    </xsd:complexContent>
  </xsd:complexType>

  <xsd:complexType name="BaseDataGraphType" abstract="true">
    <xsd:sequence>
      <xsd:element name="models" type="sdo:ModelsType" minOccurs="0"/>
      <xsd:element name="xsd" type="sdo:XSDType" minOccurs="0"/>
      <xsd:element name="changeSummary"
        type="sdo:ChangeSummaryType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>

  <xsd:complexType name="ModelsType">
    <xsd:sequence>
      <xsd:any minOccurs="0" maxOccurs="unbounded"
        namespace="##other" processContents="lax"/>
    </xsd:sequence>
  </xsd:complexType>

  <xsd:complexType name="XSDType">
    <xsd:sequence>
      <xsd:any minOccurs="0" maxOccurs="unbounded"
        namespace="http://www.w3.org/2001/XMLSchema" processContents="lax"/>
    </xsd:sequence>
  </xsd:complexType>

  <xsd:complexType name="ChangeSummaryType">
    <xsd:sequence>
      <xsd:any minOccurs="0" maxOccurs="unbounded"
        namespace="##any" processContents="lax"/>
    </xsd:sequence>
    <xsd:attribute name="create" type="xsd:string"/>
    <xsd:attribute name="delete" type="xsd:string"/>
  </xsd:complexType>

</xsd:schema>
```

WebSphere Application Server defines the CustomBinder interface that implements concrete custom bindings for a specific XML schema type.

The custom binding provider is used to import the custom bindings into the run time. To learn how to plug your custom data binders into the WSDL2Java command-line tool for development, read about custom binding providers. You can also read about usage patterns for deploying custom data binders to learn more about how to deploy the provider package to your runtime, as well as the roles involved in the custom binding process.

Custom binding providers for JAX-RPC applications

A *custom binding provider* is the packaging of custom data binder classes with a declarative metadata file. The main purpose of a custom binding provider is to aggregate related custom data binders to support particular user scenarios. The custom binding provider is used to plug the custom data binders into the

emitter tools and the run time system so that the emitter tools can generate the appropriate artifacts and the run time system can augment its existing type mapping system to reflect the applied custom data binders and invoke them.

A custom binding provider works with a specific XML schema type, while applications involve a few related XML schema types. You need a mechanism to aggregate and declare various custom data binders to provide a complete binding solution. The concept of the custom binding provider defines a declarative model that can be used to plug in a set of custom data binders to either emitter tools or the run time system.

See the custom data binders information and the information on the CustomBinder interface to learn more about custom data binders and the CustomBinder API included in WebSphere Application Server to define the custom data binders. After you have defined the custom data binders, you are ready to deploy the custom binder package. To learn how to deploy this package, see the information on usage patterns for deploying custom data binders for JAX-RPC applications.

The declarative metadata file, CustomBindingProvider.xml, is an XML file that is packaged with the custom provider classes in a single Java archive (JAR) file and located in the /META-INF/services/directory. After a provider JAR file is packaged, the binary information and the metadata file located in the JAR file can be used by the WSDL2Java command-line tool and the run time system.

The following example is the XML schema for the CustomBindingProvider.xml file. The top level type is the providerType that contains a list of mapping elements. Each mapping element defines the associated custom data binder and properties, including xmlQName, javaName and qnameScope. You can read more about these properties in the information for CustomBinder interface for JAX-RPC applications. The providerType also has an attribute called scope that has a value of *server*, *application* or *module*. The scope attribute is used by the server deployment to resolve the conflict and to realize a custom binding hierarchy.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsd:schema
  targetNamespace=
    "http://www.ibm.com/webservices/customdatabinding/2004/06"
  xmlns:customdatabinding=
    "http://www.ibm.com/webservices/customdatabinding/2004/06"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  elementFormDefault="qualified" attributeFormDefault="qualified">

  <xsd:element name="provider" type="customdatabinding:providerType"/>

  <xsd:complexType name="providerType">
    <xsd:sequence>
      <xsd:element name="description" type="xsd:string" minOccurs="0"/>
      <xsd:element name="mapping" minOccurs="0" maxOccurs="unbounded">
        <xsd:complexType>
          <xsd:sequence>
            <xsd:element name="description" type="xsd:string" minOccurs="0"/>
            <xsd:element name="xmlQName" type="xsd:QName"/>
            <xsd:element name="javaName" type="xsd:string"/>
            <xsd:element name="qnameScope"
              type="customdatabinding:qnameScopeType"/>
            <xsd:element name="binder" type="xsd:string"/>
          </xsd:sequence>
        </xsd:complexType>
      </xsd:element>
      <xsd:attribute name="scope"
        type="customdatabinding:ProviderScopeType" default="module"/>
    </xsd:sequence>
  </xsd:complexType>

  <xsd:simpleType name="qnameScopeType">
    <xsd:restriction base="xsd:string">
      <xsd:enumeration value="simpleType"/>
      <xsd:enumeration value="complexType"/>
      <xsd:enumeration value="element"/>
    </xsd:restriction>
  </xsd:simpleType>
</xsd:schema>
```

```

<xsd:simpleType name="ProviderScopeType">
  <xsd:restriction base="xsd:string">
    <xsd:enumeration value="server"/>
    <xsd:enumeration value="application"/>
    <xsd:enumeration value="module"/>
  </xsd:restriction>
</xsd:simpleType>
</xsd:schema>

```

The following is an example of the CustomBindingProvider.xml file for the SDO DataGraph schema that was introduced in CustomBinder interface. The example displays the mapping between a schema type, DataGraphType, and a Java type, commonj.sdo.DataGraph. The binder that represents this mapping is called test.sdo.SDODataGraphBinder.

```

<cdb:provider
  xmlns:cdb="http://www.ibm.com/webservices/customdatabinding/2004/06"
  xmlns:sdo="commonj.sdo">
  <cdb:mapping>
    <cdb:xmlQName>sdo:DataGraphType</cdb:xmlQName>
    <cdb:javaName>commonj.sdo.DataGraph</cdb:javaName>
    <cdb:qnameScope>complexType</cdb:qnameScope>
    <cdb:binder>test.sdo.SDODataGraphBinder</cdb:binder>
  </cdb:mapping>
</cdb:provider>

```

You need to import your custom data binders into the WSDL2Java command-line tool for development purposes. The custom data binders affect how the development artifacts, including the Service Endpoint Interface and the JSR 109 mapping data, are generated from the Web Services Description Language (WSDL) file. The WSDL2Java command-line tool ships with WebSphere Application Server and uses the custom binder Java archive file, or custom binder package, to generate these the development artifacts.

The following example is a WSDL file that references the SDO DataGraph schema that is introduced in the CustomBinder interface topic.

```

<?xml version="1.0" encoding="UTF-8"?>
<wsdl:definitions targetNamespace="http://sdo.test"
  xmlns:impl="http://sdo.test"
  xmlns:intf="http://sdo.test"
  xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
  xmlns:wsdlsoap="http://schemas.xmlsoap.org/wsdl/soap/"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:sdo="commonj.sdo">

  <wsdl:types>
    <schema elementFormDefault="qualified" targetNamespace="http://sdo.test"
      xmlns="http://www.w3.org/2001/XMLSchema" xmlns:sdo="commonj.sdo">
      <import namespace="commonj.sdo" schemaLocation="sdo.xsd"/>
    </schema>
  </wsdl:types>

  <wsdl:message name="echoResponse">
    <wsdl:part element="sdo:datagraph" name="return"/>
  </wsdl:message>

  <wsdl:message name="echoRequest">
    <wsdl:part element="sdo:datagraph" name="parameter"/>
  </wsdl:message>

  <wsdl:portType name="EchoService">
    <wsdl:operation name="echo">
      <wsdl:input message="impl:echoRequest" name="echoRequest"/>
      <wsdl:output message="impl:echoResponse" name="echoResponse"/>
    </wsdl:operation>
  </wsdl:portType>

  <wsdl:binding name="EchoServiceSoapBinding" type="impl:EchoService">
    <wsdlsoap:binding style="document"
      transport="http://schemas.xmlsoap.org/soap/http"/>
    <wsdl:operation name="echo">
      <wsdlsoap:operation soapAction=""/>
      <wsdl:input name="echoRequest">
        <wsdlsoap:body use="literal"/>
      </wsdl:input>
    </wsdl:operation>
  </wsdl:binding>

```

```

        <wsdl:output name="echoResponse">
            <wsdl:soap:body use="literal"/>
        </wsdl:output>
    </wsdl:operation>
</wsdl:binding>

<wsdl:service name="EchoServiceService">
    <wsdl:port binding="impl:EchoServiceSoapBinding" name="EchoService">
        <wsdl:soap:address location="http://<uri>"/>
    </wsdl:port>
</wsdl:service>
</wsdl:definitions>

```

If you run the WSDL2Java command without the custom data binding package, the following Service Endpoint Interface is generated with a parameter type, as dictated by the JAX-RPC specification:

```

public interface EchoService extends java.rmi.Remote {
    public javax.xml.soap.SOAPElement
        echo(javax.xml.soap.SOAPElement parameter)
            throws java.rmi.RemoteException;
}

```

When you run the WSDL2Java command with the custom data binding package, the custom data binders are used to generate the parameter types. To apply the custom data binders, use the `-classpath` option on the WSDL2Java tool. The tool searches its classpath to locate all the files with the same file path of `/META-INF/services/CustomBindingProvider.xml`. The following is an example how you can use the command to generate a Service Endpoint Interface with the parameter type of `commonj.sdo.DataGraph`:

```
WSDL2Java -role develop-server -container web classpath sdoBinder.jar echo.wsdl
```

The Service Endpoint Interface that is generated looks like the following:

```

public interface EchoService extends java.rmi.Remote {
    public commonj.sdo.DataGraph
        echo(commonj.sdo.DataGraph parameter)
            throws java.rmi.RemoteException;
}

```

The custom binder packaged JAR file has to be made available at runtime to make sure the web service client is invoked, regardless if it is a stub-based client or a Dynamic Invocation Interface (DII) client. The same applies to the service.

CustomBinder interface for JAX-RPC applications

WebSphere Application Server defines a CustomBinder interface that you can implement for Java API for XML-based Remote Call Procedure (JAX-RPC) applications to provide concrete custom data binders for a specific XML schema type.

The CustomBinder interface has three properties, in addition to `deserialize` and `serialize` methods. These properties are `QName` for the XML schema type, the `QName` scope, and the Java type that the schema type maps to. The properties are accessible through the corresponding getter methods.

getQName

The `getQName` method returns the `QName` of the target XML schema type. Custom data binders only work with the root level schema type.

For anonymous types, the `getQName` method returns the `QName` of the containing element.

For named types, the `getQName` method returns the `QName` of the `complexType` or the `simpleType`.

getQNameScope

The `getQNameScope` method returns the binder `qnameScope` property that indicates whether the schema type is a named type or an anonymous type. The `qnameScope` property value can be *complexType* for an `<xsd:complexType>`, *simpleType* for an `<xsd:simpleType>` or *element* for an `<xsd:element>` that is defined with an anonymous type.

In the following schema, `data1` is an element that is defined with an anonymous type. The element, `data2`, is defined using the named type, `data2Type`.

```
<xsd:element name="data1">
  <xsd:complexType>
    ...
  </xsd:complexType>
</xsd:element>

<xsd:element name="data2" type="data2Type"/>
<xsd:complexType name="data2Type">
  ...
</xsd:complexType>
```

The anonymous type, `data1`, has a `qNameScope` of `element` and a `qName` of `data1`. The type, `data2Type`, has a `qNameScope` of `complexType` and a `qName` of `data2Type`.

The element, `data2`, is not represented in the custom data binder. The custom data binder only processes types and not elements.

getJavaName

The `getJavaName` method returns the fully-qualified class name for the Java type that is mapped to the named or anonymous type. The class can be an interface or a concrete class. The object returned from the `deserialize` method has a type that is compatible with the Java type that is returned by the `getJavaName` method.

serialize

The `serialize` method returns the `SOAPElement` that the custom data binder builds from the Java object. The Java object is passed from the run time system and is expected to match what is returned from the `getJavaName` method. The `SOAPElement` parameter does not have child elements, but it does have a valid `QName`. This parameter is a reference for the binder to create the final `SOAPElement`.

In most cases, the binder implementation appends the child elements to the root `SOAPElement`. The run time system guarantees that the `SOAPElement` `QName` is correct. Therefore, the custom data binder for named types keeps the `QName` of the root element because the binder does not know the enclosing element. The binder implementation for an anonymous type should always include the `QName` in the returned `SOAPElement` that matches the defined schema type. WebSphere Application Server does not have concrete methods in the `CustomBindingContext` parameter.

deserialize

The `deserialize` method returns a Java object that the custom data binder builds from the passed root `SOAPElement`. The object type of the returned Java object must match what is returned from the `getJavaName` method. Unlike the parameter `serialize` method, the passed `SOAPElement` contains the original XML data with the necessary namespace declarations.

The following is an example of an implementation of the SDO `DataGraph` binder, where the `convertToSDO` and `convertToSAAJ` utility methods convert between `SOAPElement` and an SDO object.

```
package test.sdo.binder;

import javax.xml.namespace.QName;
```

```

import javax.xml.soap.SOAPElement;

import com.ibm.wsspi.webservices.binding.CustomBinder;
import com.ibm.wsspi.webservices.binding.CustomBindingContext;

public class DataGraphBinder implements CustomBinder {
    public QName getQName() {
        return new QName("commonj.sdo", "DataGraphyType");
    }
    public String getJavaName() {
        return CustomBinder.QNAME_SCOPE_COMPLEXTYPE;
    }
    public String getJavaName() {
        return commonj.sdo.DataGraph.class.getName();
    }
    public javax.xml.soap.SOAPElement serialize(
        Object bean,
        SOAPElement rootNode,
        CustomBindingContext context)
        throws javax.xml.soap.SOAPException {
        // convertToSAAJ is a utility method to convert
        // the SDO DataGraph to the SOAPElement
        return convertToSAAJ(bean, rootNode);
    }
    public Object deserialize(
        SOAPElement source,
        CustomBindingContext context)
        throws javax.xml.soap.SOAPException {
        // convertToSDO is a utility method to convert
        // the SOAPElement to the SDO DataGraph
        return convertToSDO(source);
    }
}

```

To learn more about custom data binders, see the custom data binders for JAX-RPC applications information. To learn how to plug your custom data binders into the WSDL2Java command-line tool for development, see the custom binding providers for JAX-RPC applications information.

Usage patterns for deploying custom data binders for JAX-RPC applications

Custom data binders are used to map XML schema types with Java objects. Custom data binders provide bindings for XML schema types that are not supported by the current Java API for XML-based Remote Call Procedure (JAX-RPC) specification. WebSphere Application Server provides an extension to the Web Services for Java Platform, Enterprise Edition (Java EE) programming model called the CustomBinder interface that implements these custom bindings for a specific XML schema type. The custom binding provider is the package for the custom data binders that is imported into the runtime.

To learn more about the CustomBinder API, see the CustomBinder interface for JAX-RPC applications information. For general information about custom binders, see the custom data binders for JAX-RPC applications information. See the custom binding providers for JAX-RPC applications information to review how custom binding providers are packaged for development.

This usage pattern reviews how to deploy the provider package to your runtime, as well as the roles involved in the custom binding process.

Roles involved in custom data binding

Four roles are involved with custom data binding. These roles that are defined by the Web Services for Java Platform, Enterprise Edition (Java EE) specification are as follows:

- **Custom binding provider** is responsible for implementing the required custom data binders, declaring these binders in a CustomBindingProvider.xml file and packaging the binding classes into a Java archive (JAR) file.
- **Application developer** is responsible for applying the custom binding provider JAR file and generating the development artifacts.
- **Application assembler** needs to understand the application requirements in terms of the custom data binding and decides how to package the custom provider JAR file as a part of the application.

- **Application deployer** configures the shared libraries to make custom data binding support available to the applications. This needs to be done if the custom provider JAR file is not packaged with the application. If the application is not deployed, the deployer has to run the web services deployment tools after the application is installed.

Common usage patterns

The custom binder provider package can be deployed in various ways to provide flexibility beyond the standard JAX-RPC mapping standards. Three primary deployment usage patterns are as follows:

- **Deploy the custom data binders at the server level**

This pattern ensures that all the applications that are running on the server are affected by the custom data binders and is useful if fundamental XML types are introduced but are not supported by the standard JAX-RPC mapping rules.

This type of situation occurs frequently for new web services specifications that define new schema types. For example, the WS-Addressing specification defines an `EndpointReferenceType` schema type that is not supported by the JAX-RPC mapping rules. Because this pattern requires augmenting the server classpath, it has a significant impact on the server runtime and affects the installed applications. This pattern is most suitable for WebSphere Application Server internal components.

- **Deploy the custom binders for one or more application**

Use this pattern if you only want specified applications to be affected by the custom data binders and if relevant XML schema types apply to a set of applications. You can share the custom data binders within a set of applications while achieving isolation between different sets of applications.

- **Deploy the custom binders for a specific web module within an application**

Using this pattern ensures that a specific Web module is affected by the deployed custom data binders. This pattern is useful when fine granularity for custom binding is required. You cannot use this pattern with EJB modules because the module and its referenced library belong to the entire application.

Usage patterns

This section reviews deploying custom data binders using one of the three patterns:

- **Server level deployment**

If you deploy the custom data binders at the server level, you need to set the scope attribute of the declared binding provider as `server`. Setting the value to `server` guarantees a higher priority for declared binders if there are conflicts between the server and applications. The custom binding provider JAR file needs to be in the appropriate place to be picked up by the server runtime. Configure the server path and make the custom binding provider JAR file a part of the server classpath. To learn about values used in configuring the server classpath, see the Java virtual machine settings information.

- **Deploying custom data binders for one or more applications**

To deploy custom data binders for one or more applications, set the scope attribute of the declared custom binding provider as `application`. Setting the value to `application` guarantees higher priority binders in case of conflicts between the application and the module. If the custom data binders are used by more than one application, configure a shared library for the applications to reference. To learn about values used in configuring the shared libraries path, see the managing shared libraries information.

- **Deploy the custom data binders for a specific web module within an application**

To deploy custom data binders for a specific web module within an application, set the scope attribute of the declared custom binding provider to the value `module`. The only way to apply the custom data binder for this pattern is to pre-package the custom binding provider JAR file with the web module, for example, place the JAR file in the `/WEB-INF/lib` directory.

Sending implicit SOAP headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to send values in implicit SOAP headers. By modifying your client code to send implicit SOAP headers, you can send specific information within an outgoing web service request.

Before you begin

To complete this task, you need a web services client that you can enable to send implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a portType element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

You cannot manipulate protected SOAP headers. A SOAP header that is declared protected by its owning component, for example, Web Services Security, is not accessible to client applications. An exception occurs if you try to manipulate protected SOAP headers.

About this task

The client application sets properties on the Stub or Call object to send and receive implicit SOAP headers.

Procedure

1. Create a `java.util.HashMap` object.
2. Add an entry to the `HashMap` object for each implicit SOAP header that the client wants to send. The `HashMap` entry key is the `QName` of the SOAP header. The `HashMap` entry value is either an `SAAJ SOAPElement` object or a `String` that contains the XML text of the entire SOAP header element.
3. Set the `HashMap` object as a property on the Stub or Call object. The property name is `com.ibm.websphere.webservices.Constants.REQUEST_SOAP_HEADERS`. The value of the property is the `HashMap`.
4. Issue the remote method calls using the Stub or Call object. The headers within the `HashMap` object are sent in the outgoing message.

A `JAXRPCException` error can occur if any of the following are true:

- The `HashMap` object contains a key that is not a `QName` object or if the `HashMap` object contains a value that is not a `String` or a `SOAPElement` object.
- The `HashMap` object contains a key that represents a SOAP header that is declared protected by the owning component.

Results

You have a JAX-RPC web services client that is configured to send implicit SOAP headers.

Example

The following programming example illustrates how to send two request SOAP headers and receive one response SOAP header within a web services request and response:

```
1 //Create the request and response hashmaps.
2 HashMap requestHeaders=new HashMap();
3 HashMap responseHeaders=new HashMap();
4
5 //Add "AtmUid1" and "AtmUid2" to the request hashmap.
6 requestHeaders.put(new QName("com.rotbank.security", "AtmUid1"),
7   "<AtmUid1 xmlns=\><uid>ROTB-0A01254385FCA09</uid></AtmUid1>");
8 requestHeaders.put(new QName("com.rotbank.security", "AtmUid2"),
9   ((IBMSOAPFactory)SOAPFactory.newInstance()).createElementFromXMLString(
10   "x:AtmUid2 xmlns:x=\"com.rotbank.security\"><x:uid>ROTB-0A01254385FCA09
```

```

        </x:uuid><x:AtmUuid2>"));
11
12 //Add "ServerUuid" to the response hashmap.
13 //If "responseHeaders" is empty, all the SOAP headers are
14 //extracted from the response message.
15 responseHeaders.put(new QName("com.rotbank.security","ServerUuid"), null);
16
17 //Set the properties on the Stub object.
18 stub.setProperty(Constants.REQUEST_SOAP_HEADERS.requestHeaders);
19 stub.setProperty(Constants.RESPONSE_SOAP_HEADERS.responseHeaders);
20
21 //Call the operation on the Stub.
22 stub.foo(parm2, parm2);
23
24 //Retrieve "ServerUuid" from the response hashmap.
25 SOAPElement serverUuid =
26     (SOAPElement) responseHeaders.get(new QName("com.rotbank.security","ServerUuid"));
27
28 //Note: "serverUuid" now equals a SOAPElement object that represents the
29 //following code:
30//"<y:ServerUuid xmlns:y=\"com.rotbank.security\"><x:uuid>ROTB-0A03519322FSA01
    </y:uuid></y:ServerUuid.\"");

```

On lines 2-3, new HashMaps are created that are used for the request and response SOAP headers.

On lines 6-10, the AtmUuid1 and AtmUuid2 headers elements are added to the request HashMap.

On line 15, the ServerUuid header element name, along with a null value, is added to the response HashMap.

On line 18, the request HashMap is set as a property on the Stub object. This causes the AtmUuid1 and AtmUuid2 headers to be added to each request message that is associated with an operation that is invoked on the Stub object.

On line 19, the response HashMap is set as a property on the Stub object. This causes the ServerUuid header to be extracted from each response message that is associated with an operation that is invoked on the Stub object.

On line 22, the web service operation is invoked on the Stub object.

On lines 25-26, the ServerUuid header is retrieved from the response HashMap. The header was extracted from the response message and inserted into the HashMap by the web services engine.

Receiving implicit SOAP headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to receive values from implicit SOAP headers. By modifying your client code to receive implicit SOAP headers, you can receive specific information within an incoming web service response.

Before you begin

To complete this task, you need a web services client that you can enable to receive implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a portType element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

You cannot manipulate protected SOAP headers. A SOAP header that is declared protected by its owning component, for example, Web Services Security, is not accessible to client applications. An exception occurs if you try to manipulate protected SOAP headers.

About this task

The client application sets properties on the Stub or Call object to send and receive implicit SOAP headers.

Procedure

1. Create a `java.util.HashMap` object
2. Add an entry to the `HashMap` object for each implicit SOAP header that the client wants to receive. The `HashMap` entry key is the `QName` of the SOAP header. The `HashMap` entry value is `null`.
3. Set the `HashMap` entry on the Stub or Call object. The property name is `com.ibm.websphere.webservices.Constants.RESPONSE_SOAP_HEADERS`. The value of the property is the `HashMap`.
4. Issue remote method calls against the Stub or Call object. The web services engine extracts the specified response headers from the web services response message and inserts them into the `HashMap`. After the remote method returns, the response headers are accessible from the `HashMap` object.

A `JAXRPCException` error can occur if any of the following are true:

- The `HashMap` contains a key that is not a `QName`.
- The `HashMap` contains a key that represents a SOAP header that is declared protected by the owning component.

Results

You have a JAX-RPC web services client that can receive values from implicit SOAP headers.

Sending transport headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to send application-defined information along with your Web services requests by using transport headers.

Before you begin

You need a JAX-RPC web services client that you can enable to send transport headers.

Sending transport headers is supported only by web services clients, and only supported for the HTTP and JMS transports. The web services client must call the JAX-RPC APIs directly and not through any intermediary layers, such as a gateway function. Sending and retrieving transport headers on the web services server is done through non-web services APIs.

About this task

When using the JAX-RPC programming model, the client must set a property on the Stub or Call object to send values in transport headers. After you set the property, the values are set in all the requests for subsequent remote method invocations against that Stub or Call object until the associated property is set to `null` or the Stub or Call object is discarded.

To send values in the transport headers on outbound requests, modify the client code as follows:

Procedure

1. Create a `java.util.HashMap` object that contains the transport header identifiers.
2. Add an entry to the `HashMap` object for each transport header that you want the client to send.

- a. Set the HashMap entry key to a string that exactly matches the transport header identifier. You can define the header identifier with a reserved header name, such as Cookie in the case of HTTP, or the header identifier can be user defined, such as MyTransportHeader. Certain header identifiers are processed in a unique manner, but no other checks are made as to the header identifier value. To learn more about the HTTP header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as HTTP_HEADER_SET_COOKIE in the com.ibm.websphere.webservices.Constants class.
 - b. Set the HashMap entry value to a string that contains the value of the transport header.
3. Set the HashMap entry on the Stub or Call object using the com.ibm.websphere.webservices.Constants.REQUEST_TRANSPORT_PROPERTIES property. When the REQUEST_TRANSPORT_PROPERTIES property value is set, that HashMap is used on subsequent invocations to set the header values in the outgoing requests. If the REQUEST_TRANSPORT_PROPERTIES property value is set to null, no HashMap is used on subsequent invocations to set header values in outgoing requests. To learn more about these properties, see the transport header properties documentation.
 4. Issue remote method calls against the Stub or Call object. The headers and the associated values from the HashMap are added to the outgoing request for each method invocation. If the invocation uses HTTP, then the transport headers are sent as HTTP headers within the HTTP request. If the invocation uses JMS, then the transport headers are sent as JMS message properties.
If the property is not set correctly, you might experience API usage errors that result in a JAXRPCException error. The following requirements must be met, or the process fails:
 - The property value that is set on the Stub or Call object must be a HashMap object or null.
 - The HashMap must not be empty.
 - Each key in the HashMap must be a String object.
 - Each value in the HashMap must be a String object.

Results

You have a JAX-RPC web services client that is configured to send transport headers.

Retrieving transport headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to retrieve values from transport headers. For a request that uses HTTP, the transport headers are retrieved from HTTP headers found in the HTTP response message. For a request that uses Java Message Service (JMS), the transport headers are retrieved from the JMS message properties found on the JMS response message.

Before you begin

You need a web services client that you can enable to retrieve transport headers.

Retrieving transport headers is supported only by web services clients, and only supported for the HTTP and JMS transports. The web services client must call the JAX-RPC APIs directly and not through any intermediary layers, such as a gateway function. Sending and retrieving transport headers on the web services server is done through non-web services APIs.

About this task

When using the JAX-RPC programming model, the client must set a property on the Stub or Call object in order to retrieve values from the transport headers. After you set the property, values are read from responses for the subsequent method invocations against that Stub or Call instance until the associated property is set to null or the Stub or Call object is discarded.

To retrieve values from the transport headers on inbound responses, modify the client code.

Procedure

1. Create a `java.util.HashMap` object that contains the names of the transport headers to be retrieved from incoming response messages.
2. Add an entry to the `HashMap` for each header that you want to retrieve a value from every incoming response message.
 - a. Set the `HashMap` entry key to a string that exactly matches the transport header identifier. You can define the header identifier with a reserved header name, such as `Cookie` in the case of `HTTP`, or the header identifier can be user-defined, such as `MyTransportHeader`. Certain header identifiers are processed in a unique manner, but no other checks are made to confirm the header identifier value. To learn more about the `HTTP` header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as `HTTP_HEADER_SET_COOKIE` in the `com.ibm.websphere.webservices.Constants` class. The `HashMap` entry value is ignored and does not need to be set. An empty `HashMap`, for example, one that is non-null, but does not contain any keys, causes all the transport headers in the response to be retrieved.
3. Set the `HashMap` entry on the `Stub` or `Call` object using the `com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES` property. When the `HashMap` is set, the `RESPONSE_TRANSPORT_PROPERTIES` property is used in subsequent invocations to retrieve the headers from the responses. If you set the property to null, no headers are retrieved from the response. To learn more about these properties, see the transport header properties documentation.
4. Issue remote method calls against the `Stub` or `Call` object. The values from the specified transport headers are retrieved from the response message and placed in the `HashMap`.

If the property is not set correctly, you might experience API usage errors that result in a `JAXRPCException` error. The following requirements must be met, or the process fails:

- The property value that is set on the `Stub` or `Call` object must be either null or an instance of a `HashMap`.
- All the `HashMap` keys must be a string data type, and the keys must not be null.

Results

You have a JAX-RPC web service that can receive transport headers from incoming response messages.

Assembling web services applications

Assembling web services applications

You can assemble Java-based web services applications using assembly tools.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with the application server.

About this task

After you develop your web service application, you are now ready to assemble the application. Assembling a web service application consists of creating the Java Platform, Enterprise Edition (Java EE) modules that you can deploy onto application servers. The modules are created from code artifacts such as web application archives (WAR) files for JavaBeans applications or enterprise beans Java archive (JAR) files for enterprise beans applications. This packaging and configuring of code artifacts into enterprise application modules (EAR files) or standalone web modules is necessary for deploying the modules onto an application server.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. Assemble your web services enabled bean into the appropriate module.
 - For JavaBeans enabled as web services:
 - a. “Assembling a WAR file that is enabled for web services from Java code” on page 1380.
 - b. “Assembling a web services-enabled WAR file from a WSDL file” on page 1381.
 - For enterprise beans enabled as web services:
 - a. “Assembling a JAR file that is enabled for web services from an enterprise bean.”
 - b. “Assembling a web services-enabled enterprise bean JAR file from a WSDL file” on page 1378.

Note: This product supports packaging enterprise beans in WAR files. If you include a web services-enabled enterprise bean JAR file into a WAR file, you must merge any information in the webservices.xml deployment descriptor files that are in the JAR files into the webservices.xml deployment descriptor in the WEB-INF directory of the WAR file. To learn more, see the EJB content in WAR modules information.

Note: When developing faults for a JAX-WS application, it is a best practice to always include the fault bean that is generated by the JAX-WS tooling in the packaging of your JAX-WS application. However if your application does not use the fault bean classes that are generated by the JAX-WS tooling (that is, you use a bottom-up development approach starting from Java and you choose not to package the fault bean classes), the application server runtime environment dynamically generates the fault beans. Even so, it is a best practice to always package the fault bean.

3. Assemble the web services enabled module into an enterprise archive (EAR) file.
 - “Assembling a web services-enabled WAR into an EAR file” on page 1383.
 - “Assembling an enterprise bean JAR file into an EAR file” on page 1382.
4. Enable the EAR file for EJB modules that contain web services. When the EAR file contains Enterprise JavaBeans (EJB) modules that contain web services, you must run the endptEnabler command-line tool or an assembly tool before deployment to produce a web services endpoint WAR file. This tool is also used to specify whether the web services are exposed using SOAP over Java Message Service (JMS) or SOAP over HTTP.
5. Assemble a web services-enabled WAR file into an EAR file.

Results

You have a web services-enabled EAR file that you can deploy onto the application server.

What to do next

Now you need to deploy the web services-enabled EAR file onto your application server. To learn more, read about deploying web services applications onto application servers

Assembling a JAR file that is enabled for web services from an enterprise bean

You can assemble a web service-enabled enterprise bean Java archive (JAR) file with an assembly tool using artifacts generated from tooling.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

You need the following artifacts that are generated from the WSDL2Java command-line tool to complete this task:

- An assembled enterprise bean JAR file that is not enabled for web services
- A compiled Java class for the service endpoint interface
- A Web Services Description Language (WSDL) file
- The complete `webservices.xml`, `ibm-webservices-bnd.xmi`, and `ibm-webservices-ext.xmi` deployment descriptor, and Java API for XML-based remote procedure call (JAX-RPC) mapping file.

About this task

Assemble a web services-enabled enterprise bean JAR file from Java code by following the actions in the steps for this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.

Results

You have the artifacts required to web service-enable an Enterprise JavaBeans (EJB) module for web services. The artifacts are added to the JAR file. Now you need to configure the deployment descriptors so that you can deploy the web service into the application server run time environment.

Example

The `AddressBook.jar` JAR file contains the following files after assembly. The files added in this task are in bold. These files include the WSDL file, the deployment descriptors, and the JAX-RPC mapping file.

```
META-INF/MANIFEST.MF
META-INF/ejb-jar.xml
addr/Address.class
addr/AddressBook_RI.class
addr/AddressBookBean.class
addr/AddressBookHome.class
addr/Phone.class
addr/StateType.class
addr/AddressBook.class
META-INF/wsd1/AddressBook.wsdl
META-INF/ibm-webservices-bnd.xmi
META-INF/ibm-webservices-ext.xmi
META-INF/webservices.xml
META-INF/AddressBook_mapping.xml
```

What to do next

Assemble the EAR file so that you can deploy the EAR file into WebSphere Application Server.

Assembling a web services-enabled enterprise bean JAR file from a WSDL file

You can assemble a web services-enabled enterprise bean Java archive (JAR) file from a Web Services Description Language (WSDL) file with an assembly tool.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

You need the following artifacts to complete this task:

- An assembled enterprise bean JAR file that contains the Enterprise JavaBeans (EJB) implementation and all classes that generate from the WSDL2Java command-line tool when the role argument is `develop-server` and the container argument is `EJB`.
- A WSDL file
- The complete `webservices.xml`, `ibm-webservices-bnd.xmi` and `ibm-webservices-ext.xmi` deployment descriptors, and the Java API for XML-based remote procedure call (JAX-RPC) mapping file.

About this task

Assemble a web services-enabled enterprise bean JAR file from a WSDL file by following the actions in the steps for this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.

Results

You have the artifacts required to web service-enable an EJB module for web services. The artifacts are added to the JAR file. Now you need to configure the deployment descriptors so that you can deploy the web service into the application server runtime environment.

Example

The `AddressBook.jar` JAR file contains the following files after assembly. The files added in this task are in bold. These files include the WSDL file, the deployment descriptors, and the JAX-RPC mapping file.

```
META-INF/MANIFEST.MF
META-INF/ejb-jar.xml
addr/Address.class
addr/AddressBook_RI.class
addr/AddressBookSoapBindingImpl.class
addr/AddressBookHome.class
addr/Phone.class
addr/StateType.class
addr/AddressBook.class
META-INF/wsd1/AddressBook.wsdl
META-INF/ibm-webservices-bnd.xmi
META-INF/ibm-webservices-ext.xmi
META-INF/webservices.xml
META-INF/AddressBook_mapping.xml
```

What to do next

For JAX-RPC web services, configure the `webservices.xml` deployment descriptor. You need to configure the deployment descriptors for the web service so that WebSphere Application Server can process the incoming web services requests.

Assembling a WAR file that is enabled for web services from Java code

You can assemble a web application archive (WAR) file that is enabled for web services from Java code with an assembly tool.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

For Java API for XML-Based Web Services (JAX-WS) web service applications, you need the portable artifacts that are generated by the `wsgen` command-line tool when starting from a service endpoint implementation to complete this task. The `wsgen` tool processes a compiled service endpoint implementation class as input and generates the following portable artifacts:

- any additional Java Architecture for XML Binding (JAXB) classes that are required to marshal and unmarshal the message contents. The additional classes include classes that are represented by the `@RequestWrapper` annotation and the `@ResponseWrapper` annotation for a wrapped method.
- a WSDL file if the optional `-wsdl` argument is specified. The `wsgen` command does not automatically generate the WSDL file. The WSDL file is automatically generated when you deploy the service endpoint.

For Java API for XML-based RPC (JAX-RPC) web service applications, you need the following artifacts that are generated by the `WSDL2Java` command-line tool to complete this task:

- An assembled WAR file that contains the `web.xml` file, but is not enabled for web services.
- The Java class for the service endpoint interface
- A Web Services Description Language (WSDL) file
- The complete `webservices.xml`, `ibm-webservices-bnd.xmi`, and `ibm-webservices-ext.xmi` deployment descriptors, and the Java API for XML-based remote procedure call (JAX-RPC) mapping file classes that are generated by the `WSDL2Java` command.

About this task

Assemble a web services-enabled WAR file from Java code by following the actions in the steps for this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Import the JavaBeans implementation and the artifacts generated by the command-line tooling into the assembly tool.
4. Migrate WAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.

Results

The artifacts required to enable the web module for web services are added to the WAR file.

What to do next

Now you can assemble the WAR file that is enabled for Web services into an EAR file. To learn more, read about assembling a web services-enabled WAR into an EAR file.

Assembling a web services-enabled WAR file from a WSDL file

You can assemble a web application archive (WAR) file from a Web Services Description Language (WSDL) file that is enabled for web services.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

For Java API for XML-Based Web Services (JAX-WS) web service applications, you need the portable artifacts that are generated by the `wsimport` command-line tool when starting from a WSDL file to complete this task. The `wsimport` tool processes a WSDL file as input and generates the following portable artifacts:

- Service Endpoint Interface (SEI)
- Service class
- Exception classes that are mapped from the `wsdl:fault` class (if any)
- Java Architecture for XML Binding (JAXB) generated type values which are Java classes mapped from XML schema types

You can package the generated artifacts in a web application archive (WAR) file with the WSDL file and schema documents along with the endpoint implementation that you plan to deploy.

For Java API for XML-based RPC (JAX-RPC) web service applications, you need the following artifacts that are generated by the `WSDL2Java` command-line tool to complete this task:

- An assembled WAR file that contains the Enterprise JavaBeans (EJB) implementation, all the classes that generate from the `WSDL2Java` command-line tool and the `web.xml` deployment descriptor file.
- A WSDL file
- The complete `webservices.xml`, `ibm-webservices-bnd.xmi`, and `ibm-webservices-ext.xmi` deployment descriptors, and the Java API for XML-based remote procedure call (JAX-RPC) mapping file.

About this task

Assemble a web services-enabled WAR file from a WSDL file by following the actions in the steps for this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Import the JavaBeans implementation and the artifacts generated by the command-line tooling into the assembly tool.
4. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.

Results

The artifacts required to enable the web module for web services is added to the WAR file.

What to do next

Now you can assemble the WAR file that is enabled for Web services into an EAR file. To learn more, read about assembling a web services-enabled WAR into an EAR file.

Assembling an enterprise bean JAR file into an EAR file

You can assemble an enterprise bean Java archive (JAR) file into an enterprise archive (EAR) file with an assembly tool. Assembling the JAR file, and now the EAR file, are required tasks to enable Java code for web services.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

Before assembling a web services-enabled EAR file you must assemble an enterprise bean JAR file that you want to enable for Web services. To learn more about the artifacts that are needed for the assembly of the enterprise bean JAR file, see the information on assembling an enterprise bean JAR file from Java code that is enabled for web services.

Restriction: Do not include a pound sign (#) in the name of files that are packaged within an application archive. Due to internal processing, the application server fails to correctly deploy the application when a pound sign is included in a file name within the application archive. When this failure occurs, an exception might occur when the application is being processed. Also, parts of the application might be missing after the application is deployed. To address this issue, rename any file names within the application archive so that they do not contain a pound sign.

About this task

To assemble a web services-enabled EAR file:

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Assemble the web services-enabled JAR file into an EAR file. The EAR file can contain an enterprise bean or application client JAR files, WAR files, web applications, and metadata describing the applications or `application.xml` files.

Results

A web services-enabled EAR file.

Example

In the following example, there is an `application.xml` deployment descriptor packaged with a web services-enabled JAR file called `AddressBook.jar` that is packaged into an EAR file called `AddressBook.ear`. The EAR file contains:

META-INF/MANIFEST.MF
META-INF/application.xml
AddressBook.jar

An example of the application.xml deployment descriptor is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE application PUBLIC "-//Sun Microsystems, Inc.//DTD J2EE Application 1.3//EN"
"http://java.sun.com/dtd/application_1_3.dtd">
<application id="Application_ID">
  <display-name>AddressBookJ2WEE</display-name>
  <description>AddressBook EJB Example from Java</description>
  <module id="EjbModule_1">
    <ejb>AddressBook.jar</ejb>
  </module>
</application>
```

What to do next

You can enable an EAR file for EJB modules that contain web services. Then, deploy the EAR file into WebSphere Application Server.

Assembling a web services-enabled WAR into an EAR file

You can assemble a web services-enabled web application archive (WAR) file into an enterprise archive (EAR) file with an assembly tool.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

Restriction: Do not include a pound sign (#) in the name of files that are packaged within an application archive. Due to internal processing, the application server fails to correctly deploy the application when a pound sign is included in a file name within the application archive. When this failure occurs, an exception might occur when the application is being processed. Also, parts of the application might be missing after the application is deployed. To address this issue, rename any file names within the application archive so that they do not contain a pound sign.

About this task

Assemble a web services-enabled WAR file into an EAR file using the steps provided in this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. Assemble the web services-enabled WAR file into an EAR file. Assemble the EAR file that contains the JAR or WAR files. The EAR file can contain an enterprise bean or application client JAR files; web applications or WAR files; and metadata describing the applications or application.xml files. To learn more about how to assemble the WAR file, see the assembling applications documentation.

Results

A web services-enabled EAR file.

Example

In the following example, there is an application.xml deployment descriptor packaged with a web services-enabled JAR file called AddressBook.jar that is packaged into an EAR file called AddressBook.ear. The EAR file contains:

META-INF/MANIFEST.MF
META-INF/application.xml
AddressBook.war

An example of the application.xml deployment descriptor is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>  
<!DOCTYPE application PUBLIC "-//Sun Microsystems, Inc.//DTD J2EE Application 1.3//EN"  
"http://java.sun.com/dtd/application_1_3.dtd">  
<application id="Application_ID">  
  <display-name>AddressBook</display-name>  
  <description>AddressBook Example from Java bean</description>  
  <module id="WebModule_1">  
    <web>  
      <web-uri>AddressBook.war</web-uri>  
      <context-root>/AddressBook</context-root>  
    </web>  
  </module>  
</application>
```

What to do next

Deploy your web services.

Enabling an EAR file for EJB modules that contain web services

When your enterprise archive (EAR) file contains enterprise JavaBeans (EJB) modules that contain Web services, you must run the `endptEnabler` command-line tool or an assembly tool before deployment to produce a web services endpoint web application archive (WAR) file.

Before you begin

Assemble an enterprise Java archive (JAR) file that is enabled for web services from an enterprise bean. The enterprise JAR file is an artifact that is required to build the EAR file.

About this task

You can add router modules to your application that is enabled for web services with either the **endptEnabler** command-line tool or with assembly tools provided with WebSphere Application Server. The tool that you choose to use for this task depends on your preference to work with a command-line tool or a graphical user interface. See the assembly tools documentation to learn how to use assembly tool to accomplish this task.

These tools add one or more router modules to the EAR file for each web service-enabled enterprise JavaBeans (EJB) module contained in the EAR file. A router module provides an endpoint for the web service in a particular EJB module.

You should not modify the contents of the EJB module or the web module that was generated using the **endptEnabler** command-line tool. If you do, an error occurs during run time. The following is an example of the error that displays:

```
"Error]- WWS3142E: Error: Could not find web services engine.]: javax.servlet.ServletException: WWS3142E:  
Error: Could not find web services engine."
```

Each router module supports a specific transport such as HTTP or Java Message Service (JMS). If no enterprise bean JAR modules are located in the EAR file, it is not necessary to use these tools.

Procedure

Enable an EAR file with the **endptEnabler** command-line tool. In its interactive mode, the **endptEnabler** command guides you through the required steps to enable one or more services within an application.

What to do next

Deploy the EAR file into WebSphere Application Server. An assembled EAR file that is enabled for web services is required for deployment.

Enabling an EAR file for web services with the endptEnabler command:

Use the endptEnabler command-line tool to enable an enterprise archive (EAR) file for Enterprise JavaBeans (EJB) modules that contain web services and to specify whether the web services are exposed using SOAP over Java Message Service (JMS) or SOAP over HTTP.

Before you begin

Before doing this task, you need to assemble a web services-enabled enterprise Java archive (JAR) into an EAR file.

About this task

The endptEnabler command-line tool adds one or more router modules to the EAR file for each Java API for XML Web Services (JAX-WS) or Java API for XML-based RPC (JAX-RPC) based Web service-enabled enterprise bean Java archive (JAR) module within the EAR file. A router module provides an endpoint for the web services in a particular enterprise bean JAR module.

Each router module supports a specific transport such as HTTP or JMS. An HTTP router module is a web application archive (WAR) module that provides an HTTP endpoint for each of the web services contained within a particular enterprise bean JAR module. Likewise, a JMS router module is an enterprise bean JAR module that contains a Message Driven Bean (MDB) that serves as the message listener for requests intended for the web service endpoints.

If no enterprise bean JAR modules exist in the EAR file, it is not necessary to use this tool.

Procedure

1. Invoke the endptEnabler script on the Qshell command line from the *app_server_root/bin* directory.
2. Enter the name of the EAR file, when prompted.
3. Enter various input values as requested by the endptEnabler command. You are prompted for various input values for each enterprise bean JAR module that is enabled for web services in the EAR file. Typically, you accept the defaults for each prompt. To learn about the properties of this command, see the endptEnabler command documentation.
 - a. Specify an HTTP router module to transport your EJB-based web service. Use the `-transport http` option to indicate the web service is available using HTTP. One router module is created for each enterprise bean JAR file that contains either JAX-WS or JAX-RPC web services.
 - b. Specify a JMS router module to transport your EJB-based web service. Use the `-transport jms` option to indicate the web service is available using JMS. One router module is created for each enterprise bean JAR file that contains either JAX-WS or JAX-RPC web services.

Results

An HTTP or JMS router module is added to the EAR file for each enterprise bean JAR module within the EAR file that contains web services endpoints. For HTTP, a context-root is configured for the application so that the web service can be invoked through a Web address. The web address used to invoke the web service is:

```
http://host[:port]/<context-root>/services/<port-component-name>
```

Ensure that you install the HTTP or Java Message Service (JMS) router module that you generated with the endptEnabler command onto the same target as your web services enterprise bean JAR files. These

HTTP or JMS router modules are included in your web services application and they need to use the runtime libraries of the application server.

What to do next

Deploy the EAR file onto your application server. An assembled EAR file that is enabled for web services is required for deployment.

If you are using JMS as a transport for your web service requests, define the various JMS objects such as queues, topics, or connection factories, that will be used by your application prior to installing the application.

endptEnabler command:

The **endptEnabler** command is used to enable a set of web services within an enterprise archive (EAR) file. The **endptEnabler** command must run on EAR files containing Enterprise JavaBeans (EJB) modules that are enabled for web services.

Each router module provides a web service endpoint for a particular transport. For example, you can add a HTTP router module so that the web service can receive requests over the HTTP transport. Or, you can add a Java Message Service (JMS) router module so that the web service can receive requests from a JMS queue or topic.

In its interactive mode, the **endptEnabler** command guides you through the required steps to enable one or more services within an application. The **endptEnabler** command makes a backup copy of your original EAR file in the event that you need to remove or add services at a later time. If your EAR file contains an enterprise bean Java archive (JAR) file that is enabled for web services, you must run the **endptEnabler** command before the EAR file is deployed. Otherwise, you do not need to run the command.

endptEnabler usage syntax

Invoke the **endptEnabler** command from the WebSphere Application Server bin directory. The command syntax is presented in the following example:

```
endptEnabler
  [-verbose|-v]
  [-quiet|-q]
  [-help|-h|-?]
  [-properties|-p properties-filename]
  [-transport|-t default-transport]
  [-enableHttpRouterSecurity]
  [-enableClientCertSecurity]
  [ear-filename]
  [-classpath|-cp]
```

All parameters are optional and described in the following list:

- **-verbose, -v**

This parameter details and displays progress messages as the endptEnabler tool processes the EAR file. This command-line option is mapped to the verbose global property.

- **-quiet, -q**

This parameter makes sure that there are no displays of per-module progress messages as the endptEnabler tool processes the EAR file. This command-line option is mapped to the quiet global property.

- **-help, -h, -?**

This parameter displays a brief help message that explains the various options.

- **-properties, -p <properties-filename>**

This parameter reads properties from the *properties-filename* properties and controls the behavior of the endptEnabler tool.

- **-transport, -t <default-transport>**

This parameter specifies the default list of transports for which router modules are created for each enterprise bean JAR file contained in the EAR file. This command-line option is mapped to the defaultTransports global property. The following are examples of this parameter:

```
-transport http (the default)
-t transport jms
-t http,jms
```

- **-enableHttpRouterSecurity**

This parameter enables you to add a security policy for all authenticated users to protect the HTTP router module if all the EJB modules are secured in the enterprise bean JAR file. This command-line option is mapped to the http.enableRouterSecurity global property.

- **-enableClientCertSecurity**

This parameter enables you to add the following login-config stanza to the web.xml file for certificate authentication, instead of basic-auth or form-login. This command-line option is mapped to the http.enableClientCertSecurity global property.

```
<login-config>
  <auth-method>CLIENT-CERT</auth-method>
</login-config>
```

Note: Use the -enableClientCertSecurity parameter with the -enableHttpRouterSecurity parameter.

- **<ear-filename>**

This parameter specifies the name of the EAR file to be processed.

If the *ear-filename* parameter is not entered on the command line, the interactive mode is used. In the interactive mode, you are prompted for the EAR file name, the router module names and other important values as the processing occurs. The following dialog is an example of the endptEnabler interactive mode.

In this dialog, the user input is in fixed width font and the endptEnabler output is in bold.

```
endptEnabler<enter>
WSWS2004I: IBM WebSphere Application Server Release 5
WSWS2005I: Web Services Enterprise Archive Endpoint Enabler Tool.
WSWS2007I: (C) COPYRIGHT International Business Machines Corp. 1997, 2003
WSWS2006I: Please enter the name of your EAR file: AddressBook.ear<enter>

WSWS2003I: Backing up EAR file to: AddressBook.ear~

WSWS2016I: Loading EAR file: AddressBook.ear
WSWS2017I: Found EJB Module: AddressBookEJB.jar

WSWS2029I: Enter http router name for EJB Module AddressBookEJB
[AddressBookEJB_HTTPRouter.war]:<enter>
WSWS2030I: Enter http context root for EJB Module AddressBookEJB
[/AddressBookEJB]:<enter>
WSWS2024I: Adding http router for EJB Module AddressBookEJB.jar.
WSWS2036I: Saving EAR file AddressBook.ear...
WSWS2037I: Finished saving the EAR file.
WSWS2018I: Finished processing EAR file AddressBook.ear.
```

If the *ear-filename* parameter is entered on the command-line, the non-interactive mode is used. In the non-interactive mode, the router module names and other important values are determined from the user-specified properties or default values.

- **-classpath, -cp**

This parameter enables you to specify separate JAR files in the class path for the endptEnabler command. Use this parameter if the EJB file references Java types in separate JAR files that do not exist within the EAR file. You can specify multiple values for this parameter. For example:

```
endptEnabler -classpath C:\MyWork\Utility.jar;D:\SharedFiles\Hello.zip;HelloWorld.jar
```

When you do not specify this parameter, you might encounter an error that is similar to the following message:

WSWS2021I: Skipping the enterprise bean module *module_name* because it contains no web services.

endptEnabler properties

With the **endptEnabler** command you can control its run-time behavior by specifying a set of properties with the `-properties` command-line option. These properties are organized in one of two ways: global and per-module. Global properties affect the overall behavior of the tool as it processes multiple enterprise bean JAR modules within the EAR file. Per-module properties affect the processing of a particular enterprise bean JAR module.

Global properties

Table 149. Global properties for the **endptEnabler** command. Use these global properties of the *endptEnabler* command when enabling a set of web services within an enterprise archive (EAR) file.

Property name	Description	Default value
verbose	Displays detailed progress messages.	False
quiet	Displays only brief progress messages.	False
http.enableRouterSecurity	Enables you to add a security policy for all authenticated users to protect the HTTP router module if all the EJB modules are secured in the enterprise bean JAR file.	False
http.enableClientCertSecurity	Enables you to add the following login-config stanza to the <code>web.xml</code> file for certificate authentication, instead of <code>basic-auth</code> or <code>form-login</code> : <pre><login-config> <auth-method>CLIENT-CERT</auth-method> </login-config></pre>	False
http.routerModuleNameSuffix	Specifies the suffix used to construct default HTTP router module names. The <code>.war</code> extension is added by the endptEnabler command.	<code>_HTTPRouter</code>
jms.routerModuleNameSuffix	Specifies the suffix used to construct default JMS router module names. The <code>.jar</code> extension is added by the endptEnabler command.	<code>_JMSRouter</code>
jms.defaultDestinationType	Specifies the default destination type to use for all JMS router modules that are added to the EAR file. This type is either <code>queue</code> or <code>topic</code> .	<code>queue</code>
defaultTransports	Specifies the default list of transports for which router modules are created. The list can contain the values <code>http</code> and <code>jms</code> . Multiple values are separated by a comma. Examples are: <code>http</code> , <code>jms</code> and <code>http,jms</code> .	<code>http</code>

Per-module properties

The following table describes the per-module properties supported by the **endptEnabler** command. The *ejbJarName* variable refers to the name of an enterprise bean JAR module within the EAR file, without the `.jar` extension.

Table 150. Per-module properties for the **endptEnabler** command. Use these properties of the *endptEnabler* command that affect the processing of a particular enterprise bean JAR module.

Property name	Description	Default value
<code><ejbJarName>.transports</code>	Lists the transports for which router modules are created for a particular enterprise bean JAR file. The list can contain the values <code>http</code> and <code>jms</code> . Multiple values are separated by a comma. Examples are: <code>http</code> , <code>jms</code> and <code>http,jms</code> .	<code>http</code>
<code><ejbJarName>.http.skip</code>	Specifies the flag which bypasses the addition of an HTTP router module, even if it otherwise is added based on other properties. Valid values are <code>true</code> and <code>false</code> .	<code>false</code>

Table 150. Per-module properties for the **endptEnabler** command (continued). Use these properties of the **endptEnabler** command that affect the processing of a particular enterprise bean JAR module.

<ejbJarName>.http.routerModuleName	Specifies the name of the HTTP router module for a particular enterprise bean JAR file.	ejbJarName_HTTPRouter
<ejbJarName>.http.contextRoot	Specifies the context root associated with the HTTP router module for a particular enterprise bean JAR file.	/ejbJarName
<ejbJarName>.jms.skip	Specifies the flag that bypasses the addition of an JMS router module even if it otherwise is added based on other properties. Valid values are true and false.	false
<ejbJarName>.jms.routerModuleName	Specifies the name of the JMS router module for a particular enterprise bean JAR file.	ejbJarName_JMSRouter
<ejbJarName>.jms.activationSpecJndiName	Specifies the Java Naming and Directory Interface (JNDI) name of the activation specification that is configured for the Message Driven Bean (MDB) within the JMS router module.	null
<ejbJarName>.jms.listenerInputPortName	Specifies the name of the listener port to configure for the MDB within the JMS router module. The listener port is configured only if an activationSpecJndiName property is not specified.	null
<ejbJarName>.jms.destinationType	Specifies the JMS destination type associated with the MDB within the JMS router. Valid values are queue and topic.	queue
<ejbJarName>.<port_local_name>.http.urlPattern=<url_pattern_name>	Specifies the URL pattern for ports. If you have EJB module with the indicated name that has a port with the indicated local name, you can specify the HTTP URL pattern with this property. This property only applies to HTTP router modules. It has no affect on JMS router modules.	null

Properties example

Suppose an EAR file contains an enterprise bean JAR file named, StockQuoteEJB.jar that contains web services. The following set of properties can be used to control the **endptEnabler** command run-time behavior as it processes the EAR file:

```
StockQuoteEJB.transports=http,jms
StockQuoteEJB.http.routerModuleName=StockQuoteEJB_HTTP
StockQuoteEJB.http.contextRoot=/StockQuote
StockQuoteEJB.jms.routerModuleName=StockQuoteEJB_JMS
StockQuoteEJB.jms.destinationType=queue
```

endptEnabler examples

The following commands are examples of how the **endptEnabler** command can be used:

```
endptEnabler MyApp.ear
endptEnabler -t jms,http MyApp.ear
endptEnabler -v -properties MyApp.props MyApp.ear
endptEnabler -q -t jms MyApp.ear
endptEnabler -v -t http,jms
```

Assembling web services-enabled clients

Assembling a web services-enabled client JAR file into an EAR file

Now that you have generated your application artifacts, you need to assemble these artifacts to create an enterprise archive (EAR) file that is used in the web services application.

Before you begin

For Java API for XML-Based Web Services (JAX-WS) web service applications, you need the portable artifacts that are generated by the `wsimport` command-line tool when starting from a WSDL file to complete this task. The `wsimport` tool processes a WSDL file as input and generates the following portable artifacts:

- Service Endpoint Interface (SEI)
- Service class
- Exception classes that are mapped from the `wsdl:fault` class (if any)
- Java Architecture for XML Binding (JAXB) generated type values which are Java classes mapped from XML schema types
- An assembled client module that contains the implementation, all of the classes generated by the `wsimport` command-line tool and the `ejb-jar.xml` deployment descriptor or the `application-client.xml` deployment descriptor. This module can be:
 - An application client module that contains the `META-INF/application-client.xml` file.
 - An Enterprise JavaBeans (EJB) module that contains the `META-INF/ejb-jar.xml` file.

For Java API for XML-based RPC (JAX-RPC) web service applications, you need the following artifacts that are generated from the `WSDL2Java` command-line tool to complete this task:

- An assembled client module that contains the implementation, all of the classes generated by the `WSDL2Java` command-line tool and the `ejb-jar.xml` deployment descriptor or the `application-client.xml` deployment descriptor. This module can be:
 - An application client module that contains the `META-INF/application-client.xml` file.
 - An Enterprise JavaBeans (EJB) module that contains the `META-INF/ejb-jar.xml` file.
- The WSDL file that you used to develop the client.
- The templates for the `ibm-webservicesclient-ext.xmi` and `ibm-webservicesclient-bnd.xmi` deployment descriptor, if used.
- A generated Java API for XML-based remote procedure call (JAX-RPC) mapping deployment descriptor.

Restriction: Do not include a pound sign (#) in the name of files that are packaged within an application archive. Due to internal processing, the application server fails to correctly deploy the application when a pound sign is included in a file name within the application archive. When this failure occurs, an exception might occur when the application is being processed. Also, parts of the application might be missing after the application is deployed. To address this issue, rename any file names within the application archive so that they do not contain a pound sign.

About this task

You can use assembly tools included with WebSphere Application Server to assemble web services-enabled client applications.

Assemble the client code and artifacts that enable the application client to access a web service with steps provided:

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.

2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Import the client implementation and the artifacts generated by the command-line tooling into the assembly tool.
4. Migrate JAR files created with the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.
5. Assemble the JAR file into an enterprise archive (EAR) file using typical assembly techniques if the client runs in a container.

Results

You have assembled the artifacts required to enable the client application for web services into an EAR file.

Example

This example of the assembly process uses the `AddressBookClient.jar` JAR file the `AddressBookClient.ear` EAR file:

```
META-INF/MANIFEST.MF
META-INF/application-client.xml
META-INF/wsdl/AddressBook.wsdl
META-INF/AddressBook_mapping.xml

com/ibm/websphere/samples/webservices/addr/Address.class
com/ibm/websphere/samples/webservices/addr/AddressBook.class
com/ibm/websphere/samples/webservices/addr/AddressBookClient.class
com/ibm/websphere/samples/webservices/addr/AddressBookService.class
...other generated classes...
```

After assembling the `AddressBookClient.jar` file into the `AddressBookClient.ear` file, the `AddressBookClient.ear` file contains the following files:

```
META-INF/MANIFEST.MF
AddressBookClient.jar
META-INF/application.xml
```

What to do next

For Java API for XML-Based Web Services (JAX-WS) applications, you are ready to deploy the web services client application.

For Java API for XML-based RPC (JAX-RPC) applications, you need to configure the client deployment descriptor bindings with an assembly tool so that the client can communicate with a web service that is deployed on a server.

Assembling a web services-enabled client WAR file into an EAR file

Now that you have generated your application artifacts, you need to assemble these artifacts to create an enterprise archive (EAR) file that is used in the web services application.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

Restriction: Do not include a pound sign (#) in the name of files that are packaged within an application archive. Due to internal processing, the application server fails to correctly deploy the application when a pound sign is included in a file name within the application archive. When

this failure occurs, an exception might occur when the application is being processed. Also, parts of the application might be missing after the application is deployed. To address this issue, rename any file names within the application archive so that they do not contain a pound sign.

About this task

Assemble the client code and artifacts that enable the application client to access a web service with steps provided:

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Migrate WAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to an assembly tool. Read about importing web application archive (WAR) files using an assembly tool in the Rational Application Developer documentation.

Results

You have assembled the artifacts required to enable the client application for web services into an EAR file.

Example

This example of the assembly process uses the AddressBookWeb.war WAR file and the AddressBook.ear EAR file:

```
WEB-INF/MANIFEST.MF
WEB-INF/web.xml
WEB-INF/wsdl/AddressBook.wsdl
WEB-INF/AddressBook_mapping.xml
WEB-INF/ibm-webservicesclient-ext.xml (optional)
WEB-INF/ibm-webservicesclient-bnd.xml
com/ibm/websphere/samples/webservices/addr/Address.class
com/ibm/websphere/samples/webservices/addr/AddressBook.class
com/ibm/websphere/samples/webservices/addr/AddressBookClient.class
com/ibm/websphere/samples/webservices/addr/AddressBookService.class
...other generated classes...
```

After assembling the AddressBookWeb.war file into the AddressBook.ear file, the AddressBook.ear file contains the following files:

```
META-INF/MANIFEST.MF
AddressBookWeb.war
META-INF/application.xml
```

What to do next

For Java API for XML-Based Web Services (JAX-WS) applications, you are ready to deploy the web services client application.

For Java API for XML-based RPC (JAX-RPC) applications, you need to configure the client deployment descriptor bindings with an assembly tool so that the client can communicate with a web service that is deployed on a server.

Deploying web services

Deploying web services applications onto application servers

After assembling the artifacts required to enable the web module for web services into an enterprise archive (EAR) file, you can deploy the EAR file into the application server.

Before you begin

To deploy Java-based web services, you need an enterprise application, also known as an EAR file that is configured and enabled for web services.

A Java API for XML-Based Web Services (JAX-WS) application does not require additional bindings and deployment descriptors for deployment whereas a Java API for XML-based RPC (JAX-RPC) web services application requires you to add additional bindings and deployment descriptors for application deployment. JAX-WS is much more dynamic, and does not require any of the static data generated by the deployment step required for deploying JAX-RPC applications.

For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

Note: In a mixed node cell, you can only target a JAX-WS enabled enterprise beans module to a server using WebSphere Application Server Version 7.0 and later. However, you can target a JAX-WS enabled web application archives (WAR) module to a server using either WebSphere Application Server Version 7.0 and later or WebSphere Application Server Version 6.1 Feature Pack for Web Services

You can use the `wsdeploy` command with JAX-RPC applications to add WebSphere product-specific deployment classes to a web services-compatible enterprise application enterprise archive (EAR) file or an application client Java archive (JAR) file.

To install or deploy a JAX-WS application, you only need to install the JAX-WS enabled EAR file. If your web services application contains only JAX-WS endpoints, you do not need to run the `wsdeploy` command, as this command is used to process only JAX-RPC endpoints.

Ensure that you have installed the HTTP or Java Message Service (JMS) router module that was generated with the `endptEnabler` command onto the same target as your web services enterprise bean JAR files. These HTTP or JMS router modules are included in your web services application and they need to use the runtime libraries of the application server.

About this task

This task is one of the steps in developing and implementing web services.

You can use either the administrative console or the `wsadmin` scripting tool to deploy an EAR file. If you are installing an application containing web services by using the `wsadmin` command, specify the `-deployws` option for JAX-RPC applications. If you are installing an application containing web services by using the administrative console, select **Deploy WebServices** in the Install New Application wizard. For more information about installing applications using the administrative console, see the installing enterprise application files with the console information.

If your JAX-RPC web services application was previously deployed with the `wsdeploy` command, it is not necessary to specify web services deployment during installation.

The following actions deploy the EAR file with the wsadmin command:

Procedure

1. Start `install_root/bin/wsadmin` from a command prompt.
2. Deploy the EAR file.
 - For JAX-WS web service applications, enter the `$AdminApp install EARfile -usedefaultbindings` command at the wsadmin prompt.
 - For JAX-RPC web service applications, enter the `$AdminApp install EARfile -usedefaultbindings -deployws` command at the wsadmin prompt.

Results

You have a web service installed onto your application server.

Note: While installing web services applications that contain a large number of enterprise beans onto the application server, you might receive out of memory errors. If you receive out of memory errors, increase the heap size of your Java Virtual Machine (JVM). Read about tuning the IBM virtual machine for Java documentation to learn more about tuning the application server environment.

What to do next

You can confirm that the web services application was deployed by entering the web service endpoint URL in a browser, then viewing an informative page. The information page contains the following information:

```
{http://webservice.pli.tc.wssvt.ibm.com}RetireWebServices  
Hello! This is an Axis2 web service!
```

The first line of this information is variable, depending on your web service. The URI in the brackets is the namespace and the string that follows, in this example `RetireWebServices`, is the name of the port used to access the web service.

The next step you might want to consider is to apply security to your web service.

Provide options to perform the web services deployment settings

Use this page to specify options for web services deployment.

This administrative console page is a step in the application installation and update wizards.

To view this page, you must select **Deploy web services** on the **Select installation options** page.

To view this administrative console page, complete the following steps:

1. Click **Applications > New application > application_path** .
2. Select the option to **Show all installation options and parameters** .
3. Click **Next** to get to the **Step: Select installation options** page.
4. Select **Deploy web service**.
5. Click **Next** to get to the **Step: Provide options to perform the web services deployment** page.

You can specify the web services deployment options on this page only when installing or updating an application that uses web services.

The wsdeploy command is supported by Java API for XML-based RPC (JAX-RPC) applications. The Java API for XML-Based Web Services (JAX-WS) programming model that is implemented by the application server does not support the wsdeploy command. If your web services application contains only JAX-WS endpoints, you do not need to run the wsdeploy command, as this command is used to process only JAX-RPC endpoints.

The options that you specify set parameter values for the wsdeploy command. The wsdeploy command adds product-specific deployment classes to a web services-compatible enterprise archive (EAR) file or an application client Java archive (JAR) file. These classes include:

- Stubs
- Serializers and deserializers
- Implementations of service interfaces

The wsdeploy command is run during installation after you click **Finish** on the **Summary** page of the wizard.

Deploy web services option - Classpath:

Specifies entries to add to the CLASSPATH when the generated classes are compiled.

To specify the class paths of multiple entries, you need to separate the entries with a semicolon on Windows platforms and on Linux, Unix, and z/OS platforms, you need to use a colon to separate the entries. This is the same separator that is used with the CLASSPATH environment variable.

This option is the same as the wsdeploy command parameter `-cp class_path`.

Data type	String
Default	null

Deploy web services option - Extension Directories:

Specifies a directory that contains zipped or Java archive (JAR) files. All zipped and JAR files in this directory are added to the CLASSPATH used to compile the generated files.

This option is the same as the wsdeploy command parameter `-jardir directory`.

Data type	String
Default	null

wsdeploy command

Use the wsdeploy command to add WebSphere product-specific deployment classes to a web services-compatible enterprise application enterprise archive (EAR) file or an application client Java archive (JAR) file.

The wsdeploy command is supported by Java API for XML-based RPC (JAX-RPC) applications. The Java API for XML-Based Web Services (JAX-WS) programming model that is implemented by the application server does not support the wsdeploy command. If your web services application contains only JAX-WS endpoints, you do not need to run the wsdeploy command, as this command is used to process only JAX-RPC endpoints.

The deployment classes that are added by the wsdeploy tool to a web services-compatible EAR file or a JAR file include:

- Stubs
- Serializers and deserializers
- Implementations of service interfaces

This deployment step must be performed at least once, and can be performed more often. Deployment can be performed separately using the wsdeploy command, assembly tools, or when the application is installed. When using the wsadmin command for installation, specify the **-deployws** option.

The wsdeploy command operates as noted in the following list:

- Each module in the enterprise application or JAR file is examined.

- If the module contains web services implementations, indicated by the presence of the `webservices.xml` deployment descriptor, the associated Web Services Description Language (WSDL) files are located and the WSDL2Java command is run with the role `deploy-server` option.
- If the module contains web services clients, indicated by the presence of the client deployment descriptor, the associated WSDL files are located and the WSDL2Java command is run with the role `deploy-client` option.
- The files generated by the WSDL2Java command are compiled and repackaged.

See the WSDL2Java command for JAX-RPC applications command information to learn more about the files that are generated for deployment.

When the generated files are compiled, they can reference application-specific classes outside the EAR or JAR file, if the EAR or JAR file is not self-contained. In this case, use either the `-jardir` or `-cp` option to specify additional JAR or zip files to be added to CLASSPATH variable when the generated files are compiled.

wsdeploy command syntax

The command syntax is noted in the following example:

```
wsdeploy Input_filename Output_filename [options]
```

Required options:

- ***Input_filename***
Specifies the path to the EAR or JAR file to deploy.
- ***Output_filename***
Specifies the path of the deployed EAR or JAR file. If *output_filename* already exists, it is silently overwritten. The *output_filename* can be the same as the *input_filename*.

Other options:

- **`-jardir` *directory***
Specifies a directory that contains JAR or zip files. All JAR and zip files in this directory are added to the CLASSPATH used to compile the generated files. This option can be specified zero or more times.
- **`-cp` *entries***
Specifies entries to add to the CLASSPATH when the generated classes are compiled. Multiple entries are separated the same as they are in the CLASSPATH environment variable.
- **`-codegen`**
Specifies to generate but not compile deployment code. This option implicitly specifies the `-keep` option.
- **`-debug`**
Includes debugging information when compiling, that is, use `javac -g` to compile.
- **`-help`**
Displays a help message and exit.
- **`-ignoreerrors`**
Do not stop deployment if validation or compilation errors are encountered.
- **`-keep`**
Do not delete working directories containing generated classes. A message is displayed indicating the name of the working directory that is retained.
- **`-novalidate`**
Do not validate the web services deployment descriptors in the input file.
- **`-trace`**
Displays processing information, including the names of the generated files.
- **`-compliancelevel` *level***
Sets the JDK level for compiler compliance. Valid values include: 1.4, 5.0, 6.0 (default) and 7.0. This flag is optional.

Example The following example illustrates how the options are used with the wsdeploy command:

```
wsdeploy x.ear x_deployed.ear -trace -keep
Processing web service module x_client.jar.
Keeping directory: f:\temp\Base53383.tmp for module: x_client.jar.
Parsing XML file:f:\temp\Base53383.tmp\WarDeploy.wsdl
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java.
Done processing module x_client.jar.
```

Messages

- Flag *-f* is not valid.
Option *f* was not recognized as a valid option.
- Flag *-c* is ambiguous.
Options can be abbreviated, but the abbreviation must be unique. In this case, the wsdeploy command cannot determine which option was intended.
- Flag *-c* is missing parameter *-p*.
A required parameter for an option is omitted.
- Missing *p* parameter.
A required option is omitted.

JAX-WS application deployment model

The administration function of the product is enhanced to support installing and deploying Java Application Programming Interface (API) for XML Web Services (JAX-WS) applications like any other WebSphere Application Server applications.

A JAX-WS application is packaged as a web application archive (WAR) file or a WAR module within an Enterprise Archive (EAR) file. The JAX-WS application deployment model is similar to the Java API for XML Remote Protocol Call (JAX-RPC) web services application model. The main difference between them is that JAX-RPC web services application requires you to add additional bindings and deployment descriptors for application deployment. A JAX-WS application does not require additional bindings and deployment descriptors for deployment. You can deploy your JAX-WS applications as you would deploy any other WebSphere Application Server application.

JAX-WS web services is a rewrite of JAX-RPC web services. The table compares the web services stack for both JAX-WS and JAX-RPC web services.

JAX-RPC web services	JAX-WS web services
Bindings are proprietary	Bindings are based on the open source Java API for XML Bindings (JAXB)
Parsing is proprietary	Parsing is based on the open source Java Specification Request (JSR) 173
No Java annotations support	Support for Java annotations such as @WebService, @WebMethod, @WebParam, @WebResult, and @SOAPBinding

JAX-RPC web services	JAX-WS web services
<p>During deployment, some deployment descriptor files are created in a JAX-RPC based service and client.</p> <p>The following files are created on the services side, when it is an EJB based web service and EJB based module:</p> <ul style="list-style-type: none"> • webservices.xml • <name_of_service>_mapping.xml • ibm-webservices-bnd.xmi • ibm-webservices-ext.xmi <p>When the service is a JavaBeans-based or web module-based service, the following files and deployment descriptors are required:</p> <ul style="list-style-type: none"> • webservices.xml • <name_of_service>_mapping.xml • In the web.xml file, there is no additional content • ibm-webservices-bnd.xmi • ibm-webservices-ext.xmi <p>The web.xml exists in both EJB and JavaBeans based services. However, there is no additional content added to the file during deployment of a Web service application or module.</p>	<p>For JAX-WS web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.</p>

Note: Starting with WebSphere Application Server Version 7.0 and later, Java EE 5 application modules (web application modules version 2.5 or above, or EJB modules version 3.0 or above) are scanned for annotations to identify JAX-WS services and clients. However, pre-Java EE 5 application modules (web application modules version 2.4 or before, or EJB modules version 2.1 or before) are not scanned for JAX-WS annotations, by default, for performance considerations. In the Version 6.1 Feature Pack for Web Services, the default behavior is to scan pre-Java EE 5 web application modules to identify JAX-WS services and to scan pre-Java EE 5 web application modules and EJB modules for service clients during application installation. Because the default behavior for WebSphere Application Server Version 7.0 and later is to not scan pre-Java EE 5 modules for annotations during application installation or server startup, to preserve backward compatibility with the feature pack from previous releases, you must configure either the UseWSFEP61ScanPolicy property in the META-INF/MANIFEST.MF of a web application archive (WAR) file or EJB module or define the Java virtual machine custom property, com.ibm.websphere.webservices.UseWSFEP61ScanPolicy, on servers to request scanning during application installation and server startup. To learn more about annotations scanning, see the JAX-WS annotations information.

Using a third-party JAX-WS web services engine

In certain situations you might need to set up a third-party JAX-WS web services engine. For example, you must set up a third-party JAX-WS web services engine if you need to deploy applications that use a single runtime across various application servers such as WebSphere Application Server, JBoss, and WebLogic, or if you want to build JAX-WS web services applications using third party JAX-WS run-times such as CXF, Axis2, and Metro.

Before you begin

Use of a third-party JAX-WS runtime has limitations. It also requires mandatory configuration changes, and in some cases, it requires manual intervention to resolves issues that occur during deployment and when you run the application. These limitations and issues vary based on the third-party JAX-WS runtime you

decide to use. You should understand the limitations for the third-party JAX-WS runtime you are preparing to use before you configure your system to use that implementation.

The following limitations exist regardless of which third-party JAX-WS implementation you use:

- The WebSphere Application Server runtime restricts usage of application modules that use both the JAX-WS implementation provided with WebSphere Application Server, and an external JAX-WS implementation in the same application EAR file. You must use either the JAX-WS implementation provided with WebSphere Application Server or the external implementation in a single application EAR file. This limitation ensures that the runtime WebSphere Application Server does not conflict with the external third-party JAX-WS implementation.
- You must remove any conflicting JAR files from your application library before you deploy an application that uses an external JAX-WS implementation. Most of the external third-party JAX-WS runtimes include some JAR file libraries that are already installed on WebSphere Application Server. This situation causes conflicts in your application library.
- After an application that uses a third-party JAX-WS runtime is deployed on WebSphere Application Server, it is not recognized as a service client or provider. Therefore, you cannot attach application level policy sets to these applications. You must rely on external runtimes support quality of service. Following is a list of WebSphere Application Server features that are not available if you decide to deploy and run application that uses third-party JAX-WS implementations:
 - WS-Security, WS-RM, and WS-Transactions policy sets
 - WSDM
 - JNDI lookup to retrieve JAX-WS Service or Port Instance.

gotcha: Even though IBM supports the enablement of third party JAX-WS runtimes to run on WebSphere Application Server, and ensures the successful deployment of applications that use such runtimes, IBM does not provide support for resolving JAR file conflict problems, or any problem that a stack trace indicates is in the third party code.

About this task

When you deploy an application EAR file with a third-party JAX-WS implementation on WebSphere Application Server, the WebSphere Application Server runtime must ensure the use of the third-party engine, and disable the use of the existing WebSphere Application Server JAX-WS web services engine.

WebSphere Application Server does not claim support for any of the third-party JAX-WS runtimes, but has tested the deployment and execution of applications that use such runtimes.

You must complete the following steps before you can use an external JAX-WS runtime in an application.

Procedure

1. Set the class loader policy to `Classes loaded with local class loader first (parent last)` at the module level.

Changing the class loader policy to parent last ensures that the external third-party JAX-WS runtime and their dependent library JAR files are first in the class loader search path, thereby ensuring that the third-party implementation is used instead of the WebSphere Application Server.

- a. In the administrative console, click **Applications > Application Types > WebSphere enterprise applications > *application_name* > Class loading and update detection**.
 - b. Under Class reloading options, select **Override class reloading settings for web and EJB modules**.
 - c. Under Class loader order, select **Class loader order** property to `Classes loaded with local class loader first (parent last)`.
 - a. Click **OK**, and then **Save** to save your changes.
2. Turn off web services annotation scanning.

Annotation scanning can be turned off at the application level or at the server level.

To turn off annotation scanning at the application level, set the `DisableIBMJAXWSEngine` property in the `META-INF/MANIFEST.MF` of a WAR file or EJB module to true. Example:

```
Manifest-Version: 1.0
DisableIBMJAXWSEngine: true
```

To turn off web services annotation scanning at the server level:

- a. In the administrative console, go to the Custom properties page for the Java virtual machine.
Servers > Server Types > WebSphere application servers > *server_name*, and then, under Server Infrastructure, click **Java and process management > Process definition > Java virtual machine > Custom properties**
- b. Set the `com.ibm.websphere.webservices.DisableIBMJAXWSEngine` property to true
If this property does not already exist for your configuration, click **New**, and add `com.ibm.websphere.webservices.DisableIBMJAXWSEngine` in the **Name** field and true in the **Value** field.

Results

What to do next

- Deploy and run an application EAR file with a third-party JAX-WS implementation on WebSphere Application Server.

Deploying web services client applications

After you have created an enterprise archive (EAR) file for the web services client application, you can deploy the web services client application into the Application Server.

Before you begin

To deploy a Java-based web services client, you need an enterprise application, also known as an enterprise archive (EAR) file that is configured and enabled for web services.

A Java API for XML-Based Web Services (JAX-WS) application is packaged as a web application archive (WAR) file or a WAR module within an Enterprise Archive (EAR) file. A JAX-WS application does not require additional bindings and deployment descriptors for deployment whereas a Java API for XML-based RPC (JAX-RPC) web services application requires you to add additional bindings and deployment descriptors for application deployment. JAX-WS is much more dynamic, and does not require any of the static data generated by the deployment step required for deploying JAX-RPC applications. For JAX-RPC web services clients, you must configure the client deployment descriptors.

About this task

You can use either the administrative console or the `wsadmin` scripting tool to deploy an EAR file. If you are installing an application containing web services by using the `wsadmin` command, specify the `-deployws` option for JAX-RPC applications.

Use the `wsdeploy` command only with JAX-RPC applications. The `wsdeploy` command is not applicable for JAX-WS applications.

If you are installing an application containing web services by using the administrative console, select **Deploy WebServices** in the Install New Application wizard. Read about installing a new application for more information on using the administrative console.

The following actions deploy the EAR file with the `wsadmin` command:

Procedure

1. Start `install_root/bin/wsadmin` from a command prompt.
2. Deploy the EAR file.
 - For JAX-WS web service applications, enter the `$AdminApp install EARfile "-usedefaultbindings"` command at the `wsadmin` prompt.
 - For JAX-RPC web service applications, enter the `$AdminApp install EARfile "-usedefaultbindings -deployws"` command at the `wsadmin` prompt.

Results

You have a deployed a web service client in the application server runtime environment.

What to do next

Test the web services client. You can now test a web services-enabled managed client EAR file or an unmanaged client JAR file.

Making deployed web services applications available to clients

You can publish WSDL files to the file system. If you are a client developer or a system administrator, you can use WSDL files to enable clients to connect to web services.

Before you begin

The publish WSDL administrative console panel supports both JAX-RPC and JAX-WS services. The publish WSDL panel generates a compression file that contains WSDL files for all modules in an application that contains JAX-WS or JAX-RPC web services. Read about providing the HTTP endpoint URL information to learn how the URL information affects the content of the published WSDL.

To publish a Web Services Description Language (WSDL) file you need an enterprise application, also known as an enterprise archive (EAR) file, that contains a Web services-enabled module and has been deployed into WebSphere Application Server. To learn how to deploy web services, see the [deploying web services applications onto application servers information](#).

About this task

The purpose of publishing the WSDL file is to provide clients with a description of the web service, including the URL identifying the location of the service.

After installing a web services application, and optionally modifying the endpoint information, you might need WSDL files containing the updated endpoint informations to make deployed web services application to be available to clients.

Before you publish a WSDL file, you can configure web services to specify endpoint information in the form of URL fragments to enable full URL specification of WSDL ports. Refer to the tasks describing [configuring endpoint URL information](#).

The WSDL files for each web services-enabled module are published to the file system location you specify. You can provide these WSDL files to clients that want to invoke your Web services.

You can specify endpoint information for HTTP ports, for Java Message Service (JMS) ports, or you can directly access enterprise beans that are acting as web services.

Procedure

1. Configure the web services client bindings.

2. Configure the URL endpoint information for HTTP bindings. Do one of the following depending on what kind of bindings you are using:
 - Configure the URL endpoint information for JMS bindings.
3. Externalize or publish the WSDL file out of the application. You can complete this task in the following ways:
 - Publish a WSDL file with the wsadmin tool.

What to do next

Apply security to your web services. To learn more, see the securing web services applications using message level security information.

Configuring web services client bindings

When a web services application is deployed into WebSphere Application Server, an instance is created for each application or module. The instance contains deployment information for the web module or Enterprise JavaBeans (EJB) module, including client bindings.

Before you begin

Deploy a web service into your WebSphere Application Server instance. Read about deploying web services applications onto application servers.

You must know the topology of the URL endpoint address of the web services servers and which web service the client depends upon. You can view the deployment descriptors in the administrative console to find the topology information. To learn more, see the View web services server deployment descriptors information.

About this task

The client bindings define the Web Services Description Language (WSDL) file name and preferred ports. The relative path of a web service in a module is specified within a compatible WSDL file that contains the actual URL to be used for requests. The address is only needed if the original WSDL file did not contain a URL, or when a different address is needed. For a service endpoint with multiple ports, you need to define an alternative WSDL file name.

The following steps describe how to edit bindings for a web service after these bindings are deployed on a server. When one web service communicates with another web service, you must configure the client bindings to access the downstream web service.

To configure client bindings through the administrative console:

Procedure

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > *application_instance* > **Manage Modules** > *module_instance* > **Web services client bindings**.

3. Find the web service you want to update.

The web services are listed in the **Web Service** field.

4. Select the WSDL file name from the drop down box in the WSDL file name field.
5. Click **Edit** in the Preferred port mappings field to configure the default port to use.
 - a. Specify the port type and the preferred ports in the Port type and Preferred ports fields.

Configuring the preferred port enables you to select an optimal port implementation use non-SOAP protocols. See the RMI-IIOP web services using JAX-RPC information to learn more about using non-SOAP protocols.

- b. Click **Apply** and **OK**.
6. Click **Edit** in the Port information field to configure the request timeout, the overridden endpoint, and the overridden binding namespace for a port.

Configuring the request timeout accommodates complex topologies that can have multiple cascaded Web services that involve multiple hops or long-running services.

You can configure Timeout values based on observed behavior of the overall system as integration proceeds. For example, a web service client might time out because of changing network conditions or the performance of an external web service. When you have applications containing web services clients that timeout, you can change the request time out values for the clients.

You can specify an endpoint URL to override the current endpoint. A client invoking a request on this port uses this endpoint instead of the endpoint specified in the WSDL file. You can specify the **Overridden endpoint URL** value for both Java API for XML-Based Web Services (JAX-WS) clients and Java API for XML-based RPC (JAX-RPC) clients.

Note: The **Overridden endpoint URL** field is applicable for both JAX-WS and JAX-RPC clients. The other fields on this administrative console page are only applicable for JAX-RPC clients.

- a. Click **Apply** and **OK**.

Results

Your web service client bindings are configured.

What to do next

Now you can finish any other configurations, start or restart the application, and verify the expected behavior of the web service.

Web services client bindings:

The client bindings define the Web Services Description Language (WSDL) file name, preferred ports and other port information. Use this page to specify the client bindings and the port mappings for the web services in a module.

A web service can specify the relative path within the module of a compatible WSDL file containing the actual URL to be used for requests. The relative path only needs to be specified if the original WSDL file does not contain a URL or when a different URL is needed. For a service endpoint with multiple ports defined, a preferred mapping specifies the default port to use for a port type.

To view this administrative console page, complete the following steps:

1. Click **Applications > Application Types > WebSphere enterprise applications > *application_name*** .
2. Click **Manage modules > *URI_file_name* > web services client bindings** .

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

Web service:

Identifies the name of this web service. A module can contain one or more web services.

EJB:

Identifies the name of the EJB for the EJB modules.

WSDL file name:

Specifies the WSDL file name, which is relative to the module. Locate the WSDL file name in the drop down menu.

Preferred port mappings:

Specifies and manages the preferred port type mapping for a web service when a particular port type is requested.

Click **Edit** to edit the preferred port mapping information on the **Preferred port mappings** panel.

Port information:

Specifies additional configuration information for the ports of this web service.

Click **Edit** to edit the port information on the **Port information** panel. You can set a request timeout, override an endpoint and override a binding namespace for each client port.

Preferred port mappings:

Use this page to view and manage a preferred portType mapping for a web service.

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

When you have multiple ports that reference the same portType (service endpoint interface), a preferred port specifies the port to use when the `Service.getPort(Class SEI)` method is called with only the service endpoint interface.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > application_name > Manage Modules > module_instance > Web services client bindings > Edit > preferred_port_instance**.

portType:

Specifies the portType.

The preferred port and the portType values are both of the type `java.xml.namespace.QName`.

Preferred port:

Specifies the preferred port to be associated with a particular portType. The `Service.getPort(Class)` method returns the preferred port associated with the specified service endpoint interface class (portType).

The preferred ports available are listed, as well as a value of None, which indicates no preferred port is selected.

Web services client port information:

Use this page to specify a request timeout, override an endpoint, and override a binding namespace for a web services client port.

A web service can have multiple ports. You can view and configure the port attributes for each defined web service port. The web services are listed on the web services client bindings panel.

To view this page, click **Applications > Application Types > WebSphere enterprise applications application_name > Manage Modules > module_instance > Web services client bindings > Edit**.

This administrative console panel applies to both Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services. The **Overridden endpoint URL** field is the only field supported for JAX-WS clients. The other fields are not applicable for JAX-WS clients.

Port:

Specifies the name of a port.

Request timeout:

Specifies the time, in seconds, that a web service client waits for a request to complete on this port. If a timeout is not specified, the default request timeout for the client to wait is 300 seconds. If the value is set at 0 (zero), the timeout used is the default value for the underlying transport mechanism. This field is supported only for JAX-RPC clients.

A typical use for this setting is to customize the client's behavior when it is configured to use a JMS transport to access a web service to make it wait longer for an expected completion. Depending upon network conditions, or the nature of a web service implementation, it might be necessary to tune the timeout.

Overridden endpoint URL:

Specifies the name of an endpoint that is used to override the current endpoint. A client invoking a request on this port uses this endpoint instead of the endpoint specified in the WSDL file. This field is supported for both JAX-WS and JAX-RPC clients.

If an assembled application contains a web service client that is statically bound, the client is locked into using the implementation (service end point) identified in the WSDL file used during development. Overriding the endpoint is an alternative to configuring the deployed WSDL attribute.

The overridden endpoint URI attribute is specified on a per port basis. It does not require an alternative WSDL file within the module. The overridden endpoint URI takes precedence over the deployed WSDL attribute. The client uses this value for the service end point URI or SOAP address, instead of the value in the static client bindings.

Note: You can edit this field if you have managed clients or a mixture of both managed and unmanaged clients. You cannot edit the field if you have unmanaged clients only.

If you do not want a request by an unmanaged JAX-WS client service to be sent to the endpoint URL that is specified in this field, you can specify the `com.ibm.ws.websvcs.unmanaged.client.dontUseOverriddenEndpointUri` Java virtual machine (JVM) system property. For more information about this custom property, read about the Java virtual machine custom properties.

Overridden binding:

Specifies the WSDL file binding namespace URI to use with this port, instead of the namespace in the WSDL file. This binding does not need to exist in the WSDL file. A client invoking a request on this port uses this binding instead of the binding specified in the WSDL file. An overridden binding namespace cannot be specified unless an overridden endpoint is specified. This field is supported only for JAX-RPC clients.

Configuring endpoint URL information for HTTP bindings

Configuring a service endpoint is necessary to connect Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services clients to any web services among the components being assembled or to any external web services.

Before you begin

You can develop an HTTP accessible Java API for XML-based remote procedure call (JAX-RPC) or Java API for XML Web Services (JAX-WS) web service when you have an existing JavaBeans object to enable as a web service. For additional information, see the using HTTP to transport web services requests information.

You can use either the administrative console or property files to configure and manage HTTP endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

This task describes using the administrative console to configure endpoint URL information for HTTP bindings.

About this task

You can specify HTTP URL prefixes for web services that are accessed through HTTP by using the Provide HTTP endpoint URL information panel in the administrative console. The HTTP URL prefixes provide location specific information and are used to form complete endpoint URLs that are included within published WSDL files.

Note: The Provide HTTP panel in the administrative console displays modules that contain Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services. You can use the Provide HTTP panel to provide URL information for both types of web services, however, the panel does not indicate which type of service that you are working with.

To configure these prefixes with the administrative console:

Procedure

1. Open the administrative console.
2. Click **Applications > Enterprise Applications > *application_instance* > Provide HTTP endpoint URL information**.
3. Specify the URL prefixes for the web service.

In this step you specify the protocol (HTTP or HTTPS), as well as the *host_name* and *port_number* used in the endpoint URL. You can select a prefix from a predefined list, by selecting the default HTTP URL prefix, or you can use a custom HTTP URL prefix.

- a. Select **Default HTTP URL prefix** or **Custom HTTP URL Prefix**.

If you select the default HTTP URL prefix, a list provides you with a choice of endpoint URL prefixes. The list is a combination of two sets of ports in the module: the virtual host ports and the application server ports. Use a prefix from this list if the application server of the web service is accessed directly. Select a value and also select the check box of the modules to use the prefix.

If you want to use a custom HTTP URL prefix, type the value in the field. Select the check box to use in the prefix.

If you configure a custom HTTP URL prefix, you must also configure the custom JVM property, `com.ibm.ws.webservices.enableHTTTPrefix` in the administrative console and set the value to `true`. You must restart the application server after this custom property has been defined so that this property is used by the system. Setting this custom JVM property is required so the custom HTTP endpoint prefix information is correctly displayed in the `?WSDL` query that is returned from the browser and the URL field of the WSDL file that is returned to the client. If this custom property is not defined with the value of `true`, the custom HTTP URL prefix is not reflected in the WSDL file that the service returns to the client. To learn how to configure this custom JVM property, see the documentation on configuring additional HTTP transport properties using the JVM custom property panel in the administrative console.

Note: The `com.ibm.ws.webservices.enableHTTPPrefix` custom property applies to JAX-RPC web services applications only.

- b. Click **Apply**.

The URL prefix, whether default or custom, is copied to the selected module HTTP URL prefix field.

- c. Click **OK**. The URL information is saved to your workspace.

Results

You have specified the partial URL information that is used to form the target endpoint addresses in the WSDL files that are published using the Publish WSDL files panel.

What to do next

Configure any other URL endpoint information for Java Message Service (JMS) bindings and direct Enterprise JavaBeans (EJB) access. Then publish the WSDL files to make the deployed web services application available to clients.

Provide HTTP endpoint URL information:

Use this page to specify endpoint URL prefix information for web services accessed by HTTP. Prefixes are used to form complete endpoint addresses included in published Web Services Description Language (WSDL) files.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *application_name* > Provide HTTP endpoint URL information**.

You can specify a portion of the endpoint URL to be used in each web service module. In a published WSDL file, the URL defining the target endpoint address is found in the location attribute of the port's `soap:address` element.

This administrative console page applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

In addition to the using the administrative console, you can use property files to configure and manage HTTP endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

Specify endpoint URL prefixes for web services:

Specifies the *protocol* (either `http` or `https`), *host_name*, and *port_number* to be used in the endpoint URL.

You can select a prefix from a predefined list using the **HTTP URL prefix** or **Custom HTTP URL prefix** field.

The URL prefix format is *protocol://host_name:port_number*, for example, `http://myHost:9045`. The actual endpoint URL that is contained in a published WSDL file consists of the prefix followed by the module's context-root and the web service url-pattern, for example, `http://myHost:9045/services/myService`.

Select default HTTP URL prefix:

Specifies the drop down list associated with a default list of URL prefixes. This list is the intersection of the set of ports for the module's virtual host and the set of ports for the module's application server. Use items from this list if the web services application server is accessed directly.

To set an HTTP endpoint URL prefix, select **Select default HTTP URL prefix** and select a value from the drop down list. Select the check box of the modules that are to use the prefix and click **Apply**. When you click **Apply**, the entry in the **Select default HTTP URL prefix** or **Select custom HTTP URL prefix** fields, depending on which is selected, is copied into the **HTTP URL prefix** field of any module whose check box is selected.

Select custom HTTP URL prefix:

Specifies the *protocol*, *host*, and *port_number* of the intermediate service if the web services in a module are accessed through an intermediate node, for example the web services gateway or an IHS server.

To set a custom HTTP endpoint URL prefix, you must also configure the custom JVM property, `com.ibm.ws.webservices.enableHTTTPrefix` in the administrative console and set the value to true. Setting this custom JVM property is required so the custom HTTP URL is correctly populated in the URL field of the WSDL file that is returned to the client. If this custom JVM property is not configured, the custom HTTP URL prefix is not in the URL field in the copy of the WSDL file that the service returns to the client. To learn how to configure this custom JVM property, see the documentation on configuring additional HTTP transport properties using the JVM custom property panel in the administrative console. You must restart the application server after this custom property has been defined so that this property is used by the system.

After the `com.ibm.ws.webservices.enableHTTTPrefix` custom JVM property is configured, select **Select custom HTTP URL prefix** and enter a value. Select the check box of the modules that are to use the prefix and click **Apply**. When you click **Apply**, the entry in the **Select default HTTP URL prefix** or **Select custom HTTP URL prefix** fields, depending on which is selected, is copied into the **HTTP endpoint URL prefix** field of any module whose check box is selected.

Note: The `com.ibm.ws.webservices.enableHTTTPrefix` custom property applies to JAX-RPC web services applications only.

Configuring endpoint URL information for JMS bindings

WebSphere Application Server supports the use of the Java Message Service (JMS) API to transport web services requests, as an alternative to using HTTP.

Before you begin

The application server supports use of the Java Message Service (JMS) API to transport web services requests, as an alternative to HTTP transport. Read about using the Java Message Service (JMS) to transport web services requests to learn more about how web service clients and servers can communicate through JMS queues and topics instead of through HTTP connections.

You can use either the administrative console or property files to configure and manage JMS endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

This task describes using the administrative console to configure endpoint URL information for JMS bindings.

About this task

Configuring a service endpoint is necessary to connect web service clients to any web services among the components being assembled or to any external web services. You can configure the endpoint URL information for JMS during application installation

In this task, enter the JMS endpoint URL prefix to use for each web service-enabled Enterprise JavaBeans (EJB) Java archive (JAR) file that belong to the application. The JMS endpoint URLs are included in the Web Services Description Language (WSDL) files published for clients to use.

You can specify HTTP URL prefixes for web services that are accessed through HTTP by using the Provide HTTP endpoint URL information panel in the administrative console. These prefixes are used to form complete endpoint addresses that are included in WSDL files when published.

You can specify JMS URL prefixes by using the Provide JMS and EJB endpoint URL information panel in the administrative console during or after application installation.

This task applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

To configure JMS URL prefixes:

Procedure

1. Open the administrative console.
2. Click **Applications > Enterprise Applications > *application_instance* > Provide JMS and EJB endpoint URL information**.
3. Locate the list of web services modules that are accessible through JMS transport.
4. Type the JMS URL fragment in the **URL fragment** field. Enter a URL fragment that is a prefix to the initial URL part that is obtained by examining the deployment information of the Web service. See the usage scenario following this task for more information.

The value that you enter is used to define the location attribute of the port soap:address element within the WSDL file that is published using the *application_name_ExtendedWSDLFiles.zip* or the *application_name_WSDLFiles.zip* file on the Publish WSDL zip files panel.

Results

You have a web service that is accessible through the JMS transport and configured with JMS bindings.

Example

Suppose an application called StockQuoteService contains an EJB JAR file that is named StockQuoteEJB, which contains one or more web services that are accessible through the JMS transport.

See the using SOAP over Java Message Service to transport web services information to review the example that defines a queue with the Java Naming and Directory Interface (JNDI) name of `jms/StockQuote_Q`, and a connection factory with the JNDI name of `jms/StockQuote_CF`, for your application.

In this example, you specify the following string as the JMS URL prefix within the Provide JMS and EJB endpoint URL information panel:

```
jms:/queue?destination=jms/StockQuote_Q&connectionFactory=jms/StockQuote_CF
```

The WSDL publisher uses this partial URL string to produce the actual JMS URL for each port component that is defined in the module. The `targetService=<port_name>` string is added to the end of the JMS URL, for example:

```
jms:/queue?destination=jms/StockQuote_Q&connectionFactory=jms/StockQuote_CF&targetService=getQuote
```

The published WSDL file is used by clients to invoke the web service.

What to do next

Publish the WSDL files to make the deployed web services application available to clients.

Provide JMS and EJB endpoint URL information:

Use this page to specify Java Message Service (JMS) and Enterprise JavaBeans (EJB) endpoint URL fragments for web services accessed through SOAP and Java Message Service (JMS) or directly as enterprise beans. Fragments are used to form complete endpoint addresses included in published Web Services Description Language (WSDL) files.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *application_name* > Provide JMS and EJB endpoint URL information.**

You can specify a fragment of the endpoint URL to be used in each web service module. In a published WSDL file, the URL defining the target endpoint address is found in the location attribute of the port's soap:address element.

If you are using web services modules that are configured to use JMS or configured to access enterprise beans directly, these modules are listed on this panel.

This administrative console page applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

In addition to the using the administrative console, you can use property files to configure and manage JMS and EJB endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

URL fragment for JMS:

Specifies a URL fragment for web services accessed through a JMS transport. You can enter a value that is used to define the soap:address of a web service. When WSDL files are published, a URL is formed using this fragment and is contained in the WSDL files.

The URL fragment that is entered as a value is a prefix to which the targetService property is appended to form a complete JMS URL endpoint. The default value is obtained by examining the installed service's deployment information, for example, `jms:jndi:jms/MyQueue&jndiConnectionFactoryName=jms/MyCF`.

This information is obtained from the configured JMS endpoint for the web service, which is a Message Driven Bean (MDB) defined by the **endpointEnabler** command-line tool. You can modify the URL fragment, for example, by adding properties. The URL fragment is combined with the targetService property to form the complete URL, for example, `jms:jndi:jms/MyQueue&jndiConnectionFactoryName=jms/MyCF&priority=5&targetService=GetQuote`.

URL fragment for EJB:

Specifies a URL fragment for web services accessed through an EJB binding. You can enter a value used to define the location attribute of the port's generic:address element of a Web service. This port address is contained in the WSDL compression file when the compression file is published using the `application_name_ExtendedWSDLFiles.zip` field on the **Publish WSDL zip file** panel.

The URL fragment value entered is a suffix, which is appended to the initial part of the URL obtained by examining the web service's deployment information. For example, the following URL fragment can be obtained from the EJB's deployment information: `wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome`.

In this case, you can enter the following information in the URL fragment field, `jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2809`, which results in this endpoint URL, `wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome&jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2809`.

Configuring endpoint URL information to directly access enterprise beans

WebSphere Application Server supports directly accessing an enterprise bean as a web service, as an alternative to using HTTP or Java Message Service (JMS) to transport requests between the server and the client. The Enterprise JavaBeans (EJB) module that is used as a web service contains a Web Services Description Language (WSDL) file that contains EJB bindings.

Before you begin

To learn more about the process of directly accessing an enterprise bean as a web service, see the using WSDL EJB bindings to invoke an EJB from a JAX-RPC web services client.

You can use either the administrative console or property files to configure and manage EJB endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

This task describes using the administrative console to configure endpoint URL information to directly access enterprise beans.

About this task

Configuring a service endpoint is necessary to connect web service clients to any web services among the components being assembled or to any external web services.

You can specify web address endpoints of the enterprise bean for web services that are accessed directly by EJB bindings using the Provide JMS and EJB endpoint web address information panel in the administrative console.

If you have modules that are configured for using direct EJB access, the modules are listed on the Provide JMS and EJB endpoint web address information panel in the administrative console. The EJB endpoint is only available in the WSDL that is found in the `application_name_ExtendedWSDLfiles.zip` file.

You can specify a fragment of the endpoint web address for the web services in each module.
