Submit the task to a scheduler for creation, as described in the Submitting a task to a scheduler topic.

Scheduling long-running tasks

The default behavior of the scheduler is designed to run business logic that runs for a short period of time. In version 6.0.2 and later, two API methods on the com.ibm.websphere.scheduler.TaskInfo interface help avoid some of the problems that can occur when running tasks for an extended time.

About this task

The TaskInfo.setQOS method supports tasks with both a transactional and non-transactional quality of service. When running tasks that run for long periods, you can use the TaskInfo.QOS_ATLEASTONCE quality of service to run the task without a global transaction. This process prevents various timeout issues

that can occur when resources are held by a long-running transaction. See the Transactions and schedulers topic for details on the `TaskInfo.setQOS` method and how it can be used.

Using the `TaskInfo.setExpectedDuration` method, the scheduler can to adjust timeout values, as appropriate, for a given task for all qualities of service. The application server attempts to adjust various run-time parameters to accommodate the estimated run time of the task.

Procedure

1. When you assemble the `TaskInfo` object with the Scheduler API or the `WASScheduler` MBean, use the following methods on the `TaskInfo` interface:
 - a. Set the quality of service.
 - 1) If the task must be transactional, use the `setQOS` method with the `QOS_ONLYONCE` constant, which is the default, if not set.
 - 2) If the task does not need to be transactional, use the `setQOS` method with the `QOS_ATLEASTONCE` constant.
 - b. Set the expected duration.
 - 1) Use the `setExpectedDuration` method to set the expected duration of the task in seconds.
2. Schedule the task using the `Scheduler.create` method.

What to do next

View the Access schedulers topic.

Receiving scheduler notifications

Various notification events are generated by a scheduler when it performs an operation on a task. These notifications events are described in this topic.

About this task

The notification events generated by a scheduler when it performs a task include:

Scheduled

A task has been scheduled.

Purged

A task has been permanently deleted from the persistent store.

Suspended

A task was suspended.

Resumed

A task was resumed.

Complete

A task has run completely. If it was a repeating task, all repeats have been performed.

Cancelled

A task has been cancelled. It will not run again.

Firing

A task is prepared to run.

Fired

A task completed successfully.

Fire failed

A task could not run successfully.

To receive notification events, call the `setNotificationSink()` method on the `TaskInfo` interface before creating the task. The `setNotificationSink()` method enables you to specify the session bean that is to act as the callback, and a mask that restricts which events are generated.

Procedure

1. Create a NotificationSink session bean. Create a stateless session bean that implements the handleEvent() method in the com.ibm.websphere.scheduler.NotificationSink remote interface. The handleEvent() method is called when the notification is fired. The Home and Remote interfaces can be set as follows in the bean's deployment descriptor:

```
com.ibm.websphere.scheduler.NotificationSinkHome  
com.ibm.websphere.scheduler.NotificationSink
```

The NotificationSink interface defines the following method:

```
public void handleEvent(TaskNotificationInfo task) throws java.rmi.RemoteException;
```

2. Specify the notification sink session bean prior to submitting the task to the Scheduler using the TaskInfo interface API setNotificationSink() method.

If using the WASScheduler MBean API to set the notification sink, then the Java™ Naming and Directory Interface (JNDI) name must be the fully-qualified global JNDI name. Using a JavaServer Pages (JSP) file, servlet or Enterprise JavaBeans (EJB) component, look up and set the notification sink on a task as shown in the following code example:

```
TaskInfo taskInfo = ...  
Object o = new InitialContext().lookup("java:comp/env/ejb/NotificationSink");  
NotificationSinkHome home = (NotificationSinkHome )javax.rmi.PortableRemoteObject.narrow  
(o,NotificationSinkHome.class);  
taskInfo.setNotificationSink(home,TaskNotificationInfo.ALL_EVENTS);
```

You can also use the wsadmin tool to set the notification sink callback session bean as shown in the following JACL scripting example:

```
# Use the NotificationSinkHome's Global JNDI name  
# Assume that a TaskInfo was already created...  
$taskInfo setNotificationSink "ejb/MyNotificationSink"
```

3. Specify the event mask. The event mask is specified as an integer bitmap. You can either use an individual mask such as TaskNotificationInfo.CREATED to receive specific events, TaskNotificationInfo.ALL_EVENTS to receive all events or a combination of specific events. If you use Java, your script might look like the following example:

```
int eventMask = TaskNotificationInfo.FIRED | TaskNotificationInfo.COMPLETE;  
taskInfo.setNotificationSink(home,eventMask);
```

If you use JACL, your script might look like the following example:

```
# Set the event mask based on two event constants.  
set eventmask [expr [java::field com.ibm.websphere.scheduler.TaskNotificationInfo FIRED] +  
[java::field com.ibm.websphere.scheduler.TaskNotificationInfo COMPLETE]]  
  
# Set our Notification Sink based on our global JNDI name AND event mask.  
# Note: We need to use the full method signature here since the  
# method resolver can't always detect the right method.  
$taskInfo {setNotificationSink String int} "ejb/MyNotificationSink" $eventmask
```

Results

A notification sink bean is now set on a TaskInfo object and can now be submitted to a scheduler using the create method.

Submitting a task to a scheduler

This topic describes the process of submitting a task to a configured scheduler.

Before you begin

This task assumes that you have already configured a scheduler and created and configured a TaskInfo object that calls a session bean or sends a Java Messaging Service (JMS) message.

About this task

Once you have developed a `TaskInfo` object that contains all relevant data for a task, submit the task to a scheduler for creation. When the task is created, the scheduler runs it.

Procedure

Create the task. After you configure `TaskInfo`, submit it to the appropriate scheduler, using the Scheduler API `create` method.

```
// Create the TaskInfo using the Scheduler that you already looked up and print out the Task ID
TaskStatus ts = scheduler.create(taskInfo);
System.out.println("Task created with id: " + ts.getTaskId())
```

You can also create the task using the `wsadmin` tool as shown in the following JACL scripting example:

```
# Create the TaskInfo using the WASScheduler MBean that you previously located and print out the Task ID
puts "Creating the task..."

set params [java::new {java.lang.Object[]} 1]
$params set 0 $taskInfo

set sigs [java::new {java.lang.String[]} 1]
$sigs set 0 com.ibm.websphere.scheduler.TaskInfo

set taskStatus [java::cast com.ibm.websphere.scheduler.TaskStatus [$AdminControl invoke_jmx $sched0
create $params $sigs]]

puts "Task Created. TaskID= [$taskStatus getTaskId]"

puts $taskStatus
```

When the call to the `create()` method is complete, the task exists in the persistent store and is run at the time specified in the `TaskInfo` object. If a global transactional context is present on the thread, and the `create()` transaction rolls back or is aborted, the task does not run.

The `TaskStatus` object, which has been returned by the call to the `create()` method, contains information about the state of the task, as well as the task ID. The task ID is the unique identifier for this task, and is required if the task is to be suspended, resumed, cancelled, and so on, at a later time.

Tip: The `TaskStatus` object is only a snapshot of the current state of the task. Use the `Scheduler.getStatus()` method to receive the current state when needed.

Task management methods using a scheduler

The scheduler provides several task management methods.

When a task is created by calling the `create()` method on a scheduler, a `TaskStatus` object is returned to the caller. The `TaskStatus` object contains the task ID, which is a unique identifier. The Scheduler API and `WASScheduler` MBean define several additional methods that pertain to the management of tasks, each of which accepts the task ID as a parameter. The following task management methods are defined:

suspend()

Suspends a task. The task does not run until it has been resumed.

resume()

Resumes a previously suspended task.

cancel()

Cancels a task. The task is not run and cannot be resumed.

purge()

Permanently deletes a cancelled task from the persistent store.

getStatus()

Returns the current status of the task.

Use the following API example to create and cancel a task:

```
//Create the task.
TaskInfo taskInfo = ...
TaskStatus status = scheduler.create(taskInfo);

//Get the task ID
String taskId = status.getTaskId();

//Cancel the task. Specify the purgeAlso flag so that the task does not remain in the persistent store
scheduler.cancel(taskId,true);
```

Use the following example JACL script operations in the wsadmin tool to create and cancel a task:

```
set jndiName sched/MyScheduler

# Map the JNDI name to the mbean name. The mbean name is
# formed by replacing the / in the jndi name with . and prepending
# Scheduler_
regsub -all_{/} $jndiName "." jndiName
set mbeanName Scheduler_.$jndiName

puts "Looking-up Scheduler MBean $mbeanName"
set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]
puts $sched

# Get the ObjectName format of the Scheduler MBean
set schedO [$AdminControl makeObjectName $sched]

# Create a TaskInfo object...
# (Some code excluded...)
set params [java::new {java.lang.Object[]} 1]
$params set 0 $taskInfo

set sigs [java::new {java.lang.String[]} 1]
$sigs set 0 com.ibm.websphere.scheduler.TaskInfo

set taskStatus [java::cast com.ibm.websphere.scheduler.TaskStatus [$AdminControl invoke_jmx $schedO
  create $params $sigs]]

set taskID [$taskStatus getTaskId]
puts "Task Created. TaskID= $taskID"

# Cancel the task using the Task ID from the TaskStatus object returned during create.
set params [java::new {java.lang.Object[]} 1]
$params set 0 false

set sigs [java::new {java.lang.String[]} 1]
$sigs set 0 java.lang.boolean

set taskStatus [java::cast com.ibm.websphere.scheduler.TaskStatus [$AdminControl invoke_jmx $schedO
  cancel $params $sigs]]
```

Transactionality. All methods of the Scheduler API are transactional. If a global transactional context is present, it is used to perform the operation. If an unexpected exception is thrown, the transaction is marked to roll back, and the caller must handle it appropriately. If an expected or declared exception is thrown, the transaction remains intact and the caller must choose to roll back or to commit the transaction. If the transaction is rolled back at some point, all scheduler operations performed within the transaction are also rolled back.

If a local transactional context is present, it is suspended and a new global transactional context begins. Likewise, if no transactional context is active, a global transactional context begins. In both cases, if an unexpected exception is thrown, the transaction rolls back. If a declared exception is thrown, the transaction is committed.

If another thread is concurrently modifying the task in question, a `TaskPending` exception is thrown. This is because schedulers lock the database optimistically. The calling application can then retry the operation.

Task management functions may block if the task is currently running. Because the scheduler guarantees that each task will run only once, the task must be locked for the duration of a running task. Likewise, if a task is changed using one of the management functions but the global transaction is not committed, any other management functions issued from another transaction for that task will be blocked.

A stateless session bean task's `TaskHandler.process()` method can change its own state. However, the task must be running within the same transaction as the scheduler. Therefore, a running task can only modify itself if it is using the `Required` or `Mandatory` container managed transaction types. If the `RequiresNew` transaction type is specified on the `process()` method, all management functions will deadlock.

All methods defined by the Scheduler API are described in the API documentation.

Identifying tasks that are currently running

When a task runs, the task database record is locked until the task completes. This topic describes how to determine whether or not a task is running.

About this task

Prior to version 6.0.2, all tasks ran in a single global transaction. This process not only prevented the task from running more than once successfully, but it also blocked all attempts at reading the state of the task, since each task used read-committed transaction isolation.

There are two methods for determining whether a task is running:

1. **NotificationSink**

A `NotificationSink` EJB can be set on the task using the `setNotificationSink` method on the `TaskInfo` object. The `NotificationSink` bean can then log the life cycle of the task to a separate database record in a custom table. This would result in a history log of the task that can be queried independently from the scheduler. This solution works for all versions of the scheduler service. See the `Receiving Scheduler Notifications` topic for details.

2. **Delayed Execution and Uncommitted Read**

In Version 6.0.2 and later, two behaviors enable the scheduler find and retrieve API methods, such as `getTask`, `getTaskStatus` or `findTasksByName`, to see the current state of the task without blocking. To see the current state of the task, including its uncommitted running state, complete the following steps:

Procedure

1. Enable read-uncommitted transaction isolation for the scheduler read methods to prevent these methods from blocking while a task is running. To set the default transaction isolation for read methods, see the `Configuring scheduler default transaction isolation` topic for read operation details.

Important: If the scheduler database does not support uncommitted reads, such as Oracle, it might not be possible to determine if a task is running unless you use the `QOS_ATLEASTONCE` quality of service.

2. Use the `TaskInfo.EXECUTION_DELAYEDUPDATE` option on the `TaskInfo.setTaskExecutionOptions` method to force the scheduler to write the `TaskStatus.RUNNING` state to the task when that task starts running.

Stopping tasks that are failing

The scheduler runs tasks in a global transactional context, by default. If a task is failing due to a configuration problem or application error, the scheduler attempts to retry the task until the scheduler failure threshold is reached. This topic describes how to stop the tasks that are failing.

Before you begin

The default scheduler failure threshold is 10 and can be configured using the `taskFailureThreshold` scheduler custom property. To configure this custom property, in the administrative console click **Resources > Schedulers > *scheduler_name*** and click **Custom Properties**. Valid values are non-negative integers, that is, integers greater than 0.

About this task

When the task reaches the failure threshold, the scheduler stops running the task until the scheduler daemon is restarted using the `WASScheduler` MBean, the scheduler fails over to another server, or until the scheduler is resumed using the `resume` method on the Scheduler API or `WASScheduler` MBean.

Procedure

1. Cancel or suspend a transactional (`QOS_ONLYONCE`) task that is continually failing. This action can be difficult if the scheduler has not yet reached the failure threshold. The cancel and suspend Scheduler API methods or `WASScheduler` MBean operations block until the task fails or the method times out, while waiting for a database lock and throws a `TaskPending` exception. If this occurs, then the application can retry the cancel or suspend operation until it completes.
2. Alternatively, stop the scheduler daemon using the `stopDaemon` operation on the `WASScheduler` MBean to avoid running the task multiple times, and run the cancel or suspend operation while it is stopped. While the daemon is stopped, the scheduler does not run tasks. However, all MBean operations and API methods are still available.

Scheduler tasks and Java EE context

When a task is created using the Scheduler API `create()` method, the Java Platform, Enterprise Edition (Java EE) thread context of the creator is stored with the scheduled task. When the task runs, the original Java EE thread context is reapplied to the thread before calling the customer `TaskInfo` instance.

The scheduler service utilizes the asynchronous beans deferred start mechanism to propagate Java EE service context information to a task when it runs. The amount of service context information that is propagated is controlled by the Service Context settings on the `WorkManager` configuration object that schedulers reference. For example, security and internationalization service contexts can be enabled. See the [Using asynchronous beans](#) topic for details on how to configure the Application Server to propagate these service contexts.

Transactions and schedulers

The scheduler runs a task in a single global transaction, by default. You can use the `QOS_ONLYONCE` or `QOS_ATLEASTONCE` quality of service to specify whether the task runs as a single unit of work once or as independent transactions.

Transaction behavior when running a task

Because the scheduler runs a task in a single global transaction, by default, the transaction is open until the task completes or fails. The resources involved in that transaction are subject to various timeouts and the thread of the task could be identified as hung if the task runs for a long period of time that can span many minutes or hours.

QOS_ONLYONCE

Scheduled tasks execute only one time successfully when using the `QOS_ONLYONCE` quality of service. This action is accomplished by grouping all of the work done in the task as a single unit of work. When each task fires, the following events occur in a single global transactional context:

1. The context of the application that created the task is applied to the thread.
2. A global transactional context is started.

3. The next fire time and start-by time are calculated using the UserCalendar bean or the DefaultUserCalendar.

Important: If using the TaskInfo.setTaskExecutionOptions method with the TaskInfo.EXECUTION_DELAYEDUPDATE option, this step will occur after the record is updated.

4. The task database task record is updated in the database with the state of the next task or deleted if the task is complete and the task's auto-purge setting is true.
5. The task database record is updated in the database with the state of the next task or deleted if the task is complete and the task's auto-purge setting is true. If the EXECUTION_DELAYEDUPDATE option is used, the database will not reflect the next state of the task, but the current state with the TaskStatus.RUNNING state set.
6. If the NotificationSink bean is set, a FIRING notification is fired.
7. The BeanTaskInfo or MessageTaskInfo object starts.
8. If the task fails and the NotificationSink bean is set, a FIRE_FAILED notification is fired on a separate transaction.
9. If the task's NotificationSink bean is set, then the various notifications are fired as required.
10. If the EXECUTION_DELAYEDUPDATE option is used for the task, the database will be updated a second time with the next state of the task.
11. The global transaction is committed.

Because all events belonging to a task are executed in a single global transactional context, consider the following points in order to avoid transaction-related errors:

- Each resource participating in the task transaction must be two-phase XA capable. This includes the Java Database Connectivity (JDBC) datasource that is configured for the scheduler, any Java Messaging Service (JMS) services used by the MessageTaskInfo objects, and any resources used within any of the UserCalendar, TaskHandler, or NotificationSink beans that have a transaction setting of "Required".
- One resource can be single-phase, if last participant support is enabled for the application that created the transaction. Enable last participant support using an assembly tool. You can also enable last participant support through the administrative console. See the Last participant support extension settings topic for details.

All unexpected exceptions are logged to the activity log and all events participating in the task global transaction are rolled back. This includes changes to the task database record, which force the task to be executed again when the scheduler daemon polls the database during the next poll cycle. The UserCalendar, TaskHandler, and NotificationSink beans can choose not to participate in the global transaction by configuring the bean transaction setting to "Requires new".

QOS_ATLEASTONCE

Scheduled tasks that use the QOS_ATLEASTONCE quality of service do not have a single transactional context. In this case, each calendar calculation, event notification and database update occurs in an independent transaction:

1. The context of the application that created the task is applied to the thread.
2. The task's database record is updated with the RUNNING state of the task.
3. UserCalendar, NotificationSink beans are called.
4. The BeanTaskInfo or MessageTaskInfo is started.
5. Result notifications are sent.
6. The database is updated with the next state of the task, if the task has not been changed since the RUNNING state was written.

If a failure happens after the RUNNING state is written to the database and before the result is written, then the task may run more than one time.

When using QOS_ATLEASTONCE, all NotificationSink, UserCalendar and TaskHandler beans must not mandate a transaction (TX_MANDATORY), since there is no global transaction available when the task runs. The EJB components use "Required" or "Requires new" container managed transaction or a bean managed transaction.

Transaction behavior when using the Scheduler API methods or WASScheduler MBean operations

All Scheduler interface methods participate in a single global transactional context. If a global transactional context is already present on the thread when the create(), suspend(), resume(), cancel(), and purge() methods are executed, then the existing global transaction is used. Otherwise, a new global transaction begins.

If the method participates in the global transaction of the caller and an unexpected error occurs, then the transaction is marked to roll back. If the exception is a declared exception, then the exception is resubmitted to the caller, and the transaction is left alone for the caller to commit or roll back.

If the method starts its own global transaction and any exception occurs, then the transaction is rolled back, and the exception is resubmitted to the caller.

Scheduler task user authorization

The scheduler service uses the asynchronous beans deferred start mechanism to propagate Java Platform, Enterprise Edition (Java EE) service context information to a task when it runs. If you plan to secure your application using the JAAS security context of the administrative security mechanism built into WebSphere Application Server, create each task with the correct credentials on the thread.

Tasks run with specified security credentials using the following methods:

- Using the Java Authentication and Authorization Service (JAAS) security context on the thread at the time the task was created. See the Deferred start and security topic in the Asynchronous beans section of the information center.
- Using the setAuthenticationAlias method on the TaskInfo object.
- Using a specified security identity on a BeanTaskInfo task TaskHandler EJB method.

The scheduler service utilizes the asynchronous beans deferred start mechanism to propagate Java EE service context information to a task when it runs. The amount of service context information that is propagated is controlled by the Service Context settings on the WorkManager configuration object that schedulers reference. For example, security and internationalization service contexts can be enabled. See the Using asynchronous beans topic for details on how to configure the Application Server to propagate these service contexts.

Java Authentication and Authorization Service Security context

If you intend to secure your application using the JAAS security context of the administrative security mechanism built into WebSphere Application Server, create each task with the correct credentials on the thread. Once each task has the correct credentials, you can disable and re-enable administrative security without causing any security problems. If you do not set the security context when the scheduler task is created and you later enable security in the target application, a security exception or error message might display, such as SECJ0053E. You might also see this error if two or more schedulers on different servers are accessing the same tables (a clustered or redundant scheduler) and the security settings are different.

The JAAS security context is not set if any of the follow conditions are true:

- Administrative security is disabled.
- Security context policies are disabled on the configured WorkManager for the associated scheduler configuration.

- A credential is not set on the thread. For example, the enterprise bean or servlet that is used to create the scheduled task is not secured, or the task was created with a WASScheduler MBean.

If any of the previously mentioned conditions are true when you create your task and you need to enable security on your application server or application, you must complete the following steps for each task:

1. Find the task using the Scheduler API find or get methods.
2. Cancel the task using the Scheduler.cancel() API.
3. Recreate the task using the Scheduler.create() method with security enabled. Submitting a task that was retrieved from the scheduler using the find or get methods will automatically generate a new task ID.

Security order of precedence

As previously noted, there are three ways of verifying that a task will run with the correct user credentials. In addition, each TaskInfo implementation may have its own way of supplying user information, which may override the standard mechanisms. If multiple methods are used, refer to the following lists to determine which security mechanism is going to be employed.

BeanTaskInfo

1. TaskHandler security identity set on the process() method of the Enterprise Java Bean file
2. Authentication Alias set with the setAuthenticationAlias method on the TaskInfo interface
3. JAAS security context

MessageTaskInfo

1. Authentication Alias set with the setAuthenticationAlias method on the TaskInfo interface
2. The setUsername and setPassword methods on the MessageTaskInfo interface. See the [Deprecated features](#) article for more information.

Securing scheduler tasks

Scheduled tasks are protected using application isolation and administrative roles. This topic describes how to secure scheduler tasks.

About this task

If a task is created using a Java Platform, Enterprise Edition (Java EE) server application, only applications with the same name can access those tasks. Tasks created with a WASScheduler MBean using the AdminClient interface or scripting are not part of a J2EE application and have access to all tasks regardless of the application with which they were created. Tasks created with a WASScheduler MBean are only accessible from the WASScheduler MBean API and are not accessible from the Scheduler API.

If the Use Administration Roles attribute is enabled on a scheduler and administrative security is enabled on the Application Server, all Scheduler API methods and WASScheduler MBean API operations enforce access based on the WebSphere Administration Roles. If either of these attributes are disabled, then all API methods are fully accessible by all users.

Procedure

1. Enable security for all application servers.
2. Manage schedulers.

Scheduler configuration or topology

The scheduler uses a database to persist information concerning which tasks to run and when. Errors might occur when changing the application server topology or when changing the application or server configuration. When you change the configuration or topology, carefully consider how this action affects the scheduler.

Restricting security

If you created tasks with an application server while security is disabled, and you later decide to enable security, then the scheduler might have difficulty running tasks. When you create a task, the security context of the application thread is automatically stored with the task. If security is not stored with the task (see Scheduler task user authorization), and you later enable security on the server or application where the task is to run, then the following errors might be logged:

```
SECJ0053E: Authorization failed for /UNAUTHENTICATED while invoking (Home)com/ibm/websphere/scheduler
/TaskHandler create:2 securityName: /UNAUTHENTICATED;accessID: UNAUTHENTICATED is not granted any of
the required roles: MySecurityRole
```

Before you enable security on the server or application, determine if any tasks might be adversely affected. If so, use the Scheduler API or WASScheduler MBean to cancel the tasks and recreate them after you configure security.

Application server topology changes

The scheduler stores `javax.ejb.HomeHandle` objects for `TaskHandler`, `NotificationSink` and `UserCalendar` *homes* when the task is created. When you run the task later, these home handles are reinflated and used to access the Enterprise JavaBeans (EJB) component home. When the home handle references an EJB on a single-server environment, the home handles have affinity to that server. When the home handle references an EJB component on a cluster, then the home handles have affinity to the cluster.

If the application server or the Workload Managed (WLM) cluster that a home handle is referencing is not available, then the scheduler fails to run the task, and the following error is logged:

```
SCHD0063E: A task with ID 123 failed to run on Scheduler MyScheduler (sched/MyScheduler) because of
an exception: {cause of failure}
```

If you upgrade the application server to a cluster, or if the Object Request Broker (ORB) `ORB_LISTENER_ADDRESS` is not set to a fixed port number (see [Configuring Inbound Transports](#)), then the task might also fail, since the information stored within the home handle does not have the appropriate information to find the desired server.

Upgrading to a scheduler cluster

A scheduler cluster (not to be confused with a WLM cluster) is a collection of scheduler configurations on different application servers that share the same Java Naming and Directory Interface (JNDI) name, Java Database Connectivity (JDBC) data source and table prefix. If you upgrade a stand-alone scheduler to a clustered scheduler, then the application and any associated resources that the application requires must be available. If this is not the case, the scheduled task fails to run and error messages might be logged:

```
SCHD0103W: The Scheduler MyScheduler (sched/MyScheduler) was unable to run task 123 because the
application or module is unavailable: MyTaskHandlerEJB
```

To avoid issues with application availability and achieve optimal results, use the same servers in a scheduler cluster as those used in a WLM cluster.

Reusing scheduler tables

When changing any topology, moving from development to production environments, or making any configuration changes that make the environment more restrictive, you might get optimal results if you use

a different set of scheduler tables. Reusing scheduler tables that have scheduled tasks from previous releases without careful planning might cause problems:

- EJB components running on unexpected application servers.
- Tasks failing to run due to invalid or missing security credentials.
- Tasks failing to run due to invalid or missing Java Platform, Enterprise Edition (Java EE) context information.

Diagnosing such problems is challenging and requires analyzing logs on all servers that have a scheduler installed and configured. When the problem tasks are located, the tasks can be cancelled using the Scheduler APIs, or the tables can be dropped and recreated.

Scheduler interface

Use the `com.ibm.websphere.scheduler.Scheduler` Java object (in the Java™ Naming and Directory Interface (JNDI) namespace for the scheduler configuration) to find a reference to a scheduler and work with tasks.

A `com.ibm.websphere.scheduler.Scheduler` Java object exists in the JNDI namespace for each scheduler configuration. A reference to a scheduler can be obtained by performing a lookup on the JNDI name; however, the lookup is valid only from the server process where the scheduler instance exists. Once a reference has been obtained, tasks can be created, suspended, cancelled, and so on, if the caller has access to the scheduler instance.

For details, see Interface Scheduler in the API documentation.

Task creation

The task is created in the persistent store using the global transactional context of the caller, if present. See the topic, “Transactions and schedulers” on page 666, for more details. Since this is a transactional operation, the task cannot be run or modified from another thread until the current transaction commits.

Task modification

Tasks that have been created can be modified with the `suspend()`, `resume()`, `cancel()`, and `purge()` methods. These methods take a Task Identifier string as a parameter, which is generated by the `create()` method and can be found in the `TaskStatus` object. If a task is currently running or being modified by another thread, an operation that attempts to modify the state of the task might block on the attempt. Tasks can only be modified by the same application (EAR file) that was used to create the task.

Task execution

Tasks are run in the thread pool specified by the configuration's work manager. If multiple schedulers are configured to share the same database tables, the scheduler is clustered and the tasks found in the table can be run on any of the schedulers, whether or not they are in the same server, node, or cell.

Task lookup

Tasks can be located using the `Name` property that was assigned at creation time. This is useful when you need to modify a group of tasks and tracking individual task ID's is not convenient.

TaskInfo interface

`TaskInfo` objects contain the information to create a task. Several implementations of this class exist, one for each type of task that can run.

Available `TaskInfo` implementations include:

BeanTaskInfo

Calls a stateless session bean.

MessageTaskInfo

Sends a Java™ Messaging Service (JMS) message to a queue or publishes a message to a topic. For details, see the Interface `TaskInfo` in the API documentation.

After a `TaskInfo` object is created, it can be submitted to the scheduler for task creation by calling the `Scheduler.create()` method.

For details about the `TaskInfo` interface, see the API documentation .

TaskHandler interface

A task handler is a user-defined stateless session bean that is called by tasks created using a `BeanTaskInfo` object.

A task handler bean uses the following home and remote interfaces, which are defined in the deployment descriptor using an assembly tool, such as Rational Application Developer:

```
com.ibm.websphere.scheduler.TaskHandlerHome  
com.ibm.websphere.scheduler.TaskHandler
```

The bean itself needs to implement the `process()` method defined in the remote interface. For details, see the `Interface TaskHandler` in the API documentation.

Once an EJB is created and available within an enterprise application, it can be called by a `BeanTaskInfo` task when it runs. See the `Developing a task that calls a session bean` topic for details.

When a task is created using a `BeanTaskInfo` object, the `process()` method on the `TaskHandler` session bean is called whenever the task runs. Because the `TaskStatus` object for the task is passed as a parameter to the `process()` method, the task handler determines different types of information about the task, such as when it will fire next, the number of repeats remaining, its name and its ID.

The `process()` method can also change its own state. However, the task must be running within the same transaction as the scheduler. Therefore, a running task can only modify itself if it is using the **Required** or **Mandatory** container managed transaction types. If the **Requires New** transaction type is specified on the `process()` method, all management functions deadlock.

NotificationSink interface

A notification sink is a user-defined stateless session bean that is called when the task changes state.

A notification sink bean uses the following home and remote interfaces, which are defined in the deployment descriptor using an assembly tool, such as Rational Application Developer:

```
com.ibm.websphere.scheduler.NotificationSinkHome  
com.ibm.websphere.scheduler.NotificationSink
```

The bean itself needs to implement the `handleEvent()` method defined in the remote interface. For details, see the `Interface NotificationSink` section of the API documentation and the `Receiving scheduler notifications` topic.

A `NotificationSink` provides an event notification callback on a task-by-task basis. A notification sink is set on the `TaskInfo` interface, using the `setNotificationSink()` method. If a notification sink is not specified on a task, all notifications are lost; however, the status of a task can be determined by calling the `getStatus()` method from the `Scheduler` interface. A notification callback is made for each of the following events:

- Scheduled
- Suspended
- Resumed
- Fired
- Firing
- Fire Failed
- Complete
- Purged

UserCalendar interface

A user calendar is a user-defined stateless session bean that is called by tasks when they need to calculate date-related values.

A user calendar bean uses the following home and remote interfaces, which are defined in the deployment descriptor using an assembly tool, such as Rational Application Developer:

```
com.ibm.websphere.scheduler.UserCalendarHome  
com.ibm.websphere.scheduler.UserCalendar
```

The bean itself needs to implement the `applyDelta()`, `validate()`, and `getCalendarNames()` methods defined in the remote interface. For details, see the Interface `UserCalendar` in the API documentation.

User calendars are used to calculate time intervals, such as the time between task runs. A user calendar takes a `java.util.Date` object, applies the interval string and returns the resulting `java.util.Date`.

User calendars are set with the `setUserCalendar()` method on the `TaskInfo` interface and called by the scheduler run-time code when a delta calculation is necessary.

The following methods on the `TaskInfo` interface specify delta strings that use the user calendar for calculation:

- `setStartTimeInterval`
- `setStartByInterval`
- `setRepeatInterval`

Default user calendar

If a user calendar has not been specified using the `TaskInfo.setUserCalendar()` method, a default user calendar is used. The default calendar allows for simple delta specifications, such as seconds, minutes, hours, days, and months. See the API documentation for details on the default calendar. The default user calendar also provides a CRON-like syntax for calculating absolute times versus time deltas.

Calendar identifiers

A single user calendar can contain logic for multiple calendars. A calendar specifier string determines which calendar is used. For example, a calendar bean might be implemented to recognize the interval *day*. However, the identifier also recognizes two calendar implementations: *standard* (for a standard calendar day) and *business* (for a business day).

Internationalization and time zones

Scheduler makes use of the `java.util.Date` class when storing and processing dates. Internally, this class saves the time as milliseconds since the Epoch, Greenwich Mean Time. Since the `Date` is not converted to local time until converted to a string, the scheduler respects the time zone where the date was created.

Writing user calendars

Because the user calendar is a stateless session bean, the same Java Platform, Enterprise Edition (Java EE) programming model available to other session beans is available to the user calendar as well.

Chapter 20. Developing security

Secure specific types of applications, such as applications that include portlets, SIP servlets, enterprise beans, web services. Find security information that focuses on specific concerns, such as messaging, transaction support, naming and directory, data access.

Developing extensions to the WebSphere security infrastructure

WebSphere Application Server provides various plug points so that you can extend the security infrastructure. Extending this security infrastructure involves several activities including: Developing custom user registries, developing applications that use programmatic security, and customizing web application login forms.

About this task

The following topics are covered in this section:

Procedure

- Developing custom user registries
- Developing applications that use programmatic security
- Customizing web application login forms
- Customizing application login forms with Java Authentication and Authorization Service (JAAS)
- Securing transports with Java Secure Sockets Extension (JSSE) and Java Cryptography Extension (JCE) programming interfaces
- Implementing tokens for security attribute propagation
- Implementing a custom authentication provider using JASPI

Developing stand-alone custom registries

This development provides considerable flexibility in adapting WebSphere Application Server security to various environments where some notion of a user registry, other than LDAP or Local OS, already exists in the operational environment.

Before you begin

WebSphere Application Server security supports the use of stand-alone custom registries in addition to the local operating system registry, stand-alone Lightweight Directory Access Protocol (LDAP) registries, and federated repositories for authentication and authorization purposes. A stand-alone custom-implemented registry uses the UserRegistry Java interface as provided by WebSphere Application Server. A stand-alone custom-implemented registry can support virtually any type or notion of an accounts repository from a relational database, flat file, and so on.

Implementing a stand-alone custom registry is a software development effort. Implement the methods that are defined in the `com.ibm.websphere.security.UserRegistry` interface to make calls to the appropriate registry to obtain user and group information. The interface defines a general set of methods for encapsulating a wide variety of registries. You can configure a stand-alone custom registry as the selected repository when configuring WebSphere Application Server security on the Global security panel.

In WebSphere Application Server Version 8.5, make sure that your implementation of the stand-alone custom registry does not depend on any WebSphere Application Server components such as data sources, Enterprise JavaBeans (EJB) and Java Naming and Directory Interface (JNDI). You can not have this dependency because security is initialized and enabled prior to most of the other WebSphere Application Server components during startup. If your previous implementation used these components,

make a change that eliminates the dependency. For example, if your previous implementation used data sources to connect to a database, instead use the JDBC `java.sql.DriverManager` interface to connect to the database.

If your previous implementation uses data sources to connect to a database, change the implementation to use Java database connectivity (JDBC) connections.

Procedure

1. Implement all the methods in the interface except for the `CreateCredential` method, which is implemented by WebSphere Application Server.
2. Build your implementation.

IBM i To compile your code, you need the `com.ibm.ws.runtime.jar` and the `com.ibm.ws.security.crypto.jar` files in your class path. For example:

```
javac -extdirs app_server_root/java/ext:/QIBM/UserData/Java400/ext:/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit/jre/lib/ext:app_server_root/lib -classpath app_server_root/plugins/com.ibm.ws.runtime.jar:app_server_root/plugins/com.ibm.ws.security.crypto.jar com/ibm/websphere/security/FileRegistrySample.java
```

The previous lines of code for your class path are one continuous line.

3. **IBM i** Create a `classes` subdirectory in your profile for custom classes. For more information, see “Creating a classes subdirectory in your profile for custom classes.”
4. Copy the class files that are generated in the previous step to the product class path.
IBM i The preferred location is the `app_server_root\classes` directory. For more information, see “Creating a classes subdirectory in your profile for custom classes.” Copy the class files to all the product process class paths including the cell, all of the node agents.
5. To configure your implementation using the administrative console, follow the steps in topics about configuring stand-alone custom registries. This step is required to implement custom user registries.

Example

Viewing stand-alone custom registries.

Use these links to view registry examples.

A *stand-alone custom registry* is a customer-implemented registry that implements the `UserRegistry` Java interface, as provided by WebSphere Application Server. A custom-implemented registry can support virtually any type or form of an accounts repository from a relational database, flat file, and so on. The custom registry provides considerable flexibility in adapting WebSphere Application Server security to various environments where some form of a registry, other than a federated repository, Lightweight Directory Access Protocol (LDAP) registry, or local operating system registry, already exist in the operational environment.

What to do next

If you enable security, make sure that you complete the remaining steps:

1. Save and synchronize the configuration and restart all of the servers.
2. Try accessing some J2EE resources to verify that the custom registry implementation is correct.

Creating a classes subdirectory in your profile for custom classes

You can create a `classes` subdirectory in the profile in which you can place your custom security components.

About this task

WebSphere Application Server resides in two main default directories:

app_server_root

Contains product Java archive (JAR) files, scripts, and the master copies of the administrative application, samples, and properties files. This directory is referred to by the `${WAS_INSTALL_ROOT}` WebSphere Application Server variable. Do not modify files in these directories.

profile_root

Contains user profile data, that is a combination of unique files and symmetric links to files in the `app_server_root` directories. This directory is referred to by the `${USER_INSTALL_ROOT}` WebSphere Application Server variable.

The product files are separated for the following reasons:

- To separate the files that run the product from files that you can modify, either by editing or through the administrative interfaces. When you apply product fixes, the separate directory structure keeps these fixes from overwriting user-defined data, such as modifying properties files.
- To isolate configuration differences between profiles. For example, each profile subdirectory can have its own copy of the Java 2 Security files, by which the profile can have a unique Java 2 Security configuration, rather than all profiles conforming to one product-wide configuration only.

WebSphere Application Server provides application programming interfaces (APIs) that you can use to develop your own security components for WebSphere Application Server. For example, you can create custom user registries, custom trust association interceptors, and custom login modules. For other WebSphere Application Server platforms, place the files for your custom security component in the `app_server_root/classes` directory.

For the IBM i platform, this action is not recommended because the files are accessible from all server profiles, which might not be a desirable or secure behavior. Additionally, the `classes` directory is granted Java 2 Security AllPermissions authority, which might not be appropriate for your secured environment.

Therefore, create a `/classes` subdirectory in the profile in which you can place your custom security components. Additionally, the QEJBSVR user profile must have authority to the directory. To create the `classes` subdirectory and grant the necessary authorities, complete the following steps:

Procedure

1. Use the **CRTDIR DIR** command to create the `classes` subdirectory. For example, run the following command from the CL command line:

```
CRTDIR DIR('profile_root/classes')
```

Alternatively, you can map or mount a workstation network drive to the iSeries server and create the `/classes` subdirectory from the workstation command prompt or a graphical file explorer utility such as Windows Explorer.

2. If you are using Java 2 Security, update your `profile_root/properties/server.policy` file to grant the appropriate Java 2 Security permissions to the `classes` in the directory. For more information about the permissions, see “server.policy file permissions” on page 703.
3. If you create the directory from the Qshell command line, explicitly grant the QEJBSVR user profile read, write, and run (*RWX) authority to the directory because the proper authorities are not inherited from the parent directory. For example, run the following command:

```
CHGAUT OBJ('profile_root/classes') USER(QEJBSVR) DTAUT(*RWX)
```

Results

You have a `classes` subdirectory that you can use for custom classes.

Result.java file

This module is used by user registries in WebSphere Application Server when calling the getUsers and getGroups methods. The user registries use this method to set the list of users and groups and to indicate if more users and groups in the user registry exist than requested.

            CustomRegistryException,
            RemoteException;

    /**
     * Returns the realm of the registry.
     *
     * @return the realm. The realm is a registry-specific string indicating
     *         the realm or domain for which this registry
     *         applies. For example, for OS400 or AIX this would be the
     *         host name of the system whose user registry this object
     *         represents.
     *         If null is returned by this method realm defaults to the
     *         value of "customRealm". It is recommended that you use
     *         your own value for realm.
     **/

```

```

* @exception CustomRegistryException if there is any registry specific
*   problem
* @exception RemoteException as this extends java.rmi.Remote
**/
public String getRealm()
    throws CustomRegistryException,
           RemoteException;

/**
* Gets a list of users that match a pattern in the registry.
* The maximum number of users returned is defined by the limit
* argument.
* This method is called by administrative console and by scripting (command
* line) to make available the users in the registry for adding them (users)
* to roles.
*
* @parameter pattern the pattern to match. (For example., a* will match all
*   userSecurityNames starting with a)
* @parameter limit the maximum number of users that should be returned.
* This is very useful in situations where there are thousands of
*   users in the registry and getting all of them at once is not
*   practical. A value of 0 implies get all the users and hence
*   must be used with care.
* @return a Result object that contains the list of users
*   requested and a flag to indicate if more users exist.
* @exception CustomRegistryException if there is any registry specific
*   problem
* @exception RemoteException as this extends java.rmi.Remote
**/

 * are modeled using groups.
 *
 * In rare situations where you are working with a user registry and it is not
 * practical to get all of the users from any of your groups (for example if
 * a large number of users exist) you can create the NotImplementedException
 * for those particular groups. Make sure that if the WebSphere Business
 * Integration Server Foundation Process Choreographer is installed (or

```

```

* if installed later) that the users are not modeled using these particular groups.
* If no concern exists about the staff assignments returning the users from
* groups in the registry it is recommended that this method be implemented
* without throwing the NotImplementedException.
*
* @parameter groupSecurityName that represents the name of the group
* @parameter limit the maximum number of users to return.
*     This option is very useful in situations where lots of
*     users are in the registry and getting all of them at
*     once is not practical. A value of 0 means get all of
*     the users and must be used with care.
* @return a Result object that contains the list of users
*         requested and a flag to indicate if more users exist.
* @deprecated This method will be deprecated in the future.
* @exception NotImplementedException create this exception in rare situations
*         if it is not practical to get this information for any of the
*         groups from the registry.
* @exception EntryNotFoundException if the group does not exist in
*         the registry
* @exception CustomRegistryException if any registry-specific
*         problem occurs
* @exception RemoteException as this extends java.rmi.Remote interface
**/
public Result getUsersForGroup(String groupSecurityName, int limit)
    throws NotImplementedException,
        EntryNotFoundException,
        CustomRegistryException,
        RemoteException;

/**
* This method is implemented internally by the WebSphere Application Server
* code in this release. This method is not called for the custom registry
* implementations for this release. Return null in the implementation.
*
* Note that because this method is not called you can also return the
* NotImplementedException as the previous documentation says.
*
**/
public com.ibm.websphere.security.cred.WSCredential
    createCredential(String userSecurityName)
    throws NotImplementedException,
        EntryNotFoundException,
        CustomRegistryException,
        RemoteException;
}

```

Implementing custom password encryption

WebSphere Application Server supports the use of custom password encryption.

Before you begin

An installation can implement any password encryption algorithm it chooses.

About this task

Complete the following steps to implement custom password encryption:

Procedure

1. Build your custom password encryption class. An example of a custom password encryption class follows.

```

// CustomPasswordEncryption
// Encryption and decryption functions
public interface CustomPasswordEncryption {
    public EncryptedInfo encrypt(byte[] clearText) throws PasswordEncryptException;
    public byte[] decrypt(EncryptedInfo cipherTextInfo) throws PasswordEncryptException;
    public void initialize(HashMap initParameters);
};
// Encapsulation of cipher text and label
public class EncryptedInfo {
    public EncryptedInfo(byte[] bytes, String keyAlias);
    public byte[] getEncryptedBytes();
    public String getKeyAlias();
};

```

2. If you need to custom encode passwords in property files, manually edit the PropFilePasswordEncoder.sh or PropFilePasswordEncoder.bat file.
 - a. Use a file editor to open the PropFilePasswordEncoder.sh or PropFilePasswordEncoder.bat file.
 - b. Locate the following lines near the end of the file:

```
"%JAVA_HOME%/bin/java" -Dcmd.properties.file=%TMPJAVAPROFFILE%
"-Dwas.install.root=%WAS_HOME%" com.ibm.ws.bootstrap.WSLauncher
com.ibm.ws.security.util.PropFilePasswordEncoder %1 %2
```

- c. Add following lines to the call.

These custom properties will be passed to the command so that PropFilePasswordEncoder will look for custom encoding classes and utilize it.

```
-Dcom.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled=true
-Dcom.ibm.wsspi.security.crypto.customPasswordEncryptionClass=(customEncoding class file)
```

The updated lines should look like the following lines:

```
"%JAVA_HOME%/bin/java" -Dcmd.properties.file=%TMPJAVAPROFFILE%
-Dcom.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled=true
-Dcom.ibm.wsspi.security.crypto.customPasswordEncryptionClass=(customEncoding class file)
"-Dwas.install.root=%WAS_HOME%" com.ibm.ws.bootstrap.WSLauncher
com.ibm.ws.security.util.PropFilePasswordEncoder %1 %2
```

3. Enable custom password encryption.
 - a. Set the custom property **com.ibm.wsspi.security.crypto.customPasswordEncryptionClass** to the name of the class that is to be given control.
 - b. Enable the function. Set the custom property, **com.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled** to true.

Results

Custom password encryption at the installation is complete.

Developing applications that use programmatic security

For some applications, declarative security is not sufficient to express the security model of the application. Use this topic to develop applications that use programmatic security.

About this task

IBM WebSphere Application Server provides security components that provide or collaborate with other services to provide authentication, authorization, delegation, and data protection. WebSphere Application Server also supports the security features that are described in the Java Platform, Enterprise Edition (Java EE) specification. An application goes through three stages before it is ready to run:

- Development
- Assembly
- Deployment

Most of the security for an application is configured during the assembly stage. The security that is configured during the assembly stage is called *declarative security* because the security is *declared* or *defined* in the deployment descriptors. The declarative security is enforced by the security runtime. For some applications, declarative security is not sufficient to express the security model of the application. For these applications, you can use *programmatic security*.

Procedure

1. Develop secure web applications. For more information, see “Developing with programmatic security APIs for web applications” on page 706.
2. Develop servlet filters for form login processing. For more information, see “Developing servlet filters for form login processing” on page 721.
3. Develop form login pages. For more information, see “Customizing web application login” on page 718.

4. Develop enterprise bean component applications. For more information, see “Developing with programmatic APIs for EJB applications” on page 714.
5. Develop with Java Authentication and Authorization Service to log in programmatically.
For more information, see topics about developing programmatic logins with the Java Authentication and Authorization Service.
6. Develop your own Java EE security mapping module.
For more information, see topics about configuring programmatic logins for Java Authentication and Authorization Service.
7. Develop custom user registries. For more information, see “Developing stand-alone custom registries” on page 675.
8. Develop a custom interceptor for trust associations.

Protecting system resources and APIs (Java 2 security) for developing applications

Java 2 security is a programming model that is very pervasive and has a huge impact on application development.

Before you begin

Java 2 security is orthogonal to Java Platform, Enterprise Edition (Java EE) role-based security; you can disable or enable it independently of administrative security.

However, it does provide an extra level of access control protection on top of the Java EE role-based authorization. It particularly addresses the protection of system resources and application programming interfaces (API). Administrators need to consider the benefits against the risks of disabling Java 2 security.

The following recommendations are provided to help enable Java 2 security in a test or production environment:

1. Make sure the application is developed with the Java 2 security programming model. Developers have to know whether or not the APIs that are used in the applications are protected by Java 2 security. It is very important that the required permissions for the APIs used are declared in the policy file (`was.policy`), or the application fails to run when Java 2 security is enabled. Developers can reference the website for Development Kit APIs that are protected by Java 2 security. See the Programming model and decisions section of the Security: Resources for Learning topic to visit this website.
2. Make sure that migrated applications from previous releases are given the required permissions. Because Java 2 security is not supported or partially supported in previous WebSphere Application Server releases, applications developed prior to Version 5 most likely are not using the Java 2 security programming model. No easy way to find out all the required permissions for the application is available. The following are activities you can perform to determine the extra permissions that are required by an application:
 - Code review and code inspection
 - Application documentation review
 - Sandbox testing of migrated enterprise applications with Java 2 security enabled in a preproduction environment. Enable tracing in WebSphere Java 2 security manager to help determine the missing permissions in the application policy file. The trace specification is:
`com.ibm.ws.security.core.SecurityManager=all=enabled.`
 - Use the `com.ibm.websphere.java2secman.norethrow` system property to aid debugging. Do not use this property in a production environment.

IBM i The default permission set for applications is the recommended permission set defined in the J2EE 1.3 Specification. The default is declared in the `profile_root/config/cells/cell_name/nodes/node_name/app.policy` policy file with permissions defined in the Development Kit policy file that grants permissions to everyone. The `java.policy` file is located in the `java_home` directory depending on the Java virtual machine (JVM) that is enabled for the profile.

Note: Only Java SE 6 has a JRE.(for example, /QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit/jre/lib/ext).

For all Java virtual machines, the `java.policy` file is used system-wide. Do not edit the `java.policy` file on the server. Applications are denied permissions that are declared in the `profile_root/config/cells/cell_name/filter.policy` file. Permissions declared in the `filter.policy` file are filtered for applications during the permission check.

IBM i Use the `showVariables` command of the AdminTask object to retrieve `JAVA_HOME` for the node associated with the server's profile. For example, if the node is `myNode`:

1. Enter QShell.
2. `cd` to `profile_root/bin`
3. Run the following command:

```
wsadmin -conntype NONE -c '$AdminTask showVariables {-scope Node=myNode -variableName JAVA_HOME}'
```

Define the required permissions for an application in a `was.policy` file and embed the `was.policy` file in the application enterprise archive (EAR) file as `YOURAPP.ear/META-INF/was.policy`, see “Configuring Java 2 security policy files” on page 688 for details.

The following steps describe how to enforce Java 2 security on the cell level for WebSphere Application Server, Network Deployment and the server level for WebSphere Application Server, Express

Procedure

1. Click **Security > Global security**. The Global security panel is displayed.
2. Select the **Use Java 2 security to restrict application access to local resources** option.
3. Click **OK** or **Apply**.
4. Click **Save** to save the changes.
5. Restart the server for the changes to take effect.

Results

Java 2 security is enabled and enforced for the servers. Java 2 security permission is selected when a Java 2 security protected API is called.

When to use Java 2 security

1. Enable protection on system resources, for example when opening or listening to a socket connection, reading or writing to operating system file systems, reading or writing Java virtual machine system properties, and so on.
2. Prevent application code from calling destructive APIs, for example, calling the `System.exit` method brings down the application server.
3. Prevent application code from obtaining privileged information (passwords) or gaining extra privileges (obtaining server credentials).

What to do next

The Java 2 security manager is enhanced to dump the Java 2 security permissions that are granted to all classes on the call stack when an application is denied access to a resource. The `java.security.AccessControlException` exception is created. However, this tracing capability is disabled by default. You can enable this capability by specifying the server trace service with the `com.ibm.ws.security.core.SecurityManager=all=enabled` trace specification. When the exception is created, the trace dump provides hints to determine whether the application is missing permissions or the product runtime code or the third-party libraries that are used are not properly marked as `privileged` when accessing Java 2 security-protected resources.

Using PolicyTool to edit policy files for Java 2 security:

Use the **PolicyTool** utility to update policy files.

Before you begin

Java 2 security uses several policy files to determine the granted permission for each Java program. The Java Development Kit provides the **PolicyTool** tool to edit these policy files. This tool is recommended for editing any policy file to verify the syntax of its contents. Syntax errors in the policy file cause an `AccessControlException` exception when the application runs, including the server start. Identifying the cause of this exception is not easy because the user might not be familiar with the resource that has an access violation. Be careful when you edit these policy files.

IBM i You must install either the client or plug-ins component of WebSphere Application Server on a workstation in order to access the **PolicyTool**. It is not currently supported on the iSeries server.

Procedure

- IBM i** Map a drive to the operating system to navigate the directory tree to the policy file.
- IBM i** Start the **PolicyTool**.
Click **OK**.
- Click **File > Open**.
- Navigate the directory tree in the **Open** window to pick up the policy file that you need to update. After selecting the policy file, click **Open**. The code base entries are listed in the window.
- Create or modify the code base entry.
 - Modify the existing code base entry by double-clicking the code base, or click the code base and click **Edit Policy Entry**. The Policy Entry window opens with the permission list defined for the selected code base.
 - Create a new code base entry by clicking **Add Policy Entry**.
The Policy Entry window opens. At the code base column, enter the code base information as a URL format.
IBM i For example, you can enter:
profile_root/InstalledApps/testcase.ear
- Modify or add the permission specification.
 - Modify the permission specification by double-clicking the entry that you want to modify, or by selecting the permission and clicking **Edit Permission**. The Permissions window opens with the selected permission information.
 - Add a new permission by clicking **Add Permission**. The Permissions window opens. In the Permissions window are four rows for Permission, Target Name, Actions, and Signed By.
- Select the permission from the Permission list. The selected permission displays. After a permission is selected, the Target Name, Actions, and Signed By fields automatically show the valid choices or they enable text input in the right text input area.
 - Select **Target Name** from the list, or enter the target name in the right text input area.
 - Select **Actions** from the list.
 - Input **Signed By** if it is needed.

Important: The Signed By keyword is not supported in the following policy files: `app.policy`, `spi.policy`, `library.policy`, `was.policy`, and `filter.policy` files. However, the Signed By keyword is supported in the following policy files: `#java.policy`, `server.policy`, and `client.policy` files. The Java Authentication and Authorization Service (JAAS) is not supported in the `app.policy`, `spi.policy`, `library.policy`, `was.policy`, and `filter.policy` files. However, the JAAS principal keyword is supported in a JAAS policy file when it is specified by the `java.security.auth.policy` Java virtual machine (JVM) system property.

8. Click **OK** to close the Permissions window. Modified permission entries of the specified code base display.
9. Click **Done** to close the window. Modified code base entries are listed. Repeat the previous steps until you complete editing.
10. Click **File > Save** after you finish editing the file.

Results

A policy file is updated. If any policy files need editing, use the **PolicyTool** utility. Do not edit the policy file manually. Syntax errors in the policy files can potentially cause application servers or enterprise applications to not start or function incorrectly. For the changes in the updated policy file to take effect, restart the Java processes.

Configuring Java 2 security policy files:

Users can configure Java 2 security policy files so that the required permission is granted for the specified WebSphere Application Server enterprise application.

Before you begin

Java 2 security uses several policy files to determine the permissions for each Java programs.

See the Java 2 security policy files topic for the list of available policy files that are supported by WebSphere Application Server.

Two types of policy files are supported by WebSphere Application Server: dynamic policy files and static policy files. Static policy files provide the default permissions. Dynamic policy files provide application permissions. Six dynamic policy files are provided:

Table 60. Dynamic policy files. This table lists the dynamic policy files.

Policy file name	Description
app.policy	Contains default permissions for all of the enterprise applications in the cell. Note: Updates to the app.policy file only apply to the enterprise applications on the node to which the app.policy file belongs.
was.policy	Contains application-specific permissions for an WebSphere Application Server enterprise application. This file is packaged in an enterprise archive (EAR) file.
ra.xml	Contains connector application specific permissions for a WebSphere Application Server enterprise application. This file is packaged in a resource adapter archive (RAR) file.
spi.policy	Contains permissions for Service Provider Interface (SPI) or third-party resources that are embedded in WebSphere Application Server. The default contents grant everything. Update this file carefully when the cell requires more protection against SPI in the cell. This file is applied to all of the SPIs that are defined in the resources.xml file.
library.policy	Contains permissions for the shared library of enterprise applications.
filter.policy	Contains the list of permissions that require filtering from the was.policy file and the app.policy file in the cell. This filtering mechanism only applies to the was.policy and app.policy files.

In WebSphere Application Server, applications must have the appropriate thread permissions specified in the was.policy or app.policy file. Without the thread permissions specified, the application cannot manipulate threads and WebSphere Application Server creates a java.security.AccessControlException exception. The app.policy file applies to a specified node. If you change the permissions in one app.policy file, you must incorporate the new thread policy in the same file on the remaining nodes. Also, if you add the thread permissions to the app.policy file, you must restart WebSphere Application Server to enforce the new permissions. However, if you add the permissions to the was.policy file for a specific

application, you do not need to restart WebSphere Application Server. An administrator must add the following code to a `was.policy` or `app.policy` file for an application to manipulate threads:

```
grant codeBase "file:${application}" {
    permission java.lang.RuntimePermission "stopThread";
    permission java.lang.RuntimePermission "modifyThread";
    permission java.lang.RuntimePermission "modifyThreadGroup";
};
```

Important: The Signed By keyword is not supported in the following policy files: `app.policy`, `spi.policy`, `library.policy`, `was.policy`, and `filter.policy` files. However, the Signed By keyword is supported in the following policy files: `java.policy`, `server.policy`, and `client.policy` files. The Java Authentication and Authorization Service (JAAS) is not supported in the `app.policy`, `spi.policy`, `library.policy`, `was.policy`, and `filter.policy` files. However, the JAAS principal keyword is supported in a JAAS policy file when it is specified by the `java.security.auth.policy` Java virtual machine (JVM) system property. You can statically set the authorization policy files in `java.security.auth.policy` with `auth.policy.url.n=URL`, where `URL` is the location of the authorization policy.

Procedure

1. Identify the policy file to update.

- If the permission is required by an application, update the static policy file. Refer to “Configuring static policy files in Java 2 security” on page 701.
- If the permission is required by all of the WebSphere Application Server enterprise applications in the node, refer to “spi.policy file permissions” on page 697.
- If the permission is required only by specific WebSphere Application Server enterprise applications and the permission is required only by connector, update the `ra.xml` file. Refer to Refer to the Assembling resource adapter (connector) modules article for more information. Otherwise, update the `was.policy` file. Refer to “Configuring the was.policy file for Java 2 security” on page 694 and “Adding the was.policy file to applications for Java 2 security” on page 699.
- If the permission is required by shared libraries, refer to “library.policy file permissions” on page 698.
- If the permission is required by SPI libraries, refer to “spi.policy file permissions” on page 697.

Tip: Pick up the policy file with the smallest scope. You can avoid giving an extra permission to the Java programs and protect the resources. You can update the `ra.xml` file or the `was.policy` file rather than the `app.policy` file. Use specific component symbols (`$(ejbcomponent)`, `$(webComponent)`, `$(connectorComponent)` and `$(jars)`) than `$(application)` symbols. Update dynamic policy files, rather than static policy files.

Add any permission that you never want granted to the WebSphere Application Server enterprise application in the cell to the `filter.policy` file. Refer to “filter.policy file permissions” on page 692.

2. Restart the WebSphere Application Server enterprise application.

Results

The required permission is granted for the specified WebSphere Application Server enterprise application.

IBM i Example

If an WebSphere Application Server enterprise application in a cell requires permissions, some of the dynamic policy files need updating. The symptom of the missing permission is the `java.security.AccessControlException` exception. The missing permission is listed in the exception data, which will appear as one line, but is split in sections below for readability. 

```
java.security.AccessControlException: access denied (java.io.FilePermission
${was.install.root}/java/ext/mail.jar read)
```

When a Java program receives this exception and adding this permission is justified, add a permission to an adequate dynamic policy file. 

```
grant codeBase "file:user_client_installed_location" {  
    permission java.io.FilePermission  
    "${was.install.root}${(/)}java${(/)}jre${(/)}lib${(/)}ext${(/)}mail.jar", "read";  
};
```

The previous permission information lines are split for the illustration. Enter the permission on one line.

To decide whether to add a permission, refer to the Access control exception for Java 2 security topic.

app.policy file permissions:

Java 2 security uses several policy files to determine the granted permissions for each Java program. The union of the permissions that are contained in these following files is applied to the WebSphere Application Server enterprise application. This union determines the granted permissions.

For the list of available policy files that are supported by WebSphere Application Server, see the topic about Java 2 security policy files. The `app.policy` file is a default policy file that is shared by all of the WebSphere Application Server enterprise applications. The union of the permissions that are contained in the following files is applied to the WebSphere Application Server enterprise application:

- Any policy file that is specified in the `policy.url.*` properties in the `java.security` file.
- The `app.policy` files, which are managed by configuration and file replication services.
- The `server.policy` file.
- The `java.policy` file.
- The application `was.policy` file.
- The permission specification of the `ra.xml` file.
- The shared library, which is the `library.policy` file.

In WebSphere Application Server, applications that manipulate threads must have the appropriate thread permissions specified in the `was.policy` or `app.policy` file. Without the thread permissions specified, the application cannot manipulate threads and WebSphere Application Server creates a `java.security.AccessControlException` exception. If an administrator adds thread permissions to the `app.policy` file, the permission change requires a restart of the WebSphere Application Server. An administrator must add the following code to a `was.policy` or `app.policy` file for an application to manipulate threads:

```
grant codeBase "file:${application}" {  
    permission java.lang.RuntimePermission "stopThread";  
    permission java.lang.RuntimePermission "modifyThread";  
    permission java.lang.RuntimePermission "modifyThreadGroup";  
};
```

Important: The Signed By and the Java Authentication and Authorization Service (JAAS) principal keywords are not supported in the `app.policy` file. However, the Signed By keyword is supported in the following files: `java.policy`, `server.policy`, and the `client.policy` files. The JAAS principal keyword is supported in a JAAS policy file when it is specified by the `java.security.auth.policy` Java virtual machine (JVM) system property. You can statically set the authorization policy files in the `java.security.auth.policy` property with `auth.policy.url.n=URL` where URL is the location of the authorization policy.

If the default permissions for enterprise applications (the union of the permissions that is defined in the `java.policy` file, the `server.policy` file and the `app.policy` file) are enough; no action is required. The default `app.policy` file is used automatically. If a specific change is required to all of the enterprise applications in the cell, update the `app.policy` file. Syntax errors in the policy files cause start failures in the application servers. Edit these policy files carefully.

Note: Updates to the `app.policy` file only apply to the enterprise applications on the node to which the `app.policy` file belongs.

To extract the policy file, use a command prompt to enter the following command on one line using the appropriate variable values for your environment:

IBM i

```
wsadmin> set obj [$AdminConfig extract cells/cell_name/node/node_name/app.policy /temp/test/app.policy]
```

Edit the extracted `app.policy` file with the Policy Tool. For more information, see “Using PolicyTool to edit policy files for Java 2 security” on page 686. Changes to the `app.policy` file are local for the node.

To check in the policy file, use a command prompt to enter the following command on one line using the appropriate variable values for your environment:

IBM i

```
wsadmin> $AdminConfig checkin cells/cell_name/nodes/node_name/app.policy temp/test/app.policy $obj
```

Table 61. Symbols used to associate permission lists to a specific type of resource. Several product-reserved symbols are defined to associate the permission lists to a specific type of resource.

Symbol	Meaning
<code>file:\${application}</code>	Permissions apply to all resources within the application
<code>file:\${jars}</code>	Permissions apply to all utility Java archive (JAR) files within the application
<code>file:\${ejbComponent}</code>	Permissions apply to enterprise bean resources within the application
<code>file:\${webComponent}</code>	Permissions apply to web resources within the application
<code>file:\${connectorComponent}</code>	Permissions apply to connector resources both within the application and within stand-alone connector resources.

Table 62. Symbols provided to specify the path and name for the `java.io.FilePermission` permission. Five embedded symbols are provided to specify the path and name for the `java.io.FilePermission` permission. These symbols enable flexible permission specifications. The absolute file path is fixed after the installation of the application.

Symbol	Meaning
<code>\${app.installed.path}</code>	Path where the application is installed
<code>\${was.module.path}</code>	Path where the module is installed
<code>\${current.cell.name}</code>	Current cell name
<code>\${current.node.name}</code>	Current node name
<code>\${current.server.name}</code>	Current server name

Tip: You cannot use the `${was.module.path}` in the `${application}` entry.

IBM i

The `app.policy` file supplied by WebSphere Application Server is located in the `profile_root/config/cells/cell_name/nodes/node_name/app.policy`, which contains the following default permissions:

Attention: In the following code sample, the first two lines that are related to `java.io.FilePermission` permission are split into two lines for illustrative purposes only.

```
grant codeBase "file:${application}" {
  // The following are required by JavaMail
  permission java.io.FilePermission "${was.install.root}${/}lib${/}activation-impl.jar", "read";
  permission java.io.FilePermission "${was.install.root}${/}lib${/}mail-impl.jar", "read";
};

grant codeBase "file:${jars}" {
  permission java.net.SocketPermission "*", "connect";
  permission java.util.PropertyPermission "*", "read";
};

grant codeBase "file:${connectorComponent}" {
  permission java.net.SocketPermission "*", "connect";
  permission java.util.PropertyPermission "*", "read";
};
```

```

};

grant codeBase "file:${webComponent}" {
    permission java.io.FilePermission "${was.module.path}${/}-", "read, write";
    permission java.lang.RuntimePermission "loadLibrary.*";
    permission java.lang.RuntimePermission "queuePrintJob";
    permission java.net.SocketPermission "*", "connect";
    permission java.util.PropertyPermission "*", "read";
};

grant codeBase "file:${ejbComponent}" {
    permission java.lang.RuntimePermission "queuePrintJob";
    permission java.net.SocketPermission "*", "connect";
    permission java.util.PropertyPermission "*", "read";
};

```

If all of the WebSphere Application Server enterprise applications in a cell require permissions that are not defined as defaults in the `java.policy` file, the `server.policy` file and the `app.policy` file, then update the `app.policy` file. The symptom of a missing permission is the `java.security.AccessControlException` exception.

Note: Updates to the `app.policy` file only apply to the enterprise applications on the node to which the `app.policy` file belongs.

When a Java program receives this exception and adding this permission is justified, add a permission to the `server.policy` file, for example:

IBM i

```

grant codeBase "file:user_client_installed_location" {
    permission java.io.FilePermission
"${was.install.root}${/}java${/}jre${/}lib${/}ext${/}mail.jar", "read";
};

```

The previous permission information lines are split for the illustration. You actually enter the permission on one line.

To decide whether to add a permission, refer to the `AccessControlException` topic.

Restart all WebSphere Application Server enterprise applications to ensure that the updated `app.policy` file takes effect.

filter.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program. Java 2 security policy filtering is only in effect when Java 2 security is enabled.

Before modifying the `filter.policy` file, you must start the `wsadmin` tool.

Refer to “Protecting system resources and APIs (Java 2 security) for developing applications” on page 685. The filtering policy defined in the `filter.policy` file is cell wide. The `filter.policy` file is the only policy file that is used when restricting the permission instead of granting permission. The permissions that are listed in the filter policy file are filtered out from the `app.policy` file and the `was.policy` file. Permissions that are defined in the other policy files are not affected by the `filter.policy` file.

When a permission is filtered out, an audit message is logged. However, if the permissions that are defined in the `app.policy` file and the `was.policy` file are compound permissions like the `java.security.AllPermission` permission, for example, the permission is not removed. A warning message is logged. If the Issue Permission Warning flag is enabled (default) and if the `app.policy` file and the `was.policy` file contain custom permissions (non-Java API permission, the permission package name begins with characters other than `java` or `javax`), a warning message is logged and the permission is not removed. You can change the value of the Warn if applications are granted custom permissions option on the Global security panel. It is not recommended that you use the `AllPermission` permission for the enterprise application.

Some default permissions that are defined in the `filter.policy` file. These permissions are the minimal ones that are recommended by the product. If more permissions are added to the `filter.policy` file, certain operations can fail for enterprise applications. Add permissions to the `filter.policy` file carefully.

You cannot use the Policy Tool to edit the `filter.policy` file. Editing must be completed in a text editor. Be careful and verify that no syntax errors exist in the `filter.policy` file. If any syntax errors exist in the `filter.policy` file, the file is not loaded by the product security runtime, which implies that filtering is disabled.

To extract the `filter.policy` file, enter the following command using information from your environment:

IBM i

```
set obj [$AdminConfig extract cells/cell_name/filter.policy /temp/test/filter.policy]
```

To check in the policy file, enter the following command using information from your environment:

IBM i

```
$AdminConfig checkin cells/cell_name/filter.policy /temp/test/filter.policy $obj
```

An updated `filter.policy` file is applied to all of the WebSphere Application Server enterprise applications after the servers are restarted. The `filter.policy` file is managed by configuration and file replication services.

IBM i

The `filter.policy` file supplied by WebSphere Application Server resides at: `profile_root/config/cells/cell_name/filter.policy`.

This file contains these permissions as defaults:

```
filterMask {
  permission java.lang.RuntimePermission "exitVM";
  permission java.lang.RuntimePermission "setSecurityManager";
  permission java.security.SecurityPermission "setPolicy";
  permission javax.security.auth.AuthPermission "setLoginConfiguration"; };
runtimeFilterMask {
  permission java.lang.RuntimePermission "exitVM";
  permission java.lang.RuntimePermission "setSecurityManager";
  permission java.security.SecurityPermission "setPolicy";
  permission javax.security.auth.AuthPermission "setLoginConfiguration"; };
```

The permissions that are defined in `filterMask` filter are for static policy filtering. The security runtime tries to remove the permissions from applications during application startup. Compound permissions are not removed, but are issued with a warning, and application deployment is stopped if applications contain permissions that are defined in the `filterMask` filter, and if scripting is used. The `runtimeFilterMask` filter defines permissions that are used by the security runtime to deny access to those permissions to application thread. Do not add more permissions to the `runtimeFilterMask` filter. Application start failure or incorrect functioning might result. Be careful when adding more permissions to the `runtimeFilterMask` filter. Usually, you only need to add permissions to the `filterMask` stanza.

WebSphere Application Server relies on the filter policy file to restrict or disallow certain permissions that can compromise the integrity of the system. For instance, WebSphere Application Server considers the `exitVM` and `setSecurityManager` permissions as those permissions that most applications never have. If these permissions are granted, the following scenarios are possible:

exitVM

A servlet, JavaServer Pages (JSP) file, enterprise bean, or other library that is used by the aforementioned might call the System.exit API and cause the entire WebSphere Application Server process to terminate.

setSecurityManager

An application might install its own security manager and either grant more permissions or bypass the default policy that the WebSphere Application Server security manager enforces.

Important: In application code, do not use the setSecurityManager permission to set a security manager. When an application uses the setSecurityManager permission, a conflict exists with the internal security manager within WebSphere Application Server. If you must set a security manager in an application for Remote Method Invocation (RMI) purposes, you also must select the Use Java 2 security to restrict application access to local resources option on the Global security panel within the WebSphere Application Server administrative console. WebSphere Application Server then registers a security manager, which the application code can verify is registered by using the System.getSecurityManager application programming interface (API).

For the updated filter.policy file to take effect, restart related Java processes.

Configuring the was.policy file for Java 2 security:

You should update the was.policy file if the application has specific resources to access.

Before you begin

Java 2 security uses several policy files to determine the granted permission for each Java program. The was.policy file is an application-specific policy file for WebSphere Application Server enterprise applications. This file is embedded in the META-INF/was.policy enterprise archive (.EAR) file. The was.policy file is located in:

```
profile_root/config/cells/cell_name/applications/  
ear_file_name/deployments/application_name/META-INF/was.policy
```

See Java 2 security policy files for the list of available policy files that are supported by WebSphere Application Server Version 6.1.

The union of the permissions that are contained in the following files is applied to the WebSphere Application Server enterprise application:

- Any policy file that is specified in the policy.url.* properties in the java.security file.
- The app.policy files, which are managed by configuration and file replication services.
- The server.policy file.
- The java.policy file.
- The application was.policy file.
- The permission specification of the ra.xml file.
- The shared library, which is the library.policy file.

Table 63. Symbols defined to associate permission lists to a specific type of resource. Several product-reserved symbols are defined to associate the permission lists to a specific type of resource.

Symbol	Definition
file:\${application}	Permissions apply to all resources used within the application.
file:\${jars}	Permissions apply to all utility Java archive (JAR) files within the application
file:\${ejbComponent}	Permissions apply to enterprise bean resources within the application
file:\${webComponent}	Permissions apply to web resources within the application

Table 63. Symbols defined to associate permission lists to a specific type of resource (continued). Several product-reserved symbols are defined to associate the permission lists to a specific type of resource.

Symbol	Definition
file:\${connectorComponent}	Permissions apply to connector resources within the application

In WebSphere Application Server, applications that manipulate threads must have the appropriate thread permissions specified in the `was.policy` or `app.policy` file. Without the thread permissions specified, the application cannot manipulate threads and WebSphere Application Server creates a `java.security.AccessControlException` exception. If you add the permissions to the `was.policy` file for a specific application, you do not need to restart WebSphere Application Server. An administrator must add the following code to a `was.policy` or `app.policy` file for an application to manipulate threads:

```
grant codeBase "file:${application}" {
    permission java.lang.RuntimePermission "stopThread";
    permission java.lang.RuntimePermission "modifyThread";
    permission java.lang.RuntimePermission "modifyThreadGroup";
};
```

An administrator can add the thread permissions to the `app.policy` file, but the permission change requires a restart of WebSphere Application Server.

Important: The Signed By and the Java Authentication and Authorization Service (JAAS) principal keywords are not supported in the `was.policy` file. The Signed By keyword is supported in the `java.policy`, `server.policy`, and `client.policy` policy file. The JAAS principal keyword is supported in a JAAS policy file when it is specified by the `java.security.auth.policy` Java virtual machine (JVM) system property. You can statically set the authorization policy files in the `java.security.auth.policy` file with the `auth.policy.url.n=URL`, where `URL` is the location of the authorization policy.

Other than these blocks, you can specify the module name for granular settings. For example,

```
grant codeBase "file:DefaultWebApplication.war" {
    permission java.security.SecurityPermission "printIdentity";
};

grant codeBase "file:IncCMP11.jar" {
    permission java.io.FilePermission
        "${user.install.root}${/}bin${/}DefaultDB${/}-",
        "read,write,delete";
};
```

Table 64. Embedded symbols provided to specify the path and name for the `java.io.FilePermission` permission. Five embedded symbols are provided to specify the path and name for the `java.io.FilePermission` permission. These symbols enable flexible permission specification. The absolute file path is fixed after the application is installed.

Symbol	Definition
\${app.installed.path}	Path where the application is installed
\${was.module.path}	Path where the module is installed
\${current.cell.name}	Current cell name
\${current.node.name}	Current node name
\${current.server.name}	Current server name

About this task

If the default permissions for the enterprise application are enough, an action is not required. The default permissions are a union of the permissions that are defined in the `java.policy` file, the `server.policy` file, and the `app.policy` file. If an application has specific resources to access, update the `was.policy` file. The first two steps assume that you are creating a new policy file.

Tip: Syntax errors in the policy files cause the application server to fail. Use care when editing these policy files.

Procedure

1. Create or edit a new `was.policy` file by using the PolicyTool. For more information, see “Using PolicyTool to edit policy files for Java 2 security” on page 686.
2. Package the `was.policy` file into the enterprise archive (EAR) file.
For more information, see “Adding the `was.policy` file to applications for Java 2 security” on page 699. The following instructions describe how to import a `was.policy` file.
 - a. Import the EAR file into an assembly tool.
 - b. Open the Project Navigator view.
 - c. Expand the EAR file and click **META-INF**. You might find a `was.policy` file in the META-INF directory. If you want to delete the file, right-click the file name and select **Delete**.
 - d. At the bottom of the Project Navigator view, click **J2EE Hierarchy**.
 - e. Import the `was.policy` file by right-clicking the **Modules** directory within the deployment descriptor and by clicking **Import > Import > File system**.
 - f. Click **Next**.
 - g. Enter the path name to the `was.policy` file in the **From directory** field or click **Browse** to locate the file.
 - h. Verify that the path directory that is listed in the **Into directory** field lists the correct META-INF directory.
 - i. Click **Finish**.
 - j. To validate the EAR file, right-click the EAR file, which contains the Modules directory, and click **Run Validation**.
 - k. To save the new EAR file, right-click the EAR file, and click **Export > Export EAR file**. If you do not save the revised EAR file, the EAR file will contain the new `was.policy` file. However, if the workspace becomes corrupted, you might lose the revised EAR file.
 - l. To generate deployment code, right-click the EAR file and click **Generate Deployment Code**.
3. Update an existing installed application, if one already exists. Modify the `was.policy` file with the Policy Tool. For more information, see “Using PolicyTool to edit policy files for Java 2 security” on page 686.

Results

The updated `was.policy` file is applied to the application after the application restarts.

Example

```
java.security.AccessControlException: access denied (java.io.FilePermission  
${was.install.root}/java/ext/mail.jar read)
```

 If an application must access a specific resource that is not defined as a default in the `java.policy` file, the `server.policy` file, and the `app.policy`, delete the `was.policy` file for that application. The symptom of the missing permission is the `java.security.AccessControlException` exception. The missing permission is listed in the exception data:

Note: Examples that appear below are split into several lines for illustration only. You actually enter the permission on one line.

```
java.security.AccessControlException: access denied (java.io.FilePermission  
${was.install.root}/java/ext/mail.jar read)
```

When a Java program receives this exception and adding this permission is justified, add the following permission to the `was.policy` file: 

```
grant codeBase "file:user_client_installed_location" {  
    permission java.io.FilePermission  
    "${was.install.root}/${}/java${}/jre${}/lib${}/ext${}/mail.jar", "read";  
};
```

To determine whether to add a permission, see [Access control exception for Java 2 security](#).

What to do next

Restart all applications for the updated `app.policy` file to take effect.

spi.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

For the list of available policy files that are supported by WebSphere Application Server Version 6.0.x, see [Java 2 security policy files](#).

Because the default permission for the Service Provider Interface (SPI) is the `AllPermission` permission, the only reason to update the `spi.policy` file is a restricted SPI permission. When a change in the `spi.policy` is required, complete the following steps.

Syntax errors in the policy files cause the application server to fail. Edit these policy files carefully.

Important: Do not place the `codebase` keyword or any other keyword after the `filterMask` and `runtimeFilterMask` keywords. The `Signed By` and the Java Authentication and Authorization Service (JAAS) `Principal` keywords are not supported in the `spi.policy` file. The `Signed By` keyword is supported in the `java.policy`, `server.policy`, and `client.policy` policy files. The JAAS `Principal` keyword is supported in a JAAS policy file that is specified by the `java.security.auth.policy` Java virtual machine (JVM) system property. You can statically set the authorization policy files in `java.security.auth.policy` with `auth.policy.url.n=URL`, where URL is the location of the authorization policy.

To extract the `filter.policy` file, enter the following command using information from your environment:

IBM i

```
set obj [$AdminConfig extract profiles/profile_name/cells/cell_name/nodes/node_name/spi.policy /tmp/test/spi.policy]
```

Edit the file using the Policy Tool. For more information, see [“Using PolicyTool to edit policy files for Java 2 security”](#) on page 686.

To check in the policy file, enter the following command using information from your environment:

The updated `spi.policy` is applied to the Service Provider Interface (SPI) libraries after the Java process is restarted.

IBM i

```
$AdminConfig checkin profiles/profile_name/cells/cell_name/nodes/node_name/spi.policy /tmp/test/spi.policy $obj
```

Examples

The `spi.policy` file is the template for SPIs or third-party resources embedded in the product. Examples of SPIs are Java Message Services (JMS) (MQSeries) and Java database connectivity (JDBC) drivers. They are specified in the `resources.xml` file. The dynamic policy grants the permissions that are defined in the `spi.policy` file to the class paths defined in the `resources.xml` file. The union of the permission that is contained in the `java.policy` file and the `spi.policy` file are applied to the SPI libraries. The `spi.policy` files are managed by configuration and file replication services.

IBM i You can find the `spi.policy` file that is supplied by WebSphere Application Server in the following location: `profile_root/config/cells/cell_name/nodes/node_name/spi.policy`. It contains the following default permission:

```
grant {  
    permission java.security.AllPermission;  
};
```

Restart the related Java processes for the changes in the `spi.policy` file to become effective.

library.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

For the list of available policy files that are supported by WebSphere Application Server, see Java 2 security policy files.

The `library.policy` file is the template for shared libraries (Java library classes). Multiple enterprise applications can define and use shared libraries. Refer to *Managing shared libraries* for information on how to define and manage the shared libraries.

If the default permissions for a shared library (union of the permissions defined in the `java.policy` file, the `app.policy` file and the `library.policy` file) are enough, no action is required. The default library policy is picked up automatically. If a specific change is required to share a library in the cell, update the `library.policy` file.

Syntax errors in the policy files cause the application server to fail. Edit these policy files carefully.

Important: Do not place the `codebase` keyword or any other keyword after the `grant` keyword. The `Signed By` keyword and the Java Authentication and Authorization Service (JAAS) `Principal` keyword are not supported in the `library.policy` file. The `Signed By` keyword is supported in the `java.policy`, the `server.policy`, and the `client.policy` policy files. The JAAS `Principal` keyword is supported in a JAAS policy file when it is specified by the Java virtual machine (JVM) system property, `java.security.auth.policy`. You can statically set the authorization policy files in the `java.security.auth.policy` file with `auth.policy.url.n=URL` where URL is the location of the authorization policy.

To extract the policy file, use a command prompt to enter the following command using the appropriate variable values for your environment: The previous two lines were split onto two lines for illustrative purposes only.

IBM i

```
wsadmin> set obj [$AdminConfig extract cells/cell_name/nodes/  
node_name/library.policy /temp/test/library.policy]
```

Edit the extracted `library.policy` file with the Policy Tool. For more information, see “Using PolicyTool to edit policy files for Java 2 security” on page 686.

To check in the policy file, use a command prompt to enter the following command using the appropriate variable values for your environment: An updated `library.policy` is applied to shared libraries after the servers restart.

IBM i

```
wsadmin> $AdminConfig checkin cells/cell_name/nodes/node_name/library.policy
temp/test/library.policy $obj
```

Example

The union of the permission that is contained in the `java.policy` file, the `app.policy` file, and the `library.policy` file are applied to the shared libraries. The `library.policy` file is managed by configuration and file replication services.

IBM i The `library.policy` file supplied by WebSphere Application Server resides in the `profile_root/config/cells/cell_name/nodes/node_name/` directory. The file contains an empty permission entry as a default. For example:

```
grant {
};
```

If the shared library in a cell requires permissions that are not defined as defaults in the `java.policy` file, the `app.policy` file and the `library.policy` file, update the `library.policy` file. The missing permission causes the `java.security.AccessControlException` exception. The missing permission is listed in the exception data.

IBM i For example:

```
java.security.AccessControlException: access denied (java.io.FilePermission
app_server_rootBase/lib/mail-impl.jar read)
```

The previous lines are split into two lines for illustrative purposes only.

When a Java program receives this exception and adding this permission is justified, add a permission to the `library.policy` file.

IBM i For example:

```
grant codeBase "file:user_client_installed_location" { permission
java.io.FilePermission "app_server_rootBase/lib/mail-impl.jar", "read"; };
```

The previous lines are split into two lines for illustrative purposes only

To decide whether to add a permission, refer to Access control exception for Java 2 security.

Restart the related Java processes for the changes in the `library.policy` file to become effective.

Adding the was.policy file to applications for Java 2 security:

An application might need a `was.policy` file if it accesses resources that require more permissions than those granted in the default `app.policy` file.

About this task

When Java 2 security is enabled for a WebSphere Application Server, all the applications that run on WebSphere Application Server undergo a security check before accessing system resources. An application might need a `was.policy` file if it accesses resources that require more permissions than those granted in the default `app.policy` file. By default, the product security reads an `app.policy` file that is located in each node and grants the permissions in the `app.policy` file to all the applications. Include any additional required permissions in the `was.policy` file. The `was.policy` file is only required if an application requires additional permissions.

The default policy file for all applications is specified in the `app.policy` file. This file is provided by the product security, is common to all applications, and you do not change this file. Add any new permissions that are required for an application in the `was.policy` file.

The `app.policy` file supplied by WebSphere Application Server resides at `app_server_root/config/cells/profile/profile_name/config/cell_name/nodes/node_name/app.policy`. The contents of the `app.policy` file are presented in the following example:

Attention: In the following code sample, the two permissions that are required by JavaMail are split onto two lines for illustration only. You actually enter the permission on one line.

// The following permissions apply to all the components under the application.

```
grant codeBase "file:${application}" {
    // The following are required by JavaMail

    permission java.io.FilePermission "
        ${was.install.root}${/}lib${/}activation-impl.jar",
    "read";

    permission java.io.FilePermission "
        ${was.install.root}${/}lib${/}mail-impl.jar", "read";

};
// The following permissions apply to all utility .jar files (other
// than enterprise beans JAR files) in the application.
grant codeBase "file:${jars}" {
    permission java.net.SocketPermission "*", "connect";
    permission java.util.PropertyPermission "*", "read";
};

// The following permissions apply to connector resources within the application
grant codeBase "file:${connectorComponent}" {
    permission java.net.SocketPermission "*", "connect";
    permission java.util.PropertyPermission "*", "read";
};

// The following permissions apply to all the web modules (.war files)
// within the application.
grant codeBase "file:${webComponent}" {
    permission java.io.FilePermission "${was.module.path}${/}-", "read, write";
    // where "was.module.path" is the path where the web module is
    // installed. Refer to Dynamic policy concepts for other symbols.
    permission java.lang.RuntimePermission "loadLibrary.*";
    permission java.lang.RuntimePermission "queuePrintJob";
    permission java.net.SocketPermission "*", "connect";
    permission java.util.PropertyPermission "*", "read";
};

// The following permissions apply to all the EJB modules within the application.
grant codeBase "file:${ejbComponent}" {
    permission java.lang.RuntimePermission "queuePrintJob";
    permission java.net.SocketPermission "*", "connect";
    permission java.util.PropertyPermission "*", "read";
};
```

If additional permissions are required for an application or for one or more modules of an application, use the `was.policy` file for that application. For example, use `codeBase` of `${application}` and add required permissions to grant additional permissions to the entire application. Similarly, use `codeBase` of `${webComponent}` and `${ejbComponent}` to grant additional permissions to all the web modules and all the enterprise bean modules in the application. You can assign additional permissions to each module (`.war` file or `.jar` file), as shown in the following example.

This example illustrates adding extra permissions for an application in the `was.policy` file:

Attention: In the following code sample, the permission for the EJB module was split onto two lines for illustration only. You actually enter the permission on one line.

```
// grant additional permissions to a web module
grant codeBase " file:aWebModule.war" {
    permission java.security.SecurityPermission "printIdentity";
};

// grant additional permission to an EJB module
grant codeBase "file:aEJBModule.jar" {
    permission java.io.FilePermission "
        ${user.install.root}${/}bin${/}DefaultDB${/}-", "read,write,delete";
    // where, ${user.install.root} is the system property whose value is
    // located in the app_server_root directory.
};
```

To use a `was.policy` file for your application, perform the following steps:

Procedure

1. Create a `was.policy` file using the policy tool. For more information on using the policy tool, see “Using PolicyTool to edit policy files for Java 2 security” on page 686.
2. Add the required permissions in the `was.policy` file using the policy tool.
3. Place the `was.policy` file in the application enterprise archive (EAR) file under the META-INF directory. Update the application EAR file with the newly created `was.policy` file by using the `jar` command.
4. Verify that the `was.policy` file is inserted and start an assembly tool.

Note:  An assembly tool is not available. Use an assembly tool on another platform such as Linux Intel or Windows.

5. Verify that the `was.policy` file in the application is syntactically correct. In an assembly tool, right-click the enterprise application module and click **Run Validation**.

Results

An application EAR file is now ready to run when Java 2 security is enabled.

Example

This step is required for applications to run properly when Java 2 security is enabled. If the `was.policy` file is not created and it does not contain required permissions, the application might not access system resources.

The symptom of the missing permissions is the `java.security.AccessControlException` exception. The missing permission is listed in the exception data, for example,

`java.security.AccessControlException: access denied (java.io.FilePermission
${was.install.root}/java/ext/mail.jar read)`

When an application program receives this exception and adding this permission is justified, include the permission in the `was.policy` file, for example, 

```
grant codeBase "file:user_client_installed_location" {  
    permission java.io.FilePermission  
    "${was.install.root}/${}/java${}/jre${}/lib${}/ext${}/mail.jar", "read";  
};
```

The previous permission information lines are split for the illustration. Enter the permission on one line.

What to do next

Install the application.

Configuring static policy files in Java 2 security:

By configuring the static policy files, the required permission will be granted for all of the Java programs.

Before you begin

Java 2 security uses several policy files to determine the granted permission for each Java program.

See the topic about Java 2 security policy files for the list of available policy files that are supported by WebSphere Application Server.

Two types of policy files are supported by WebSphere Application Server: dynamic policy files and static policy files. Static policy files provide the default permissions. Dynamic policy files provide application permissions.

Table 65. Policy Files. This table lists the policy files.

Policy file name	Description
java.policy	Contains default permissions for all of the Java programs on the node. This file seldom changes.
server.policy	Contains default permissions for all of the WebSphere Application Server programs on the node. This file is rarely updated.
client.policy	Contains default permissions for all of the applets and client containers on the node.

The static policy file is not a configuration file that is managed by the repository and the file replication service. Changes to this file are local and do not get replicated to the other machine.

Procedure

1. Identify the policy file to update.
 - If the permission is required only by an application, update the dynamic policy file. Refer to “Configuring Java 2 security policy files” on page 688.
 - If the permission is required only by applets and client containers, update the `client.policy` file. Refer to “client.policy file permissions” on page 704.
 - If the permission is required only by WebSphere Application Server (servers, agents, managers and application servers), update the `server.policy` file. Refer to “server.policy file permissions” on page 703.
 - If the permission is required by all of the Java programs running on the Java virtual machine (JVM), update the `java.policy` file. Refer to “java.policy file permissions.”
2. Stop and restart WebSphere Application Server.

Results

The required permission is granted for all of the Java programs that run with the restarted JVM.

Example

If Java programs on a node require permissions, the policy file needs updating. If the Java program that required the permission is not part of an enterprise application, update the static policy file. The missing permission results in the creation of the `java.security.AccessControlException` exception. The missing permission is listed in the exception data.

IBM i For example:

```
java.security.AccessControlException: access denied (java.io.FilePermission
app_server_root/lib/mail-impl.jar read)
```

When a Java program receives this exception and adding this permission is justified, add a permission to an adequate policy file.

IBM i For example:

```
grant codeBase "file:user_client_installed_location" {
  permission java.io.FilePermission
    "app_server_root/Base/lib/mail-impl.jar",
    "read";
};
```

To decide whether to add a permission, refer to Access control exception for Java 2 security.

java.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

See Java 2 security policy files for the list of available policy files that are supported by WebSphere Application Server.

IBM i For IBM Technology for Java, the `java.policy` file is located in the `java_home/jre/lib/security` directory. For all JVMs, the `java.policy` file is used system-wide. Do not edit the `java.policy` file on the server.

IBM i Use the `showVariables` command of the `AdminTask` object to retrieve `java_home` for the node associated with the server's profile. For example, if the node is `myNode`:

1. Enter `QShell`.
2. `cd` to `profile_root/bin`.
3. Invoke `wsadmin -conntype NONE -c '$AdminTask showVariables {-scope Node=myNode -variableName JAVA_HOME}'`.

server.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

See Java 2 security policy files for the list of available policy files that are supported by WebSphere Application Server.

The `server.policy` file is a default policy file that is shared by all of the WebSphere Application Servers on a node. The `server.policy` file is not a configuration file that is managed by the repository and the file replication service. Changes to this file are local and do not replicate to the other machine.

If the default permissions for a server (the union of the permissions that is defined in the `java.policy` file and the `server.policy` file) are enough, no action is required. The default server policy is picked up automatically. If a specific change is required to some of the server programs on a node, update the `server.policy` file with the Policy Tool. Refer to the "Using PolicyTool to edit policy files for Java 2 security" on page 686 topic to edit policy files. Changes to the `server.policy` file are local for the node. Syntax errors in the policy files cause the application server to fail. Edit these policy files carefully. An updated `server.policy` file is applied to all the server programs on the local node. Restart the servers for the updates to take effect.

If you want to add permissions to an application, use the `app.policy` file and the `was.policy` file.

Note: Updates to the `app.policy` file only apply to the enterprise applications on the node to which the `app.policy` file belongs.

When you do need to modify the `server.policy` file, locate this file at: `profile_root/properties/server.policy`. This file contains these default permissions: **IBM i**

```
// Allow to use sun tools
grant codeBase "file:${java.home}/../lib/tools.jar" {
permission java.security.AllPermission;
};

// Allow to use ibm jdk extensions
grant codeBase "file:${was.install.root}/java/ext/-" {
permission java.security.AllPermission;
};

// Allow to use additional ibm jdk extensions with j9
grant codeBase "file:${was.install.root}/java/extj9/-" {
permission java.security.AllPermission;
};

// Allow to use sun and ibm tools
grant codeBase "file:${was.install.root}/java/tools/-" {
permission java.security.AllPermission;
};
```

```

};

// WebSphere system classes
grant codeBase "file:${was.install.root}/plugins/-" {
permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/lib/-" {
permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/classes/-" {
permission java.security.AllPermission;
};

// Allow the WebSphere deploy tool all permissions
grant codeBase "file:${was.install.root}/deploytool/-" {
permission java.security.AllPermission;
};

// Allow the WebSphere deploy tool all permissions
grant codeBase "file:${was.install.root}/optionalLibraries/-" {
permission java.security.AllPermission;
};

// Allow Channel Framework classes all permission
grant codeBase "file:${was.install.root}/installedChannels/-" {
permission java.security.AllPermission;
};

grant codeBase "file:${was.install.root}/util/-" {
permission java.security.AllPermission;
};

grant codeBase "file:${user.install.root}/lib/-" {
permission java.security.AllPermission;
};

grant codeBase "file:${user.install.root}/classes/-" {
permission java.security.AllPermission;
};

```

If some server programs on a node require permissions that are not defined as defaults in the `server.policy` file and the `server.policy` file, update the `server.policy` file. The missing permission creates the `java.security.AccessControlException` exception. The missing permission is listed in the exception data.

IBM i For example:

```
java.security.AccessControlException: access denied (java.io.FilePermission
app_server_rootBase/lib/mail-impl.jar read)
```

The previous two lines are split into two lines for illustrative purposes only.

When a Java program receives this exception and adding this permission is justified, add a permission to the `server.policy` file.

IBM i For example:

```
grant codeBase "file:user_client_installed_location" {
permission java.io.FilePermission
"app_server_root/Base/lib/mail-impl.jar", "read"; };
```

To decide whether to add a permission, refer to [Access control exception for Java 2 security](#).

Restart all of the Java processes for the updated `server.policy` file to take effect.

client.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

For the list of available policy files that are supported by WebSphere Application Server, see Java 2 security policy files.

- The `client.policy` file is a default policy file that is shared by all of the WebSphere Application Server client containers and applets on a node.
- The union of the permissions that is contained in the `java.policy` file and the `client.policy` file are given to all of the client containers for WebSphere Application Server and applets running on the node.
- The `client.policy` file is not a configuration file that is managed by the repository and the file replication service. Changes to this file are local and do not replicate to the other machine.
- The `client.policy` file supplied by WebSphere Application Server is located in the `profile_root/properties/client.policy`.
- If the default permissions for a client (union of the permissions defined in the `java.policy` file and the `client.policy` file) are enough, no action is required. The default client policy is picked up automatically.
- If a specific change is required to some of the client containers and applets on a node, modify the `client.policy` file with the Policy Tool. Refer to “Using PolicyTool to edit policy files for Java 2 security” on page 686, to edit policy files. Changes to the `client.policy` file are local for the node.

This file contains these default permissions:

```
IBM i
grant codeBase "file:${was.install.root}/java/ext/*" {
    permission java.security.AllPermission;
};

// JDK classes
grant codeBase "file:${was.install.root}/java/ext/-" {
    permission java.security.AllPermission;
};

// Allow to use additional ibm jdk extensions with j9
grant codeBase "file:${was.install.root}/java/extj9/-" {
    permission java.security.AllPermission;
};

// Allow to use sun and ibm tools
grant codeBase "file:${was.install.root}/java/tools/-" {
    permission java.security.AllPermission;
};

// WebSphere system classes
grant codeBase "file:${was.install.root}/lib/-" {
    permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/plugins/-" {
    permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/classes/-" {
    permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/installedConnectors/-" {
    permission java.security.AllPermission;
};
grant codeBase "file:${user.install.root}/installedConnectors/-" {
    permission java.security.AllPermission;
};

grant codeBase "file:${was.install.root}/installedChannels/-" {
    permission java.security.AllPermission;
};

grant codeBase "file:${was.install.root}/util/-" {
    permission java.security.AllPermission;
};
```

```

grant codeBase "file:${user.install.root}/lib/-" {
    permission java.security.AllPermission;
};

grant codeBase "file:${user.install.root}/classes/-" {
    permission java.security.AllPermission;
};

// J2EE 1.4 permissions for client container applications in $WAS_HOME/installedApps
grant codeBase "file:${user.install.root}/installedApps/-" {
    //Application client permissions
    permission java.awt.AWTPermission "accessClipboard";
    permission java.awt.AWTPermission "accessEventQueue";
    permission java.awt.AWTPermission "showWindowWithoutWarningBanner";
    permission java.lang.RuntimePermission "exitVM";
    permission java.lang.RuntimePermission "loadLibrary";
    permission java.lang.RuntimePermission "queuePrintJob";
    permission java.net.SocketPermission "*", "connect";
    permission java.net.SocketPermission "localhost:1024-", "accept,listen";
    permission java.io.FilePermission "*", "read,write";
    permission java.util.PropertyPermission "*", "read";
};

// J2EE 1.4 permissions for client container - expanded ear file code base
grant codeBase "file:${com.ibm.websphere.client.applicationclient.archivedir}/-" {
    permission java.awt.AWTPermission "accessClipboard";
    permission java.awt.AWTPermission "accessEventQueue";
    permission java.awt.AWTPermission "showWindowWithoutWarningBanner";
    permission java.lang.RuntimePermission "exitVM";
    permission java.lang.RuntimePermission "loadLibrary";
    permission java.lang.RuntimePermission "queuePrintJob";
    permission java.net.SocketPermission "*", "connect";
    permission java.net.SocketPermission "localhost:1024-", "accept,listen";
    permission java.io.FilePermission "*", "read,write";
    permission java.util.PropertyPermission "*", "read";
};

```

All of the client containers and applets on the local node are granted the updated permissions when they start. If some client containers or applets on a node require permissions that are not defined as defaults in the `java.policy` file and the default `client.policy` file, update the `client.policy` file. The missing permission creates the `java.security.AccessControlException` exception. The missing permission is listed in the exception data, for example,

IBM i

```
java.security.AccessControlException: access denied (java.io.FilePermission
app_server_root/Base/lib/mail-impl.jar read)
```

The previous two lines of the example are one continuous line, but presented as such for illustrative purposes only.

IBM i

When a client program receives this exception and adding this permission is justified, add a permission to the `client.policy` file, for example:

```
grant codebase "file:user_client_installed_location" { permission
    java.io.FilePermission "app_server_root/lib/mail-impl.jar", "read"; };
```

To decide whether to add a permission, refer to Access control exception for Java 2 security.

If you update the policy file, you must restart the browser and any client applications.

Developing with programmatic security APIs for web applications

Use this information to programmatically secure APIs for web applications.

Before you begin

Programmatic security is used by security-aware applications when declarative security alone is not sufficient to express the security model of the application.

The `authenticate`, `login`, `logout`, `getRemoteUser`, `isUserInRole` and `getAuthType` servlet security methods are methods of the `javax.servlet.http.HttpServletRequest` interface. For more detailed information about these servlet security methods, read the [Servlet security methods](#) article.

Note:

The `logout`, `login`, and `authenticate` APIs are new for Java Servlet 3.0 in this release of WebSphere Application Server.

You can configure several options for web authentication that determine how the web client interacts with protected and unprotected Uniform Resource Identifiers (URI). Also, you can specify whether WebSphere Application Server challenges the web client for basic authentication information if the certificate authentication for the HTTPS client fails. For more information, see the [Selecting an authentication mechanism](#) article.

When the `isUserInRole` method is used, declare a `security-role-ref` element in the deployment descriptor with a `role-name` subelement containing the role name that is passed to this method, or use the `@DeclareRoles` annotation. Because actual roles are created during the assembly stage of the application, you can use a logical role as the role name and provide enough hints to the assembler in the description of the `security-role-ref` element to link that role to the actual role. During assembly, the assembler creates a `role-link` subelement to link the role name to the actual role. Creation of a `security-role-ref` element is possible if an assembly tool, such as Rational Application Developer, is used. You also can create the `security-role-ref` element during assembly stage using an assembly tool.

Procedure

1. Add the required security methods in the servlet code.
2. Create a `security-role-ref` element with the **role-name** field. If a `security-role-ref` element is not created during development, make sure it is created during the assembly stage.

Results

A programmatically secured servlet application.

Example

These steps are required to secure an application programmatically. This action is particularly useful when a web application needs to access external resources and wants to control the access to external resources using its own authorization table (external-resource to remote-user mapping). In this case, use the `getUserPrincipal` or the `getRemoteUser` methods to get the remote user, then the application can consult its own authorization table to perform authorization. The remote user information also can help retrieve the corresponding user information from an external source such as a database or from an enterprise bean. You can use the `isUserInRole` method in a similar way.

After development, you can create a `security-role-ref` element:

```
<security-role-ref>
  <description>Provide hints to assembler for linking this role
    name to an actual role here<\description>
  <role-name>Mgr<\role-name>
</security-role-ref>
```

During assembly, the assembler creates a `role-link` element:

```

<security-role-ref>
  <description>Hints provided by developer to map the role
    name to the role-link</description>
  <role-name>Mgr</role-name>
  <role-link>Manager</role-link>
</security-role-ref>

```

You can add programmatic servlet security methods inside any servlet doGet, doPost, doPut, and doDelete service methods. The following example depicts using a programmatic security API:

```

public void doGet(HttpServletRequest request,
  HttpServletResponse response) {

  ....
  // to logoff the current user
  request.logout();

  // to login with a new user
  request.login("bob","bobpwd")

  // to get remote user using getUserPrincipal()
  java.security.Principal principal = request.getUserPrincipal();
  String remoteUser = principal.getName();

  // to get remote user using getRemoteUser()
  remoteUser = request.getRemoteUser();

  // to check if remote user is granted Mgr role
  boolean isMgr = request.isUserInRole("Mgr");

  // use the above information in any way as needed by
  // the application
  ....
}

```

You can programmatic login with a user ID and password inside any servlet doGet, doPost, doPut, and doDelete service methods. The following example depicts using a programmatic login/logout API:

```

public void doGet(HttpServletRequest request,
  HttpServletResponse response) {

  ....
  // to logout the current user. If you are not already authenticate, then no need to call the logout() method.
  request.logout();

  // to login with a new user
  request.login("utle","mypwd")

  // the user utle subject now set on the thread and the LTPA SSO cookie is set in the response
  ....
}

```

You can programmatic authenticate with a different identity inside any servlet doGet, doPost, doPut, and doDelete service methods. In this example, if the web servlet is configured to use basicAuth, the web server returns a response code 401, the login prompt is displayed, and you can enter the user ID and password to authenticate. The following example depicts using a programmatic login/logout API:

```

public void doGet(HttpServletRequest request,
  HttpServletResponse response) {

  ....
  // to logout the current user. If you are not already authenticate, then no need to call the logout() method.

  // to login with a new user
  request.authenticate(response);

  // the new user subject now set on the thread and the LTPA SSO cookie is set in the response
  ....
}

```

When developing Servlet 3.0 modules, the value of the rolename argument in isCallerInRole method can be defined using Java annotations instead of declaring a security-role-ref elements in the deployment descriptor.

```

@javax.annotation.security.DeclareRoles("Mgr")
public void doGet(HttpServletRequest request,
  HttpServletResponse response) {

  ....
}

```

```

// to get remote user using getUserPrincipal()
java.security.Principal principal = request.getUserPrincipal();
String remoteUser = principal.getName();

// to get remote user using getRemoteUser()
remoteUser = request.getRemoteUser();

// to check if remote user is granted Mgr role
boolean isMgr = request.isUserInRole("Mgr");

// use the above information in any way as needed by
// the application
....
}

```

The following example depicts a web application or servlet using the programmatic security model.

This example illustrates one use and not necessarily the only use of the programmatic security model. The application can use the information that is returned by the `getUserPrincipal`, `isUserInRole`, and the `getRemoteUser` methods in any other way that is meaningful to that application. Use the declarative security model whenever possible.

File : `HelloServlet.java`

```

public class HelloServlet extends javax.servlet.http.HttpServlet {

    public void doPost(
        javax.servlet.http.HttpServletRequest request,
        javax.servlet.http.HttpServletResponse response)
        throws javax.servlet.ServletException, java.io.IOException {
    }

    public void doGet(
        javax.servlet.http.HttpServletRequest request,
        javax.servlet.http.HttpServletResponse response)
        throws javax.servlet.ServletException, java.io.IOException {

        String s = "Hello";

        // get remote user using getUserPrincipal()
        java.security.Principal principal = request.getUserPrincipal();
        String remoteUserName = "";
        if( principal != null )
            remoteUserName = principal.getName();
        // get remote user using getRemoteUser()
        String remoteUser = request.getRemoteUser();

        // check if remote user is granted Mgr role
        boolean isMgr = request.isUserInRole("Mgr");

        // display Hello username for managers and bob.
        if ( isMgr || remoteUserName.equals("bob") )
            s = "Hello " + remoteUserName;

        String message = "<html> \n" +
            "<head><title>Hello Servlet</title></head>\n" +
            "<body> /n " +
            "<h1> " + s + "</h1>/n " +
            "</body>";
        byte[] bytes = message.getBytes();

        // displays "Hello" for ordinary users
        // and displays "Hello username" for managers and "bob".
        response.getOutputStream().write(bytes);
    }
}

```

After developing the servlet, you can create a security role reference for the `HelloServlet` servlet as shown in the following example:

```

<security-role-ref>
  <description> </description>
  <role-name>Mgr</role-name>
</security-role-ref>

```

What to do next

After developing an application, use an assembly tool to create roles and to link the actual roles to role names in the security-role-ref elements. See the information about securing web applications using an assembly tool.

Servlet security methods:

The authenticate, login, logout, getRemoteUser, isUserInRole and getAuthType servlet security methods are methods of the javax.servlet.http.HttpServletRequest interface.

authenticate

Note: The authenticate, login and logout servlet security methods are new for Java Servlet 3.0 in this release of WebSphere Application Server.

The authenticate method authenticates a user by using the WebSphere Application Server container login mechanism configured for the servlet context.

The syntax of the authenticate method is as follows:

```
boolean authenticate(HttpServletRequest response)
```

The previous example uses the following element:

response

The HttpServletResponse associated with the HttpServletRequest.

The authenticate method returns true when authentication has been established or authentication is successful.

The authenticate method returns false if authentication is incomplete and the underlying login mechanism has committed, in the response, the message and HTTP status code to be returned to the user.

A java.io.IOException occurs if an error occurs while writing the response.

A ServletException occurs if the authentication failed, and the caller is responsible for handling the error (for example, the underlying login mechanism did not establish the message and the HTTP status code to be returned to the user).

Note: When the authenticate method is called, be aware of the following:

- WebSphere Application Server returns HTTP 401 code to a client.
- The method depends on the WebSphere Application Server container login mechanism that is configured for the servlet context. For example, if you have a form login defined for this servlet, it prompts for a user name and password. The client sends the user ID and password to WebSphere Application Server for authentication.

Important: Make sure that the authenticate method returns true before using the new subject to call another service. For example:

```
Boolean authResultTrue = req.authenticate(response);
    if (!authResultTrue) {
        return;
    } else {
        // Use the new invocation subject to call other services.
    }
}
```

login

The login method authenticates a user to the WebSphere Application Server with a user ID and password. If authentication is successful, it creates a user subject on the thread and Lightweight Third Party Authentication (LTPA) cookies (if single sign-on (SSO) is enabled).

The syntax of the login method is as follows:

```
login(java.lang.String username, java.lang.String password)
```

The previous example uses the following elements:

username

The string value that corresponds to the login identifier of the user.

password

The password of the user.

A `ServletException` occurs if the configured login mechanism does not support username and password authentication, if an identity had already been authenticated (prior to the call to login), or if validation of the provided username and password fails.

Note: You can set the security custom property `com.ibm.websphere.security.webAlwaysLogin` to `true` and it will authenticate to the WebSphere application with the username and password, even if it is already authenticated.

For more information about modifying security custom properties, read the [Modifying an existing custom property in a global security configuration or in a security domain configuration](#) article.

Note: The login method always uses the user ID and password to authenticate to the WebSphere application server and even the SSO information that is present in the `HttpServletRequest`.

Note: The `authenticate` and `login` methods set the invocation subject to the new subject. If the caller subject is null, it then sets the caller subject to the new subject. If the caller subject is not null, then the caller subject is not set to the new subject.

Since the `authenticate` and `login` methods set the invocation subject to the new subject, the `RunAs` defined by the `run-As` attribute in deployment descriptor, security annotation or dynamic annotation is ignored.

logout

The logout method logs the user out of the WebSphere Application Server and invalidates the HTTP session. During this process, WebSphere Application Server completes the following processes:

- Clears the LTPA cookies if SSO is enabled
- Invalidates the HTTP session
- Removes the user from the authentication cache
- Removes the user subject from the thread
- Clears the caller and invocation subjects
- Sets the authentication type to `null`

After logging out, access to a protected web resource requires re-authentication and the `getUserPrincipal`, `getRemoteUser` and `getAuthType` methods return `null`.

The syntax of the logout method is as follows:

```
logout()
```

A ServletException occurs if the logout fails.

Audit event types for the authenticate, login and logout methods

To audit authenticate, login and logout methods, you must create or extend some audit event type files. These event type are not part of the default event type files.

Table 66. Audit event types for the authenticate, login, and logout methods.

The audit event types required for the authenticate, login, and logout methods are:

Method	Audit event name	Audit outcome of the event
authenticate/login	SECURITY_AUTHN	SUCCESS and or FAILURE
logout	SECURITY_AUTHN_TERMINATE	SUCCESS
logout	SECURITY_AUTHN_TERMINATE	FAILURE

isUserInRole

(String role name): Returns true if the remote user is granted the specified security role. If the remote user is not granted the specified role, or if no user is authenticated, it returns false.

getRemoteUser

The getRemoteUser method returns the login of the user that makes the request if the user has been authenticated. If the user has not been authenticated, the getRemoteUser method returns null.

getAuthType

The getAuthType method returns the name of the authentication scheme that is used to protect the servlet. If the servlet is not protected, the getAuthType method returns null.

The authentication schemes used are:

FORM when form-based authentication is used

BASIC
when basic authentication is used.

CLIENT_CERT
when client certificate authentication is used.

Note:

For both the getRemoteUser and getAuthType methods, the data that is returned depends upon whether security is enabled in the application server where the servlet is deployed. The following possibilities exist:

- If application security is enabled and a servlet is protected, then the getRemoteUser method returns the login and the getAuthType method returns the configured authentication scheme.
- If application security is not enabled, both methods return null.

Web authentication settings:

Use this page to specify the web authentication settings that are associated with a web client.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under Authentication, expand Web and SIP security and click General settings.

You can override the global Web authentication settings that you select on this panel by specifying one or more of the following system properties on the server level. Complete the following steps to specify one of these system properties:

1. Click **Servers > Server Types > WebSphere application servers > *server_name***.
2. Under Server infrastructure, click **Java and Process Management > Process definition**.
3. Under Additional properties, click **Java Virtual Machine > Custom Properties > New**.

Table 67. Web authentication system property values. This table lists the web authentication system property values.

Property name	Value	Explanation
com.ibm.wsspi.security.web.webAuthReq	lazy	This value is equivalent to the Authenticate only when the URI is protected option. Note: You can set webAuthReq differently through the administrative console or scripting when using a global or a security domain, but the global level always takes precedence.
com.ibm.wsspi.security.web.webAuthReq	persisting	This value is equivalent to the Use available authentication data when an unprotected URI is accessed option.
com.ibm.wsspi.security.web.webAuthReq	always	This value is equivalent to the Authenticate when any URI is accessed option.
com.ibm.wsspi.security.web.failOverToBasicAuth	true	This value is equivalent to the Default to basic authentication when certificate authentication for the HTTPS client fails option.

Authenticate only when the URI is protected:

The application server challenges the web client to provide authentication data when the web client accesses a Uniform Resource Identifier (URI) that is protected by a Java 2 Platform, Enterprise Edition (J2EE) role. The authenticated identity is available only when the web client accesses a protected URI.

This option is the default J2EE web authentication behavior that is also available in previous releases of WebSphere Application Server.

Note: When you select this option, the administrative console login page is missing images. You might encounter the following error in the administrative console: “CWLAA6003: Could not display the portlet, the portlet may not be started. Check the error logs”.

The missing images and the error message are a side-effect of this option. The images do not display because the URIs for the images now need authentication, which requires you to log in. You can ignore this error message.

Information

Default:

Value

Enabled

Use available authentication data when an unprotected URI is accessed:

The web client can access validated authenticated data that it previously could not access. This option enables the web client to call the getRemoteUser, isUserInRole, and getUserPrincipal methods to retrieve an authenticated identity from an unprotected URI.

When you select this option with the Authenticate only when the URI is protected option, the web client can use authenticated data when the URI is protected or not protected.

When this option is selected and Form-based authentication is being used, a WASPostParam cookie is generated during the authentication procedure of the HTTP POST request even if the target URL is unprotected. A WASPOSTParam cookie is a temporary cookie used to store HTTP POST parameters. This

results in the Web client being sent the unnecessary cookie with an HTTP response. This might cause unexpected behavior when the size of the cookie is larger than the browser limit. To avoid this behavior, a custom property, `com.ibm.websphere.security.util.postParamMaxCookieSize` can be set to cause the security code to stop generating the cookie if the maximum size is reached.

Important: This option does not challenge the web client to provide authenticated data if the web client accesses an unprotected URI without authenticated data.

Information	Value
Default:	Enabled

Authenticate when any URI is accessed:

The web client must provide authentication data regardless of whether the URI is protected.

Information	Value
Default:	Disabled

Default to basic authentication when certificate authentication for the HTTPS client fails:

When the required HTTPS client certificate authentication fails, the application server uses the basic authentication method to challenge the web client to provide a user ID and password.

The HTTP client certification authentication that is performed by the application server security is different from the client authentication that is performed by the web server plug-in. If you configure the web server plug-in for mutual authentication and client authentication fails, the following situations will occur:

- The web server produces a error and the web request is not processed by application server security.
- The application server cannot fail over to basic authentication.

Information	Value
Default:	Disabled

Developing with programmatic APIs for EJB applications

Use this topic to programmatically secure your Enterprise JavaBeans (EJB) applications.

About this task

Programmatic security is used by security-aware applications when declarative security alone is not sufficient to express the security model of the application. The `javax.ejb.EJBContext` application programming interface (API) provides two methods whereby the bean provider can access security information about the enterprise bean caller.

- **isCallerInRole**(String rolename): Returns `true` if the bean caller is granted the security role that is specified by role name. If the caller is not granted the specified role, or if the caller is not authenticated, it returns `false`. If the specified role is granted Everyone access, it always returns `true`.
- **getCallerPrincipal**: Returns the `java.security.Principal` object that contains the bean caller name. If the caller is not authenticated, it returns a principal that contains an unauthorized name.

You can enable a login module to indicate which principal class is returned by these calls.

When the `isCallerInRole` method is used, declare a `security-role-ref` element in the deployment descriptor with a `role-name` that is subelement containing the role name that is passed to this method. Because actual roles are created during the assembly stage of the application, you can use a logical role as the role name and provide enough hints to the assembler in the description of the `security-role-ref` element to link that role to an actual role. During assembly, the assembler creates a `role-link` subelement to link the

role-name to the actual role. Creation of a security-role-ref element is possible if an assembly tool such as Rational Application Developer is used. You also can create the security-role-ref element during the assembly stage using an assembly tool.

Procedure

1. Add the required security methods in the EJB module code.
2. Create a security-role-ref element with a role-name field for all the role names used in the isCallerInRole method. If a security-role-ref element is not created during development, make sure it is created during the assembly stage.

Results

Performing the previous steps result in a programmatically secured EJB application.

Example

Hard coding security policies in applications is strongly discouraged. The Java Platform, Enterprise Edition (Java EE) security model capabilities of declaratively specifying security policies is encouraged wherever possible. Use these APIs to develop security-aware EJB applications.

Using Java EE security model capabilities to specify security policies declaratively is useful when an EJB application wants to access external resources and wants to control the access to these external resources using its own authorization table (external-resource to user mapping). In this case, use the getCallerPrincipal method to get the caller identity and then the application can consult its own authorization table to perform authorization. The caller identification also can help retrieve the corresponding user information from an external source, such as database or from another enterprise bean. You can use the isCallerInRole method in a similar way.

After development, you can create a security-role-ref element:

```
<security-role-ref>
<description>Provide hints to assembler for linking this role-name to
actual role here</description>
<role-name>Mgr</role-name>
</security-role-ref>
```

During assembly, the assembler creates a role-link element:

```
<security-role-ref>
<description>Hints provided by developer to map role-name to role-link</description>
<role-name>Mgr</role-name>
<role-link>Manager</role-link>
</security-role-ref>
```

You can add programmatic EJB component security methods for example isCallerInRole and getCallerPrincipal, inside any business methods of an enterprise bean. The following example of programmatic security APIs includes a session bean:

```
public class aSessionBean implements SessionBean {

    ....

    // SessionContext extends EJBContext. If it is entity bean use EntityContext
    javax.ejb.SessionContext context;

    // The following method will be called by the EJB container
    // automatically
    public void setSessionContext(javax.ejb.SessionContext ctx) {
        context = ctx; // save the session bean's context
    }

    ....
}
```

```

private void aBusinessMethod() {
    ....

    // to get bean's caller using getCallerPrincipal()
    java.security.Principal principal = context.getCallerPrincipal();
    String callerId= principal.getName();

    // to check if bean's caller is granted Mgr role
    boolean isMgr = context.isCallerInRole("Mgr");

    // use the above information in any way as needed by the
    //application

    ....
}
}

```

When developing EJB 3.x modules, the value of the rolename argument in isCallerInRole method can be defined using Java annotations instead of declaring a security-role-ref elements in the deployment descriptor.

```

@javax.annotation.security.DeclareRoles("Mgr")
@Stateless // annotation is used to indicate a session bean
public class aSessionBean implements MyBusinessInterface { //you don't have to extend sessionbean interface
    ....
    // SessionContext extends EJBContext. In EJB 3.0 use Resource annotation to inject context
    @Resource
    javax.ejb.SessionContext context;    }

    ....

    private void aBusinessMethod() {
    ....

    // to get bean's caller using getCallerPrincipal()
    java.security.Principal principal = context.getCallerPrincipal();
    String callerId= principal.getName();

    // to check if bean's caller is granted Mgr role
    boolean isMgr = context.isCallerInRole("Mgr");

    // use the above information in any way as needed by the
    //application

    ....
}
}

```

What to do next

After developing an application, use an assembly tool to create roles and to link the actual roles to role names in the security-role-ref elements. See the information about securing web applications using an assembly tool.

Example: Enterprise bean application code:

The following Enterprise JavaBeans (EJB) component example illustrates the use of the isCallerInRole and the getCallerPrincipal methods in an EJB module.

Using declarative security is recommended. The following example is one way of using the isCallerInRole and the getCallerPrincipal methods. The application can use this result in any way that is suitable.

A remote interface

File : Hello.java

```
package tests;
import java.rmi.RemoteException;
/**
 * Remote interface for Enterprise Bean: Hello
 */
public interface Hello extends javax.ejb.EJBObject {
    public abstract String getMessage()throws RemoteException;
    public abstract void setMessage(String s)throws RemoteException;
}
```

A home interface

File : HelloHome.java

```
package tests;
/**
 * Home interface for Enterprise Bean: Hello
 */
public interface HelloHome extends javax.ejb.EJBHome {
    /**
     * Creates a default instance of Session Bean: Hello
     */
    public tests.Hello create() throws javax.ejb.CreateException,
        java.rmi.RemoteException;
}
```

A bean implementation

File : HelloBean.java

```
package tests;
/**
 * Bean implementation class for Enterprise Bean: Hello
 */
public class HelloBean implements javax.ejb.SessionBean {
    private javax.ejb.SessionContext mySessionCtx;
    /**
     * getSessionContext
     */
    public javax.ejb.SessionContext getSessionContext() {
        return mySessionCtx;
    }
    /**
     * setSessionContext
     */
    public void setSessionContext(javax.ejb.SessionContext ctx) {
        mySessionCtx = ctx;
    }
    /**
     * ejbActivate
     */
    public void ejbActivate() {
    }
    /**
     * ejbCreate
     */
    public void ejbCreate() throws javax.ejb.CreateException {
    }
    /**
     * ejbPassivate
     */
    public void ejbPassivate() {
    }
    /**
     * ejbRemove
     */
    public void ejbRemove() {
    }
}
```

```

public java.lang.String message;

    //business methods

    // all users can call getMessage()
    public String getMessage() {
        return message;
    }

    // all users can call setMessage() but only few users can set new message.
    public void setMessage(String s) {

        // get bean's caller using getCallerPrincipal()
        java.security.Principal principal = mySessionCtx.getCallerPrincipal();
        java.lang.String callerId= principal.getName();

        // check if bean's caller is granted Mgr role
        boolean isMgr = mySessionCtx.isCallerInRole("Mgr");

        // only set supplied message if caller is "bob" or caller is granted Mgr role
        if ( isMgr || callerId.equals("bob") )
            message = s;
        else
            message = "Hello";
    }
}

```

After the development of the entity bean, create a security role reference in the deployment descriptor under the session bean, Hello:

```

<security-role-ref>
  <description>Only Managers can call setMessage() on this bean (Hello)</description>
  <role-name>Mgr</role-name>
</security-role-ref>

```

For an explanation of how to create a <security-role-ref> element, see [Securing enterprise bean applications](#). Use the information under `Map security-role-ref` and `role-name` to `role-link` to create the element.

Customizing web application login

You can create a form login page and an error page to authenticate a user.

Before you begin

A web client or a browser can authenticate a user to a Web server using one of the following mechanisms:

- **HTTP basic authentication:** A web server requests the Web client to authenticate and the web client passes a user ID and a password in the HTTP header.
- **HTTPS client authentication:** This mechanism requires a user (web client) to possess a public key certificate. The web client sends the certificate to a web server that requests the client certificates. This authentication mechanism is strong and uses the Hypertext Transfer Protocol with Secure Sockets Layer (HTTPS) protocol.
- **Form-based Authentication:** A developer controls the look and feel of the login screens using this authentication mechanism.

The Hypertext Transfer Protocol (HTTP) basic authentication transmits a user password from the web client to the web server in simple base64 encoding. Form-based authentication transmits a user password from the browser to the web server in plain text. Therefore, both HTTP basic authentication and form-based authentication are not very secure unless the HTTPS protocol is used.

The web application deployment descriptor contains information about which authentication mechanism to use. When form-based authentication is used, the deployment descriptor also contains entries for login

and error pages. A login page can be either an HTML page or a JavaServer Pages (JSP) file. This login page is displayed on the web client side when a secured resource (servlet, JSP file, HTML page) is accessed from the application. On authentication failure, an error page is displayed. You can write login and error pages to suit the application needs and control the look and feel of these pages. During assembly of the application, an assembler can set the authentication mechanism for the application and set the login and error pages in the deployment descriptor.

Form login uses the servlet `sendRedirect` method, which has several implications for the user. The `sendRedirect` method is used twice during form login:

- The `sendRedirect` method initially displays the form login page in the web browser. It later redirects the web browser back to the originally requested protected page. The `sendRedirect(String URL)` method tells the web browser to use the HTTP GET request to get the page that is specified in the web address. If HTTP POST is the first request to a protected servlet or JavaServer Pages (JSP) file, and no previous authentication or login occurred, then HTTP POST is not delivered to the requested page. However, HTTP GET is delivered because form login uses the `sendRedirect` method, which behaves as an HTTP GET request that tries to display a requested page after a login occurs.
- Using HTTP POST, you might experience a scenario where an unprotected HTML form collects data from users and then posts this data to protected servlets or JSP files for processing, but the users are not logged in for the resource. To avoid this scenario, structure your web application or permissions so that users are forced to use a form login page before the application performs any HTTP POST actions to protected servlets or JSP files.

Procedure

1. Create a form login page with the required look and feel, including the required elements to perform form-based authentication.
2. Create an error page. You can program error pages to retry authentication or to display an appropriate error message.
3. Place the login page and error page in the web application archive (.war) file relative to the top directory. For example, if the login page is configured as `/login.html` in the deployment descriptor, place it in the top directory of the WAR file. An assembler can also perform this step using the assembly tool.
4. Create a form logout page and insert it to the application only when the web application requires a form-based authentication mechanism.

By default the URL to the logout page should point to the host to which the request was made or its domain. Otherwise, a generic logout page is displayed. If you need to point this URL to a different host, then you need to set the `com.ibm.websphere.security.logoutExitPageDomainList` property in the `security.xml` file with a list of URLs that are allowed for the logout page. You can choose to allow any logout exit page to be used by setting the `com.ibm.websphere.security.allowAnyLogoutExitPageHost` property to a value of `true`. Setting this property to `true` might open your systems to a potential URL redirect attacks.

Example: Form login

You can use the WebSphere Application Server login facilities to implement and configure form login procedures. Use the following technologies for WebSphere Application Server and Java Platform, Enterprise Edition (Java EE) login functionality:

- Java EE form-based login
- Java EE servlet filter with login
- IBM extension: form-based login

The form login sample is part of the Technology Samples package. For more information on how to access the form login sample, see [Accessing the samples](#).

Form login usage

For the authentication to proceed appropriately, the action of the login form must always have the `j_security_check` action. The following example shows how to code the form into the HTML page:

```
<form method="POST" action="j_security_check">
<input type="text" name="j_username">
<input type="text" name="j_password">
</form>
```

Use the `j_username` input field to get the user name, and use the `j_password` input field to get the user password.

On receiving a request from a web client, the web server sends the configured form page to the client and preserves the original request. When the web server receives the completed form page from the web client, the server extracts the user name and password from the form and authenticates the user. On successful authentication, the web server redirects the call to the original request. If authentication fails, the web server redirects the call to the configured error page.

The following example depicts a login page in HTML (`login.html`):

```
<!DOCTYPE HTML PUBLIC "-//W3C/DTD HTML 4.0 Transitional//EN">
<html>
<META HTTP-EQUIV = "Pragma" CONTENT="no-cache">
<title> Security FVT Login Page </title>
<body>
<h2>Form Login</h2>
<FORM METHOD=POST ACTION="j_security_check">
<p>
<font size="2"> <strong> Enter user ID and password: </strong></font>
<BR>
<strong> User ID</strong> <input type="text" size="20" name="j_username">
<strong> Password </strong> <input type="password" size="20" name="j_password">
<BR>
<BR>
<font size="2"> <strong> And then click this button: </strong></font>
<input type="submit" name="login" value="Login">
</p>
</form>
</body>
</html>
```

The following example depicts an error page in a JSP file:

```
<!DOCTYPE HTML PUBLIC "-//W3C/DTD HTML 4.0 Transitional//EN">
<html>
<head><title>A Form login authentication failure occurred</head></title>
<body>
<H1><B>A Form login authentication failure occurred</H1></B>
<P>Authentication may fail for one of many reasons. Some possibilities include:
<OL>
<LI>The user-id or password may be entered incorrectly; either misspelled or the
wrong case was used.
<LI>The user-id or password does not exist, has expired, or has been disabled.
</OL>
</P>
</body>
</html>
```

After an assembler configures the web application to use form-based authentication, the deployment descriptor contains the login configuration as shown:

```
<login-config id="LoginConfig_1">
<auth-method>FORM</auth-method>
<realm-name>Example Form-Based Authentication Area</realm-name>
<form-login-config id="FormLoginConfig_1">
<form-login-page>/login.html</form-login-page>
<form-error-page>/error.jsp</form-error-page>
</form-login-config>
</login-config>
```

A sample web application archive (WAR) file directory structure that shows login and error pages for the previous login configuration follows:

```
META-INF
  META-INF/MANIFEST.MF
  login.html
  error.jsp
WEB-INF/
  WEB-INF/classes/
  WEB-INF/classes/aServlet.class
```

Form logout

Form logout is a mechanism to log out without having to close all Web-browser sessions. After logging out of the form logout mechanism, access to a protected web resource requires re-authentication. This feature is not required by J2EE specifications, but it is provided as an additional feature in WebSphere Application Server security.

Suppose that you want to log out after logging into a web application and perform some actions. A form logout works in the following manner:

1. The logout-form URI is specified in the web browser and loads the form.
2. The user clicks **Submit** on the form to log out.
3. The WebSphere Application Server security code logs the user out. During this process, the Application Server completes the following processes:
 - a. Clears the Lightweight Third Party Authentication (LTPA) / single sign-on (SSO) cookies
 - b. Invalidates the HTTP session
 - c. Removes the user from the authentication cache
4. Upon logout, the user is redirected to a logout exit page.

Form logout does not require any attributes in a deployment descriptor. The form-logout page is an HTML or a JavaServer Pages (JSP) file that is included with the web application. The form-logout page is like most HTML forms except that like the form-login page, the form-logout page has a special post action. This post action is recognized by the web container, which dispatches the post action to a special internal form-logout servlet. The post action in the form-logout page must be `ibm_security_logout`.

You can specify a logout-exit page in the logout form and the exit page can represent an HTML or a JSP file within the same web application to which the user is redirected after logging out. Additionally, the logout-exit page permits a fully qualified URL in the form of `http://hostname:port/URL`. The logout-exit page is specified as a parameter in the form-logout page. If no logout-exit page is specified, a default logout HTML message is returned to the user.

Here is a sample form logout HTML form. This form configures the logout-exit page to redirect the user back to the login page after logout.

```
<!DOCTYPE HTML PUBLIC "-//W3C/DTD HTML 4.0 Transitional//EN">
<html>
  <META HTTP-EQUIV = "Pragma" CONTENT="no-cache">
  <title>Logout Page </title>
  <body>
    <h2>Sample Form Logout</h2>
    <FORM METHOD=POST ACTION="ibm_security_logout" NAME="logout">
      <p>
        <BR>
        <BR>
        <font size="2"><strong> Click this button to log out: </strong></font>
        <input type="submit" name="logout" value="Logout">
        <INPUT TYPE="HIDDEN" name="logoutExitPage" VALUE="/login.html">
      </p>
    </form>
  </body>
</html>
```

What to do next

After developing login and error pages, add them to the Web application. Use the assembly tool to configure an authentication mechanism and insert the developed login page and error page in the deployment descriptor of the application.

Developing servlet filters for form login processing

You can control the look and feel of the login screen using the form-based login mechanism. In form-based login, you specify a login page that is used to retrieve the user ID and password information. You also can specify an error page that displays when authentication fails.

About this task

If additional authentication or additional processing is required before and after authentication, servlet filters are an option. Servlet filters can dynamically intercept requests and responses to transform or to use the information that is contained in the requests or responses. One or more servlet filters can be attached to a servlet or to a group of servlets. Servlet filters also can attach to JavaServer Pages (JSP) files and HTML pages. All of the attached servlet filters are called before the servlet is invoked.

Both form-based login and servlet filters are supported by any servlet Version 2.3 specification-complaint web container. The form login servlet performs the authentication and servlet filters perform additional authentication, auditing, or logging information.

To perform pre-login and post-login actions using servlet filters, configure these filters for either form login page support or for the `/j_security_check` URL. The `j_security_check` is posted by a form login page with the `j_username` parameter that contains the user name and the `j_password` parameter that contains the password. A servlet filter can use the user name parameter and password information to perform more authentication or other special needs.

Procedure

1. A servlet filter implements the `javax.servlet.Filter` class. Implement three methods in the filter class:
 - **init(javax.servlet.FilterConfig cfg)**. This method is called by the container once, when the servlet filter is placed into service. The `FilterConfig` passed to this method contains the init-parameters of the servlet filter. Specify the init-parameters for a servlet filter during configuration using the assembly tool.
 - **destroy**. This method is called by the container when the servlet filter is taken out of a service.
 - **doFilter(ServletRequest req, ServletResponse res, FilterChain chain)**. This method is called by the container for every servlet request that maps to this filter before invoking the servlet. The `FilterChain` chain that is passed to this method can be used to invoke the next filter in the chain of filters. The original requested servlet runs when the last filter in the chain calls the `chain.doFilter` method. Therefore, all filters call the `chain.doFilter` method for the original servlet to run after filtering. If an additional authentication check is implemented in the filter code and results in failure, the original servlet does not run. The `chain.doFilter` method is not called and can be redirected to some other error page.
2. If a servlet maps to many servlet filters, servlet filters are called in the order that is listed in the `web.xml` deployment descriptor of the application. Place the servlet filter class file in the `WEB-INF/classes` directory of the application.

Example

An example of a servlet filter.

This login filter can map to the `/j_security_check` URL to perform pre-login and post-login actions.

```
import javax.servlet.*;
public class LoginFilter implements Filter {
    protected FilterConfig filterConfig;
    // Called once when this filter is instantiated.
    // If mapped to j_security_check, called
    // very first time j_security_check is invoked.
    public void init(FilterConfig filterConfig) throws ServletException {
        this.filterConfig = filterConfig;
    }
    public void destroy() {
        this.filterConfig = null;
    }
    // Called for every request that is mapped to this filter.
    // If mapped to j_security_check,
    // called for every j_security_check action
    public void doFilter(ServletRequest request,
        ServletResponse response, FilterChain chain)
        throws java.io.IOException, ServletException {
        // perform pre-login action here
        chain.doFilter(request, response);
    }
}
```

```

    // calls the next filter in chain.
    // j_security_check if this filter is
    // mapped to j_security_check.
    // perform post-login action here.
}

```

Using servlet filters to perform pre-login and post-login processing during form login

This example illustrates one way that the servlet filters can perform pre-login and post-login processing during form login.

Servlet filter source code: LoginFilter.java

```

/**
 * A servlet filter example: This example filters j_security_check and
 * performs pre-login action to determine if the user trying to log in
 * is in the revoked list. If the user is on the revoked list, an error is
 * sent back to the browser.
 *
 * This filter reads the revoked list file name from the FilterConfig
 * passed in the init() method. It reads the revoked user list file and
 * creates a revokedUsers list.
 *
 * When the doFilter method is called, the user logging in is checked
 * to make sure that the user is not on the revoked Users list.
 */

import javax.servlet.*;
import javax.servlet.http.*;
import java.io.*;

public class LoginFilter implements Filter {

    protected FilterConfig filterConfig;

    java.util.List revokeList;

    /**
     * init() : init() method called when the filter is instantiated.
     * This filter is instantiated the first time j_security_check is
     * invoked for the application (When a protected servlet in the
     * application is accessed).
     */
    public void init(FilterConfig filterConfig) throws ServletException {
        this.filterConfig = filterConfig;

        // read revoked user list
        revokeList = new java.util.ArrayList();
        readConfig();
    }

    /**
     * destroy() : destroy() method called when the filter is taken
     * out of service.
     */
    public void destroy() {
        this.filterConfig = null;
        revokeList = null;
    }

    /**
     * doFilter() : doFilter() method called before the servlet to
     * which this filter is mapped is invoked. Since this filter is
     * mapped to j_security_check, this method is called before
     * j_security_check action is posted.
     */
    public void doFilter(ServletRequest request, ServletResponse response,
        FilterChain chain) throws java.io.IOException, ServletException {

        HttpServletRequest req = (HttpServletRequest)request;
        HttpServletResponse res = (HttpServletResponse)response;

        // pre login action

        // get username
        String username = req.getParameter("j_username");

        // if user is in revoked list send error
        if ( revokeList.contains(username) ) {
            res.sendError(javax.servlet.http.HttpServletResponse.SC_UNAUTHORIZED);
            return;
        }
    }
}

```

```

// call next filter in the chain : let j_security_check authenticate
// user
chain.doFilter(request, response);

// post login action
}

/**
 * readConfig() : Reads revoked user list file and creates a revoked
 * user list.
 */
private void readConfig() {
    if ( filterConfig != null ) {

        // get the revoked user list file and open it.
        BufferedReader in;
        try {
            String filename = filterConfig.getInitParameter("RevokedUsers");
            in = new BufferedReader( new FileReader(filename));
        } catch ( FileNotFoundException fnfe) {
            return;
        }

        // read all the revoked users and add to revokeList.
        String userName;
        try {
            while ( (userName = in.readLine()) != null )
                revokeList.add(userName);
        } catch (IOException ioe) {
        }

    }
}
}
}

```

Important: In the previous code sample, the line that begins `public void doFilter(ServletRequest request` is broken into two lines for illustrative purposes only. The `public void doFilter(ServletRequest request` line and the line after it are one continuous line.

An example of the `web.xml` file that shows the `LoginFilter` filter configured and mapped to the `j_security_check` URL:

```

<filter id="Filter_1">
  <filter-name>LoginFilter</filter-name>
  <filter-class>LoginFilter</filter-class>
  <description>Performs pre-login and post-login operation</description>
  <init-param>
    <param-name>RevokedUsers</param-name>
    <param-value>c:\WebSphere\AppServer\installedApps\
      <app-name>\revokedUsers.lst</param-value>
  </init-param>
</filter-id>

<filter-mapping>
  <filter-name>LoginFilter</filter-name>
  <url-pattern>/j_security_check</url-pattern>
</filter-mapping>

```

An example of a revoked user list file:

```

user1
cn=user1,o=ibm,c=us
user99
cn=user99,o=ibm,c=us

```

Configuring servlet filters for form login processing:

IBM Rational Application Developer or an assembly tool can configure the servlet filters. Two steps are involved in configuring a servlet filter.

Procedure

1. Name the servlet filter and assign the corresponding implementation class to the servlet filter.

Optionally, assign initialization parameters that get passed to the init method of the servlet filter. After configuring the servlet filter, the `web.xml` application deployment descriptor contains a servlet filter configuration similar to the following example:

```
<filter id="Filter_1">
  <filter-name>LoginFilter</filter-name>
  <filter-class>LoginFilter</filter-class>
  <description>Performs pre-login and post-login
    operation</description>
  <init-param>// optional
    <param-name>ParameterName</param-name>
    <param-value>ParameterName</param-value>
  </init-param>
</filter>
```

2. Map the servlet filter to a URL or a servlet.

After mapping the servlet filter to a URL or a servlet, the `web.xml` application deployment descriptor contains servlet mapping similar to the following example:

```
<filter-mapping>
  <filter-name>LoginFilter</filter-name>
  <url-pattern>/j_security_check</url-pattern>
  // can be servlet <servlet>servletName</servlet>
</filter-mapping>
```

Example

You can use servlet filters to replace the CustomLoginServlet servlet, and to perform additional authentication, auditing, and logging.

The WebSphere Application Server Samples provide a form login sample that demonstrates how to use the WebSphere Application Server login facilities to implement and configure form login procedures. The sample integrates the following technologies to demonstrate the WebSphere Application Server and Java Platform, Enterprise Edition (Java EE) login functionality:

- Java EE form-based login
- Java EE servlet filter with login
- IBM extension: form-based login

The form login sample is part of the Technology Samples package.

Secure transports with JSSE and JCE programming interfaces

This topic provides detailed information about transport security using Java Secure Socket Extension (JSSE) and Java Cryptography Extension (JCE) programming interfaces. Within this topic, there is a description of the IBM version of the Java Cryptography Extension Federal Information Processing Standard (IBMJCE/FIPS).

Java Secure Socket Extension

Java Secure Socket Extension (JSSE) provides the transport security for WebSphere Application Server. JSSE provides the application programming interface (API) framework and the implementation of the APIs for Secure Sockets Layer (SSL) and Transport Layer Security (TLS) protocols, including functionality for data encryption, message integrity, and authentication.

JSSE APIs are integrated into the Java 2 SDK, Standard Edition (J2SDK), Version 5. The API package for JSSE APIs is `javax.net.ssl.*`. Documentation for using JSSE APIs can be found in the J2SE 6 API documentation that is located at <http://java.sun.com/javase/6/docs/technotes/guides/security/jsse/JSSERefGuide.html>.

Several JSSE providers ship with the Java 2 SDK Version 5 that comes with WebSphere Application Server. The IBMJSSE provider is used in previous WebSphere Application Server releases. Associated with the IBMJSSE provider is the IBMJSSE/FIPS provider, which is used when FIPS is enabled on the

server. Both of these providers do not work with the Java Message Service (JMS) and HTTP transports in WebSphere Application Server Version 8.5. These transports take advantage of the J2SDK Verison 5 network input/output (NIO) asynchronous channels.

For more information on the new IBMJSSE2 provider, please review the documentation located at <http://www.ibm.com/developerworks/java/jdk/security/60/>.

Customizing Java Secure Socket Extension

You can customize a number of aspects of JSSE by plugging in different implementations of Cryptography Package Provider, X509Certificate and HTTPS protocols, or specifying different default keystore files, key manager factories, and trust manager factories. The following table summarizes which aspects can be customized, what the defaults are, and which mechanisms are used to provide customization.

Table 68. Customizable items. You can customize the following key aspects:

Customizable item	Default	How to customize
X509Certificate	X509Certificate implementation from IBM	The <code>cert.provider.x509v1</code> security property
HTTPS protocol	Implementation from IBM	The <code>java.protocol.handler.pkgs</code> system property
Cryptography Package Provider	IBMJSSE2	A <code>security.provider.n=</code> line in security properties file. See description.
Default keystore	None	The <code>* javax.net.ssl.keyStore</code> system property
Default truststore	<code>jssecacerts</code> , if it exists. Otherwise, <code>cacerts</code>	The <code>* javax.net.ssl.trustStore</code> system property
Default key manager factory	<code>IbmX509</code>	The <code>ssl.KeyManagerFactory.algorithm</code> security property
Default trust manager factory	<code>IbmX509</code>	The <code>ssl.TrustManagerFactory.algorithm</code> security property

For aspects that you can customize by setting a system property, statically set the system property by using the `-D` option of the Java command. You can set the system property using the administrative console, or set the system property dynamically by calling the `java.lang.System.setProperty` method in your code: `System.setProperty(propertyName, "propertyValue")`.

For aspects that you can customize by setting a Java security property, statically specify a security property value in the `java.security` properties file. The security property is `propertyName=propertyValue`. Dynamically set the Java security property by calling the `java.security.Security.setProperty` method in your code.

The `java.security` properties file is located in the following directory:

IBM i `profile_root/properties` directory.

Application Programming Interface

The JSSE provides a standard application programming interface (API) that is available in packages of the `javax.net` file, `javax.net.ssl` file, and the `javax.security.cert` file. The APIs cover:

- Sockets and SSL sockets
- Factories to create the sockets and SSL sockets
- Secure socket context that acts as a factory for secure socket factories
- Key and trust manager interfaces
- Secure HTTP URL connection classes
- Public key certificate API

IBM i You can find more information documented for the JSSE APIs if you access the following information:

Version 1.6

1. Access the <http://www.ibm.com/developerworks/java/jdk/security/> website.
2. Click Java 1.6.
3. Click Javadoc HTML documentation in the Java Secure Socket Extension (JSSE) Guide section.

Samples using Java Secure Socket Extension

The Java Secure Socket Extension (JSSE) also provides samples to demonstrate its functionality. The Java Secure Socket Extension (JSSE) also provides samples to demonstrate its functionality. You can access the samples in the following location:

Version 1.6

1. Access the <http://www.ibm.com/developerworks/java/jdk/security/> website.
2. Click Java 1.6.
3. Click `jssedocs_samples.zip` in the Java Secure Socket Extension (JSSE) Guide section.

Table 69. Extracted files. This table lists the following extracted files:

Files	Description
ClientJsse.java	Demonstrates a simple client and server interaction using JSSE. All enabled cipher suites are used.
OldServerJsse.java	Back-level samples
ServerPKCS12Jsse.java	Demonstrates a simple client and server interaction using JSSE with the PKCS12 keystore file. All enabled cipher suites are used.
ClientPKCS12Jsse.java	Demonstrates a simple client and server interaction using JSSE with the PKCS12 keystore file. All enabled cipher suites are used.
UseHttps.java	Demonstrates accessing an SSL or non-SSL web server using the Java protocol handler of the <code>com.ibm.net.ssl.www.protocol</code> class. The URL is specified with the <code>http</code> or <code>https</code> prefix. The HTML that is returned from this site is displayed.

See more instructions in the source code. Follow these instructions before you run the samples.

Permissions for Java 2 security

You might need the following permissions to run an application with JSSE: This list is for reference only.

- `java.util.PropertyPermission "java.protocol.handler.pkgs", "write"`
- `java.lang.RuntimePermission "writeFileDescriptor"`
- `java.lang.RuntimePermission "readFileDescriptor"`
- `java.lang.RuntimePermission "accessClassInPackage.sun.security.x509"`
- `java.io.FilePermission "${user.install.root}${}/etc${}/.keystore", "read"`
- `java.io.FilePermission "${user.install.root}${}/etc${}/.truststore", "read"`

For the IBMJSSE provider:

- `java.security.SecurityPermission "putProviderProperty.IBMJSSE"`
- `java.security.SecurityPermission "insertProvider.IBMJSSE"`

For the SUNJSSE provider:

- `java.security.SecurityPermission "putProviderProperty.SunJSSE"`
- `java.security.SecurityPermission "insertProvider.SunJSSE"`

Debugging

By configuring through the `javax.net.debug` system property, JSSE provides the following dynamic debug tracing: `-Djavax.net.debug=true`.

A value of `true` turns on the trace facility, provided that the debug version of JSSE is installed.

Documentation

See the Security: Resources for learning topic for documentation references to JSSE.

JCE

Java Cryptography Extension (JCE) provides cryptographic, key and hash algorithms for WebSphere Application Server. JCE provides a framework and implementations for encryption, key generation, key agreement, and Message Authentication Code (MAC) algorithms. Support for encryption includes symmetric, asymmetric, block and stream ciphers.

IBMJCE

The IBM version of the Java Cryptography Extension (IBMJCE) is an implementation of the JCE cryptographic service provider that is used in WebSphere Application Server. The IBMJCE is similar to SunJCE, except that the IBMJCE offers more algorithms:

- Cipher algorithm (AES, DES, TripleDES, PBEs, Blowfish, and so on)
- Signature algorithm (SHA1withRSA, MD5withRSA, SHA1withDSA)
- Message digest algorithm (MD5, MD2, SHA1, SHA-256, SHA-384, SHA-512)
- Message authentication code (HmacSHA1, HmacMD5)
- Key agreement algorithm (DiffieHellman)
- Random number generation algorithm (IBMSecureRandom, SHA1PRNG)
- Key store (JKS, JCEKS, PKCS12, JCERACFKS [z/OS only])

The IBMJCE belongs to the `com.ibm.crypto.provider.*` packages.

For further information, see the information on JCE on the following website: <http://www.ibm.com/developerworks/java/jdk/security/60/>.

IBMJCEFIPS

The IBM version of the Java Cryptography Extension Federal Information Processing Standard (IBMJCEFIPS) is an implementation of the JCE cryptographic service provider that is used in WebSphere Application Server. The IBMJCEFIPS service provider implements the following:

- Signature algorithms (SHA1withDSA, SHA1withRSA)
- Cipher algorithms (AES, TripleDES, RSA)
- Key agreement algorithm (DiffieHellman)
- Key (pair) generator (DSA, AES, TripleDES, HmacSHA1, RSA, DiffieHellman)
- Message authentication code (MAC) (HmacSHA1)
- Message digest (MD5, SHA-1, SHA-256, SHA-384, SHA-512)
- Algorithm parameter generator (DiffieHellman, DSA)
- Algorithm parameter (AES, DiffieHellman, DES, TripleDES, DSA)
- Key factory (DiffieHellman, DSA, RSA)
- Secret key factory (AES, TripleDES)
- Certificate (X.509)
- Secure random (IBMSecureRandom)

Application Programming Interface

Java Cryptography Extension (JCE) has a provider-based architecture. Providers can be plugged into the JCE framework by implementing the APIs that are defined by the JCE. The JCE APIs cover:

- Symmetric bulk encryption, such as DES, RC2, and IDEA
- Symmetric stream encryption, such as RC4

- Asymmetric encryption, such as RSA
- Password-based encryption (PBE)
- Key agreement
- Message authentication codes

IBM i There is more information documented for the JCE APIs on the <http://www.ibm.com/developerworks/java/jdk/security/> website.

Samples using Java Cryptography Extension

There are samples located on the <http://www.ibm.com/developerworks/java/jdk/security/> website in the `jceDocs_samples.zip` file. Unzip the file and locate the following samples in the `jceDocs/samples` directory:

Table 70. Samples using Java Cryptography Extension. This table describes samples using Java Cryptography Extension.

File	Description
SampleDSASignature.java	Demonstrates how to generate a pair of DSA keys (a public key and a private key) and use the key to digitally sign a message using the SHA1withDSA algorithm
SampleMarsCrypto.java	Demonstrates how to generate a Mars secret key, and how to do Mars encryption and decryption
SampleMessageDigests.java	Demonstrates how to use the message digest for MD2 and MD5 algorithms
SampleRSACrypto.java	Demonstrates how to generate an RSA key pair, and how to do RSA encryption and decryption
SampleRSASignatures.java	Demonstrates how to generate a pair of RSA keys (a public key and a private key) and use the key to digitally sign a message using the SHA1withRSA algorithm
SampleX509Verification.java	Demonstrates how to verify X509 certificates

Documentation

Refer to the Security: Resources for learning topic for documentation on JCE.

Configuring Federal Information Processing Standard Java Secure Socket Extension files

Use this topic to configure Federal Information Processing Standard Java Secure Socket Extension files.

About this task

In WebSphere Application Server, the Java Secure Socket Extension (JSSE) provider used is the IBMJSSE2 provider. This provider delegates encryption and signature functions to the Java Cryptography Extension (JCE) provider. Consequently, IBMJSSE2 does not need to be Federal Information Processing Standard (FIPS)-approved because it does not perform cryptography. However, the JCE provider requires FIPS-approval.

WebSphere Application Server provides a FIPS-approved IBMJCEFIPS provider that IBMJSSE2 can utilize. The IBMJCEFIPS provider that is shipped in WebSphere Application Server Version 8.5 supports the following SSL ciphers:

- SSL_RSA_WITH_AES_128_CBC_SHA
- SSL_RSA_WITH_3DES_EDE_CBC_SHA
- SSL_RSA_FIPS_WITH_3DES_EDE_CBC_SHA
- SSL_DHE_RSA_WITH_AES_128_CBC_SHA
- SSL_DHE_RSA_WITH_3DES_EDE_CBC_SHA
- SSL_DHE_DSS_WITH_AES_128_CBC_SHA
- SSL_DHE_DSS_WITH_3DES_EDE_CBC_SHA

Even though the IBMJSSEFIPS provider is still present, the runtime does not use this provider. If IBMJSSEFIPS is specified as a contextProvider, WebSphere Application Server automatically defaults to the IBMJSSE2 provider (with the IBMJCEFIPS provider) for supporting FIPS. When enabling the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option on the server SSL certificate and key management panel, the runtime always uses IBMJSSE2, despite the contextProvider that you specify for SSL (IBMJSSE, IBMJSSE2 or IBMJSSEFIPS). Also, because FIPS requires the SSL protocol be TLS, the runtime always uses TLS when FIPS is enabled, regardless of the SSL protocol setting in the SSL repertoire. This simplifies the FIPS configuration in Version 8.5 because an administrator needs to enable only the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option on the server SSL certificate and key management panel to enable all transports using SSL.

Procedure

1. Click **Security > SSL certificate and key management > Manage FIPS**.
2. Select the **Enable FIPS 140-2** option and click **Apply**. This option makes IBMJSSE2 and IBMJCEFIPS the active providers.
3. Accommodate Java clients that must access enterprise beans.
Change the `com.ibm.security.useFIPS` property value from `false` to `true` in the `profile_root/properties/ssl.client.props` file.
4. Ensure that the `com.ibm.ssl.protocol` property within the `profile_root/properties/ssl.client.props` file is set to `TLS`.
5. Ensure that the `java.security` file includes the provider.

What to do next

After completing these steps, a FIPS-approved JSSE or JCE provider offers increased encryption capabilities. However, when you use FIPS-approved providers:

- By default, Microsoft Internet Explorer might not have TLS enabled. To enable TLS, open the Internet Explorer browser and click **Tools > Internet Options**. On the Advanced tab, select the Use TLS 1.0 option.

Note: Netscape Version 4.7.x and earlier versions might not support TLS.

- If you have an administrative client that uses a SOAP connector and you enable FIPS, add the following line to the `profile_root/properties/soap.client.props` file:
`com.ibm.ssl.contextProvider=IBMJSSEFIPS`
- When you select the **Use the Federal Information Processing Standard (FIPS)** option on the SSL certificate and key management panel, the Lightweight Third-Party Authentication (LTPA) token format is not backwards-compatible with previous releases of WebSphere Application Server. However, you can import the LTPA keys from a previous version of the application server.

Note: When enabling FIPS, you cannot configure cryptographic token devices in the SSL repertoires. IBMJSSE2 must use IBMJCEFIPS when utilizing cryptographic services for FIPS.

The following FIPS 140-2 approved cryptographic providers that are the only devices that are supported with the FIPS option:

- IBMJCEFIPS (certificate 376)
- IBM Cryptography for C (ICC) (certificate 384)

The relevant certificates are listed on the NIST website: Cryptographic Module Validation Program FIPS 140-1 and FIPS 140-2 Pre-validation List

To unconfigure the FIPS provider, reverse the changes that you made in the previous steps. After you reverse the changes, verify that you have made the following changes to the `ssl.client.props`, `soap.client.props`, and `java.security` files:

- In the `ssl.client.props` file, you must change the `com.ibm.security.useFIPS` value to `false`.
-  Edit the `java.security` file to remove the FIPS provider and renumber the providers as in the following example:

```
security.provider.1=sun.security.provider.Sun
#security.provider.2=com.ibm.crypto.fips.provider.IBMJCEFIPS
security.provider.2=com.ibm.crypto.provider.IBMJCE
security.provider.3=com.ibm.jsse.IBMJSSEProvider
security.provider.4=com.ibm.jsse2.IBMJSSEProvider2
security.provider.5=com.ibm.security.jgss.IBMJGSSProvider
security.provider.6=com.ibm.security.cert.IBMCertPath
security.provider.7=com.ibm.i5os.jsse.JSSEProvider
#security.provider.8=com.ibm.crypto.pkcs11.provider.IBMPKCS11
security.provider.8=com.ibm.security.jgss.mech.spnego.IBMSPNEGO
```

WebSphere Application Server security standards configurations

WebSphere Application Server can be configured to work with various security standards, which are typically used to meet security requirements required by the government.

Note: WebSphere Application Server integrates cryptographic modules, which include Java Secure Socket Extension (JSSE) and Java Cryptography Extension (JCE). Most of the requirements in the standards are handled in the JSSE and JCE, which must undergo the certification process to meet government standards. WebSphere Application Server must be configured to run with the JSSE and JCE enabled for a particular standard, and now supports the FIPS 140-2, SP800-131 and Suite B security standards.

- **FIPS 140-2** are Federal Information Processing Standards (FIPS) that specify requirements on cryptographic modules. WebSphere Application Server has been able to configure using this standard the longest. Many users can be configured to use this level, but might be required to move up to the newer SP800-131 or Suite B standard.

See The National Institute of Standards and Technology web site for more information about the 140-2 standard.

To configure FIPS 140-2, see the topic “Configuring Federal Information Processing Standard Java Secure Socket Extension files”.

- **SP800-131** is a requirement originated by the National Institute of Standards and Technology (NIST) which requires longer key lengths and stronger cryptography. The specification also provides a transition configuration to enable users to move to a strict enforcement of SP800-131. The transition configuration also enables users to run with a mixture of settings from both FIPS140-2 and SP800-131. SP800-131 can be run in two modes, `transition` and `strict`.

Strict enforcement of SP800-131 requirements on WebSphere Application server includes the following:

- The use of the TLSv1.2 protocol for the Secure Sockets Layer (SSL) context.
- Certificates must have a minimum length of 2048. Elliptical Curve (EC) certificate require a minimum size of 244-bit curves.
- Certificates must be signed with a signature algorithm of SHA256, SHA384, or SHA512. Valid signatureAlgorithms include:
 - SHA256withRSA
 - SHA384withRSA
 - SHA512withRSA
 - SHA256withECDSA
 - SHA384withECDSA
 - SHA512withECDSA
- SP800-131 approved Cipher suites

See The National Institute of Standards and Technology web site for more details about the SP800-131 standard.

See the topic “Transitioning WebSphere Application Server to the SP800-131 security standard” for information on how to transition WebSphere Application Server to the SP800-131 strict standard. See the topic “Configuring WebSphere Application Server for SP800-131 standard strict mode” for information on how to configure SP800-131.

- **Suite B** is a requirement originated by the National Security Agency (NSA) to specify a cryptographic interoperability strategy. This standard is similar to SP800-131 with some tighter restrictions. Suite B can run in 2 modes: 128-bit or 192-bit. If using 192-bit mode, users must apply the unrestricted policy file to the JDK so that the stronger cipher required for the 192-bit mode can be used.

See the topic "Configuring WebSphere Application Server for the Suite B security standard" for information on to configure Suite B.

Suite B requirements on WebSphere Application Server includes the following:

- The use of the TLSv1.2 protocol for the SSL Context
- Suite B approved Cipher suites
- Certificates:
 - 128 bit mode certificates must be signed with SHA256withECDSA
 - 192 bit mode certificates must be signed with SHA384withECDSA
- Ciphers:
 - SSL_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
 - SSL_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384.

Properties used to enable the Security Standards

The IBM virtual machine for Java (JVM) runs in a given security mode based on system properties. WebSphere Application Server sets these system properties based on security configuration settings. The security configuration can be set up through the administrative console or through scripting admin tasks. If an application sets these properties directly it can affect WebSphere Application Server SSL communication.

Table 71. JVM system properties to enable the security standard

Security standard	System property to enable	Valid values
FIPS 140-2	com.ibm.jsse2.usefipsprovider	true or false
SP800-131	com.ibm.jsse2.sp800-131	transition or strict
Suite B	com.ibm.jsse2.suiteB	128 or 192

WebSphere Application Server configuration clears out all of these properties if they are set, then sets them to how the security configuration is specified. WebSphere Application Server enables the security standard based on the custom properties set in the security configuration.

WebSphere Application Server security custom properties to enable the security standard

Table 72. WebSphere Application Server security custom properties to enable the security standard

Security standard	Security custom properties	JVM system property
FIPS 140-2	com.ibm.security.useFips=true com.ibm.websphere.security.FIPSLevel=FIPS140-2	com.ibm.jsse2.usefipsprovider=true
SP800-131- transition	com.ibm.security.useFips=true com.ibm.websphere.security.FIPSLevel=transition	com.ibm.jsse2.sp800-131=transition
SP800-131 – strict	com.ibm.security.useFips=true com.ibm.websphere.security.FIPSLevel=SP800-131	com.ibm.jsse2.sp800-131=strict
Suite B 128	com.ibm.security.useFips=true com.ibm.websphere.security.suiteB=128	com.ibm.jsse2.suiteB=128

Table 72. WebSphere Application Server security custom properties to enable the security standard (continued)

Security standard	Security custom properties	JVM system property
Suite B 192	com.ibm.security.useFips=true com.ibm.websphere.security.suiteB=192	com.ibm.jsse2.suiteB=192

Convert certificates

Use this page to convert certificates to the selected security standard. All certificates in keystores associated with an Secure Socket Layer (SSL) configuration are converted.

To view this administrative console page, click **Security > SSL certificate and key management > Manage FIPS > Convert certificates**.

Algorithm: Specifies the signature algorithm used to convert the certificate to the selected security standard.

The following choices are available:

Strict Select for the strict enforcement of the SP800-131 standard.

Strict enforcement of SP800-131 requirements on WebSphere Application Server includes the following:

- The use of the TLSv1.2 protocol for the Secure Sockets Layer (SSL) context.
- Certificates must have a minimum length of 2048. Elliptical Curve (EC) certificate require a minimum size of 244-bit curves.
- Certificates must be signed with a signature algorithm of SHA256, SHA384, or SHA512. Valid signatureAlgorithms include:
 - SHA256withRSA
 - SHA384withRSA
 - SHA512withRSA
 - SHA256withECDSA
 - SHA384withECDSA
 - SHA512withECDSA
- SP800-131 approved Cipher suites

Suite B with 128 bit keys

This requirement places some tighter restrictions on the SP800-131 specification. 128-bit mode certificates must be signed with SHA256withECDSA.

Suite B with 192 bit keys

192 bit mode certificates must be signed with SHA384withECDSA.

To run in 192-bit mode, the unrestricted policy files must be in place on the JDK.

New certificate key size: Specifies the key size to use when converting the certificates.

The valid values are 512, 1024, 2048, 4096 and 8192. The default value is 2048.

Note: Elliptical Curve signature algorithms require specific sizes, so you must provide a size.

Certificates that can not be converted: Lists the certificates that are not compliant with the specified security standard and cannot be converted.

If certificates show up listed in this box, the server is unable to convert the certificates for you. You must replace these certificates with ones that meet Suite B requirements. Reasons why the server cannot convert the certificates might include:

- The certificate was created by a Certificate Authority (CA).
- The certificate is in a read-only keystore.

Manage FIPS

Use this page to disable Federal Information Processing Standards (FIPS) or to enable security standards that are required by the government.

WebSphere Application Server integrates cryptographic modules, which include Java Secure Socket Extension (JSSE) and Java Cryptography Extension (JCE). JSSE and JCE must undergo the certification process to meet government standards, and WebSphere Application Server must be configured to use them as specified by the standards.

To view this administrative console page, click **Security > SSL certificate and key management > Manage FIPS**.

Disable FIPS: Select to disable FIPS, which is the default.

Data type:	Default:	Range:
Boolean	Enabled	Enabled or Disabled

Enable FIPS 140-2: Select to enable FIPS 140-2. This option makes IBMJSSE2 and IBMJCEFIPS the active providers.

Federal Information Processing Standards (FIPS) specifies requirements on cryptographic modules. WebSphere Application Server has been able to configure using the FIPS 140-2 standard the longest. Many users can be configured to use this level, but might be required to move up to the newer SP800-131 or Suite B standard.

Data type:	Default:	Range:
Boolean	Enabled	Enabled or Disabled

Enable SP800-131: Select to enable SP800-131.

SP800-131 is a requirement originated by the National Institute of Standards and Technology (NIST) which requires longer key lengths and stronger cryptography. The specification also provides a transition configuration to enable users to move to a strict enforcement of SP800-131. The transition configuration also enables users to run with a mixture of settings from both FIPS140-2 and SP800-131. SP800-131 can be run in two modes, transition and strict.

Data type:	Default:	Range:
Boolean	Enabled	Enabled or Disabled

Enable Suite B: Accept 128 bit keys: Select to specify that suite B cryptography is used, and is configured to accept a 128-bit key size. Keystore certificate algorithms require Elliptical curve (EC) cryptography.

Data type:	Default:	Range:
Boolean	Enabled	Enabled or Disabled

Enable Suite B: Accept 192-bit keys: Select to specify that suite B cryptography is used, and is configured to accept a 192-bit key size. Keystore certificate algorithms require Elliptical curve (EC) cryptography.

Suite B can run in 2 modes: 128-bit or 192-bit. If using 192-bit mode, you must apply the unrestricted policy file to the JDK so that the stronger cipher required for the 192-bit mode can be used.

Data type:	Default:	Range:
Boolean	Enabled	Enabled or Disabled

Convert certificates: Select to convert certificates to the selected security standard. All certificates in keystores associated with an Secure Socket Layer (SSL) configuration are converted.

Configuring WebSphere Application Server for the Suite B security standard

You can configure WebSphere Application Server to use the new Suite B security standard.

Before you begin

Read the “WebSphere Application Server security standards configurations” topic for more background information regarding security standards.

About this task

The National Security Agency (NSA) created a cryptographic interoperability strategy called Suite B. It places specific requirements on the National Institute of Standards and Technology (NIST) SP800-131 standard.

Suite B requirements:

WebSphere Application Server must be compliant with the following Suite B requirements:

- SSL configuration must use the TLSv1.2 protocol.
- The `com.ibm.jsse.suiteb` system property must be set to 128 or 192.
- Certificates running in 128-bit mode must be created with the SHA256withECDSA signature algorithm. Certificates running in 192-bit mode must be created with the SHA384withECDSA signature algorithm.

Note: To run in 192-bit mode, the unrestricted policy files must be in place on the JDK.

- Suite B approved cipher suites must be used.

To configure the server for the Suite B standard:

Procedure

1. Click **Security > SSL certificate and key management > Manage FIPS** To run in a Suite B mode, all of the certificates used for SSL on the server must be converted to certificates that comply with Suite B requirements.
2. To convert certificates, under Related Items click **Convert Certificates**.
3. Select the radio button labeled **128-bit or 192-bit** in the Algorithm box.

Note: Elliptical Curve signature algorithms require specific sizes, so you must provide a size.

4. Click **Apply/Save**. If no certificates show up in the box labeled **Certificates that can not be converted**, then you can enable the standard.

If certificates show up listed in the box labeled **Certificates that can not be converted**, the server is unable to convert the certificates for you. You must replace these certificates with ones that meet Suite B requirements. Reasons why the server cannot convert the certificates might include:

- The certificate was created by a Certificate Authority (CA).
- The certificate is in a read-only keystore.

After certificates are converted to meet the Suite B specifications, follow the remaining steps to enable the Suite B standard.

5. Click **SSL certificate and key management > Manage FIPS**.
6. Select the **Suite B: Accept 128 bit key** for 128-bit mode or the **Suite B: Accept 192 bit key** for 192-bit mode.
7. Click **Apply/Save**.
8. Restart the servers and manually sync the nodes for the Suite B standard to take effect.

When these changes are applied and the server is restarted, the SSL configurations on the server is modified to use the TLSv1.2 protocol, and the `com.ibm.jsse.suiteb` system property is set to the desired Suite B mode. The SSL configuration uses the appropriate SSL ciphers for the standard.

There are wsadmin tasks also available that can enable the Suite B standard using scripting. :

- Check the status of certificates for the security standard by using the `listCertStatusForSecurityStandard` task.
 - Convert certificates for the security standard by using the `convertCertForSecurityStandard` task.
 - Enable the security standard by using the `enableFips` task.
 - To see the security standard setting, use the `getFipsInfo` task.
9. Once the server is configured for SP800-131 strict mode, the `ssl.client.props` file must be modified so that administrative clients are running in SP800-131 strict mode. They are unable to make a SSL connection to the server with the change. Edit the `ssl.client.props` file by doing the following:
 - a. Modify `com.ibm.security.useFIPS` to be set to `true`.
 - b. Add the `com.ibm.jsse.suiteb` property, and set it to 128 or 192.
 - c. Change the `com.ibm.ssl.protocol` property to `TLSv1.2`.

What to do next

The Suite B standard requires that the SSL connection use the TLSv1.2 protocol. For a browser to access the administrative console or an application, the browser must support and first be configured to use the TLSv1.2 protocol.

Note: When enabling the security standards on a Network Deployed, the node and deployment manager can be in an incompatible protocol state. Since configuring the security standard requires the server to be restarted, it is recommended that all node agents and servers be stopped, leaving the deployment manager running. Once the configuration changes are made through the console, restart the deployment manager.

Manually sync the nodes with `syncNode`, and start the node agents and servers. To use `syncNode`, you might need to update the `ssl.client.props` file to communicate with the deployment manager.

Transitioning WebSphere Application Server to the SP800-131 security standard

The National Institute of Standards and Technology (NIST) Special Publications 800-131 standard strengthens algorithms and increases the key lengths to improve security. The standard also provides for a transition period to move to the new standard. You can configure WebSphere Application Server for SP800-131 standard transition mode.

Before you begin

Read the "WebSphere Application Server security standards configurations" topic for more background information regarding security standards.

About this task

The transition period enables a user to run in a mixed environment of settings not supported under the standard along with those that are supported. The NIST SP800-131 standard requires that users be configured for strict enforcement of the standard by a specific timeframe. See The National Institute of Standards and Technology web site for more details.

The transition options can be very useful when trying to get to strict SP800-131. The servers can accept a mixture old settings and new requirements. For example, they can convert certificates but continue to use the TLS protocol.

WebSphere Application Server can be configured to run SP800-131 in a transition mode or a strict mode. For information on how to configure strict mode, read the Configuring WebSphere Application Server for strict mode SP800-131 security standard topic.

To run in the SP800-131 transition mode, the server must be in a specific configuration setting as well. Other strict requirements can be include as wanted.

- The `com.ibm.jsse2.sp800-131` system property must be set to `transition` for the JSSE to run in the transition mode.
- The SSL configuration protocols must be one of the TLS settings. Valid values include TLS, TLSv1, TLSv1.1, and TLSv1.2.

Procedure

1. Click **Security > SSL certificate and key management > Manage FIPS**.
2. Select the **Enable SP800-131** radio button.
3. Select the **Transition** radio button.
4. You have the choice to change the protocols in SSL configuration to TLSv1.2 by optionally selecting the **Update the SSL configuration to require TLSv1.2** box. If you do not select this box, all SSL configurations are set to TLS.
5. Click **Apply/Save**.
6. Restart the servers.

When these changes are applied, and the server is restarted, all of the SSL configuration on the server are modified to use the TLS or TLSv1.2 protocol, and the `com.ibm.jsse2.sp800-131` system property is set to `transition`. The SSL configuration uses the appropriate SSL ciphers for the standard.

Before you can move to the strict mode certificate, the protocol in the configuration must meet the strict requirements.

You can go to directly to the SSL configuration and set protocols to TLSv1.2 by doing the following:

7. Click **Security > SSL certificate and key management > SSL Configurations**.
8. Select a SSL configuration from the collection panel.
9. Under Related Items, select **Quality of protection (QoP)**.
10. Select **TLSv1.2** from the pull-down box labeled Protocol
11. Click **Apply/Save**. To change the SSL protocol using scripting, the `modifySSLConfig` task can also be used.

Certificates must have a minimum size of 2048 (244 if an Elliptical Curve certificate), and signed with SHA256, SHA384, or SHA512. You can create new ones on the console and replace the old one, or import certificates that meet the standards requirements.

There are a number of options you can use to replace certificates.

- Use the Convert Certificate panel. This panel converts all certificates to meet the standard specified.

- a. Click **Security > SSL certificate and key management > Manage FIPS > Convert Certificate**

Note: If there are any certificates in the box labeled **Certificates** that can not be converted, then a certificate can not be converted using this option.

- b. Select the **Strict** radio button and choose which signatureAlgorithm to use when creating the new certificates from the pull-down box.
- c. Select the size of the certificate from the pull-down box labeled **New Certificate Key Size**. Note that Elliptical Curve signature algorithms require a specific size, so there is no need to provide a size.
- d. Click **Apply/Save**.

The convertCertForSecurityStandard scripting task can also be used to convert all certificates to meet a specified standard.

- Use the personal certificate panels to create new certificates and replace a certificate that does not meet the requirements by doing the following:

- a. Click **Security > SSL certificate and key management > Key stores and certificates**.

- b. Select a keystore from the collection panel.

- c. Select **Personal Certificate**.

- 1) From the pull-down list on the Create button, select **Self-Signed Certificate**.
- 2) Fill in an alias for the certificate. Select a signature algorithm for the certificate that is signed with SHA256, SHA384, or SHA512. Choose a size that is 2048 or greater. Note that Elliptical Curve signature algorithms require a specific size, so there is no need to specify a size.
- 3) Click **Apply/Save**.
- 4) Go back to the Personal certificate collection panel and select the certificate that does not meet the standard. Click **Replace**.
- 5) On the Replace panel, select the certificate created that meets the standard from the pull-down list in the box labeled **Replace with**.
- 6) Select **Delete old certificate** after replacement, and **Delete old signer boxes**.
- 7) Click **Apply/Save**.

Note: To replace chained certificates, a root certificate must be created that meets the standard. Follow the previous navigation path to the root certificate in the defaultRootStore, then create a chained certificate with that new root certificate.

The createSelfSignCertificate scripting task can also be used to create self-signed certificate. The replaceCertificate scripting task can also be used to replace the new certificate for the old one.

- Use the personal certificate panels to import certificates and to replace the certificate that does not meet the requirements. Some certificate come from external sources such as a Certificate Authority (CA).

- a. Click **Security > SSL certificate and key management > Key stores and certificates**.

- b. Select a keystore from the collection panel.

- c. Select **Personal Certificate**.

- 1) Select **Import Certificate**.
- 2) Fill in the information needed to access the certificate in an existing keystore file.
- 3) Click **Apply/Save**.
- 4) Go back to the Personal certificate collection panel and select the certificate that does not meet the standard. Click the **Replace** button.

- 5) On the Replace panel, select the certificate created that meets the standard from the pull-down list in the box labeled **Replace with**. Select **Delete old certificate after replacement** and **Delete old signer boxes**.
- 6) Click **Apply/Save**.
The importCertificate scripting task can also be used to import a certificate. The replaceCertificate scripting task can also be used to replace the new certificate for the old one.
12. To enable strict SP800-131, click **Security > SSL certificate and key management > Manage FIPS**.
13. Click the **Enable SP800-131**.
14. Click the **Strict**.
15. Click **Apply/Save**.
16. Restart your servers and manually sync your nodes for the changes to take effect.
17. Configure the client `ssl.client.props` file for the transition mode SP800-131 standard. Once the server is configured for SP800-131 transition mode, the `ssl.client.props` file might need to be modified so that the admin client can connect to the server.
Edit the `ssl.client.props` file. Change the `com.ibm.ssl.protocol` property to match the protocol the server is using.
18. Configure the client `ssl.client.props` file for strict mode SP800-131 standard. Once the server is configured for SP800-131 strict mode, the `ssl.client.props` file must be modified so that the admin client is running in SP800-131 strict mode. It is not able to make a SSL connection to the server without the change.
Edit the `ssl.client.props` file as follows:
 - a. Modify the `com.ibm.security.useFIPS` to be set to `true`.
 - b. Add the `com.ibm.websphere.security.FIPSLLevel=SP800-131` just below the `useFips` property.
 - c. Change the `com.ibm.ssl.protocol` property to `TLSv1.2`

What to do next

The browser used to access the administrative console or an application must use a protocol that is compatible with the server. If the server is running in a transition mode, the browser must be set to use the protocol that matches the server. The SP800-131 standard requires that the SSL connection use the TLSv1.2 protocol, so the browser must support TLSv1.2 and use it to access the administrative console.

Configuring WebSphere Application Server for SP800-131 standard strict mode

You can configure WebSphere Application Server to use the SP800-131 standard strict mode.

Before you begin

Read the “WebSphere Application Server security standards configurations” topic for more background information regarding security standards.

About this task

The National Institute of Standards and Technology (NIST) Special Publications (SP) 800-131 standard strengthens algorithms and increases the key lengths to improve security. The standard also provides for a transition period to move to the new standard. The transition period enables a user to run in a mixed environment of settings not supported under the standard along with those that are supported. The NIST SP800-131 standard requires that users be configured for strict enforcement of the standard by a specific timeframe. See The National Institute of Standards and Technology web site for more details.

WebSphere Application Server can be configured to run SP800-131 in a transition mode or a strict mode. For instructions on how to configure transition mode, read the topic “Transitioning WebSphere Application Server to the SP800-131 Security Standard”.

To run in strict mode, there are several changes necessary to the server configuration:

- Secure Sockets Layer (SSL) configuration must use the TLSv1.2 protocol.
- The `com.ibm.jsse2.sp800-131` system property must be set to `strict` for the JSSE to run in a strict SP800-131 mode.
- Certificates used for SSL communication must have a minimum length of 2048, and for Elliptical Curve (EC) certificates they must have a minimum length of 244.
- Certificates must be signed with a signature algorithm of SHA256, SHA384, or SHA512.
- SP800-131 approved cipher suites must be used.

Procedure

1. Click **Security > SSL certificate and key management > Manage FIPS** To run in a strict SP800-131 mode, all of the certificates used for SSL on the server must be converted to certificates that comply with the SP800-131 requirements.
2. To convert certificates, under Related Items, click **Convert Certificates**.
3. Select the radio button marked **Strict**, and choose which signatureAlgorithm to use when creating the new certificates from the pull-down box.
4. Select the size of the certificate from the pull-down box labeled **New Certificate Key Size**.

Note: If you choose an Elliptical Curve signature algorithm, they require specific sizes; you are not able to fill in a size. The correct size is used instead.

5. If no certificates are displayed in the box labeled **Certificates that can not be converted**, click **Apply/Save**.
6. If certificates are displayed in the box labeled **Certificates that can not be converted**, the server is unable to convert the certificate for you. You must replace these certificates with ones that meet SP800-131 requirements. Reasons why the server can not convert a certificate for you include:
 - The certificate was created by a Certificate Authority (CA)
 - The certificate is in a read only keystore

Once certificates are converted to meet the SP800-131 specification, perform the following steps to enable SP800-131 strict mode.

7. Click **SSL certificate and key management > Manage FIPS**.
 8. Enable the radio button labeled **Enable SP800-131**.
 9. Enable the radio button labeled **Strict**.
 10. Click **Apply/Save**.
 11. Restart the servers and manually sync the nodes for the SP800-131 strict mode to take effect.
- When these changes are applied, and the server is restarted, all of the SSL configuration on the server are modified to use the TLSv1.2 protocol and the `com.ibm.jsse2.sp800-131` system property is set to `strict`. The SSL configuration uses the appropriate SSL ciphers for the standard.

There are several wsadmin tasks that can be used to enable strict SP800-131 using scripting

- Check the status of certificates for the security standard by using the `listCertStatusForSecurityStandard` task.
- Convert certificates for the security standard by using the `convertCertForSecurityStandard` task.
- Enable the security standard by using the `enableFips` task.
- To see the security standard setting, use the `getFipsInfo` task.

12. Once the server is configured for SP800-131 strict mode, the `ssl.client.props` file must be modified so that the administrative client is running in SP800-131 strict mode. They are not able to make a SSL connection to the server without the change.

Edit the `ssl.client.props` file by doing the following:

- a. Modify `com.ibm.security.useFIPS` to be set to `true`.
- b. Add `com.ibm.websphere.security.FIPSLevel=SP800-131` just below the `useFips` property.
- c. Change the `com.ibm.ssl.protocol` property to `TLSv1.2`.

What to do next

The SP800-131 standard strict mode requires that the SSL connection use the TLSv1.2 protocol. For a browser to access the administrative console or an application, the browser must support and first be configured to use the TLSv1.2 protocol.

Manually sync the nodes with `syncNode`, and start the node agents and servers. To use `syncNode`, you might need to update the `ssl.client.props` file to communicate with the deployment manager.

Implementing tokens for security attribute propagation

As part of an extensible architecture, WebSphere Application Server enables you to implement your own tokens in which to propagate security attributes.

About this task

The following topics are covered in this section:

Procedure

- Implementing a custom propagation token
- Implementing a custom authorization token
- Implementing a custom a single sign-on token
- Implementing a custom authentication token
- Propagating a custom Java serializable object

Implementing a custom propagation token for security attribute propagation

This topic explains how you might create your own propagation token implementation, which is set on the running thread and propagated downstream.

About this task

The default propagation token usually is sufficient for propagating attributes that are not user-specific. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. You must deserialize the bytes at the target and add that information back on the thread by plugging in a custom login module into the inbound system login configurations. This task also might include encryption and decryption.

To implement a custom propagation token, you must complete the following steps:

Procedure

1. Write a custom implementation of the `PropagationToken` interface. Many different methods are available for implementing the `PropagationToken` interface. However, make sure that the methods that are required by the `PropagationToken` interface and the token interface are fully implemented.

IBM i After you implement this interface, you can place it in the *profile_root/classes* directory. For more information on classes, see “Creating a classes subdirectory in your profile for custom classes” on page 676.

Tip: All of the token types that are defined by the propagation framework have similar interfaces. The token types are marker interfaces that implement the `com.ibm.wsspi.security.token.Token` interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the `com.ibm.wsspi.security.token.Token` interface. All of your token implementations, including the propagation token, might extend the abstract class and then most of the work is complete.

To see an implementation of the propagation token, see “Example: `com.ibm.wsspi.security.token.PropagationToken` implementation.”

2. Add and receive the custom propagation token during WebSphere Application Server logins. This task is typically accomplished by adding a custom login module to the various application and system login configurations. You also can add the implementation from an application. However, to deserialize the information, you need to plug in a custom login module, which is discussed in “Propagating a custom Java serializable object for security attribute propagation” on page 770. The `WSSecurityPropagationHelper` class has APIs that are used to set a propagation token on the thread and to retrieve the token from the thread to make updates.

The code sample in “Example: Custom propagation token login module” on page 746 shows how to determine if the login is an initial login or a propagation login. The difference between these login types is whether the `WSTokenHolderCallback` callback contains propagation data. If the callback does not contain propagation data, initialize a new custom propagation token implementation and set it on the thread. If the callback contains propagation data, look for your specific custom propagation token `TokenHolder` instance, convert the byte array back into your custom `PropagationToken` object, and set it back on the thread. The code sample shows both instances.

You can add attributes any time your custom propagation token is added to the thread. If you add attributes between requests and the `getUniqueld` method changes, the Common Secure Interoperability Version 2 (CSIv2) client session is invalidated so that it can send the new information downstream. Adding attributes between requests can affect performance. In many cases, you want the downstream requests to receive the new propagation token information.

To add the custom propagation token to the thread, call the `WSSecurityPropagationHelper.addPropagationToken` method. This call requires the WebSphereRuntimePerMission “setPropagationToken” Java 2 Security permission.

3. Add your custom login module to WebSphere Application Server system login configurations that already contain the `com.ibm.ws.security.server.Im.wsMapDefaultInboundLoginModule` login module for receiving serialized versions of your custom propagation token. You can also add this login module to any of the application logins where you might want to generate your custom propagation token on the thread during the login. Alternatively, you can generate the custom `PropagationToken` implementation from within your application. However, to deserialize it, you need to add the implementation to the system login modules.

Results

After completing these steps, you have implemented a custom `PropagationToken`.

Example: `com.ibm.wsspi.security.token.PropagationToken` implementation:

Use this file to see an example of a propagation token implementation. The following sample code does not extend an abstract class, but implements the `com.ibm.wsspi.security.token.PropagationToken` interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if considerable differences exist between how you handle the various token implementations.

For information on how to implement a custom propagation token, see “Implementing a custom propagation token for security attribute propagation” on page 741.

}

```

Example: Custom propagation token login module:

This example shows how to determine if the login is an initial login or a propagation login.

```

public customLoginModule()
{
    public void initialize(Subject subject, CallbackHandler callbackHandler,
        Map sharedState, Map options)
    {
        // (For more information on what to do during initialization, see
        // Developing custom login modules for a system login configuration for JAAS.)
    }

    public boolean login() throws LoginException
    {
        // (For more information on what to do during login, see
        // Developing custom login modules for a system login configuration for JAAS.)

        // Handles the WSTokenHolderCallback to see if this is an initial
        // or propagation login.
        Callback callbacks[] = new Callback[1];
        callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");

        try
        {
            callbackHandler.handle(callbacks);
        }
        catch (Exception e)
        {
            // handle exception
        }

        // Receives the ArrayList of TokenHolder objects (the serialized tokens)
    }
}

```

```

List authzTokenList = ((WSTokenHolderCallback) callbacks[0]).getTokenHolderList();
if (authzTokenList != null)
{
    // Iterates through the list looking for your custom token
    for (int i=0; i<authzTokenList.size(); i++)
    {
        TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

        // Looks for the name and version of your custom PropagationToken implementation
        if (tokenHolder.getName().equals("
            com.ibm.websphere.security.token.CustomPropagationTokenImpl") &&
            tokenHolder.getVersion() == 1)
        {
            // Passes the bytes into your custom PropagationToken constructor
            // to deserialize
            customPropToken = new
            com.ibm.websphere.security.token.CustomPropagationTokenImpl(tokenHolder.
                getBytes());
        }
    }
}
else // This is not a propagation login. Create a new instance of
    // your PropagationToken implementation
{
    // Adds a new custom propagation token. This is an initial login
    customPropToken = new com.ibm.websphere.security.token.CustomPropagationTokenImpl();

    // Adds any initial attributes
    if (customPropToken != null)
    {
        customPropToken.addAttribute("key1", "value1");
        customPropToken.addAttribute("key1", "value2");
        customPropToken.addAttribute("key2", "value1");
        customPropToken.addAttribute("key3", "something different");
    }
}

// Note: You can add the token to the thread during commit in case
// something happens during the login.
}

public boolean commit() throws LoginException
{
    // For more information on what to do during commit, see
    // Developing custom login modules for a system login configuration for JAAS.
    if (customPropToken != null)
    {
        // Sets the propagation token on the thread
        try
        {
            System.out.println(tc, "*** ADDED MY CUSTOM PROPAGATION TOKEN TO THE THREAD ***");
            // Prints out the values in the deserialized propagation token
            java.util.Enumeration keys = customPropToken.getAttributeNames();
            while (keys.hasMoreElements())
            {
                String key = (String) keys.nextElement();
                String[] list = (String[]) customPropToken.getAttributes(key);
                for (int k=0; k<list.length; k++)
                System.out.println("Key/Value: " + key + "/" + list[k]);
            }

            // This sets it on the thread using getName() + getVersion() as the key
            com.ibm.wsspi.security.token.WSSecurityPropagationHelper.addPropagationToken(
                customPropToken);
        }
        catch (Exception e)
        {
            // Handles exception
        }
    }

    // Now you can verify that you have set it properly by trying to get
    // it back from the thread and print the values.
    try
    {
        // This gets the PropagationToken from the thread using getName()
        // and getVersion() parameters.
        com.ibm.wsspi.security.token.PropagationToken tempPropagationToken =
            com.ibm.wsspi.security.token.WSSecurityPropagationHelper.getPropagationToken(
                "com.ibm.websphere.security.token.CustomPropagationTokenImpl", 1);

        if (tempPropagationToken != null)
        {
            System.out.println(tc, "*** RECEIVED MY CUSTOM PROPAGATION
                TOKEN FROM THE THREAD ***");
            // Prints out the values in the deserialized propagation token
            java.util.Enumeration keys = tempPropagationToken.getAttributeNames();

```

```

while (keys.hasMoreElements())
{
    String key = (String) keys.nextElement();
    String[] list = (String[]) tempPropagationToken.getAttributes(key);
    for (int k=0; k<list.length; k++)
        System.out.println("Key/Value: " + key + "/" + list[k]);
}
}
catch (Exception e)
{
    // Handles exception
}
}

// Defines your login module variables
com.ibm.wsspi.security.token.PropagationToken customPropToken = null;
}

```

Implementing a custom authorization token for security attribute propagation

This task explains how you might create your own AuthorizationToken implementation, which is set in the login Subject and propagated downstream.

About this task

The default AuthorizationToken usually is sufficient for propagating attributes that are user-specific. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. You must deserialize the bytes at the target and add that information back on the thread. This task also might include encryption and decryption.
- Affect the overall uniqueness of the Subject using the getUniqueID() application programming interface (API).

To implement a custom authorization token, you must complete the following steps:

Procedure

1. Write a custom implementation of the AuthorizationToken interface. There are many different methods for implementing the AuthorizationToken interface. However, make sure that the methods required by the AuthorizationToken interface and the token interface are fully implemented.

IBM i After you implement this interface, place it in the *profile_root/classes* directory. For more information on classes, see “Creating a classes subdirectory in your profile for custom classes” on page 676.

Tip: All of the token types defined by the propagation framework have similar interfaces. Basically, the token types are marker interfaces that implement the `com.ibm.wsspi.security.token.Token` interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the `com.ibm.wsspi.security.token.Token` interface. All of your token implementations, including the `AuthorizationToken`, might extend the abstract class and then most of the work is completed.

To see an implementation of `AuthorizationToken`, see “Example: `com.ibm.wsspi.security.token.AuthorizationToken` implementation” on page 749

2. Add and receive the custom `AuthorizationToken` during WebSphere Application Server logins. This task is typically accomplished by adding a custom login module to the various application and system login configurations. However, in order to deserialize the information, you must plug in a custom login module, which is discussed in “Propagating a custom Java serializable object for security attribute propagation” on page 770. After the object is instantiated in the login module, you can add the object to the Subject during the `commit()` method.

If you only want to add information to the Subject to get propagated, see “Propagating a custom Java serializable object for security attribute propagation” on page 770. If you want to ensure that the

information is propagated, want to do your own custom serialization, or want to specify the uniqueness for Subject caching purposes, then consider writing your own AuthorizationToken implementation.

The code sample in “Example: custom AuthorizationToken login module” on page 753 shows how to determine if the login is an initial login or a propagation login. The difference between these login types is whether the WSTokenHolderCallback contains propagation data. If the callback does not contain propagation data, initialize a new custom AuthorizationToken implementation and set it into the Subject. If the callback contains propagation data, look for your specific custom AuthorizationToken TokenHolder instance, convert the byte[] back into your custom AuthorizationToken object, and set it back into the Subject. The code sample shows both instances.

You can make your AuthorizationToken read-only in the commit phase of the login module. If you do not make the token read-only, then attributes can be added within your applications.

3. Add your custom login module to WebSphere Application Server system login configurations that already contain the com.ibm.ws.security.server.Im.wSMapDefaultInboundLoginModule for receiving serialized versions of your custom authorization token.

Because this login module relies on information in the sharedState added by the com.ibm.ws.security.server.Im.wSMapDefaultInboundLoginModule, add this login module after com.ibm.ws.security.server.Im.wSMapDefaultInboundLoginModule. For information on how to add your custom login module to the existing login configurations, see Developing custom login modules for a system login configuration for JAAS.

Results

After completing these steps, you have implemented a custom AuthorizationToken.

Example: com.ibm.wsspi.security.token.AuthorizationToken implementation:

Use this file to see an example of a AuthorizationToken implementation. The following sample code does not extend an abstract class, but rather implements the com.ibm.wsspi.security.token.AuthorizationToken interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if there are considerable differences between how you handle the various token implementations.

For information on how to implement a custom AuthorizationToken, see “Implementing a custom authorization token for security attribute propagation” on page 748.

```

Example: custom AuthorizationToken login module:

This file shows how to determine if the login is an initial login or a propagation login.

For information on what to do during initialization, login and commit, see [Developing custom login modules for a system login configuration for JAAS](#).

```

public customLoginModule()
{
    public void initialize(Subject subject, CallbackHandler callbackHandler,
        Map sharedState, Map options)
    {
        _sharedState = sharedState;
    }

    public boolean login() throws LoginException
    {
        // Handles the WSTokenHolderCallback to see if this is an initial or
        // propagation login.
        Callback callbacks[] = new Callback[1];
        callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");

        try
        {
            callbackHandler.handle(callbacks);
        }
        catch (Exception e)
        {
            // Handles exception
        }

        // Receives the ArrayList of TokenHolder objects (the serialized tokens)
        List authzTokenList = ((WSTokenHolderCallback) callbacks[0]).getTokenHolderList();

        if (authzTokenList != null)
        {
            // Iterates through the list looking for your custom token
            for (int i=0; i
            for (int i=0; i<authzTokenList.size(); i++)
            {
                TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

                // Looks for the name and version of your custom AuthorizationToken
                // implementation
                if (tokenHolder.getName().equals("com.ibm.websphere.security.token.
                    CustomAuthorizationTokenImpl") &&
                    tokenHolder.getVersion() == 1)
                {
                    // Passes the bytes into your custom AuthorizationToken constructor
                    // to deserialize
                    customAuthzToken = new
                        com.ibm.websphere.security.token.CustomAuthorizationTokenImpl(
                            tokenHolder.getBytes());
                }
            }
        }
        else
        {
            // This is not a propagation login. Create a new instance of your
            // AuthorizationToken implementation
        {
            // Gets the principal from the default AuthenticationToken. This must match
            // all tokens.
            defaultAuthToken = (com.ibm.wsspi.security.token.AuthenticationToken)
                sharedState.get(com.ibm.wsspi.security.auth.callback.Constants.WSAUTHTOKEN_KEY);
        }
    }
}

```

```

String principal = defaultAuthToken.getPrincipal();

    // Adds a new custom authorization token. This is an initial login. Pass the
    // principal into the constructor
    customAuthzToken = new com.ibm.websphere.security.token.
        CustomAuthorizationTokenImpl(principal);

// Adds any initial attributes
if (customAuthzToken != null)
{
    customAuthzToken.addAttribute("key1", "value1");
    customAuthzToken.addAttribute("key1", "value2");
    customAuthzToken.addAttribute("key2", "value1");
    customAuthzToken.addAttribute("key3", "something different");
}

    // Note: You can add the token to the Subject during commit in case something
    // happens during the login.
}

public boolean commit() throws LoginException
{

}

```

Implementing a custom single sign-on token for security attribute propagation

You can create your own single sign-on token implementation. The single sign-on token implementation is set in the login Subject and added to the HTTP response as an HTTP cookie.

About this task

The cookie name is the concatenation of the SingleSignonToken.getName application programming interface (API) and the SingleSignonToken.getVersion API. There is no delimiter. When you add a single sign-on token to the Subject, it also gets propagated horizontally and downstream in case the Subject is used for other web requests. You must deserialize your custom single sign-on token when you receive it from a propagation login. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.

- Serialize the information using custom serialization. Encrypt the information because it is out to the HTTP response and is available on the Internet. You must deserialize or decrypt the bytes at the target and add that information back into the Subject.
- Affect the overall uniqueness of the Subject using the `getUniqueID` API.

To implement a custom single sign-on token, complete the following steps:

Procedure

1. Write a custom implementation of the `SingleSignonToken` interface.

Many different methods are available for implementing the `SingleSignonToken` interface. However, make sure the methods that are required by the `SingleSignonToken` interface and the token interface are fully implemented.

IBM i After you implement this interface, you can place it in the `profile_root/classes` directory. For more information on classes, see “Creating a classes subdirectory in your profile for custom classes” on page 676.

Tip: All of the token types that are defined by the propagation framework have similar interfaces. Basically, the token types are marker interfaces that implement the `com.ibm.wsspi.security.token.Token` interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the `com.ibm.wsspi.security.token.Token` interface. All of your token implementations, including the single sign-on token, might extend the abstract class and then most of the work is complete.

To see an implementation of the single sign-on token, see “Example: A `com.ibm.wsspi.security.token.SingleSignonToken` implementation” on page 756

2. Add and receive the custom single sign-on token during WebSphere Application Server logins. This task is typically accomplished by adding a custom login module to the various application and system login configurations. However, to deserialize the information, you need to plug in a custom login module, which is discussed in a subsequent step. After the object is instantiated in the login module, you can add it to the Subject during the commit method.

The code sample in “Example: A custom single sign-on token login module” on page 759, shows how to determine if the login is an initial login or a propagation login. The difference is whether the `WSTokenHolderCallback` callback contains propagation data. If the callback does not contain propagation data, initialize a new custom single sign-on token implementation and set it into the Subject. Also, look for the HTTP cookie from the HTTP request if the HTTP request object is available in the callback. You can get your custom single sign-on token both from a horizontal propagation login and from the HTTP request. However, it is recommended that you make the token available in both places because then the information arrives at any front-end application server, even if that server does not support propagation.

You can make your single sign-on token read-only in the commit phase of the login module. If you make the token read-only, additional attributes cannot be added within your applications.

Restriction:

- HTTP cookies have a size limitation. Size restrictions should be included in the documentation for your specific browser.
 - The WebSphere Application Server runtime does not handle cookies that it does not generate, so this cookie is not used by the runtime.
 - The `SingleSignonToken` object, when in the Subject, does affect the cache lookup of the Subject if you return something in the `getUniqueID` method.
3. Get the HTTP cookie from the HTTP request object during login or from an application. The sample code that is found in “Example: An HTTP cookie retrieval” on page 761 shows how you can retrieve the HTTP cookie from the HTTP request, decode the cookie so that it is back to your original bytes, and create your custom `SingleSignonToken` object from the bytes.

4. Add your custom login module to WebSphere Application Server system login configurations that already contain the `com.ibm.ws.security.server.Im.wsMapDefaultInboundLoginModule` for receiving serialized versions of your custom propagation token. Because this login module relies on information in the `sharedState` state that is added by the `com.ibm.ws.security.server.Im.wsMapDefaultInboundLoginModule` login module, add this login module after the `com.ibm.ws.security.server.Im.wsMapDefaultInboundLoginModule` login module.

For information on adding your custom login module into the existing login configurations, see [Developing custom login modules for a system login configuration for JAAS](#).

Results

After completing these steps, you have implemented a custom single sign-on token.

Example: A `com.ibm.wsspi.security.token.SingleSignonToken` implementation:

Use this file to see an example of a single sign-on implementation. The following sample code does not extend an abstract class, but implements the `com.ibm.wsspi.security.token.SingleSignonToken` interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if considerable differences exist between how you handle the various token implementations.

For information on how to implement a custom single sign-on token, see [“Implementing a custom single sign-on token for security attribute propagation”](#) on page 754.

Example: A custom single sign-on token login module:

This file shows how to determine if the login is an initial login or a propagation login.

For information on initialization and on what to do during login and commit, see [Developing custom login modules for a system login configuration for JAAS](#).

```

public customLoginModule()
{
    public void initialize(Subject subject, CallbackHandler callbackHandler,
        Map sharedState, Map options)
    {
        _sharedState = sharedState;
    }

    public boolean login() throws LoginException
    {
        // Handles the WSTokenHolderCallback to see if this is an initial or
        // propagation login.
        Callback callbacks[] = new Callback[1];
        callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");

        try
        {
            callbackHandler.handle(callbacks);
        }
        catch (Exception e)
        {
            // handle exception
        }

        // Receives the ArrayList of TokenHolder objects (the serialized tokens)
        List authzTokenList = ((WSTokenHolderCallback) callbacks[0]).getTokenHolderList();

        if (authzTokenList != null)
        {
            // iterate through the list looking for your custom token
            for (int i=0; i
            for (int i=0; i<authzTokenList.size(); i++)
            {
                TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

                // Looks for the name and version of your custom SingleSignonToken
                // implementation
                if (tokenHolder.getName().equals("myCookieName")
                    && tokenHolder.getVersion() == 1)
                {
                    // Passes the bytes into your custom SingleSignonToken constructor
                    // to deserialize
                    customSSOToken = new
                        com.ibm.websphere.security.token.CustomSingleSignonTokenImpl
                            (tokenHolder.getBytes());
                }
            }
        }
        else
        {
            // This is not a propagation login. Create a new instance of your
            // SingleSignonToken implementation
        {
            // Gets the principal from the default SingleSignonToken. This principal
            // must match all tokens.
            defaultAuthToken = (com.ibm.wsspi.security.token.AuthenticationToken)
                sharedState.get(com.ibm.wsspi.security.auth.callback.Constants.WSAUTHTOKEN_KEY);

Implementing a custom authentication token for security attribute propagation

This topic explains how you might create your own authentication token implementation, which is set in the login Subject and propagated downstream.

About this task

With this implementation you can specify an authentication token that can be used by a custom login module or application. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. You must deserialize the bytes at the target and add that information back on the thread. This task also might include encryption and decryption.
- Affect the overall uniqueness of the Subject using the getUniqueID application programming interface (API).

Important: Custom authentication token implementations are not used by the security runtime in WebSphere Application Server to enforce authentication. WebSphere Application Security runtime uses this token in the following situations only:

- Call the getBytes method for serialization
- Call the getForwardable method to determine whether to serialize the authentication token.
- Call the getUniqueid method for uniqueness
- Call the getName and the getVersion methods for adding serialized bytes to the token holder that is sent downstream

All of the other uses are custom implementations.

To implement a custom authentication token, you must complete the following steps:

Procedure

1. Write a custom implementation of the AuthenticationToken interface. Many different methods are available for implementing the AuthenticationToken interface. However, make sure the methods that are required by the AuthenticationToken interface and the token interface are fully implemented. After you implement this interface, you can place it in the *app_server_root/classes* directory. Alternatively, you can place the class in any private directory. However, make sure that the WebSphere Application Server class loader can locate the class and that it is granted the appropriate permissions. You can add the Java archive (JAR) file or directory that contains this class into the server.policy file so the class has the necessary permissions required by the server code.

Tip: All of the token types that are defined by the propagation framework have similar interfaces. The token types are marker interfaces that implement the com.ibm.wsspi.security.token.Token interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the com.ibm.wsspi.security.token.Token interface. All of your token implementations, including the authentication token, might extend the abstract class and then most of the work is complete.

To see an implementation of the AuthenticationToken interface, see “Example: A com.ibm.wsspi.security.token.AuthenticationToken implementation.”

2. Add and receive the custom authentication token during WebSphere Application Server logins. This task is typically accomplished by adding a custom login module to the various application and system login configurations. However, to deserialize the information you must plug in a custom login module. After the object is instantiated in the login module, you can add the object to the Subject during the commit method.

If you only want to add information to the Subject to get propagated, see “Propagating a custom Java serializable object for security attribute propagation” on page 770. If you want to ensure that the information is propagated, do your own custom serialization, or specify the uniqueness for Subject caching purposes, consider writing your own authentication token implementation.

The code sample in “Example: A custom authentication token login module” on page 768, shows how to determine if the login is an initial login or a propagation login. The difference between these login types is whether the WSTokenHolderCallback callback contains propagation data. If the callback does not contain propagation data, initialize a new custom authentication token implementation and set it into the Subject. If the callback contains propagation data, look for your specific custom authentication token TokenHolder instance, convert the byte array back into your custom AuthenticationToken object, and set it back into the Subject. The code sample shows both instances.

You can make your authentication token read-only in the commit phase of the login module. If you do not make the token read-only, attributes can be added within your applications.

3. Add your custom login module to WebSphere Application Server system login configurations that already contain the com.ibm.ws.security.server.Im.wsspi.MapDefaultInboundLoginModule login module for receiving serialized versions of your custom authorization token.

Because this login module relies on information in the shared state that is added by the com.ibm.ws.security.server.Im.wsspi.MapDefaultInboundLoginModule login module, add this login module after the com.ibm.ws.security.server.Im.wsspi.MapDefaultInboundLoginModule login module. For information on how to add your custom login module to the existing login configurations, see Developing custom login modules for a system login configuration for JAAS.

Results

After completing these steps, you have implemented a custom authentication token.

Example: A com.ibm.wsspi.security.token.AuthenticationToken implementation:

The following example illustrates an authentication token implementation. The following sample code does not extend an abstract class, but rather implements the com.ibm.wsspi.security.token.AuthenticationToken interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if considerable differences exist between how you handle the various token implementations.

```
package com.ibm.websphere.security.token;

import com.ibm.websphere.security.WSSecurityException;
import com.ibm.websphere.security.auth.WSLoginFailedException;
import com.ibm.wsspi.security.token.*;
import com.ibm.websphere.security.WebSphereRuntimePermission;
import java.io.ByteArrayOutputStream;
import java.io.ByteArrayInputStream;
import java.io.DataOutputStream;
import java.io.DataInputStream;
import java.io.ObjectOutputStream;
import java.io.ObjectInputStream;
import java.io.OutputStream;
import java.io.InputStream;
import java.util.ArrayList;

Example: A custom authentication token login module:

This examples shows how to determine if the login is an initial login or a propagation login.

For information on what to do during initialization, login and commit, see [Developing custom login modules for a system login configuration for JAAS](#).

```

public customLoginModule()
{
    public void initialize(Subject subject, CallbackHandler callbackHandler,
        Map sharedState, Map options)
    {
        _sharedState = sharedState;
    }

    public boolean login() throws LoginException
    {
        // Handles the WSTokenHolderCallback to see if this is an initial or
        // propagation login.
        Callback callbacks[] = new Callback[1];
        callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");

        try
        {
            callbackHandler.handle(callbacks);
        }
        catch (Exception e)
        {
            // Handles exception
        }

        // Receives the ArrayList of TokenHolder objects (the serialized tokens)
        List authzTokenList = ((WSTokenHolderCallback) callbacks[0]).getTokenHolderList();

        if (authzTokenList != null)
        {
            // Iterates through the list looking for your custom token
            for (int i=0; i<authzTokenList.size(); i++)
            {
                TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

                // Looks for the name and version of your custom AuthenticationToken
                // implementation
                if (tokenHolder.getName().equals("your_oid_name") && tokenHolder.getVersion() == 1)
                {

```

```

        // Passes the bytes into your custom AuthenticationToken constructor
        // to deserialize
        customAuthzToken = new
        com.ibm.websphere.security.token.
        CustomAuthenticationTokenImpl(tokenHolder.getBytes());
    }
}
else
    // This is not a propagation login. Create a new instance of your
    // AuthenticationToken implementation
    {
        // Gets the principal from the default AuthenticationToken. This principal
        // should match all default tokens.
        // Note: WebSphere Application Server runtime only enforces this for
        // default tokens. Thus, you can choose
        // to do this for custom tokens, but it is not required.
        defaultAuthToken = (com.ibm.wsspi.security.token.AuthenticationToken)
        sharedState.get(com.ibm.wsspi.security.auth.callback.Constants.WSAUTHTOKEN_KEY);
        String principal = defaultAuthToken.getPrincipal();

        // Adds a new custom authentication token. This is an initial login. Pass
        // the principal into the constructor
        customAuthToken = new com.ibm.websphere.security.token.
        CustomAuthenticationTokenImpl(principal);

com.ibm.wsspi.security.token.AuthenticationToken defaultAuthToken = null;
java.util.Map _sharedState = null;
}

```

Propagating a custom Java serializable object for security attribute propagation

This document describes how to add an object into the Subject from a login module and describes other infrastructure considerations to make sure that the Java object gets propagated.

Before you begin

Prior to completing this task, verify that security propagation is enabled in the administrative console.

About this task

With security attribute propagation enabled, you can propagate data either horizontally with single sign-on (SSO) enabled or downstream using Common Secure Interoperability Version 2 (CSIv2). When a login occurs, either through an application login configuration or a system login configuration, a custom login module can be plugged in to add Java serialized objects into the Subject during login. This document describes how to add an object into the Subject from a login module and describes other infrastructure considerations to make sure that the Java object gets propagated.

Procedure

1. Add your custom Java object into the Subject from a custom login module. A two-phase process exists for each Java Authentication and Authorization Service (JAAS) login module. WebSphere Application Server completes the following processes for each login module present in the configuration:

login method

In this step, the login configuration callbacks are analyzed, if necessary, and the new objects or credentials are created.

commit method

In this step, the objects or credentials that are created during login are added into the Subject.

After a custom Java object is added into the Subject, WebSphere Application Server serializes the object on the sending server, deserializes the object on the receiving server, and adds the object back into the Subject downstream. However, some requirements exist for this process to occur successfully. For more information on the JAAS programming model, see the JAAS information provided in the Security: Resources for learning article.

Important:  Whenever you plug a custom login module into the login infrastructure of WebSphere Application Server, make sure that the code is trusted. When you add the login module into the *profile_root/classes* directory, the login module has Java 2 Security AllPermissions permissions. For more information, see “Creating a classes subdirectory in your profile for custom classes” on page 676. However, because the login module might be run after the application code on the call stack, you might add `doPrivileged` code so that you do not need to add additional properties to your applications.

The following code sample shows how to add `doPrivileged` code. For information on what to do during initialization, login and commit, see *Developing custom login modules for a system login configuration for JAAS*.

```
public customLoginModule()
{
    public void initialize(Subject subject, CallbackHandler callbackHandler,
        Map sharedState, Map options)
    {
    }
}

public boolean login() throws LoginException
{
    // Construct callback for the WSTokenHolderCallback so that you
    // can determine if
    // your custom object has propagated
    Callback callbacks[] = new Callback[1];
    callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");

    try
```

```

    {
        _callbackHandler.handle(callbacks);
    }
    catch (Exception e)
    {
        throw new LoginException (e.getLocalizedName());
    }

    // Checks to see if any information is propagated into this login
    List authzTokenList = ((WSTokenHolderCallback) callbacks[1]).
        getTokenHolderList();

    if (authzTokenList != null)
    {
        for (int i = 0; i < authzTokenList.size(); i++)
        {
            TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

            // Look for your custom object. Make sure you use
            // "startsWith"because there is some data appended
            // to the end of the name indicating in which Subject
            // Set it belongs. Example from getName():
            // "com.acme.CustomObject (1)". The class name is
            // generated at the sending side by calling the
            // object.getClass().getName() method. If this object
            // is deserialized by WebSphere Application Server,
            // then return it and you do not need to add it here.
            // Otherwise, you can add it below.
            // Note: If your class appears in this list and does
            // not use custom serialization (for example, an
            // implementation of the Token interface described in
            // the Propagation Token Framework), then WebSphere
            // Application Server automatically deserializes the
            // Java object for you. You might just return here if
            // it is found in the list.

            if (tokenHolder.getName().startsWith("com.acme.CustomObject"))
                return true;
        }
        // If you get to this point, then your custom object has not propagated
        myCustomObject = new com.acme.CustomObject();
        myCustomObject.put("mykey", "mydata");
    }

    public boolean commit() throws LoginException
    {
        try
        {
            // Assigns a reference to a final variable so it can be used in
            // the doPrivileged block
            final com.acme.CustomObject myCustomObjectFinal = myCustomObject;
            // Prevents your applications from needing a JAAS getPrivateCredential
            // permission.
            java.security.AccessController.doPrivileged(new java.security.
                PrivilegedExceptionAction()
            {
                public Object run() throws java.lang.Exception
                {
                    // Try not to add a null object to the Subject or an object
                    // that already exists.
                    if (myCustomObjectFinal != null && !subject.getPrivateCredentials().
                        contains(myCustomObjectFinal))
                    {
                        // This call requires a special Java 2 Security permission,
                        // see the JAAS application programming interface (API)
                        // documentation.
                        subject.getPrivateCredentials().add(myCustomObjectFinal);
                    }
                    return null;
                }
            });
        }
        catch (java.security.PrivilegedActionException e)
        {
            // Wraps the exception in a WSLoginFailedException
            java.lang.Throwable myException = e.getException();
            throw new WSLoginFailedException (myException.getMessage(), myException);
        }
    }

    // Defines your login module variables
    com.acme.CustomObject myCustomObject = null;
}

```

2. Verify that your custom Java class implements the `java.io.Serializable` interface. An object that is added to the Subject must be serialized if you want the object to propagate. For example, the object must implement the `java.io.Serializable` interface. If the object is not serialized, the request does not fail, but

the object does not propagate. To make sure an object that is added to the Subject is propagated, implement one of the token interfaces that is defined in topics about security attribute propagation or add attributes to one of the following existing default token implementations:

AuthorizationToken

Add attributes if they are user-specific.

PropagationToken

Add attributes that are specific to an invocation.

If you are careful adding custom objects and follow all the steps to make sure that WebSphere Application Server can serialize and deserialize the object at each hop, then it is sufficient to use custom Java objects only.

3. Verify that your custom Java class exists on all of the systems that might receive the request.

 When you add a custom object into the Subject and expect WebSphere Application Server to propagate the object, make sure that the class definition for that custom object exists in the *profile_root/classes* directory on all of the nodes where serialization or deserialization might occur. Also, verify that the Java class versions are the same.

4. Verify that your custom login module is configured in all of the login configurations used in your environment where you need to add your custom object during a login. Any login configuration that interacts with WebSphere Application Server generates a Subject that might be propagated outbound for an Enterprise JavaBeans (EJB) request. If you want WebSphere Application Server to propagate a custom object in all cases, make sure that the custom login module is added to every login configuration that is used in your environment. For more information, see *Developing custom login modules for a system login configuration for JAAS*.
5. Verify that security attribute propagation is enabled on all of the downstream servers that receive the propagated information. When an EJB request is sent to a downstream server and security attribute propagation is disabled on that server, only the authentication token is sent for backwards compatibility. Therefore, you must review the configuration to verify that propagation is enabled in all of the cells that might receive requests. You must check several places in the administrative console to make sure propagation is fully enabled.
6. Add any custom objects to the propagation exclude list that you do not want to propagate. You can configure a property to exclude the propagation of objects that match specific class names, package names, or both. For example, you can have a custom object that is related to a specific process. If the object is propagated, it does not contain valid information. You must tell WebSphere Application Server not to propagate this object. Complete the following steps to specify the object in the propagation exclude list, using the administrative console:
 - a. Click **Security > Global security > Custom properties > New**.
 - b. Add `com.ibm.ws.security.propagationExcludeList` in the **Name** field.
 - c. Add the name of the custom object in the **Value** field. You can add a list of custom objects to the propagation exclude list, separated by a colon (:). For example, you might enter `com.acme.CustomLocalObject:com.acme.private.*`. You can enter a class name such as `com.acme.CustomLocalObject` or a package name such as `com.acme.private.*`. In this example, WebSphere Application Server does not propagate any class that equals `com.acme.CustomLocalObject` or begins with `com.acme.private`.

Although you can add custom objects to the propagation exclude list, you must be aware of a side effect. WebSphere Application Server stores the opaque token, or the serialized Subject contents, in a local cache for the life of the single sign-on (SSO) token. The life of the SSO token, which has a default of two hours, is configured in the SSO properties on the administrative console. The information that is added to the opaque token includes only the objects not in the exclude list.

Ensure that your SSO token timeout value is greater than the authentication cache timeout value. To modify the authentication cache, see the documentation about the authentication cache settings.

Results

As a result of this task, custom Java serializable objects are propagated horizontally or downstream. For more information on the differences between horizontal and downstream propagation, see topics about security attribute propagation or add attributes to one of the following existing default token implementations:

Developing a custom interceptor for trust associations

You can define the interceptor class method that you want to use. WebSphere Application Server supports two trust association interceptor interfaces: `com.ibm.wsspi.security.TrustAssociationInterceptor` and `com.ibm.wsspi.security.tai.TrustAssociationInterceptor`.

Before you begin

If you are using a third party reverse proxy server other than Tivoli® WebSEAL, you must provide an implementation class for the product interceptor interface for your proxy server. This article describes the `com.ibm.wsspi.security.TrustAssociationInterceptor.java` interface that you must implement.

Note: The Trust Association Interceptor (TAI) interface (`com.ibm.wsspi.security.tai.TrustAssociationInterceptor`) supports several new features and is different from the existing `com.ibm.wsspi.security.TrustAssociationInterceptor` interface.

Procedure

1. Define the interceptor class method. WebSphere Application Server provides the interceptor Java interface, `com.ibm.wsspi.security.TrustAssociationInterceptor`, which defines the following methods:

- **public boolean isTargetInterceptor(HttpServletRequest req)** creates `WebTrustAssociationException`;

The `isTargetInterceptor` method determines whether the request originated with the proxy server associated with the interceptor. The implementation code must examine the incoming request object and determine if the proxy server forwarding the request is a valid proxy server for this interceptor. The result of this method determines whether the interceptor processes the request or not.

- **public void validateEstablishedTrust (HttpServletRequest req)** creates `WebTrustAssociationException`;

The `validateEstablishedTrust` method determines if the proxy server from which the request originated is trusted or not. This method is called after the `isTargetInterceptor` method. The implementation code must authenticate the proxy server. The authentication mechanism is proxy-server specific. For example, in the product implementation for the WebSEAL server, this method retrieves the basic authentication information from the HTTP header and validates the information against the user registry used by WebSphere Application Server. If the credentials are invalid, the code creates the `WebTrustAssociationException`, indicating that the proxy server is not trusted and the request is to be denied.

- **public String getAuthenticatedUsername(HttpServletRequest req)** creates `WebTrustAssociationException`;

The `getAuthenticatedUsername` method is called after trust is established between the proxy server and WebSphere Application Server. The product has accepted the proxy server authentication of the request and must now authorize the request. To authorize the request, the name of the original requestor must be subjected to an authorization policy to determine if the requestor has the necessary privilege. The implementation code for this method must extract the user name from the HTTP request header and determine if that user is entitled to the requested resource. For example, in the product implementation for the WebSEAL server, the method looks for an `iv-user` attribute in the HTTP request header and extracts the user ID associated with it for authorization.

2. Configuring the interceptor. To make an interceptor configurable, the interceptor must extend `com.ibm.wsspi.security.WebSphereBaseTrustAssociationInterceptor`. Implement the following methods:

public int init (java.util.Properties props);

The `init(Properties)` method accepts a `java.util.Properties` object, which contains the set of properties required to initialize the interceptor. All the properties set for an interceptor (by using the **Custom Properties** link for that interceptor or using scripting) is sent to this method. The interceptor then can use these properties to initialize itself. For example, in the product implementation for the WebSEAL server, this method reads the hosts and ports so that a request coming in can be verified to originate from trusted hosts and ports. A return value of **0** implies that the interceptor initialization is successful. Any other value implies that the initialization is not successful and the interceptor is ignored.

Applicability of the following list

If a previous implementation of the trust association interceptor returns a different error status you can either change your implementation to match the expectations or make one of the following changes:

- Add the `com.ibm.wsspi.security.trustassociation.initState` property in the trust association interceptor custom properties. Set the property to the value that indicates that the interceptor is successfully initialized. All of the other possible values imply failure. In case of failure, the corresponding trust association interceptor is not used.
- Add the `com.ibm.wsspi.security.trustassociation.ignoreInitStatus` property in the trust association interceptor custom properties. Set the value of this property to **true**, which tells WebSphere Application Server to ignore the status of this method. If you add this property to the custom properties, WebSphere Application Server does not check the return status, which is similar to previous versions of WebSphere Application Server.

public void cleanup ();

This method is called when the application server is stopped. It is used to prepare the interceptor for termination.

public void setVersion (String s);

This method is optional. The method is used to set the version and is for informational purpose only. The default value is `Unspecified`.

You must configure the following methods implemented by the custom interceptor implementation. **This listing only shows the methods and does not include any implementation.**

```
*****
import java.util.*;
import javax.servlet.http.HttpServletRequest;
import com.ibm.websphere.security.*;

public class myTAImpl extends WebSphereBaseTrustAssociationInterceptor
    implements TrustAssociationInterceptor
{

    public myTAImpl ()
    {
    }

    public boolean isTargetInterceptor (HttpServletRequest req)
        throws WebTrustAssociationException
    {

        //return true if this is the target interceptor, else return false.
    }

    public TAIResult negotiateValidateandEstablishTrust (HttpServletRequest req, HttpServletResponse res)
        throws WebTrustAssociationFailedException
    {
        //validate the request and establish trust.
        //create and return the TAIResult
    }

    public int initialize (Properties props)
    {
        //initialize the implementation. If successful return 0, else return 1.
    }
}
```

```

    public String getVersion()
    {
        //Return version
    }

    public String getType()
    {
        //Return type
    }

    public void cleanup ()
    {
        //Cleanup code.
    }
}

```

Note: If the `init(Properties)` method is implemented as described previously in your custom interceptor, this note does not apply to your implementation, and you can move on to the next step. Previous versions of `com.ibm.wsspi.security.WebSphereBaseTrustAssociationInterceptor` include the public `int init (String propsfile)` method. This method is no longer required since the interceptor properties are not read from a file. The properties are now entered in the administrative console **Custom Properties** link of the interceptor using the administrative console or scripts. These properties then are made available to your implementation in the `init(Properties)` method. However, for backward compatibility, the `init(String)` method still is supported. The `init(String)` method is called by the default implementation of `init(Properties)` as shown in the following example.

```

// Default implementation of init(Properties props) method. A Custom
// implementation should override this.
public int init (java.util.Properties props)
{
    String type =
        props.getProperty("com.ibm.wsspi.security.trustassociation.types");
    String classfile=
        props.getProperty("com.ibm.wsspi.security.trustassociation."
            +type+".config");
    if (classfile != null && classfile.length() > 0 ) {
        return init(classfile);
    } else {
        return -1;
    }
}

```

Change your implementation to implement the `init(Properties)` method instead of relying on `init(String propsfile)` method. As shown in the previous example, this default implementation reads the properties to load the property file. The `com.ibm.wsspi.security.trustassociation.types` property gets the file containing the properties by concatenating `.config` to its value.

Note: The `init(String)` method still works if you want to use it instead of implementing the `init(Properties)` method. The only requirement is that the file name containing the custom trust association properties should now be entered using the **Custom Properties** link of the interceptor in the administrative console or by using scripts. You can enter the property using *either* of the following methods. The first method is used for backward compatibility with previous versions of WebSphere Application Server.

Method 1:

The same property names used in the previous release are used to obtain the file name. The file name is obtained by concatenating the `.config` to the `com.ibm.wsspi.security.trustassociation.types` property value.

IBM i If the file name is called `myTAI.properties` and is located in the `app_server_root/properties` directory, set the following properties:

- `com.ibm.wsspi.security.trustassociation.types = myTAItype`

- `com.ibm.wsspi.security.trustassociation.myTAItype.config = app_server_root/properties/myTAI.properties`

Method 2:

You can set the `com.ibm.wsspi.security.trustassociation.initPropsFile` property in the trust association custom properties to the location of the file. For example, set the following property:

```
com.ibm.wsspi.security.trustassociation.initPropsFile=
app_server_root/properties/myTAI.properties
```

Type the previous code as one continuous line.

The location of the properties file is fully qualified (for example, `app_server_root/properties/myTAI.properties`). Because the location can be different in a WebSphere Application Server, Network Deployment environment, use variables such as `${USER_INSTALL_ROOT}` to refer to the WebSphere Application Server installation directory. For example, if the file name is called `myTAI.properties` and it is located in the `app_server_root/properties` directory, then set the following properties:

3. Compile the implementation once you have implemented it. For example, `app_server_root/java/bin/javac -classpath install_root/plugins/com.ibm.ws.runtime.jar;<install_root>/dev/JavaEE/j2ee.jar myTAIImpl.java`
 - a. Copy the custom trust association interceptor class files to a location in your product class path. Copy these class files into the `profile_root/classes` directory.
 - b. Restart all the servers.
4. Delete the default WebSEAL interceptor in the administrative console and click **New** to add your custom interceptor. Verify that the class name is dot separated and appears in the class path.
5. Click the **Custom Properties** link to add additional properties that are required to initialize the custom interceptor. These properties are passed to the `init(Properties)` method of your implementation when it extends the `com.ibm.wsspi.security.WebSphereBaseTrustAssociationInterceptor` as described in the previous step.
6. Save and synchronize (if applicable) the configuration.
7. Restart the servers for the custom interceptor to take effect.

Example

Refer to the Security: Resources for Learning article for a reference to an example of a custom interceptor.

Trust association interceptor support for Subject creation

The trust association interceptor (TAI) `com.ibm.wsspi.security.tai.TrustAssociationInterceptor` interface supports several features that are different from the existing `com.ibm.websphere.security.TrustAssociationInterceptor` interface.

The TAI interface supports a multiphase, negotiated authentication process. For example, some systems require a challenge response protocol back to the client. The two key methods in this interface are:

Key method name

```
public boolean isTargetInterceptor (HttpServletRequest req)
```

The `isTargetInterceptor` method determines whether the request originated with the proxy server that is associated with the interceptor. The implementation code must examine the incoming request object and determine if the proxy server that forwards the request is a valid proxy server for this interceptor. The result of this method determines whether the interceptor processes the request.

Method result

A true value tells WebSphere Application Server to have the TAI handle the request.

A false value, tells WebSphere Application Server to ignore the TAI.

Key method name

public TAIResult negotiateValidateandEstablishTrust (HttpServletRequest req, HttpServletResponse res)

The negotiateValidateandEstablishTrust method determines whether to trust the proxy server from which the request originated. The implementation code must authenticate the proxy server. The authentication mechanism is proxy-server specific. For example, in the product implementation for the WebSEAL server, this method retrieves the basic authentication information from the HTTP header and validates the information against the user registry that WebSphere Application Server uses. If the credentials are not valid, the code creates the WebTrustAssociationException exception, which indicates that the proxy server is not trusted and the request is denied. If the credentials are valid, the code returns a TAIResult result, which indicates the status of the request processing with the client identity (Subject and principal name) to use for authorizing the web resource.

Method result

Returns a TAIResult result, which indicates the status of the request processing. You can query the Request object and modify the Response object can be modified.

The TAIResult class has three static methods for creating a TAIResult result. The TAIResult create methods take an int type as the first parameter. WebSphere Application Server expects the result to be a valid HTTP request return code and is interpreted in one of the following ways:

- If the value is HttpServletResponse.SC_OK, this response tells WebSphere Application Server that the TAI completed its negotiation. The response also tells WebSphere Application Server to use the information in the TAIResult result to create a user identity.
- Other values tell WebSphere Application Server to return the TAI output, which is placed into the HttpServletResponse response, to the web client. Typically, the web client provides additional information and then places another call to the TAI.

Table 73. TAIResults definitions. The created TAIResults results have the following meanings:

TAIResult	Explanation
public static TAIResult create(int status);	Indicates a status to WebSphere Application Server. The status cannot be SC_OK because the identity information is provided.
public static TAIResult create(int status, String principal);	Indicates a status to WebSphere Application Server and provides the user ID or the unique ID for this user. WebSphere Application Server creates credentials by querying the user registry.
public static TAIResult create(int status, String principal, Subject subject);	Indicates a status to WebSphere Application Server, the user ID or the unique ID for the user, and a custom Subject. If the Subject contains a hashtable, the principal is ignored. The contents of the Subject become part of the eventual user Subject.

All of the following examples are within the negotiateValidateandEstablishTrust method of a TAI.

The following code sample indicates that additional negotiation is required:

```
// Modify the HttpServletResponse object
// The response code is meaningful only on the client
return TAIResult.create(HttpServletResponse.SC_CONTINUE);
```

The following code sample indicates that the TAI determined the user identity. WebSphere Application Server receives the user ID only and queries the user registry for additional information:

```
// modify the HttpServletResponse object
return TAIResult.create(HttpServletResponse.SC_OK, userid);
```

The following code sample indicates that the TAI determined the user identity. WebSphere Application Server receives the complete user information that is contained in the hashtable. In this code sample, the hashtable is placed in the public credential portion of the Subject:

```
// create Subject and place Hashtable in it
Subject subject = new Subject();
subject.getPublicCredentials().add(hashtable);
// the response code is meaningful for only the client
return TAIResult.create(HttpServletResponse.SC_OK, "ignored", subject);
```

The following code sample indicates that an authentication failure occurred. WebSphere Application Server fails the authentication request:

```
//log error message
// ....
throw new WebTrustAssociationFailedException("TAI failed for this reason");
```

The following methods are additional methods on the TrustAssociationInterceptor interface. These methods are used for initialization, for shutdown, and for identifying the TAI to WebSphere Application Server. For more information, see the Java documentation.

Method name

public int initialize(Properties props)

Method result

This method is called during TAI initialization and is called only if custom properties are configured for the interceptor.

Method name

public String getVersion()

Method result

This method returns the version of the TAI.

Method name

public String getType()

Method result

This method returns the type of the TAI.

Method name

public void cleanup()

Method result

This method is called when stopping the WebSphere Application Server process. Stopping the WebSphere Application Server process provides an opportunity for the TAI to perform any necessary cleanup. This method is not necessary if cleanup is not required.

Enabling a plugpoint for custom password encryption

Two properties govern the protection of passwords. By configuring these two properties, you can enable a plugpoint for custom password encryption.

Before you begin

To view an example code sample that illustrates the `com.ibm.wsspi.security.crypto.CustomPasswordEncryption` interface, see “Plug point for custom password encryption” on page 779.

About this task

The encryption method is called for password processing whenever the custom class is configured and custom encryption is enabled. The decryption method is called whenever the custom class is configured and the password contains the `{custom:alias}` tag. The `custom:alias` tag is stripped prior to decryption.

Procedure

1. To enable custom password encryption, you must configure two properties:

- **com.ibm.wsspi.security.crypto.customPasswordEncryptionClass** - Defines the custom class that implements the `com.ibm.wsspi.security.crypto.CustomPasswordEncryption` password encryption interface.
 - **com.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled** - Defines when the custom class is used for default password processing. When the `passwordEncryptionEnabled` option is not specified or set to `false`, and the `passwordEncryptionClass` class is specified, the decryption method is called whenever a `{custom:alias}` tag still exists in the configuration repository.
2.  To configure custom password encryption, configure both of these properties in the `security.xml` file. The custom encryption class (`com.acme.myPasswordEncryptionClass`) must be placed in a Java archive (JAR) file in the `${APP_SERVER_ROOT}/classes` directory in all WebSphere Application Server processes. Every configuration document that contains a password (`security.xml` and any application bindings that contain RunAs passwords), must be saved before all of the passwords become encrypted with the custom encryption class. For client side property files such as `sas.client.props` and `soap.client.props`, use the `PropFilePasswordEncoder.bat` or `PropFilePasswordEncode.sh` script to enable custom processing. This script must have the two properties configured as system properties on the Java command line of the script. The same tools that are used for encoding and decoding can be used for encryption and decryption when custom password encryption is enabled.
 3. If the custom implementation class defaults to the `com.ibm.wsspi.security.crypto.CustomPasswordEncryptionImpl` interface, and this class is present in the class path, then encryption is enabled by default. This simplifies the enablement process for all nodes. It is not necessary to define any other properties except for those that the custom implementation requires. To disable encryption, but still use this class for decryption, specify the following class.
 - `com.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled=false`

What to do next

Whenever a custom encryption class encryption operation is called, and it creates a run-time exception or a defined `PasswordEncryptException` exception, the WebSphere Application Server runtime uses the `{xor}` algorithm to encode the password. This encoding prevents the storage of the password in plain text. After the problem with the custom class has been resolved, it automatically encrypts the password the next time the configuration document is saved.

When a RunAs role is assigned a user ID and password, it currently is encoded using the WebSphere Application Server encoding function. Therefore, after the custom plug point is configured to encrypt the passwords, it encrypts the passwords for the RunAs bindings as well. If the deployed application is moved to a cell that does not have the same encryption keys, or the custom encryption is not yet enabled, a login failure results because the password is not readable.

One of the responsibilities of the custom password encryption implementation is to manage the encryption keys. This class must decrypt any password that it encrypted. Any failure to decrypt a password renders that password to be unusable, and the password must be changed in the configuration. All encryption keys must be available for decryption there and no passwords are left using those keys. The master secret must be maintained by the custom password encryption class to protect the encryption keys.

You can manage the master secret by using a stash file for the keystore, or by using a password locator that enables the custom encryption class to locate the password so that it can be locked down.

Plug point for custom password encryption

A plug point for custom password encryption can be created to encrypt and decrypt all passwords in WebSphere Application Server that are currently encoded or decoded using Base64-encoding.

The implementation class of this plug point has the responsibility for managing keys, determining the encryption algorithm to use, and for protecting the master secret. The WebSphere Application Server

runtime stores the encrypted passwords in their existing locations, preceded with {custom:alias} tags instead of {xor} tags. The custom part of the tag indicates that it is a custom algorithm. The alias part of the tag is specified by the custom implementation, which helps to indicate how the password is encrypted. The implementation can include the key alias, encryption algorithm, encryption mode, or encryption padding.

A custom provider of this plug point must implement an interface that is designed to encrypt and decrypt passwords. The interface is called by the WebSphere Application Server runtime whenever the custom plug point is enabled. The custom algorithm becomes one of the supported algorithms when the plug point is enabled. Other supported algorithms include {xor} (standard base64 encoding) and {os400} which is used on the iSeries platform.

The following example illustrates the com.ibm.wsspi.security.crypto.CustomPasswordEncryption interface:

```
package com.ibm.wsspi.security.crypto;
public interface CustomPasswordEncryption
{
    /**
     * The encrypt operation takes a UTF-8 encoded String in the form of a byte[].
     * The byte[] is generated from String.getBytes("UTF-8").
     * An encrypted byte[] is returned from the implementation in the EncryptedInfo
     * object. Additionally, a logical key alias is returned in the EncryptedInfo
     * object which is passed back into the decrypt method to determine which key was
     * used to encrypt this password. The WebSphere Application Server runtime has
     * no knowledge of the algorithm or the key used to encrypt the data.
     *
     * @param byte[]
     * @return com.ibm.wsspi.security.crypto.EncryptedInfo
     * @throws com.ibm.wsspi.security.crypto.PasswordEncryptException
     */
    public EncryptedInfo encrypt (byte[] decrypted_bytes) throws PasswordEncryptException;

    /**
     * The decrypt operation takes the EncryptedInfo object containing a byte[]
     * and the logical key alias and converts it to the decrypted byte[]. The
     * WebSphere Application Server runtime converts the byte[] to a String
     * using new String (byte[], "UTF-8");
     *
     * @param com.ibm.wsspi.security.crypto.EncryptedInfo
     * @return byte[]
     * @throws com.ibm.wsspi.security.crypto.PasswordDecryptException
     */
    public byte[] decrypt (EncryptedInfo info) throws PasswordDecryptException;

    /**
     * The following is reserved for future use and is currently not
     * called by the WebSphere Application Server runtime.
     *
     * @param java.util.HashMap
     */
    public void initialize (java.util.HashMap initialization_data);
}
```

The com.ibm.wsspi.security.crypto.EncryptedInfo class contains the encrypted bytes with the user-defined alias that is associated with the encrypted bytes. This information is passed back into the encryption method to help determine how the password was originally encrypted.

```
package com.ibm.wsspi.security.crypto;
public class EncryptedInfo
{
    private byte[] bytes;
    private String alias;

    /**
     * This constructor takes the encrypted bytes and a keyAlias as parameters.
     * This constructor is used to pass to or from the WebSphere Application Server
     * runtime to enable the runtime to associate the bytes with a specific key that
     * is used to encrypt the bytes.
     */

    public EncryptedInfo (byte[] encryptedBytes, String keyAlias)
    {
        bytes = encryptedBytes;
        alias = keyAlias;
    }

    /**
     * This command returns the encrypted bytes.
     *
     * @return byte[]
     */
}
```

```

*/
public byte[] getEncryptedBytes()
{
    return bytes;
}

/**
 * This command returns the key alias. The key alias is a logical string that is
 * associated with the encrypted password in the model. The format is
 * {custom:keyAlias}encrypted_password. Typically, just the key alias is placed
 * here, but algorithm information can also be returned.
 *
 * @return String
 */
public String getKeyAlias()
{
    return alias;
}
}

```

The encryption method is called for password processing whenever the custom class is configured and custom encryption is enabled. The decryption method is called whenever the custom class is configured and the password contains the {custom:alias} tag . The custom:alias tag is stripped prior to decryption. For more information, see [Enabling custom password encryption](#).

Implementing a custom authentication provider using JASPI

You can implement a custom authentication provider using Java Authentication SPI for Containers (JASPI, or sometimes called JASPIC) to handle the Java Platform, Enterprise Edition (Java EE) authentication of HTTP request and response messages destined for web applications.

Before you begin

For JASPI authentication processing to take place, application security must be enabled in the global or domain security configuration and the server must be restarted for the configuration changes to take effect. Read the [Application security](#) topic for more information.

About this task

This release of WebSphere Application Server supports the JSR 196: Java Authentication SPI for Containers (JASPI, or sometimes called JASPIC) specification, which enables third-party security providers to handle the Java Platform, Enterprise Edition (Java EE) authentication of HTTP request and response messages destined for web applications. The JASPI specification extends the pluggable authentication concepts of the Java Authentication and Authorization Service (JAAS) to the authentication of HTTP request and response messages. When application security is enabled, and a protected web resource is accessed, the web container and the security runtime collaborate to make an authentication decision for the caller. When using a third-party JASPI provider, the authentication decision is delegated to that provider.

The JASPI specification defines standard system programming interfaces that enable developers to write a pluggable custom authentication provider that can handle Java EE web authentication mechanisms as well as any extended authentication processing. The WebSphere Application Server runtime uses these standard system programming interfaces to invoke the JASPI authentication provider. Read the [Servlet Container Profile](#) section in the JSR 196: Java Authentication Service Provider Interface for Containers specification for the requirements that third-party authentication providers must satisfy for more information.

If application security is enabled with JASPI authentication, when the web resource (such as a servlet or a JavaServer Pages (JSP) file) is accessed, the security runtime checks if the web resource is mapped to a JASPI provider defined in the security configuration. If so, the runtime invokes the JASPI authentication provider to perform authentication for the HTTP request and response messages.

To implement a custom authentication provider using JASPI you must do the following:

Procedure

1. Develop a custom JASPI authentication provider.

WebSphere Application Server provides support for the development of custom JASPI authentication providers to be used to perform authentication for the HTTP request and response messages destined for web applications. Read “Developing a custom JASPI authentication provider” for more information.

2. Configure a new JASPI authentication provider.

WebSphere Application Server allows an administrator to enable JASPI authentication and to define a third-party JASPI authentication provider as part of the global or domain security configuration. Read “Configuring a new JASPI authentication provider using the administrative console” on page 786 for more information.

3. Associate a JASPI authentication provider with an application or specific web modules.

During application deployment, the administrator or deployer can use the Map JASPI Provider option to associate web applications and specific web modules with an existing JASPI authentication provider as defined in the security configuration. This association can also be made when editing the options for an existing installed application. By default, an application inherits the JASPI settings defined in the WebSphere Application Server global or domain security configuration, and web modules inherit the application setting. The Map JASPI Provider option can be used to override these defaults. Read “Enabling JASPI authentication using the Map JASPI provider option during application deployment” on page 789 for more information.

Developing a custom JASPI authentication provider

You can develop a custom Java Authentication SPI for Containers (JASPI) authentication provider by creating classes that implement the required interfaces noted in the JSR 196: Java Authentication Service Provider Interface for Containers specification.

Before you begin

Review the specific interface implementation requirements for JASPI authentication providers and modules in the JSR 196: Java Authentication Service Provider Interface for Containers specification.

About this task

WebSphere Application Server supports the use of third-party authentication providers that are compliant with the servlet container profile specified in Java Authentication SPI for Containers (JASPI) Version 1.0.

The servlet container profile defines interfaces that are used by the security runtime environment in collaboration with the web container in WebSphere Application Server to invoke authentication modules before and after a web request is processed by an application. Authentication using JASPI modules is performed only when JASPI has been enabled in the security configuration and when a configured JASPI provider has been associated with the web module that processes the received web request.

To develop a custom authentication provider, create classes that implement the required interfaces noted in the JSR 196: Java Authentication Service Provider Interface for Containers specification. A provider can use one or more authentication modules for authentication. Modules can use callbacks to perform authentication, or they can manually add the necessary user identity information to the client subject. Depending on the scope of the provider, the implementation classes can be stored in various locations on the application server.

Procedure

1. Create a class that implements the `javax.security.auth.message.config.AuthConfigProvider` interface.

The `AuthConfigProvider` implementation class must define a public two-argument constructor and the `getServerAuthConfig` public method:

```

import java.util.Map;
import javax.security.auth.callback.CallbackHandler;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.config.AuthConfigFactory;
import javax.security.auth.message.config.AuthConfigProvider;
import javax.security.auth.message.config.ServerAuthConfig;

public class SampleAuthConfigProvider implements AuthConfigProvider {

    public SampleAuthConfigProvider(Map<String, String> properties, AuthConfigFactory factory) {
        ...
    }
    public ServerAuthConfig getServerAuthConfig(String layer, String appContext, CallbackHandler handler)
        throws AuthException {
        ...
    }
}

```

An instance of the `AuthConfigProvider` implementation class is used by WebSphere Application Server when a request arrives to be processed by the web module of the application. The `getServerAuthConfig` method is used to obtain a `ServerAuthConfig` instance. The `CallbackHandler` argument in the method call is used by the authentication module(s).

2. Create a class that implements the `javax.security.auth.message.config.ServerAuthConfig` interface. The `ServerAuthConfig` implementation class must define the `getAuthContextID` and `getAuthContext` public methods:

```

import java.util.Map;
import javax.security.auth.Subject;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.MessageInfo;
import javax.security.auth.message.config.ServerAuthConfig;
import javax.security.auth.message.config.ServerAuthContext;

public class SampleServerAuthConfig implements ServerAuthConfig {

    public String getAuthContextID(MessageInfo messageInfo) throws IllegalArgumentException {
        ...
    }
    public ServerAuthContext getAuthContext(String authContextID, Subject serviceSubject, Map properties)
        throws AuthException {
        ...
    }
}

```

The `getAuthContextID` and `getAuthContext` methods in the `ServerAuthConfig` implementation class are used to obtain a `ServerAuthContext` instance.

3. Create a class that implements the `javax.security.auth.message.config.ServerAuthContext` interface. The `ServerAuthContext` implementation class must define the `validateRequest` and `secureResponse` public methods:

```

import javax.security.auth.Subject;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.AuthStatus;
import javax.security.auth.message.MessageInfo;
import javax.security.auth.message.config.ServerAuthContext;

public class SampleServerAuthContext implements ServerAuthContext {

    public AuthStatus validateRequest(MessageInfo messageInfo, Subject clientSubject, Subject serviceSubject)
        throws AuthException {
        ...
    }
    public AuthStatus secureResponse(MessageInfo messageInfo, Subject serviceSubject)
        throws AuthException {
        ...
    }
}

```

The `validateRequest` method in the `ServerAuthContext` implementation class is used to invoke the module that authenticates the received web request message. If the authentication result is successful,

the web container dispatches the received web request message that the target web module processes in the application. If the authentication result is not successful, the request is rejected with the appropriate response status.

4. Create a class that implements the `javax.security.auth.message.module.ServerAuthModule` interface. The `ServerAuthModule` implementation class must define the `initialize`, `validateRequest`, and `secureResponse` public methods:

```
import javax.security.auth.Subject;
import javax.security.auth.callback.CallbackHandler;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.AuthStatus;
import javax.security.auth.message.MessageInfo;
import javax.security.auth.message.MessagePolicy;
import javax.security.auth.message.module.ServerAuthModule;

public class SampleAuthModule implements ServerAuthModule {

    public void initialize(MessagePolicy requestPolicy, MessagePolicy responsePolicy, CallbackHandler handler, Map options)
        throws AuthException {
        ...
    }

    public AuthStatus validateRequest(MessageInfo messageInfo, Subject clientSubject, Subject serviceSubject)
        throws AuthException {
        ...
    }

    public AuthStatus secureResponse(MessageInfo messageInfo, Subject serviceSubject)
        throws AuthException {
        ...
    }
}
```

The `initialize` method in the `ServerAuthModule` implementation class is called by the `ServerAuthContext` implementation class to initialize the authentication module and to associate it with the `ServerAuthContext` instance.

The `validateRequest` and `secureResponse` methods in this class are used respectively to authenticate the `javax.servlet.http.HttpServletRequest` and `javax.servlet.http.HttpServletResponse` contained in the `javax.security.auth.message.MessageInfo` that is received. These methods can use the `CallbackHandler` instance received in the `initialize` method to interact with the WebSphere security runtime to validate a user password, and the active user registry to retrieve a unique-id and membership groups for a user. The retrieved data is placed in a `Hashtable` in the set of private credentials in the client subject. The WebSphere Application Server implementation of `CallbackHandler` supports three callbacks:

- `CallerPrincipalCallback`
- `GroupPrincipalCallback`
- `PasswordValidationCallback`

WebSphere Application Server expects the name values obtained with `PasswordValidationCallback.getUsername()` and `CallerPrincipalCallback.getName()` to be identical. If they are not, unpredictable results occur. The `CallbackHandler`'s `handle()` method processes each callback given in the argument array of the method sequentially. Therefore, the name value set in the private credentials of the client subject is the one obtained from the last callback processed.

Note: Always use `PasswordValidationCallback` to validate a user password and to add the appropriate credentials to the client subject during authentication:

```
import javax.security.auth.Subject;
import javax.security.auth.callback.Callback;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.AuthStatus;
import javax.security.auth.message.MessageInfo;
import javax.security.auth.message.callback.PasswordValidationCallback;

public AuthStatus validateRequest(MessageInfo messageInfo, Subject clientSubject, Subject serviceSubject)
    throws AuthException {
    ...
}
```

```

        PasswordValidationCallback pvcb = new PasswordValidationCallback(clientSubject, username, password);
        handler.handle(new Callback[] {pvcb});
        ...
    }

```

If CallbackHandler is not used by the authentication module, and validateRequest returns a successful status, WebSphere Application Server requires that a Hashtable instance be included in the clientSubject with user identity information so that a custom login can be performed to obtain the credentials for the user. This Hashtable can be added to the client subject as in the following example:

```

import java.util.Hashtable;
import java.util.String;
import javax.security.auth.Subject;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.AuthStatus;
import javax.security.auth.message.MessageInfo;
import com.ibm.wsspi.security.registry.RegistryHelper;
import com.ibm.wsspi.security.token.AttributeNameConstants.AttributeNameConstants;

public AuthStatus validateRequest(MessageInfo messageInfo, Subject clientSubject, Subject serviceSubject)
    throws AuthException {
    ...
    UserRegistry reg = RegistryHelper.getUserRegistry(null);
    String uniqueid = reg.getUniqueUserID(username);

    Hashtable hashtable = new Hashtable();
    hashtable.put(AttributeNameConstants.WSCREDENTIAL_UNIQUEID, uniqueid);
    hashtable.put(AttributeNameConstants.WSCREDENTIAL_SECURITYNAME, username);
    hashtable.put(AttributeNameConstants.WSCREDENTIAL_PASSWORD, password);
    hashtable.put(AttributeNameConstants.WSCREDENTIAL_GROUPS, groupList); //optional
    clientSubject.getPrivateCredentials().add(hashtable);
    ...
}

```

For more information about the Hashtable requirements and custom login, read about Developing custom login modules for a system login configuration for JAAS.

To support the login and authenticate methods of the Java Servlet 3.0 specification, the following logic must be added to the validateRequest method in the ServerAuthModule implementation class:

```

import java.util.Map;
import javax.security.auth.Subject;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.AuthStatus;
import javax.security.auth.message.MessageInfo;
import javax.servlet.http.HttpServletRequest;

public AuthStatus validateRequest(MessageInfo messageInfo, Subject clientSubject, Subject serviceSubject)
    throws AuthException {
    ...
    Map msgMap = messageInfo.getMap();

    if ("login".equalsIgnoreCase(msgMap.get("com.ibm.websphere.jaspi.request"))) {
        // This request is for the login method
        String username = msgMap.get("com.ibm.websphere.jaspi.user");
        String password = msgMap.get("com.ibm.websphere.jaspi.password");
        // Authenticate using the user name and password set above.
    }
    else if ("authenticate".equalsIgnoreCase(msgMap.get("com.ibm.websphere.jaspi.request"))) {
        // this request is for the authenticate method
        String authHeader
            = ((HttpServletRequest) messageInfo.getRequestMessage()).getHeader("Authorization");
        if (authHeader == null) {
            // The user has not provided a username and password yet, return
            // AuthStatus.SEND_CONTINUE to challenge
        }
        else {
            // Authenticate using the user name and password in the authentication header.
        }
    }
    else {
        // This is not a Servlet 3.0 login or authenticate request; handle as usual.
    }
    ...
}

```

5. Compile all newly created classes.

The following JAR files in your WebSphere Application Server installation must be specified in the class path to successfully compile the new classes:

- *app_server_root/dev/JavaEE/j2ee.jar*
- *app_server_root/dev/was_public.jar* (if any public WebSphere APIs were used)

6. Create a JAR file with the compiled classes.

Depending on the requirements, the JAR file can be placed in one of three locations:

- *app_server_root/lib*

This location is always on the classpath for the WebSphere Application Server classloader. Using this location, the provider can be registered for a set of web modules or applications as the cell or domain default provider for all web modules and applications, and it can be registered manually as a persistent provider.

- Shared library

Place the provider JAR file anywhere on the WebSphere Application Server system. Configure a shared library that points to the JAR, and add that shared library to the application or server classpath. In a shared library, the provider can be registered for a set of web modules or applications, but the provider cannot be used as the cell or domain default provider. It also cannot be registered as a persistent provider because the shared library is not in the classpath for provider registration during server startup. For more information about configuring a shared library, read about [Creating shared libraries](#).

- Embedded in the application

Include the provider JAR file in the application's EAR file as a utility JAR, or embed the compiled class files in the web module WAR. The embedded provider can be registered for the web modules in the application as long as the classes are included in the classpath for the web module. This provider cannot be used as a cell or domain default provider, nor can it be registered as a persistent provider. The classes in the application are not available for provider registration during server startup.

7. Configure the provider in the security configuration using the administrative console or an administration script.

Read about “[Configuring a new JASPI authentication provider using the administrative console](#)” for more information.

Configuring a new JASPI authentication provider using the administrative console

You can configure a new Java Authentication SPI (JASPI) authentication provider in the cell or in the given security domain by using the administrative console.

About this task

This release of WebSphere Application Server supports integration of message authentication providers that are compliant with the JASPI for Containers Version 1.0 specification.

When JASPI authentication providers are configured, and WebSphere Application Server receives an HTTP request message, the security runtime environment determines if the target application is configured to use JASPI authentication. If so, the runtime environment invokes the selected authentication provider to validate the received message. Otherwise, authentication of the message request is done according to the authentication mechanism provided by WebSphere Application Server for the appropriate messaging layer.

If you want to use JASPI message authentication services, you must supply an implementation of the required interfaces as defined in the JASPI specification. Read “[Developing a custom JASPI authentication provider](#)” on page 782 for more information on these interfaces.

Authentication of HTTP request and response messages destined for JASPI-enabled deployed applications is performed according to the requirements of the Servlet Container Profile specified in the new specification.

Note: JASPI is supported in a mixed-cell environment, but can only be used in nodes that are version 8 or higher. Back-level nodes use existing authentication mechanisms.

To configure a new JASPI authentication provider using the administrative console, do the following:

Procedure

1. Click **Security > Global security**.
2. Select **Enable Java Authentication SPI (JASPI)** to enable support for JASPI authentication.
3. Click **Providers**.

Note: It is not necessary to select **Enable Java Authentication SPI (JASPI)** until after you have configured a new JASPI authentication provider.

Note: The Default provider option is used to specify a single JASPI authentication provider to perform authentication for all web modules when JASPI authentication is enabled, and you do not override the web module to JASPI provider mapping during application deployment. During application deployment, you can override the default for every web module where it does not apply by choosing not to use JASPI or by naming a different provider to use for authentication. However, it is not recommended that you use this option unless you are certain that your default provider is capable of handling all types of web authentication (basic authentication, form authentication and client certificate authentication).

4. Click **New**.
5. Enter a name that uniquely identifies the JASPI authentication provider in the Provider name field.
6. Optional: Enter a textual description of the authentication provider in the Description field.
7. Enter the package-qualified name of the class that implements the authentication provider interface (`javax.security.auth.message.config.AuthConfigProvider`) in the Class name field.

Note: In the Message layer field, WebSphere Application Server Version 8.5 supports only the `HttpServlet` message layer profile as defined in the JASPI specification. You cannot change this value.

8. Optional: Under Custom Properties, click **New** if you require more than one property. This parameter is a list of key/value pairs.
9. Click **OK** or **Apply**.

What to do next

You can also configure a new JASPI authentication provider by using **wsadmin** commands. Read `JaspiManagement` command group for the `AdminTask` object for more information.

Verify that your server has been restarted so that the changes to configure the JASPI provider will take effect.

Modifying an existing JASPI authentication provider using the administrative console

You can modify and configure an existing Java Authentication SPI (JASPI) authentication provider in the cell or in the given security domain by using the administrative console.

About this task

To modify and configure an existing JASPI authentication provider using the administrative console, do the following:

Procedure

1. Click **Security > Global security**.
2. Click **Providers**. You also have the option to change the Default provider from the drop-down list.

Note: You can modify the value of the **Enable Java Authentication SPI (JASPI)** checkbox to indicate whether or not JASPI support is enabled at a later time.

3. Select an existing JASPI authentication provider to modify.
4. Optional: Enter a textual description of the authentication provider in the Description field.
5. Enter a new package-qualified name of the class that implements the authentication provider interface (`javax.security.auth.message.config.AuthConfigProvider`) in the Class name field if you wish to change it.

Note: In the Message layer field, WebSphere Application Server Version 8.5 supports only the HttpServlet message layer profile as defined in the JASPI specification. You cannot change this value.

6. Optional: Under Custom Properties, select an existing custom configuration property. Click **Delete** to remove the property, **Edit** to modify the property, or click **New** to create a new property. If you select **Edit** to modify an existing property, you can enter new values for the Name field and Value field if you wish to change them.
7. Click **OK** or **Apply**.

What to do next

You can also modify an existing JASPI authentication provider by using **wsadmin** commands. For more information, read `JaspiManagement` command group for the `AdminTask` object.

Verify that your server has been restarted so that the changes to configure the JASPI provider will take effect.

Deleting a JASPI authentication provider using the administrative console

You can delete an existing Java Authentication SPI (JASPI) authentication provider in the cell or in the given security domain by using the administrative console.

About this task

To delete an existing JASPI authentication provider using the administrative console, do the following:

Procedure

1. Click **Security > Global security**.
2. Click **Providers**, You can optionally select or deselect the **Enable Java Authentication SPI (JASPI)** check box.

Note: You can modify the value of the **Enable Java Authentication SPI (JASPI)** checkbox to indicate whether or not JASPI support is enabled at a later time.

3. Select an existing JASPI authentication provider to delete.
4. Click **Delete**.

What to do next

You can also delete a JASPI authentication provider by using wsadmin commands. For more information, read JspiManagement command group for the AdminTask object.

Verify that your server has been restarted so that the changes to the JASPI provider configuration will take effect.

Enabling JASPI authentication using the Map JASPI provider option during application deployment

An administrator or deployer can use the Map JASPI Provider option during application deployment to associate web applications and specific web modules with an existing Java Authentication SPI (JASPI) authentication provider as defined in the security configuration. This association can also be made when editing the options for a previously installed application.

Before you begin

Before you perform this task, verify that a JASPI authentication provider is defined as part of the global or domain security configuration. Read about “Configuring a new JASPI authentication provider using the administrative console” on page 786 for more information.

About this task

By default, an application inherits the JASPI settings defined in the WebSphere Application Server global or domain security configuration, and web modules inherit the application setting. However, you can override these default values by using the Map JASPI Provider option during application deployment. Use this option to associate a specific JASPI provider from the global or domain security configuration with the entire application or with specific web modules. You can also use this option to specify that JASPI authentication not be used for an application or specific web module.

To associate a web application or specific web modules with an existing JASPI provider:

Procedure

1. From the administrative console, click **Applications > New Application > New Enterprise Application**. Complete the required steps until you see the step for Map JASPI Provider, or click the **Map JASPI Provider** step from the installation options. A list containing the application name and associated web modules is displayed. To update a JASPI provider association after an application has been deployed, click **Applications > Application Types > WebSphere enterprise applications**, and then select the application to be modified. Click **JASPI Provider** under the Detail properties.
2. Select the application or specific web module for which the JASPI provider setting is to be modified.
3. Click the **Select JASPI Provider** menu and select one of the following options:

Do not use JASPI

Select to disable JASPI authentication for the selected web module or for the application.

Inherit JASPI provider

Select to inherit the JASPI authentication settings from default values in the cell or domain security configuration, as appropriate.

When **Inherit JASPI provider** is selected for a web module, JASPI authentication settings for the selected module are the settings that are specified for the application.

When **Inherit JASPI provider** is selected for the application, JASPI authentication settings are the settings that are specified in the appropriate cell or domain security configuration.

Provider name

When a specific provider name is selected, that provider name is used to perform authentication of web requests for the selected application or web module.

4. Complete the remaining steps to finish installing and deploying the application.

What to do next

Verify that your server has been restarted to ensure that the configuration changes to define the JASPI provider take effect. Read about “Configuring a new JASPI authentication provider using the administrative console” on page 786 for more information.

JASPI authentication providers collection

The Java Authentication Service Provider Interface (JASPI) for Containers Version 1.0 specification defines standard system programming interfaces that enable developers to write a pluggable custom authentication provider that can handle Java EE web authentication mechanisms as well as any extended authentication processing. The WebSphere Application Server runtime uses these standard system programming interfaces to invoke the JASPI authentication provider.

Read the Servlet Container Profile section in the JSR 196: Java Authentication Service Provider Interface for Containers specification for the requirements that third-party authentication providers must satisfy for more information.

If application security is enabled, and JASPI authentication is enabled with providers configured, when a web resource (such as a servlet or a JavaServer Page (JSP) file) is accessed, the security runtime checks if the web resource is mapped to a JASPI provider defined in the security configuration. If so, the runtime invokes the JASPI authentication provider to perform authentication for the HTTP request and response messages.

Note: WebSphere Application Server Version 8.5 supports only the HttpServlet message layer profile as defined in the JASPI specification.

To view this administrative console page, click **Security > Global security**. Under Authentication, click **Providers**.

To configure a new custom JASPI authentication provider in the cell or in the given security domain, click **New** and specify provider settings.

Provider name:

Specifies a name that uniquely identifies the authentication provider.

Select an existing custom JASPI authentication provider name to edit and configure it.

JASPI authentication provider details

Use this page to provide configuration details for your custom Java Authentication SPI (JASPI) authentication service provider.

To view this administrative console page, click **Security > Global security**. Under Authentication, click **Providers**. Select an existing authentication service provider name or click **New** to create a new one.

Provider name:

Specifies a name that uniquely identifies the authentication provider.

Description:

Specifies a textual description of the authentication provider.

Class name:

Specifies the package-qualified name of the class that implements the authentication provider interface (`javax.security.auth.message.config.AuthConfigProvider`).

Message layer:

WebSphere Application Server Version 8.5 supports only the `HttpServlet` message layer profile as defined in the JASPI specification.

Custom properties:

Specifies additional custom properties needed to initialize the authentication provider. This parameter is a list of key/value pairs.

Click **Delete** to remove a custom property or **Edit** to modify a custom property.

JASPI authentication enablement for applications

Use this page to enable or disable Java Authentication SPI (JASPI) authentication for an application or web module, and to specify the name of a JASPI authentication provider to be used for authenticating messages for the application or web module.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications**. Select an application, and under Detail Properties, select **JASPI provider**.

Select JASPI provider:

Select to indicate the web modules in the application that you wish to specify or to override the default JASPI authentication settings for.

Select one of the JASPI provider names to choose a provider to use to perform authentication of web requests for the selected Web module or the application.

To specify how JASPI authentication is performed for the selected web module or the application, choose one of the following:

Do not use JASPI

Select to disable JASPI authentication for the selected web module or for the application.

Inherit JASPI provider

Select to inherit the JASPI authentication settings from default values in the cell or domain security configuration, as appropriate.

When Inherit JASPI provider is selected for a web module, JASPI authentication settings for the selected module are the settings that are specified for the application.

When Inherit JASPI provider is selected for the application, JASPI authentication settings are the settings that are specified in the appropriate cell or domain security configuration.

Provider name

When a specific provider name is selected, that provider is used to perform authentication of web requests for the selected application or web module.

If JASPI authentication is enabled, and a specific provider name is not specified, then the default provider name is used. For more information, read about configuring a new JASPI authentication provider using the administrative console.

If JASPI authentication is disabled, or if no default provider is selected, JASPI authentication is not performed. Web authentication is then performed according to another authentication mechanism as selected in the cell or domain security configuration.

Chapter 21. Developing Startup beans

This page provides a starting point for finding information about startup beans.

Startup beans allow business logic to run when an application starts or stops.

Using startup beans

There are two types of startup beans: application startup beans and Module startup beans.

About this task

Note: The capabilities provided with startup singleton session beans (EJB 3.1 specification) causes the WebSphere Application Server proprietary startup beans function to be deprecated.

A module startup bean is a session bean that is loaded when an EJB Jar file starts. Module startup beans enable Java Platform Enterprise Edition (Java EE) applications to run business logic automatically, whenever an EJB module starts or stops normally. An application startup bean is a session bean that is loaded when an application starts. Application startup beans enable Java EE applications to run business logic automatically, whenever an application starts or stops normally.

Startup beans are especially useful when used with asynchronous bean features. For example, a startup bean might create an alarm object that uses the Java Message Service (JMS) to periodically publish heartbeat messages on a well-known topic. This enables clients or other server applications to determine whether the application is available. Refer to the Enabling an application to wait for a messaging engine to start article if you are using the default JMS provider.

Procedure

1. For Application startup beans, use the home interface, `com.ibm.websphere.startupservice.AppStartUpHome`, to designate a bean as an Application startup bean. For Module startup beans, use the home interface, `com.ibm.websphere.startupservice.ModStartUpHome`, to designate a bean as a Module startup bean.
2. For Application startup beans, use the remote interface, `com.ibm.websphere.startupservice.AppStartUp`, to define `start()` and `stop()` methods on the bean. For Module startup beans, use the remote interface, `com.ibm.websphere.startupservice.ModStartUp`, to define `start()` and `stop()` methods on the bean.

The startup bean `start()` method is called when the module or application starts and contains business logic to be run at module or application start time.

The `start()` method returns a boolean value. **True** indicates that the business logic within the `start()` method ran successfully. Conversely, **False** indicates that the business logic within the `start()` method failed to run completely. A return value of `False` also indicates to the Application server that application startup is aborted.

The startup bean `stop()` methods are called when the module or application stops and contains business logic to be run at module or application stop time. Any exception thrown by a `stop()` method is logged only. No other action is taken.

The `start()` and `stop()` methods must never use the `TX_MANDATORY` transaction attribute. A global transaction does not exist on the thread when the `start()` or `stop()` methods are invoked. Any other `TX_*` attribute can be used. If `TX_MANDATORY` is used, an exception is logged, and the application start is aborted.

The `start()` and `stop()` methods on the remote interface use **Run-As** mode. **Run-As** mode specifies the credential information to be used by the security service to determine the permissions that a principal has on various resources. If security is on, the **Run-As** mode needs to be defined on all of the methods called. The identity of the bean without this setting is undefined.

There are no restrictions on what code the start() and stop() methods can run, since the full Application Server programming model is available to these methods.

3. Use an *optional* environment property integer, `wasStartupPriority`, to specify the start order of multiple startup beans in the same Java Archive (JAR) file. If the environment property is found and is the wrong type, application startup is aborted. If no priority value is specified, a default priority of 0 is used. It is recommended that you specify the priority property. Beans that have specified a priority are sorted using this property. Beans with numerically lower priorities are run first. Beans that have the same priority are run in an undefined order. All priorities must be positive integers. Beans are stopped in the opposite order to their start priority. The priority values for module startup beans and application startup beans are mutually exclusive. All modules will be started prior to the application being declared as "started" and therefore the start() methods for module startup beans within an application will be invoked prior to the start() methods for any application startup beans. Likewise, all application startup bean stop() methods for a specific Java Archive (JAR) file will be invoked prior to any module startup bean stop() methods for that JAR.

Note: The `wasStartupPriority` environment property integer cannot be set through either a command or the administrative console. This environment property integer is an EJB environment entry that is to be set by an application developer not an administrator. You set the integer value in the `ejb-jar.xml` file as shown in the example below:

```
<env-entry>
  <env-entry-name>wasStartupPriority</env-entry-name>
  <env-entry-type>java.lang.Integer</env-entry-type>
  <env-entry-value>3</env-entry-value>
</env-entry>
```

As with any other EJB environment entry, you set a separate `wasStartupPriority` value for each EJB.

4. For module startup beans, the order in which EJB modules are started can be adjusted via the "Starting weight" value associated with each module
5. To control who can invoke startup bean methods via WebSphere Security do the following:
 - a. Define the method permissions for the Start() and Stop() methods as you would for any EJB module. (See "Defining method permissions for EJB modules".)
 - b. Ensure that the user that is mapped to the Security Role defined for the startup bean methods is the same user that is defined as the Server user ID within the User Registry.

What to do next

View the startup beans service settings.

Enabling startup beans in the administrative console

Enabling startup beans in the administrative console enables Java 2 Platform Enterprise Edition (J2EE) applications to run business logic automatically, whenever an application starts or stops normally.

About this task

Use the following steps to enable startup beans in the administrative console.

Procedure

1. Start the administrative console.
2. Select **Servers > Application Servers > *server_name* > Container Services > Startup beans service**.
3. Select the **Enable service at server startup** check box.
4. Click **Apply** to save the configuration.

What to do next

View the startup beans service settings.

Startup beans service settings

Use this page to enable startup beans that control whether application-defined startup beans function on this server. Startup beans are session beans that run business logic through the invocation of start and stop methods when applications start and stop. If the startup beans service is disabled, then the automatic invocation of the start and stop methods does not occur for deployed startup beans when the parent application starts or stops. This service is disabled by default. Enable this service only when you want to use startup beans. Startup beans are especially useful when used with asynchronous beans.

Note: The capabilities provided with startup singleton session beans (EJB 3.1 specification) causes the WebSphere Application Server proprietary startup beans function to be deprecated.

To view this administrative console page, click **Servers > Server types > WebSphere application servers > *server_name***. Under **Container Settings**, expand **Container Services** then click **Startup beans service**.

Enable service at server startup

Specifies whether the server attempts to initiate the startup beans service.

Information

Default

Range

Value

Cleared

Selected

When the application server starts, it attempts to initiate the startup bean service automatically.

Cleared

The server does not try to initiate the startup beans service. All startup beans do not start or stop with the application. If you use startup beans on this server, then the system administrator must start the startup beans service manually or select this property, and then restart the server.

Chapter 22. Developing Service integration

This page provides a starting point for finding information about service integration.

Service integration provides asynchronous messaging services. In asynchronous messaging, producing applications do not send messages directly to consuming applications. Instead, they send messages to destinations. Consuming applications receive messages from these destinations. A producing application can send a message and then continue processing without waiting until a consuming application receives the message. If necessary, the destination stores the message until the consuming application is ready to receive it.

Programming mediations

Several distinct tasks are involved in programming a mediation. Typically, the mediation code is written by a programmer, and is then deployed and administered by an integrator.

Before you begin

Code examples for writing a mediation are provided in the following topic: “Adding mediation function to handler code” on page 799.

The following application programming interfaces are provided for you to work with messages:

- You can use the `SIMessage` API to manipulate the contents of the message.
- You can use the `SIMediationSession` API to access the service integration bus so that your mediation can send and retrieve messages.

You can deploy mediations by using tooling such as the Rational Application Developer tools.

About this task

The tasks for programming a mediation are as follows:

Developing

Writing a mediation by adding functional code to a mediation handler.

Deploying

Adding a mediation to a mediation handler list, and deploying it.

Administering

Associating a mediation handler with a destination (optional), and configuring the parameters to be used by the mediation handler at run time.

Take the following steps to program a mediation:

Procedure

1. Create a mediation handler. For more information, see “Writing a mediation handler” on page 798.
2. Add mediation function code to your mediation handler. For more information, see “Adding mediation function to handler code” on page 799.
3. Optional: Working with the message payload, for example for logging messages within a mediation. For more information, see “Working with the message payload” on page 806.
4. Use the Rational Application Developer tools to create a handler list, add your mediation handler to the list, and deploy the handler list as an Enterprise Archive (EAR file). See the Rational Application Developer information center for information about how to do this.

Serializing the content of SIMessage

Use this task to convert an SIMessage object to a byte array.

About this task

If you want to save an SIMessage object in your local file system or in a database, you must first convert the object to a byte array and format string. You can reconstruct the message from the byte array and format string. To do this, complete the following steps.

Procedure

1. In your application program, record the format string associated with the SIMessage instance. For example:

```
String savedFormat=message.getFormat();
```

2. Call the getDataGraphAsBytes. For example:

```
Bytes newDataGraph = message.getNewDataGraph(newFormat);
```

This method returns a copy of the payload as a byte stream. You can store the bytes and the associated format string, as you require.

3. Optional: To reconstruct the message, call the method createDataGraph provided by the SIDataGraphFactory API. This method requires a byte array and a format string. For example:

```
DataGraph newDataGraph = SIDataGraphFactory.getInstance().createDataGraph(byteArray, newFormat);
```

This method creates a new data graph by parsing the bytes according to the format passed to the method.

What to do next

You can use the newly created datagraph as the payload of an SIMessage instance by using the SIMessage setDataGraph() method. For example:

```
newMessage.setDataGraph(newDataGraph, savedFormat);
```

Writing a mediation handler

You can write a mediation handler, add mediation function to it, and prepare it for installation on an application server.

Before you begin

You should have access to a Java programming environment, and an assembly tool such as IBM Rational Application Developer.

About this task

A mediation handler can be deployed. Each mediation handler executes some specific message processing at run time, for example transforming a message format, or routing a message to a particular destination. A mediation handler is a Java program framework, to which you add the code that performs the mediation function.

You can define a mediation handler class either in a Java project or an EJB project (which is needed for the deployment artifact). Your programming and deployment artifacts can be separated in different projects. The steps below are for an EJB project, but the steps are very similar if you want to create a Java project, because you define a target server for either a Java project or an EJB project and the server runtime plug-in sets the class path correctly.

Procedure

1. Create a new EJB project:
 - a. Switch to the Java EE perspective to work with Java EE projects. Click **Window > Open Perspective > Other > Java EE**.
 - b. From the File menu, select **New > Project**.
 - c. Expand the Java EE folder, and select Enterprise Application Project. Click **Next**.
 - d. Optional: If you have created a Java project instead of an EJB project, right click on the Java project folder icon for the context menu and select Properties. When the Properties panel appears, select the Server properties and target the project to an appropriate server for your system, as in the next step.
 - e. Enter a name for the project and target the project to an appropriate server for your system. (If this is the first time you target this server, click **New....**) Click **Next** to take you to the EAR Module Projects window.
 - f. Click **New Module....**
 - g. Create a new module project by selecting the check box against EJB project, and entering the name of your mediation handler.
 - h. Click **Finish**. You are returned to the EAR Module Projects window.
 - i. Click **Finish** to create the new project.
2. Create a mediation handler class by implementing the `com.ibm.websphere.sib.mediation.handler.MediationHandler` interface.
 - a. From the File menu, select **New > Java Class**.
 - b. Specify the source folder for your mediation EAR project.
 - c. Specify a name for your mediation handler.
 - d. Select Superclass `java.lang.Object`.
 - e. Select Interface `com.ibm.websphere.sib.mediation.handler.MediationHandler`.
 - f. Select the **Inherited abstract methods** check box.
 - g. Click **Finish** to create the new mediation handler class.
3. Add functional code that transforms or routes messages to your mediation handler by using the IBM Rational Application Developer. For more information, see “Adding mediation function to handler code.” Beware that the default return value for the handle method created by the toolkit is `false`, which causes the message to be discarded. You must change the return value to `true` to preserve the message.
4. Generate an EAR file from your mediation handler class. Follow the instructions in the IBM Rational Application Developer documentation.

What to do next

Next, you are ready to install the EAR file containing your mediation handler into the application server.

Adding mediation function to handler code

A mediation handler is a wrapper for the mediation code that operates on the message. You can add mediation function to an existing mediation handler by working with the message context, the message properties, the message header or the message payload.

Before you begin

Create or open a mediation handler in an EJB project. For more information, see “Writing a mediation handler” on page 798.

About this task

There are four main aspects of the message through which you can change the behavior of the mediation handler code, or influence the routing of a message. You can change the values in the message context and message properties, and you can work with the contents of the message (called the message payload), or with the message header:

- “Working with the message context”
- “Working with message properties” on page 801
- “Working with the message header” on page 802
- “Working with the message payload” on page 806

Example: Using mediations to trace, monitor and log messages

The most straightforward use of a mediation is for tracing, monitoring or logging messages that pass through a destination or topics spaces. This type of mediation does not modify the message; it only extracts information from the message and saves or displays the information elsewhere.

For example, the following mediation handler displays the API message and correlation IDs for each message it is sent:

```
public boolean(MessageContext context)
{
    SIMessageContext msgCtx = (SIMessageContext)context;
    SIMediationSession session = msgCtx.getSession();
    SIMessage msg = msgCtx.getMessage();
    String msgId = msg.getApiMessageId();
    String corrId = msg.getCorrelationId();
    String dest = session.getDestinationName();

    System.out.println(msgId+" (correlation id="+corrId) is passing through "+dest+".");

    return true;
}
```

Working with the message context

You can work with the message properties to affect the way a message is mediated.

Before you begin

Before you start this task, you should read about how information is carried in the mediation context in [Mediation context information](#)

About this task

Interface `SIMessageContext` has a superinterface `MessageContext`. Methods in `MessageContext` allow you to manage a set of message properties, which enable handlers in a handler chain to share processing-related state. Most importantly, you can get the value of a specific property from the `MessageContext` by using the method `getProperty`, and you can set the name and value of a property associated with the `MessageContext` by using the method `setProperty`. You can also view the names of the properties in this `MessageContext` and remove a property (that is, a name-value pair) from the `MessageContext`.

At mediation runtime, all of the user-defined properties that have been set during configuration for the current mediation (see [Configuring mediation context properties](#)) are applied to the `MediationContext` property set.

Procedure

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle (MessageContext context)`. As you are working with the `MessageContext` methods that give you access to message properties, you do not have to cast the interface to `SIMessageContext` **unless** you are also interested in the methods provided by `SIMessageContext`.
2. Get the `SIMessage` from the `MessageContext` object. For example, `SIMessage message = ((SIMessageContext)context).getSIMessage();`
3. Retrieve or set properties, by using the `MessageContext` methods. For instance, if a property has been defined during configuration with the name `streetName`, the type `String`, and the value "Main Street" your code to retrieve and print the street name might look like this:

Example

```
public boolean handle(MessageContext context) throws MessageContextException {  
  
    .....  
    {  
        /* Retrieve the street name property */  
        String myStreetName;  
        myStreetName = (String) getProperty(streetName);  
  
        /* Display property value */  
        System.out.println(myStreetName);  
    }  
}
```

Working with message properties

You can work with the message properties to affect subsequent processing.

Before you begin

Before you start this task, you should read about the properties that are supported by the `SIMessage` interface in `Message properties support for mediations`.

About this task

There are two different types of message properties:

- System properties (including JMS headers, JMSX properties, and JMS_IBM_properties)
- User properties.

You can work with message properties to affect which messages a later mediation should process, or to affect processing by a downstream application or mediation. The rule set in the selector field during mediation configuration tests values in the message properties.

You can access, modify and clear properties by using the `SIMessage` interface (see "SIMessage" on page 810.) There are three different sets of methods:

- These properties operate on system properties, plus user properties if the name is qualified with a prefix `user.:`
 - `getMessageProperty`
 - `setMessageProperty`
 - `deleteMessageProperty`
 - `clearMessageProperties`
- These properties operate on user properties only, without the need for the prefix `user.:`
 - `getUserProperty`

- setUserProperty
- deleteUserProperty
- clearUserProperties
- getUserPropertyNames returns a list of the names of the user properties in the message.

Typically, you can work with message properties in the following way, when programming a mediation:

Procedure

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle (MessageContext context)`. The interface is `MessageContext`, and you should cast this to `SIMessageContext` **unless** you are only interested in the methods provided by `MessageContext`.
2. Get the `SIMessage` from the `MessageContext` object. For example, `SIMessage message = ((SIMessageContext)context).getSIMessage();`
3. Build your mediation header function in a similar way to these examples, by using the reference information in `Message` properties support for mediations to help:
 - a. Get a user property of the message. For instance, `String task = (String)msg1.getUserProperty("task");`. In this case, the task string might refer to an operation that the mediation should perform.
 - b. Set a user property, where message Properties are stored as name-value pairs. The `setUserProperty` method might only be used to set user properties, so the name passed into the method should not include the "user." prefix. For example, `msg1.setUserProperty("background","green");`
 - c. Delete a user property from the message. For instance, `msg1.deleteUserProperty("task");`

Example

Mediation function code to work with message properties might look similar to the code snippet in this example:

```
String task = (String)msg1.getUserProperty("task");
if (task != null) {
    if (task.equals("addColor")) {
        msg1.setMessageProperty(SIProperties.JMS_IBM_Format, "colorful");
        msg1.setUserProperty("background","green");
        msg1.setUserProperty("foreground","purple");
        msg1.setUserProperty("depth",new Integer(3));
        msg1.deleteUserProperty("task");
    }
    else {
        msg1.clearUserProperties();
    }
}
```

Working with the message header

You can add function to a preexisting mediation handler to operate on the message header.

Before you begin

Create or open a basic mediation handler in an EJB project (see "Writing a mediation handler" on page 798. It is useful to have understood the elements of the task "Working with the message payload" on page 806, because some of those elements are used in this task

About this task

There are different types of field that you can set in message headers. Importantly, you can set the forward and return routing addresses for messages after they have been mediated at the current

destination. In addition there are other fields that you can set, such as priority and reliability for the message and its reply, and the remaining time before the message (or the reply) expires.

Procedure

1. To set routing addresses in the message header, see “Setting routing addresses in a message header.”
2. To set all other fields in the message header, see “Working with non-routing path fields in a message header” on page 805.

Setting routing addresses in a message header:

You can add function to a pre-existing mediation handler to set routing addresses in the message header.

Before you begin

Before you start this task, you should have created the basic mediation handler in an EJB project (see “Writing a mediation handler” on page 798).

About this task

To work with routing addresses, you will use the `SIDestinationAddress` and `SIDestinationAddressFactory` APIs. The `SIDestinationAddress` is the public interface that represents an service integration bus, and gives your mediation access to the name of the destination and the bus name.

`SIDestinationAddressFactory` enables you to create a new `SIDestinationAddress` to represent an service integration bus destination. For reference information about these APIs, see “`SIDestinationAddress`” on page 804 and “`SIDestinationAddressFactory`” on page 805.

Procedure

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle (MessageContext context)`. The interface is `MessageContext`, and you should cast this to `SIMessageContext` **unless** you are only interested in the methods provided by `MessageContext`.

2. Get the `SIMessage` from the `MessageContext` object. For example:

```
SIMessage message = ((SIMessageContext)context).getSIMessage();
```

3. Build your mediation header function by using these basic steps:

- a. Get a handle to the runtime environment. For example:

```
.... SIMediationSession mediationSession = mediationContext.getSession();
```

- b. Create a forward routing path to set on the cloned object. For example, use the `Vector` class to create a extendable array of objects.

- c. Get the `SIDestinationAddressFactory` that is to be used for creating `SIDestinationAddress` instances. For example:

```
SIDestinationAddressFactory destFactory = SIDestinationAddressFactory.getInstance();
```

- d. Create a new `SIDestinationAddress`, representing a service integration bus destination. For example:

```
SIDestinationAddress dest = destFactory.createSIDestinationAddress(remoteDestinationName(),false);
```

In this case, the second parameter, the Boolean “false”, indicates that the destination should not be localized to the local messaging engine, but can be anywhere on the service integration bus.

- e. Use the `add` method of the `Vector` class to add another destination name to the array.

- f. Clone the message, and modify the forward routing path in the cloned message. For example:

```
clonedMessage.setForwardRoutingPath(forwardRoutingPath);
```

- g. Send the cloned message by using the `send` method in the `SIMediationSession` interface to send the message to the service integration bus. For example, if named “clonedMessage”:

```
mediationSession.send(clonedMessage, false);
```

4. Return *true* to ensure the message passed into the handle method of the MediationHandler interface continues along the handler chain.

Example

The complete mediation function code to change the forward routing path might look like this example:

```
/* A sample mediation that clones a message
 * and sends the clone off to another destination */

public class RoutingMediationHandler implements MediationHandler {

    public String remoteDestinationName="newdest";

    public boolean handle(MessageContext context) throws MessageContextException {
        SIMessage clonedMessage = null;
        SIMessageContext mediationContext = (SIMessageContext) context;
        SIMessage message = mediationContext.getSIMessage();
        SIMediationSession mediationSession = mediationContext.getSession();

        // Create a forward routing path that will be set on the cloned message
        Vector forwardRoutingPath = new Vector();
        SIDestinationAddressFactory destFactory =
            SIDestinationAddressFactory.getInstance();
        SIDestinationAddress dest =
            destFactory.createSIDestinationAddress(remoteDestinationName, false);
        forwardRoutingPath.add(dest);

        try {
            // Clone the message
            clonedMessage = (SIMessage) message.clone();
            // Modify the forward routing path for the clone
            clonedMessage.setForwardRoutingPath(forwardRoutingPath);
            // Send the message to the next destination in the frp
            mediationSession.send(clonedMessage, false);
        } catch (SIMediationRoutingException e1) {
            e1.printStackTrace();
        } catch (SIDestinationNotFoundException e1) {
            e1.printStackTrace();
        } catch (SINotAuthorizedException e1) {
            e1.printStackTrace();
        } catch (CloneNotSupportedException e) {
            // SIMessage should clone OK so you shouldn't need to enter this block
            e.printStackTrace();
        }
        // allow original message to continue on its path
        return true;
    }
}
```

SIDestinationAddress:

The *SIDestinationAddress* public interface represents a service integration bus destination.

The API has three methods:

- *isTemporary*: This method determines whether the *SIDestinationAddress* represents a temporary or permanent Destination, returning a Boolean value.
- *getDestinationName*: Method to retrieve the name of the Destination represented by this *SIDestinationAddress*.

- `getBusName`: Method to retrieve the bus name of the Destination represented by this `SIDestinationAddress`.

For more information about the `SIDestinationAddress` interface, see the `SIDestinationAddress` generated API information.

SIDestinationAddressFactory:

The `SIDestinationAddressFactory` public interface extends `java.lang.Object`, and creates an `SIDestinationAddressFactory` at static initialization that is subsequently used for the creation of all instances of `SIDestinationAddress`.

The interface has three methods:

- `getInstance`: This method gets the singleton `SIDestinationAddressFactory` that is used for creating `SIDestinationAddress` instances.
- `createSIDestinationAddress`: These two methods are used to create a `SIDestinationAddress` to represent a service integration bus destination. The first will create a `SIDestination` that exists only on the local service integration bus (and maybe localized to the "local" messaging engine depending on the `localOnly` flag). The second method is used to create a `SIDestination` that exists on a remote service integration bus.

-

For more information about the `SIDestinationAddressFactory` interface, see the `SIDestinationAddressFactory` generated API information.

Working with non-routing path fields in a message header:

You can work with fields in a message header that identify and affect the behavior of messages.

About this task

In addition to the routing fields (see “Setting routing addresses in a message header” on page 803), there are a number of fields in the message header that you can work with. These fields affect important qualities and characteristics of the message, such as priority and reliability, identity, and so on. See “Message header information” for information about the equivalence of the header fields to JMS message header fields, and the methods available to work with them.

Procedure

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle (MessageContext context)`. The interface is `MessageContext`, and you should cast this to `SIMessageContext` **unless** you are only interested in the methods provided by `MessageContext`.
2. Get the `SIMessage` from the `MessageContext` object. For example, `SIMessage message = ((SIMessageContext)context).getSIMessage();`
3. Build your mediation header function in a similar way to these examples, and using the reference information in “Message header information” to help:
 - a. Set the reliability of the message. For instance, `siMessage.setReliability(Reliability.ASSURED_PERSISTENT);`. In this case, the quality of service is set to the highest level.
 - b. Set the time to live for a message - that is, the time, in milliseconds, that the message is allowed to remain on a queue before it is removed if it is not processed. For example, `siMessage.setRemainingTimeToLive(1000000);` will set the remaining time before the message should expire to 1000 seconds.

Message header information:

The non-routing `SIMessage` header fields, and the methods available to work with them, can be mapped to JMS message header fields.

Header fields

Table 74. Mapping of `SIMessage` header fields to JMS message header fields. The first column of the table lists the `SIMessage` header fields. The second column provides a brief description of the fields. The third column provides the corresponding JMS message header fields. The fourth column lists the `SIMessage` methods.

SIMessage header field	Field description	Corresponding JMS message header field	SIMessage methods
Priority (ReplyPriority)	Integer value 0-9, higher value is higher message priority	JMSPriority (integer)	<ul style="list-style-type: none"> • getPriority • setPriority • getReplyPriority • setReplyPriority
Reliability (ReplyReliability)	Specifies the reliability of message delivery. See Message reliability levels - JMS delivery mode and service integration quality of service for a description of the allowed values.	JMSDeliveryMode (string) supports two levels of reliability: PERSISTENT and NON_PERSISTENT	<ul style="list-style-type: none"> • getReliability • setReliability • getReplyReliability • setReplyReliability
TimeToLive (ReplyTimeToLive, RemainingTimeToLive)	An integer that represents the time in milliseconds that a message can remain on the queue before it expires.	JMSExpiration (long) is the time of expiry, calculated as "current time" plus (+) "time-to-live".	<ul style="list-style-type: none"> • getTimeToLive • getReplyTimeToLive • getRemainingTimeToLive • setTimeToLive • setReplyTimeToLive • setRemainingTimeToLive
Discriminator (ReplyDiscriminator)	A string that contains a topic name that is tested by a selector rule to determine if the message should be mediated.	No corresponding JMS field	<ul style="list-style-type: none"> • getDiscriminator • setDiscriminator • getReplyDiscriminator • setReplyDiscriminator
RedeliveredCount	Read-only field (integer) that holds that counts each time a message is re-delivered.	JMSRedelivered (Boolean) indicates that it is likely, but not guaranteed, that the message was delivered but unacknowledged in the past.	getRedeliveredCount
ApiMessageId	A string that uniquely identifies each message sent.	JMSMessageId (string)	<ul style="list-style-type: none"> • getApiMessageId • setApiMessageId
CorrelationId	A string that links two messages, typically linking a request message with its response.	JMSCorrelationId (string)	<ul style="list-style-type: none"> • getCorrelationId • setCorrelationId
UserId	A string that represents the identity of the user sending the message.	JMSX UserId is a message property not used by WebSphere Application Server.	<ul style="list-style-type: none"> • getUserId • setUserId

Working with the message payload

You can work with the message payload in a pre-existing mediation handler, and transcode the message payload from one message format to another.

Before you begin

Create or open a mediation handler in an EJB project. For more information, see “Writing a mediation handler” on page 798. You should also read the tips for successfully programming mediations in the topic Coding tips for mediations programming.

About this task

You can use this task to complete some or all of the following actions on the message payload:

- Locate the data objects within the message payload
- Convert the payload into another format
- Convert the payload into a byte array, for example if you want your mediation to log messages.

To work with the contents of a message, use the `SIMessage` and `SIMessageContext` APIs. Additionally, use `SIMediationSession` to provide your mediation with access to the service integration bus, to send and receive messages. For more information, see:

- Mediation programming
- “`MediationHandler`” on page 809
- “`SIMessageContext`” on page 809

To work with specific fields within a message, use Service Data Objects (SDO) Version 1 data graphs. For more information, see SDO data graphs. For more information about the format of supported message types, and examples of how to work with them, see “Mapping of SDO data graphs for web services messages” on page 816.

To work with the message payload, take the following steps:

Procedure

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle (MessageContext context)`. The interface is `MessageContext`, and you should cast this to `SIMessageContext` unless you only want to work with the methods provided by `MessageContext`.
2. Retrieve the data graph of the message payload as follows:
 - a. Get the `SIMessage` from the `MessageContext` object. For example:

```
SIMessage message = ((SIMessageContext)context).getSIMessage();
```
 - b. Get the message format string to determine its type. For example:

```
String messageFormat = message.getFormat();
```
 - c. Retrieve the `DataGraph` object from the message. For example:

```
DataGraph dataGraph = message.getDataGraph();
```

For more information, see SDO data graphs.

3. Optional: Locate data objects within the payload:
 - a. Navigate within the graph to a named `DataObject`. For example, where `DataObject` has the name “data”:

```
DataObject dataObject = dataGraph.getRootObject().getDataObject("data");
```
 - b. Retrieve information contained in the data object. For example, if the message is a text message:

```
String textInfo = dataObject.getString("value");
```
4. Work with the fields within the message. For an example of how to do this, see “Example code for message fields” on page 808.
5. Optional: Transcode the payload into another format:
 - a. Review the topic “Transcoding between message formats” on page 811 to understand the implications of transcoding the payload.
 - b. Call the method `getNewDataGraph`, passing the new format as a parameter, which returns a copy of the payload in the new format. For example:

```
DataGraph newDataGraph = message.getNewDataGraph(newFormat);
```
 - c. Write the data graph in the new format back to the message using the `setDataGraph` method. For example:

```
message.setDataGraph(newDataGraph, newFormat);
```

6. Optional: Convert the payload into a stream of bytes:
 - a. Review the topics “Transcoding a message payload into a byte array” on page 813 and “Transcoding a byte array into a message payload” on page 814 to understand the implications of converting between message format and byte stream, and back again.
 - b. Call the method `getDataGraphAsBytes`, which returns a copy of the payload as a byte stream. For example:

```
byte[] newByteArray = message.getDataGraphAsBytes();
```
 - c. Call the method `createDataGraph` provided by the `SIDataGraphFactory` API, which creates a new data graph by parsing the bytes according to the format passed to the method. For example:

```
DataGraph newDataGraph = SIDataGraphFactory.getInstance().createDataGraph( byteArray, format);
```
 - d. Work with the message as a stream of bytes. For an example of how to do this, see “Example code for message fields”
7. Return `True` in your mediation code so that the `MessageContext` is passed to the next mediation handler in the handler list. If the return value is `False` the `MessageContext` will be discarded and will not be delivered to the destination.

Note: If your mediation handler is the last handler in the handler list, and the forward routing path is empty, the message is made available to consuming applications on that destination. If the forward routing path not empty, the message is not made available to any consumers on that destination. Instead, the message is forwarded to the next destination in the routing path.

Example code for message fields

Below is an example of the code for a mediation for working with a field in a message:

```
public boolean handle(MessageContext context) throws MessageContextException {  
  
    /* Get the SIMessage from the MessageContext object */  
    SIMessage message = ((SIMessageContext)context).getSIMessage();  
  
    /* Get the message format string */  
    String messageFormat = message.getFormat();  
  
    /* If you have a JMS TextMessage then extract the text contained in the message. */  
    if(messageFormat.equals("JMS:text"))  
    {  
        /* Retrieve the DataGraph object from the message */  
        DataGraph dataGraph = message.getDataGraph();  
  
        /* Navigate down the DataGraph to the DataObject named 'data'. */  
        DataObject dataObject = dataGraph.getRootObject().getDataObject("data");  
  
        /* Retrieve the text information contained in the DataObject. */  
        String textInfo = dataObject.get("value");  
  
        /* Use the text information retrieved */  
        System.out.println(textInfo);  
    }  
  
    /* Return true so the MessageContext is passed to any other mediation handlers  
    * in the handler list */  
    return true;  
}
```

The complete mediation function code for working with the message payload as a stream of bytes might look like this example:

```
public boolean handle(MessageContext context) throws MessageContextException {

    /* Get the SIMessage from the MessageContext object */
    SIMessage message = ((SIMessageContext)context).getSIMessage();

    if (!SIConstants.JMS_FORMAT_MAP.equals(msg.getFormat()))
    {
        try
        {
            dumpBytes(msg.getDataGraphAsBytes());
        }
        catch(Exception e)
        {
            System.out.println("The message contents could not be retrieved due to a "+e);
        }
    }
    else
    {
        System.out.println("The bytes for a JMS:map format message cannot be shown.");
    }

    return true;
}

private static void dumpBytes(byte[] bytes)
{
    // Subroutine to dump the bytes in a readable form to System.out
}
}
```

MediationHandler:

The public interface `MediationHandler` has just one method: `handle`. This method is used by the runtime to invoke a mediation.

The method `handle` is called by the runtime when a message is to be mediated. The method returns Boolean *True* if the message passed into this method should continue along the handler list, otherwise *False*.

At the end of the handler list, the message is sent to the next destination on the routing path, unless the forward routing path is empty, when the message is made available to consuming applications on the current destination.

For more information about the `MediationHandler` interface, see the `MediationHandler` generated API information.

SIMessageContext:

Public interface `SIMessageContext` extends `javax.xml.rpc.handler.MessageContext`. This is the object that is required on the interface of a mediation handler. In addition to the context information that might be passed from one handler to another, it can return a reference to an `SIMessage` and an `SIMediationSession`.

The `SIMessage` is the service integration technologies representation of the message being processed by the `MediationHandler`. The `SIMediationSession` is a handle to the runtime resources.

The interface `MessageContext` abstracts the message context that is processed by a handler in the `handle` method. The `MessageContext` interface provides methods to manage a property set. `MessageContext` properties enable handlers in a handler chain to share processing related state.

As well as defining the method that is invoked by the mediation runtime environment, the interface might also specify properties following the Enterprise JavaBeans naming pattern, or by providing a `BeanInfo` class. Each property of the bean will be initialized from a single environment entry with the same name as the property. Bean properties of simple type are specified by using Java Platform, Enterprise Edition (Java EE) `env-entry`. If the handler has properties that are of non-simple type, then other environment definitions may be used.

The API has two methods:

- The `getSIMessage` method to get the service integration bus representation of the message being mediated. Read more about the `SIMessage` API in “`SIMessage`.”
- The `getSession` method to get an `SIMediationSession` object that is a handle to the runtime environment. Read more about the `SIMediationSession` API in “`SIMediationSession`” on page 811.

SIMessage:

The `SIMessage` interface is the public interface to a service integration bus message for use by mediations and other service integration bus components. This interface extends `java.lang.Cloneable` and `java.lang.Serializable`.

The version of Service Data Objects (SDO) supported by mediations is Version 1.

The `SIMessage` interface has many methods allowing you to work with message properties, header contents, routing path, metadata, and others:

- The method `getDataGraph` returns the SDO data graph. This contains the `SIMessage` payload content in a tree representation. Using the data graph, you can work directly with individual fields in the message payload. For more information about SDO data graphs, see `SDO data graphs`.
- You can transcode a message payload by calling the method `getNewDataGraph(format)`. It returns a copy of the payload in the new format. You can write the new datagraph back to the message by using `setDataGraph(DataGraph, format)`. For more information, see “`Transcoding between message formats`” on page 811.
- If you want to log a message as a simple byte stream, you can retrieve the message payload as a byte array by using the method `getDataGraphAsBytes`. For more information about converting from data graph to bytes, and back again, see “`Transcoding a message payload into a byte array`” on page 813 and “`Transcoding a byte array into a message payload`” on page 814.
- There are methods to get, set, delete and clear user properties and message properties. You can also retrieve a list of user property names. For more information about working with properties, see “`Working with message properties`” on page 801.
- Forward and reverse routing paths define a sequential list of intermediate bus destinations through which messages pass to reach a target bus destination. You use a routing path to apply the mediations configured on several destinations to the messages sent along the path. The following methods allow you to get and set the contents of the `ForwardRoutingPath` and `ReverseRoutingPath` for an `SIMessage`:
 - `getForwardRoutingPath()`
 - `setForwardRoutingPath()`
 - `getReverseRoutingPath()`
 - `setReverseRoutingPath()`

For more information about routing paths, see `Destination routing paths`. For information about how to work with routing addresses, see “`Setting routing addresses in a message header`” on page 803.

- If your mediation changes the content of the message, there is a risk that the message is no longer valid. If the data graph is not valid, the message cannot be sent through the service integration bus or

stored in the message store. In this case, the message is not **well formed**. A message is well formed when all the values of the message properties might be serialized, and the data graph of the message conforms to the format of the message. You can test your message by using the method `isWellFormed`. It returns `true` when the message contains a well formed data graph. This test has implications for performance. For more information, see Setting tuning properties for a mediation.

- You can work with the time for the message to live, measured in milliseconds from the time when the message was originally sent:
 - The methods `getTimeToLive` and `setTimeToLive` allow you to get and set the value of the `TimeToLive` field in the message header. A value of 0 indicates that the message will never expire.
 - The methods `getRemainingTimeToLive` and `setRemainingTimeToLive` allow you to get the remaining time in milliseconds before the message expires, and set the remaining time in milliseconds before the message should expire.

For more information about `SIMessage`, see the API documentation.

SIMediationSession:

The `SIMediationSession` public interface defines the methods for querying and interacting with the service integration bus. As well as defining the methods for working with the service integration bus, this interface also includes methods that provide information about where the mediation is invoked from, and the criteria that are applied before the message is mediated.

Both selector and discriminator control which messages are sent to the mediation, through a rule specified in a text string. The rule specified by the selector examines the header and properties of the message, whereas the discriminator examines the topic of the message. If a message contains both selector and discriminator, it must match both rules for the message to be mediated. If either the selector or the discriminator rule does not match, the message is not mediated.

The API has these methods:

- `getBusName` returns the name of the bus upon which the mediation is associated.
- `getDestinationName` returns the name of the destination with which the mediation is associated.
- `getDiscriminator` returns the discriminator that is defined in the mediation definition.
- `getMediationName` returns the name of the mediation that is being executed.
- `getMessageSelector` returns the message selector that is defined in the mediation definition.
- `getMessagingEngineName` returns the name of the messaging engine from which the mediation was invoked
- `getSIDestinationConfiguration` returns the `SIDestinationConfiguration` object associated with the destination, specified by `destinationName` or `destinationAddress`.
- `receive` receives an `SIMessage` from the service integration bus. There are four variants.
- `resetIdentity` changes the identity of the given message to the current run-as identity.
- `send` sends a copy of an `SIMessage` to the service integration bus, in addition to the message returned by the message interface.

See also the generated API information for `SIMessageContext`.

Transcoding between message formats:

A mediation can convert a message from one format to another without changing the semantic meaning of the message. This operation is referred to as transcoding a message.

The following code is an example mediation handler that transcodes a message into a new message format, providing that the message can be transcoded:

```

private static final String NEW_FORMAT = "JMS:text";

public boolean(MessageContext context) throws MessageContextException
{
    try
    {
        SIMessageContext msgCtx = (SIMessageContext)context;
        SIMessage msg = msgCtx.getMessage();
        DataGraph newDg = msg.getNewDataGraph(NEW_FORMAT);

        msg.setDataGraph(newDg,NEW_FORMAT);
        return true;
    }
    catch(Exception e)
    {
        // Reroute the original message to the exception destination
        MessageContextException mce =
            new MessageContextException("Unable to transcode to "+NEW_FORMAT",e);
        throw mce;
    }
}

```

The table below describes which messages can be transcoded, and gives the outcome for each format pairing. Note that the abbreviation DG represents "data graph". The numbers within brackets in the table are explained as follows:

- (1) A message with format JMS: cannot have a payload. It does not carry any message data other than the message properties. If a mediation calls `getDataGraph()` on a message with format JMS:, `null` is always returned. All other message formats must have a message payload. This means that a message with format JMS: cannot be transcoded into another format. If a mediation needs to change a message with format JMS: into a message with any other format, the mediation needs to call the methods `SIDataGraphFactory.getInstance().createDataGraph(newFormat)` and `setDataGraph` on the `SIMessage` object to change the message contents.
- (2) `null` is always returned if a mediation calls `getDataGraph()` on a message with format JMS:
- (3) A mediation can call the method `getNewDataGraph()` on a message to return a copy datagraph with the same format as the message. The copy can be edited, leaving the original message unchanged. For SOAP and Beans, you can change the message model by editing the format string to change the value that follows the ":".

Table 75. Message transcoding. The table contains the different formats that can be used to convert the messages from one format to another. The table shows the transcoding options that is possible between the different formats, and it also provides the effect the conversion has on the messages.

	To JMS:	To JMS:text	To JMS:bytes	To JMS:stream	To JMS:object	To SOAP:	To Bean:
From JMS:	DG=null (1)	DG=null (1)	DG=null (1)	DG=null (1)	DG=null (1)	DG=null (1)	DG=null (1)
From JMS:text	DG=null (2)	Yes (3)	Yes, bytes contain UTF-8	Yes, if text contains XML that conforms to the correct schema.	No	Yes, if message content is valid SOAP.	Yes, if message content is valid SOAP.
From JMS:bytes	DG=null (2)	Yes, but only when the bytes can correctly be interpreted as a UTF-8 string.	Yes (3)	Yes, if bytes contain XML that conforms to the correct schema.	Yes, assume that bytes are a serialized object.	Yes, if message content is valid SOAP.	Yes, if message content is valid SOAP.
From JMS:stream	DG=null (2)	Yes, text is XML transcoding.	Yes, bytes contain XML transcoding.	Yes (3)	No	No	No

Table 75. Message transcoding (continued). The table contains the different formats that can be used to convert the messages from one format to another. The table shows the transcoding options that is possible between the different formats, and it also provides the effect the conversion has on the messages.

	To JMS:	To JMS:text	To JMS:bytes	To JMS:stream	To JMS:object	To SOAP:	To Bean:
From JMS:object	DG=null (2)	No	Yes, bytes contain the object serialization.	No	Yes (3)	No	No
From SOAP:	DG=null (2)	Yes	Yes	No	No	Yes (3) - if message content matches the new WSDL.	Yes
From Bean:	DG=null (2)	Yes	Yes	No	No	Yes	Yes (3) - if message content matches the new WSDL.

XML schema definition for JMS stream messages:

This is the XML schema definition for transcoding JMS stream messages to message types.

The following XML schema definition uses the target namespace `http://www.ibm.com/xmlns/prod/websphere/messaging/jms/` to express JMS stream messages in XML. Use this definition to transcode between a byte array and a message payload.

```
<xsd:schema elementFormDefault="qualified" xml:lang="EN"
  targetNamespace="http://www.ibm.com/xmlns/prod/websphere/messaging/jms"
  xmlns="http://www.ibm.com/xmlns/prod/websphere/messaging/jms"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema">

  <xsd:element name="data" type="StreamBody"/>

  <xsd:complexType name="StreamBody">
    <xsd:sequence>
      <xsd:element name="value"
        type="streamTypes"
        minOccurs="0"
        maxOccurs="unbounded"
        nillable="true"/>
    </xsd:sequence>
  </xsd:complexType>

  <xsd:simpleType name="character">
    <xsd:restriction base="xsd:string">
      <xsd:minLength value="1"/>
      <xsd:maxLength value="1"/>
    </xsd:restriction>
  </xsd:simpleType>

  <xsd:simpleType name="streamTypes">
    <xsd:union memberTypes="xsd:long xsd:int xsd:short xsd:byte xsd:boolean
      xsd:float xsd:double xsd:string xsd:hexBinary character"/>
  </xsd:simpleType>
</xsd:schema>
```

Transcoding a message payload into a byte array:

You can transcode the message payload into a byte array.

For example, you might want to write a mediation handler that logs a message as a simple byte stream. You can retrieve the message payload as a byte array by using the method `getDataGraphAsBytes`. The table below describes the rules for transcoding an `SIMessage` data graph into a byte array.

Table 76. Rules for transcoding a message payload into a byte array. The first column of the table contains the datagraph formats used for transcoding a message into a byte array. The second column provides the preconditions for the datagraph format if available. The third column provides the result of the transcode. The fourth column contains the character set encodings if they are applicable for the messages.

Datagraph format	Pre-conditions	Outcome	Character set encoding
JMS:	None	Returns null.	Not applicable.
JMS:text	None	Returns the result of <code>java.lang.String.getBytes(String charSetName)</code> when applied to the <code>data/value</code> element of the graph, where <code>charSetName = "UTF-8"</code>	UTF-8
JMS:bytes	None	Returns a copy of the value of the <code>data/value</code> element of the data graph for the message.	Not applicable.
JMS:stream	None	Returns a byte buffer containing an XML serialization of the stream message according to the XML schema for stream messages.	UTF-8
JMS:object	None	Returns a copy of the value of the <code>data/value</code> element of the data graph for the message.	Not applicable.
SOAP:	If the byte array must be generated by this operation (instead of using an existing byte array available through lazy parsing) then the data graph must be valid with respect to the WSDL model.	Returns a byte buffer containing a SOAP serialization of the data graph. If the SOAP message contains an attachment, the buffer has the multipart MIME format.	Either UTF-8, or that of the source message for the graph, where logically equivalent to the graph state.
Bean:	The data graph must be valid with respect to the WSDL model. In the absence of a SOAP binding the serialization will be performed using RPC/literal encoding.	Returns a byte buffer containing a SOAP serialization of the data graph. If the Bean contains attachments then the buffer will be in multipart MIME format.	UTF-8

Transcoding a byte array into a message payload:

A mediation can transcode a byte array into a message payload without changing the meaning of the message.

A mediation can reconstruct the message payload from a byte array, for example after logging a message. To reconstruct the message, call the method `createDataGraph` provided by the `SIDataGraphFactory` API. This method requires a byte array and a format string and creates a new data graph by parsing the bytes according to the format passed to the method, as shown in the following example:

```
DataGraph newDataGraph = SIDataGraphFactory.getInstance().createDataGraph(byteArray, newFormat);
```

The table below describes the rules for transcoding a byte array into an `SIMessage` data graph.

Table 77. Rules for transcoding a byte array into an *SIMessage* data graph. The first column of the table contains the format arguments used for transcoding a byte array into an *SIMessage* data graph. The second column provides the preconditions if available for the format arguments. The third column provides the resultant *SIMessage* data graphs for the specified format arguments.

Format argument	Pre-conditions	Outcome
JMS:	None	Returns null
JMS:text	<code>java.lang.String(inputBytes, "UTF-8")</code> does not result in an exception.	Returns new data graph instance of format JMS:text. Value of graph at path <code>data/value</code> has value equal to <code>java.lang.String(inputBytes, "UTF-8")</code> .
JMS:bytes	<code>inputBytes</code> is not null.	Returns new data graph instance of format JMS:bytes. Value of graph at path <code>data/value</code> is a copy of the <code>inputBytes</code> byte array.
JMS:stream	Byte array is XML, and is valid with respect to the <code>JmsStreamBody</code> type of the XML schema definition.	Returns new data graph instance of format JMS:stream. Value of graph at path <code>data/value</code> has type List, containing a sequence of simple typed values according to the types and values of each of the elements in the XML document.
JMS:object	Not null Note: You must ensure that the byte array is a valid serialized object.	Returns new data graph instance of format JMS:object. Value of graph at path <code>data/value</code> is a copy of the <code>inputBytes</code> byte array.
SOAP:	The byte buffer contains valid SOAP with respect to the associated WSDL model.	Returns new data graph with type system defined by the WSDL referenced by the byte buffer, and values of the graph defined by the SOAP payload.
Bean:	The byte buffer contains valid Bean with respect to the associated WSDL model.	Returns new data graph with type system defined by the WSDL referenced by the byte buffer, and values of the graph defined by the Bean payload.

Web services messages overview:

To work with the data graph form of web services messages, you need to know the structure of the data graph, and how to develop code that can navigate the data graph.

The format of web services messages

WebSphere Application Server (base) supports two formats for web services messages: SOAP and enterprise beans. (These are similar to Java APIs for XML based RPC, or JAX-RPC.)

To work with web services messages, you need the following information:

- The structure of the Service Data Objects (SDO) Version 1 data graphs for web services messages. See “Mapping of SDO data graphs for web services messages” on page 816 for more information about the data elements and the shape of the data graph.
- Reference information to help you develop code to navigate the data graphs of the messages that your program mediates. See “Mapping XML schema definitions to the SDO type system” on page 820.
- For XML representations of the shape of each part of web services messages, sample code snippets and further information about the data graph format, see: “Web Services code example” on page 823.

Format types

The web services message type is defined by a message format string within the message. The format string is prefixed with a domain identifier, which is either SOAP or Bean, followed by four comma-separated fields as follows:

SOAP:<wsdlLocation>,<serviceNameSpace>,<serviceName>,<portName>

Bean:<wsdlLocation>,<serviceNameSpace>,<serviceName>,<portName>

The fields are described in the following table:

Field name	Message format string	Field description
WSDL location	<wsdlLocation>	The URI where the WSDL for this message is located. The WSDL is deployed to the SDO repository, by using this location as the key.
Service namespace	<serviceNameSpace>	Service namespace and Service name uniquely identify the Service definition within the WSDL.
Service name	<serviceName>	Service name and Service namespace uniquely identify the correct Service definition within the WSDL.
Port name	<portName>	Locates the Port definition within the Service, giving the PortType and Binding information that is required for message processing.

Mapping of SDO data graphs for web services messages:

The structure of web services messages is described by the Service Data Objects (SDO) Version 1 data graphs for web services messages.

Overall layout of a web services message

A web services message is described by a format string and three metadata fields: operationName, messageName, and messageType. The payload of the message is split across three other sections: headers, attachments and the body.

The Info node is the top-level of the SDO data graph for all web services messages. The following table describes the Info node properties and associated types.

Property name	Property type	Property description
operationName	java.lang.String	Identifies the WSDL operation that is associated with the message. If the data access service cannot identify the message, this field is null. See "Identifying web services messages" on page 817.
messageName	java.lang.String	Identifies the WSDL message that is associated with the message. If the data access service cannot identify the message, this field is null. See "Identifying web services messages" on page 817.

Property name	Property type	Property description
messageType	java.lang.String	Identifies WebService type of message instance. This field can have the values: <i>input</i> , <i>output</i> , <i>fault</i> , <i>ambiguous</i> . If the data access service cannot identify the message, this field is null. See “Identifying web services messages.”
headers	java.util.List of data objects.	Contains a list of header entry data objects. Each SOAP header in the message results in a header entry in this list. See “Message header layout ” on page 818.
attachments	java.util.List of data objects.	Contains a list of attachment entry data objects. For SOAP messages with attachments, each MIME part in the message (except the MIME part containing the SOAP envelope) is mapped to an entry in this list. See “Message attachment layout” on page 818.
body	commonj.sdo.DataObject	A nested data object, which represents the body of the SOAP envelope. See “Message body layout” on page 819.

Identifying web services messages

Processing of messages depends on whether the messages have WSDL definitions. The minimum amount of information required for processing without WSDL is “SOAP:”. The minimum amount of information required for processing with WSDL is: “SOAP:location,namespace,service,port”. If the format string does not include all five of these fields, the SOAP data access service attempts to process the message without WSDL.

- Processing messages without WSDL definitions: If the format string does not include full WSDL information, the SOAP data access service processes the message without attempting to match the message against definitions in WSDL. As a result, operationName and messageName are set to null, and messageType is set only when processing a fault message.
- Processing messages with WSDL definitions: If the format string includes <WSDL location>,<Service namespace>,<Service name>, and <Port name>, the SOAP and Beans data access services process the message by using the WSDL definitions of the service.

Note: In either of the following circumstances, SOAP message processing fails once it has supplied all the required WSDL information:

- the SOAP data access service fails to locate the WSDL
- the WSDL fails to corroborate the message

When the SOAP data access service processes a SOAP request or reply message, it tries to match it against the message definitions in the WSDL. Usually there is one matching definition, and the operationName, messageName, and messageType are filled in appropriately. If there is more than one matching definition, the data access service selects a message definition, fills in the operationName and messageName. and sets the messageType to *ambiguous*.

When processing fault messages, identification is slightly different. In all cases the messageType is set to *fault*. If the message matches a unique fault definition in the WSDL, the operationName and messageName properties are also set.

Message header layout

The list of headers has two types of entry, header entry or bound header entry, depending on whether the header is based on part of the message or not.

The header entry type is used to handle headers that meet either of the following criteria:

- the header is part of the message that is modeled in WSDL
- the header is part of the message that is not modeled in WSDL, but is based on a part of the message

For a model of this header, see “Header entry.”

The bound header entry type is used when the SOAP binding for the message has bound a part of the body into a MIME attachment. (This occurs when you use a <MIME:content> element to bind a part of the message to an attachment.) For consistent mediation programming, all of the body data is stored in the body node in the graph. Unlike the normal attachment entry, a bound attachment entry is placed into the attachments list. The bound attachment entry contains the MIME meta-data for the attachment and the name of the message part that contains the data taken from this attachment. This allows mediations designed to process attachments to locate the data in the body part of the data graph. For a model of this attachment see “Bound header entry.”

Header entry

Property name	Property type	Property description
mustUnderstand	java.lang.Boolean	Carries the value from the mustUnderstand attribute on the SOAP header, if present.
actor	java.lang.String	Carries the value from the actor attribute on the SOAP header, if present.
any	commonj.sdo.Sequence	Container for the contents of the SOAP header.

Bound header entry

Property name	Property type	Property description
mustUnderstand	java.lang.Boolean	Carries the value from the mustUnderstand attribute on the SOAP header, if present.
actor	java.lang.String	Carries the value from the actor attribute on the SOAP header, if present.
messagePart	java.lang.String	Contains the name of the message part that carries the data from this message header.

Message attachment layout

Message attachments are handled in a similar way to headers, and instances of them populate the attachments list in the Info node.

There are two types of attachment entry to handle MIME attachments: attachment entry and bound attachment entry.

Attachment entry is for general attachments: see “Attachment entry” on page 819.

Bound attachment entry includes <MIME:content> elements that bind a part of the body into a MIME attachment. If you are programming a mediation, you must know how to locate the data within the graph. For consistent mediation programming, the attachment data is placed in the message body, referred to by the part name in the header entry, which includes the other MIME metadata. For a model of this attachment, see “Bound attachment entry.”

Attachment entry

Property name	Property type	Property description
contentType	java.lang.String	Carries the contentType from the MIME part that is represented by the attachment entry.
contentTransferEncoding	java.lang.String	Carries the contentTransferEncoding from the MIME part that is represented by the attachment entry.
contentId	java.lang.String	Carries the contentId from the MIME part that is represented by the attachment entry.
data	byte[]	Carries the content of the MIME element as a byte array.

Bound attachment entry

Property name	Property type	Property description
contentType	java.lang.String	Carries the contentType from the MIME part that is represented by the attachment entry.
contentTransferEncoding	java.lang.String	Carries the contentTransferEncoding from the MIME part that is represented by the attachment entry.
contentId	java.lang.String	Carries the contentId from the MIME part that is represented by the attachment entry.
messagePart	java.lang.String	Contains the name of the message part that carries the data from this attachment.

Message body layout

The layout of the data object in the body is defined by the service WSDL. The type of the data object is derived from the message definition in the WSDL. The data object has one property for each part in the message definition. The layout of each message part follows the convention for mapping XML Schema into SDO. See “Web Services code example” on page 823 for more information.

Web services fault message

If the message is a fault message, the messageType field in the Info node of the graph is set to “fault”, and the message body has the following properties:

Property name	Property type	Property description
faultcode	javax.xml.namespace.QName	Carries the faultcode value from the SOAP Fault element
faultstring	java.lang.String	Carries the faultstring value from the SOAP Fault element
faultactor	java.lang.String	Carries the faultactor value from the SOAP Fault element

Property name	Property type	Property description
detail	commonj.sdo.DataObject	Carries the content within the detail child of the SOAP Fault element

Note: The detail element definition uses element and attribute wildcards, so the content of the detail data object contains a Sequence. See “Web Services code example” on page 823 for more information.

Mapping XML schema definitions to the SDO type system:

Each XML schema type is mapped to an SDO type. Use this mapping to help you develop code to navigate the data graphs of the messages that your program mediates.

The version of Service Data Objects (SDO) supported by mediations is Version 1.

XML schemas can be embedded in the WSDL sections that describe the message parts and SOAP headers. However the SOAP header description is more likely to be available as a separate schema, in which case you should load it into the SDO repository where it can be used at run time to process any message with a matching header.

Schema to Java class mapping

Each XML schema complex type is mapped to an SDO type. This means that an element with a complex type is represented by an instance of an SDO data object. The type has a property for each element, attribute, or wildcard that is contained in the schema type definition.

The instance contains a value for each property that has been set. If the property is mapped from a schema complex type, the value is another SDO data object. If the property is mapped from a schema simple type, the value is an instance of a Java class, as shown in the following table.

Table 78. Schema types and corresponding Java classes. The first column of the table lists the schema types. The second column lists the corresponding Java classes. The third column refers you to one of the two notes that is given at the end of the table for your reference.

Schema type	Java class	Notes
anyURI	java.lang.String	
base64Binary	byte[]	See Note 2
boolean	java.lang.Boolean/ boolean	See Note 1
byte	java.lang.Byte / byte	See Note 1
date	java.lang.String	
dateTime	java.lang.String	
decimal	java.math.BigDecimal	
double	java.lang.Double / double	See Note 1
duration	java.lang.String	
ENTITIES	java.util.List	
ENTITY	java.lang.String	
float	ava.lang.Float / float	See Note 1
gDay	java.lang.String	
gMonth	java.lang.String	
gMonthDay	java.lang.String	
gYear	java.lang.String	
gYearMonth	java.lang.String	
hexBinary	byte[]	See Note 2

Table 78. Schema types and corresponding Java classes (continued). The first column of the table lists the schema types. The second column lists the corresponding Java classes. The third column refers you to one of the two notes that is given at the end of the table for your reference.

Schema type	Java class	Notes
ID	java.lang.String	
IDREF	java.lang.String	
IDREFS	java.util.List	
int	java.lang.Integer / int	See Note 1
integer	java.math.BigInteger	
language	java.lang.String	
long	java.lang.Long / long	See Note 1
Name	java.lang.String	
NCName	java.lang.String	
negativeInteger	java.math.BigInteger	
NKTOKENS	java.util.List	
NMTOKEN	java.lang.String	
nonNegativeInteger	java.math.BigInteger	
nonPositiveInteger	java.math.BigInteger	
normalisedString	java.lang.String	
NOTATION	javax.xml.namespace.QName	
positiveInteger	java.math.BigInteger	
QName	javax.xml.namespace.QName	
short	java.lang.Short / short	See Note 1
string	java.lang.String	
time	java.lang.String	
token	java.lang.String	
unsignedByte	java.lang.Short / short	See Note 1
unsignedInt	java.lang.Long / long	See Note 1
unsignedLong	java.math.BigInteger	
unsignedShort	java.lang.Integer / int	See Note 1

Notes:

1. SDO automatically converts primitives (int, long and so on) into objects, as needed. This means that you can use a mixture of the specialized methods (getInt, setInt, getLong, setLong) as well as the generic get and set methods.
2. As byte arrays are mutable, you can update the value without setting it back onto the data object. However, when this occurs, the data object may not be aware of implicit update. When working with byte array values, always use the setBytes() method to explicitly update the data object.

Working with global elements and attributes

When a schema is mapped to SDO, a special SDO type - typically called 'DocumentRoot' - is defined. This type is a container for all the global elements and attributes in the schema. Whenever you have to locate an SDO property for a global element or attribute, you should locate the 'DocumentRoot' type and then locate the appropriate property within it.

The following schema defines the layout of web services messages. By comparing this schema with the information in "Mapping of SDO data graphs for web services messages" on page 816 you can see the schema to SDO mapping in action.

```

<?xml version="1.0"?>
<xsd:schema
  targetNamespace="http://www.ibm.com/ns/2004/05/webservices/messagemodel"
  xmlns:tns="http://www.ibm.com/ns/2004/05/webservices/messagemodel"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/">

```

Web Services code example:

This Web Services Description Language (WSDL) example and code snippets show how to access fields within a Web services message for programming a mediation.

Web services message definition

This topic contains an example of a web services message. The example is characterized in WSDL, an XML-based language that is used to describe the services a business offers and how those services might be accessed.

This topic shows how to program mediations to work with different parts of a web services message, which are described with the Service Data Objects (SDO) Version 1 representation in “Mapping of SDO data graphs for web services messages” on page 816. For each part of the message, there is an XML description of the message, representing its SDO data graph. Each XML description is accompanied by code snippets that illustrate how to work with that part of the message.

Note: In the following example, the SOAP header schema is included in the WSDL. Alternatively, it can be included as a separate schema in the SDO repository.

This is a WSDL description of the message that is used as an example for subsequent code snippets:

companyInfo web service message description

```
<wsdl:definitions targetNamespace="http://example.companyInfo"
  xmlns:tns="http://example.companyInfo"
  xmlns:wsi="http://schemas.xmlsoap.org/wsdl/"
  xmlns:wsoap="http://schemas.xmlsoap.org/wsdl/soap/"
  xmlns:wsmime="http://schemas.xmlsoap.org/wsdl/mime/"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema">

  <wsdl:types>
    <xsd:schema elementFormDefault="qualified"
      targetNamespace="http://example.header">

      <xsd:element name="sampleHeader">
        <xsd:complexType>
          <xsd:all>
            <xsd:element name="priority" type="xsd:int"/>
          </xsd:all>
        </xsd:complexType>
      </xsd:element>
    </xsd:schema>

    <xsd:schema elementFormDefault="qualified"
      targetNamespace="http://example.companyInfo">

      <xsd:element name="getCompanyInfo">
        <xsd:complexType>
          <xsd:all>
            <xsd:element name="tickerSymbol" type="xsd:string"/>
          </xsd:all>
        </xsd:complexType>
      </xsd:element>

      <xsd:element name="getCompanyInfoResult">
        <xsd:complexType>
          <xsd:all>
            <xsd:element name="result" type="xsd:float"/>
          </xsd:all>
        </xsd:complexType>
      </xsd:element>
    </xsd:schema>

  </wsdl:types>

  <wsdl:message name="getCompanyInfoRequest">
    <wsdl:part name="part1" element="tns:getCompanyInfo"/>
  </wsdl:message>

  <wsdl:message name="getCompanyInfoResponse">
    <wsdl:part name="part1" element="tns:getCompanyInfoResult"/>
    <wsdl:part name="part2" type="xsd:string"/>
    <wsdl:part name="part3" type="xsd:base64Binary"/>
  </wsdl:message>

  <wsdl:portType name="CompanyInfo">
    <wsdl:operation name="GetCompanyInfo">
      <wsdl:input message="tns:getCompanyInfoRequest"
        name="getCompanyInfoRequest"/>
      <wsdl:output message="tns:getCompanyInfoResponse"
```

```

        name="getCompanyInfoResponse"/>
    </wsdl:operation>
</wsdl:portType>

<wsdl:binding name="CompanyInfoBinding" type="tns:CompanyInfo">
    <wsdlsoap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http"/>

    <wsdl:operation name="GetCompanyInfo">
        <wsdlsoap:operation soapAction=""/>
        <wsdl:input name="getCompanyInfoRequest">
            <wsdlsoap:body use="literal"/>
        </wsdl:input>
        <wsdl:output name="getCompanyInfoResponse">
            <wsdlsoap:body use="literal"/>
        </wsdl:output>
    </wsdl:operation>
</wsdl:binding>

<wsdl:service name="CompanyInfoService">
    <wsdl:port binding="tns:CompanyInfoBinding" name="SOAPPort">
        <wsdlsoap:address location="http://somewhere/services/CompanyInfoService"/>
    </wsdl:port>
</wsdl:service>

</wsdl:definitions>

```

Working with the info node

This is an example of a simple SOAP request:

```

<env:Envelope
  xmlns:env='http://schemas.xmlsoap.org/soap/envelope/'
  xmlns:ns1='http://example.companyInfo'>
  <env:Body>
    <ns1:getCompanyInfo>
      <ns1:tickerSymbol>IBM</ns1:tickerSymbol>
    </ns1:getCompanyInfo>
  </env:Body>
</env:Envelope>

```

You can access the properties of the info node (see “Overall layout of a web services message” on page 816) using code snippets such as this:

```

// Get the info node (a child of the graph root object)
DataObject rootNode = graph.getRootObject();
DataObject infoNode = rootNode.getDataObject("Info");

// Query the operationName, and messageType.
String opName = infoNode.getString("operationName");
String type = infoNode.getString("messageType");

```

Working with a header

This is an example of a SOAP request including a header:

```

<env:Envelope
  xmlns:env='http://schemas.xmlsoap.org/soap/envelope/'
  xmlns:ns1='http://example.companyInfo'>
  <env:Header>
    <example:sampleHeader
      env:mustUnderstand='1'
      xmlns:example='http://example.header'>
      <example:priority>4</example:priority>
    </example:sampleHeader>
  </env:Header>

```

```

    <env:Body>
      <ns1:getCompanyInfo>
        <ns1:tickerSymbol>IBM</ns1:tickerSymbol>
      </ns1:getCompanyInfo>
    </env:Body>
  </env:Envelope>

```

For a description of the properties of the header entry with a list of headers, see “Header entry” on page 818. To work with a header entry and its properties, use code such as this:

```

// Get the info node (a child of the graph root object)
DataObject rootNode = graph.getRootObject();
DataObject infoNode = rootNode.getDataObject("Info");

// Access the list of headers
List headerEntries = infoNode.getList("headers");

// Get the first entry from the list
DataObject headerEntry = (DataObject) headerEntries.get(0);

// Query the mustUnderstand property of the header entry
boolean mustUnderstand = headerEntry.getBoolean("mustUnderstand");

// Get the Sequence that holds the content of the header entry
Sequence headerContent = headerEntry.getSequence("any");

// Get the first piece of content from the Sequence
DataObject header = (DataObject) headerContent.getValue(0);

// Read the priority from the header
int priority = header.getInt("priority");

// Shorthand for the above, using SDO path expressions that start
// from the info node.
mustUnderstand = infoNode.getBoolean("headers[1]/mustUnderstand");
priority = infoNode.getInt("headers[1]/any[1]/priority");

```

Working with an attachment

This is an example of a SOAP request including an XML attachment:

```
Content-Type: multipart/related; start="<start>"; boundary="boundary"
```

```

--boundary
Content-Type: text/xml
Content-Transfer-Encoding: 7bit
Content-ID: <start>

```

```

<env:Envelope
  xmlns:env='http://schemas.xmlsoap.org/soap/envelope/'
  xmlns:ns1='http://example.companyInfo'>
  <env:Body>
    <ns1:getCompanyInfo>
      <ns1:tickerSymbol>IBM</ns1:tickerSymbol>
    </ns1:getCompanyInfo>
  </env:Body>
</env:Envelope>

```

```

--boundary
Content-Type: text/xml; charset=UTF-8
Content-Transfer-Encoding: binary
Content-ID: <myAttachment>

```

```
<info>Some attached information</info>
```

```
--boundary--
```

For a description of the properties of the attachment entry with byte array, see “Attachment entry” on page 819. To work with a header entry and its properties, use code such as this:

```
// Get the info node (a child of the graph root object)
DataObject rootNode = graph.getRootObject();
DataObject infoNode = rootNode.getDataObject("Info");

// Access the list of attachments
List attachmentEntries = infoNode.getList("attachments");

// Get the first entry from the list
DataObject attachmentEntry = (DataObject) attachmentEntries.get(0);

// Query the contentId property of the header entry
String contentId = attachmentEntry.getString("contentId");

// Get the data contained in the attachment
byte[] data = attachmentEntry.getBytes("data");
```

Working with the message body

This is an example of a simple SOAP request:

```
<env:Envelope
  xmlns:env='http://schemas.xmlsoap.org/soap/envelope/'
  xmlns:ns1='http://example.companyInfo'>
  <env:Body>
    <ns1:getCompanyInfo>
      <ns1:tickerSymbol>IBM</ns1:tickerSymbol>
    </ns1:getCompanyInfo>
  </env:Body>
</env:Envelope>
```

To see the properties of the body, see “Message body layout” on page 819. To work with the contents of the body, use code such as this:

```
// Get the info node (a child of the graph root object)
DataObject rootNode = graph.getRootObject();
DataObject infoNode = rootNode.getDataObject("Info");

// Get hold of the body node
DataObject bodyNode = infoNode.getDataObject("body");

// Get hold of the data object for the first part of the body
DataObject part1Node = bodyNode.getDataObject("part1");

// Query the tickerSymbol
String ticker = part1Node.getString("tickerSymbol");

// Shorthand for the above, using a SDO path expression that
// starts from the info node.
ticker = infoNode.getString("body/part1/tickerSymbol");
```

JMS formats:

To write code that can access the different JMS message types, you need to know how each message type is mapped to SDO, and how to retrieve the message format string from the message.

Format types

Each JMS message type is defined by a message format string within the message. You can retrieve the format string by using the code snippet in the following example . The table shows the mapping of message format strings to Service Data Objects (SDO):

JMS Message type	Message format string	Mapping to SDO¹
JMS Bytes message	JMS:bytes	See "JMS Formats - bytes"
JMS Text message	JMS:text	See "JMS Formats - text"
JMS Stream message	JMS:stream	See "JMS formats - Stream" on page 829
JMS Object message	JMS:object	See "JMS Formats - object" on page 829
JMS Map message	JMS:map	The retrieval or construction of SDO data graphs for JMS map messages is not supported.

¹ The version of SDO supported by mediations is Version 1.

This code snippet is an example of how to retrieve the message format string from the message:

```
String format = siMsg.getFormat();
if (format.equals ....
```

JMS Formats - bytes:

Your program can retrieve the payload of a JMS bytes message by mapping the body of the message to an SDO data graph representing the message.

Bytes body

You can retrieve the payload of a JMS bytes message as a Java byte array (`byte[]`). First, you must retrieve a data graph representing the message from the `SIMessage` instance. As is common to all data graphs representing JMS messages, the root data object of the graph contains a property named "data", and that data object in turn contains a property named "value". In JMS bytes messages, the value property might be accessed as a Java byte array.

You can access the data within the data graph with code such as this:

```
SIMessage siMsg;
String format = siMsg.getFormat();
if (format.equals("JMS:bytes")) {
    DataGraph graph = siMsg.getDataGraph();
    byte[] payload = graph.getRootObject().getBytes("data/value");
}
```

JMS Formats - text:

Your program can retrieve the payload of a JMS text message by mapping the body of the message to an SDO data graph representing the message.

Text body

You can retrieve the payload of a JMS text message as a Java string value (`java.lang.String`). First, you must retrieve a data graph representing the message from the `SIMessage` instance. As is common to all data graphs representing JMS messages, the root data object of the graph contains a property named "data", and that data object in turn contains a property named "value". In JMS text messages the value property may be accessed as a Java string value.

You can access the data within the data graph with code such as this:

```

SIMessage siMsg;
String format = siMsg.getFormat();
if (format.equals("JMS:text")) {
    DataGraph graph = siMsg.getDataGraph();
    String payload = graph.getRootObject().getString("data/value");
}

```

JMS formats - Stream:

Your program can retrieve the payload of a JMS stream message by mapping the body of the message to an SDO data graph representing the message.

Stream body

You can retrieve the payload of a JMS Stream message as a Java list value (`java.util.List`). First, you must retrieve a data graph representing the message from the `SIMessage` instance. As is common to all data graphs representing JMS messages, the root data object of the graph contains a property named "data", and that data object in turn contains a property named "value". For a JMS Stream message the value property might be accessed as a List value. The member functions of the List interface can be used to access the individual objects within the JMS Stream message instance. (Note that the JMS standard places constraints on the kinds of objects that might be placed in a Stream message.)

You can access the data within the data graph with code such as this:

```

}SIMessage siMsg;
String format = siMessage.getFormat();
if (format.equals("JMS:stream")) {
    DataGraph graph = siMsg.getDataGraph();
    List payload = graph.getRootObject().getList("data/value");
    int streamLength = payload.size();
    if (streamLength > 0) {
        Object item1 = payload.get(0);
        // You can also access items directly, for example: (for the_same_value)
        item1 = graph.getRootObject().get("data/value[1]");
    }
}

```

JMS Formats - object:

Your program can retrieve the payload of a JMS object message by mapping the body of the message to an SDO data graph representing the message.

Object body

You can retrieve the payload of a JMS object message as a Java byte array (`byte[]`). First, you must retrieve a data graph representing the message from the `SIMessage` instance. As is common to all data graphs representing JMS messages, the root data object of the graph contains a property named "data", and that data object in turn contains a property named "value". For a JMS object message the value property might be accessed as a Java byte array. The original Object instance that the payload represents might be reconstructed from the byte array.

You can access the data within the data graph with code such as this:

```

SIMessage siMsg;
String format = siMsg.getFormat();
if (format.equals("JMS:object")) {
    DataGraph graph = siMsg.getDataGraph();
    byte[] payload = graph.getRootObject().getBytes("data/value");
    if(payload != null) {
        // Need to deserialize to recover original object
    }
}

```

```

    ObjectInputStream in =
        new ObjectInputStream(new ByteArrayInputStream(payload));
    Object obj = in.readObject();
}
}

```

Writing a routing mediation

Use this topic to create a mediation that chooses a particular forward route for a message.

Before you begin

For an introduction to using mediations with the service integration bus, see [Learning about mediations](#). For details of how to install a mediation into WebSphere Application Server and associate it with a bus destination, see [Working with mediations](#).

This topic assumes that you are familiar with using a Java Platform, Enterprise Edition (Java EE) session bean development environment such as the assembly tools or IBM Rational Application Developer.

About this task

A routing mediation is a mediation application that contains a routing handler. You associate a routing mediation with a service integration bus destination, and use the mediation to choose a particular route from a range of available routes. For example when you create a new outbound service configuration or modify an existing outbound service configuration you can apply a port selection mediation to choose a particular outbound port from the range of ports that are available to the outbound service.

To create a routing mediation, use a Java Platform, Enterprise Edition (Java EE) session bean development environment to complete the following steps:

Procedure

1. Create an empty mediation handler project. This creates the project, and creates the handler class that implements the handler interface. For detailed instructions on how to do this, see [Writing the mediation handler](#).
2. Use the mediation pane on the EJB descriptor to define the handler class as a mediation handler.

Note: When you do this, you specify a name by which the mediation handler list is known. Make a note of this name, for later reference when you create the mediation in the bus.

3. Add the routing function to the handler. Before you begin, review [Adding mediation function to handler code](#), in particular its subtopic [Working with message context](#). Add import statements to your handler class, and modify the handle method by adding your routing code. Specify the routing destination by adding that destination to the front of the forward routing path list. The forward routing path list is available from the message context. For example:

```

import javax.xml.rpc.handler.MessageContext;
import com.ibm.websphere.sib.mediation.handler.MediationHandler;
import com.ibm.websphere.sib.mediation.handler.MessageContextException;
import com.ibm.websphere.sib.mediation.messagecontext.SIMessageContext;
import com.ibm.websphere.sib.SIMessage;
import com.ibm.websphere.sib.SIDestinationAddress;
import com.ibm.websphere.sib.SIDestinationAddressFactory;
import java.util.List;
public class RouteMediationHandler implements MediationHandler {

    public boolean handle(MessageContext ctx) throws MessageContextException {
        SIMessageContext siCtx = (SIMessageContext) ctx;
        SIMessage msg = siCtx.getSIMessage();
        List frp = msg.getForwardRoutingPath();
        try {

```

```

SIDestinationAddress destination =
    SIDestinationAddressFactory
        .getInstance()
        .createSIDestinationAddress(
            "RoutingDestination", //this is the name of the target destination
            false);
    frp.add(0, destination);
} catch (Exception e) {
    return false;
}
msg.setForwardRoutingPath(frp);
return true;
}
}

```

For more information about the service integration technologies classes, including the mediation handler and message context classes, see the Generated API documentation - Application programming interfaces .

4. Export the routing mediation enterprise application.

What to do next

You are now ready to install your mediation into WebSphere Application Server and associate it with a bus destination, as described in *Working with mediations*.

Writing a mediation that maps between attachment encoding styles

Use this topic to create a mediation that maps from SOAP Messages with Attachments encoding style to WS-I Attachments Profile Version 1.0 encoding style.

Before you begin

For an introduction to using mediations with the service integration bus, see *Learning about mediations*. For details of how to install a mediation into WebSphere Application Server and associate it with a bus destination, see *Working with mediations*.

This topic assumes that you are familiar with using a Java Platform, Enterprise Edition (Java EE) session bean development environment such as the assembly tools or IBM Rational Application Developer.

The example mediation given in this topic is based upon the WSDL examples that are given in *Supporting bound attachments: WSDL examples*

About this task

You can use a mediation to map from a SOAP Messages with Attachments encoding of a message to WS-I Attachments Profile Version 1.0 encoding. The WSDL definition is the same in both cases, so if you create a mediation that rewrites the Content ID values to match the Version 1.0 conventions then the message is encoded by service integration technologies according to Version 1.0 rules.

To create a mapping mediation, use a Java Platform, Enterprise Edition (Java EE) session bean development environment to complete the following steps:

Procedure

1. Create an empty mediation handler project. This creates the project, and creates the handler class that implements the handler interface. For detailed instructions on how to do this, see *Writing the mediation handler*.
2. Use the mediation pane on the EJB descriptor to define the handler class as a mediation handler.

Note: When you do this, you specify a name by which the mediation handler list is known. Make a note of this name, for later reference when you create the mediation in the bus.

3. Add the mapping function to the handler. Before you begin, review Adding mediation function to handler code. Here is an example of mediation handler code that rewrites the Content ID values to match the Version 1.0 conventions:

```
int uuidBase = 0;
DataObject root = SIMessage.getDataGraph().getRootObject();
List attachments = root.getList("info/attachments");
Iterator entries = attachments.iterator();
while(entries.hasNext()) {
    DataObject entry = (DataObject) entries.next();
    if(entry.getType().equals("BoundMIMEAttachmentEntryType")) {
        String newContentId = entry.getString("messagePart") + "=" +
            Integer.toString(uuidBase++) +
            "@some.domain";
    }
}
```

Note: For messages that use a SOAP with attachments reference (swaref) or some other URI mechanism to refer to the attachments, the URI values might also have to be updated to match the new Content ID values. However such mechanisms are usually used to refer to unbound attachments.

For more information about the service integration technologies classes, including the mediation handler classes, see the Generated API documentation - Application programming interfaces .

4. Export the mapping mediation enterprise application.

What to do next

You are now ready to install your mediation into WebSphere Application Server and associate it with a bus destination, as described in Working with mediations.

Using durable subscriptions

You use *durable subscriptions* for publish/subscribe messaging. A durable subscription can be used to preserve messages published on a topic while the subscriber is not active.

About this task

If there is no active subscriber for a durable subscription, JMS retains the subscription messages until they are received by the subscriber, or until they expire, or until the durable subscription is deleted. This enables subscriber applications to operate disconnected from the JMS provider for periods of time, and then reconnect to the provider and process messages that were published during their absence.

Each JMS durable subscription is identified by a subscription name (*subName*), which is defined when the durable subscription is created. A JMS connection also has an associated client identifier (*clientID*), which is used to associate a connection and its objects with the list of messages (on the durable subscription) that is maintained by the JMS provider for the client. The *subName* assigned to a durable subscription must be unique within a given client ID.

If an application needs to receive messages published on a topic while the subscriber is inactive, it uses a *durable subscriber*.

In normal operation there can be at most one active (connected) subscriber for a durable subscription at a time. However, when running inside an application server it is possible to clone the application server for failover and load-balancing purposes. In this case, a cloned durable subscription can have multiple simultaneous consumers.

For information about durable subscriptions, see the JMS 1.1 Specification (for example, section 9.3.3 “Using Durable Subscriptions”).

The following operations for durable subscriptions are in addition to the usual JMS operations, such as to first look up a connection factory and a JMS destination, and to create a connection and session.

The following are the main operations for using durable subscriptions:

- Creating a new durable subscription
- Reconnecting to an existing durable subscription
- Unsubscribing (deleting) a durable subscription

Procedure

- Define the Durable Subscription Home This property must be set on the JMS connection factory if durable subscriptions are to be created using connections created from this connection factory. The value is the name of the messaging engine where all durable subscriptions accessed through this connection are managed.

You can also set the Durable Subscription Home on the JMS topic destination, which enables a single connection to access durable subscriptions on more than one messaging engine.

To be able to create durable subscriptions, the property on the connection factory must not be null (the default). Setting a value of null or empty string on the property of a destination indicates that the value specified on the connection factory should be inherited.

- Creating a new durable subscription A durable TopicSubscriber can be created by a Session or by a TopicSession.

Having performed the normal setup, an application can create a durable subscriber to a destination. To do this, the client program creates a durable TopicSubscriber, by using `session.createDurableSubscriber`. The name *subName* is used as an identifier of the durable subscription.

```
session.createDurableSubscriber( Topic topic,
                               java.lang.String subName,
                               java.lang.String messageSelector,
                               boolean noLocal);
```

Alternatively, you can use the two-argument form of this operation, which takes only a topic and name (*subName*) as parameters. This alternative form invokes the four-argument operation with null as the messageSelector and false as the noLocal parameters.

```
session.createDurableSubscriber( Topic topic, java.lang.String subName);
```

A JMS durable subscription is created with a unique identifier of the form `clientId+###+subName`. The characters `##` should not be used in the clientId or subName if the JMS connection is to use a durable subscription.

Handling exceptions. The following JMS exceptions can be thrown for the reasons listed in the exception messages:

- InvalidDestination - The name of this durable subscription (`clientId+###+subName`) clashes with an existing destination.
- IllegalState - The method was invoked on a closed connection.
- IllegalState - This destination is not accepting consumers. This probably means that there is already an active subscriber for this durable subscription.
- InvalidDestination - The mediation named in the parameters cannot be found.
- InvalidDestination - The destination cannot be found.
- JMSecurity - The user does not have authorization to perform this operation.
- JMSException - Errors occurred in the MsgStore, Comms or Core layers.

- Reconnecting to an existing durable subscription To reconnect to a topic that has an existing durable subscription, the subscriber application calls `session.CreateDurableSubscriber` again, using the same parameters that it used to originally create the durable subscription. However, consider the following important restrictions:

- The subscriber must be attached to the same connection.
- The destination and subscription name must be the same as in the original method call.
- If a message selector was specified, it must be the same as in the original method call.

By calling `createDurableSubscriber` again, the subscriber application reconnects to the topic, and receives any messages that arrived while the subscriber was disconnected.

- Unsubscribing (deleting) a durable subscription To unsubscribe (delete) a durable subscription to a topic, the subscriber application calls `session.unsubscribe(java.lang.String name)`.

Do not call the `unsubscribe` method to delete a durable subscription if there is a `TopicConsumer` currently consuming messages from the topic.

Sending web service messages directly over the bus from a JAX-RPC client

Use this task to send web service messages over a bus by retargeting the JAX-RPC client.

About this task

Java API for XML-based remote procedure calls (JAX-RPC) client applications send and receive web service request and response messages. JAX-RPC client applications that use the IBM JAX-RPC run-time environment can do this in a number of different ways, depending on the bindings in the WSDL document that they are developed against, and the configuration data that is used at run time.

For an introduction to basic JAX-RPC programming concepts, including the JAX-RPC client and server programming models, see *Getting Started with JAX-RPC*.

If you want to use a JAX-RPC client to send messages over the service integration bus, you have two choices:

- Use a SOAP binding (SOAP over HTTP or SOAP over JMS), and pass messages indirectly through an endpoint listener to an inbound service. You would do this if you had SOAP-specific JAX-RPC handlers that must run in the client application context.
- Pass messages directly into the service integration bus at a destination by “retargeting” the JAX-RPC client application as described in this topic.

Note: There are currently limitations regarding the Java types used by services that are retargeted through a JAX-RPC client application.

Retargeting involves setting the following two values into the client application deployment descriptor, or specifying them dynamically at run time from within the client application:

- The *binding namespace* is set to indicate that the client uses the messaging bus directly.
- The *endpoint address* is set to include the particular destination and (optionally) the format of messages that the client uses.

The destination also needs to be configured so that it knows the port type of messages that the JAX-RPC client is using. There are two ways to achieve this:

- Create an outbound service. An outbound service represents an externally-provided web service. In this case, requests from the JAX-RPC client pass through the service destination and are then sent on to the service provider defined by the outbound service configuration.

- Create an inbound service. An inbound service represents a service provided somewhere within or beyond the messaging bus. You can create an inbound service on any existing destination. The creation of an inbound service associates a WSDL port type with the destination. When retargeting to a destination with an inbound service, the client application needs to specify both the destination name and inbound service name, because it is possible to configure more than one inbound service against a single destination. In this case, requests from the JAX-RPC client pass through the destination and then onwards through the service integration bus depending on routing that is done at the initial destination.

To have web service messages sent directly to a destination using a JAX-RPC client, complete the following steps:

Procedure

1. Create the JAX-RPC client application.
2. Create the outbound service or inbound service with which you want the JAX-RPC client application to exchange messages.
3. Use the administrative console to access the port information for your JAX-RPC client application, as described in “Configuring web services client bindings” on page 1946 and Web services client port information.
4. Override the default SOAP binding for your JAX-RPC client application. Change the binding namespace to `http://www.ibm.com/ns/2004/02/wsdl/mp/sib`
5. Override the endpoint that your JAX-RPC client application uses to send web service requests. The new endpoint should use the sib: URL syntax and include either the outbound service destination name, or both the inbound service name and its corresponding destination name.

What to do next

After you change the *binding namespace*, any JAX-RPC handler lists that were configured for the retargeted port are ignored. For clients that are developed against WSDL with a SOAP binding, retargeting directly to the bus causes the handlers to be ignored. However if the client is developed against the non-bound WSDL for the service, retargeting to the bus is not considered to be changing the binding namespace, and so the handler information is retained. In this case the JAX-RPC handlers are called with the `SDOMessageContext` subclass.

Associated reference information:

- “sib: URL syntax”

sib: URL syntax

The sib: URL has the following syntax:

```
sib:[destination|path]?property_1=value_1&property_2=value_2&...
```

where:

- Square brackets (“[]”) indicate that a parameter is optional.
- Transport type is `sib:`, followed by either `/destination` to specify destination type or `/path` to specify a forward routing path, followed by a “query string” that contains one or more properties. The permitted properties are described in the subsequent sections of this topic.

Required properties

The following properties are required. They are used to specify the destination for the request.

Note: All destination names must be fully-qualified. That is, they must include the name of the service integration bus as well as the destination name itself. Use the syntax `bus:destination`. If a bus or

destination name contains a colon or comma, wrap the name in double quotation marks (""). If it contains a double quotation mark, repeat the quotation mark.

destinationName

The destination name.

path The forward routing path, in the form of a sequence of destination names separated by commas.

replyDestinationName

The name of the destination to be used for the reply.

inboundService

The name of the inbound service that identifies the specific attachment that the requester application uses. You can omit this value if the destination is a service destination with an associated outbound service configuration, because in that case the requester is attaching to the outbound service through the service destination.

timeout

The time the requester waits for a response. The default value is 60 seconds. A zero value indicates an unlimited wait.

Service integration technologies-related properties

The following properties are optional. If you do not specify a value for a property, then the default value is used. For more information regarding the permitted values for these properties, see the generated API information for the SIMessage interface.

reliability

The reliability of the request message.

timeToLive

The amount of time (in milliseconds) before the request times out. A zero value indicates that the request never times out.

Note: The **timeout** property (see the required properties) is the time delay after which the requester application blocks the application thread that is waiting for a response to a request and response operation. The **time to live** and **replyTimeToLive** optional properties indicate how long the request and reply messages should be processed by the messaging engines. This does not include the processing time at the service implementation. You would therefore usually set the timeout to be the sum of the request and response times to live, plus some amount for the service processing time.

priority

The priority of the request message.

user

The user ID required to access the request destination.

password

The password required to access the request destination.

replyReliability

The reliability of the reply message.

replyTimeToLive

The amount of time (in milliseconds) before the reply times out. A zero value indicates that the reply never times out.

replyPriority

The priority of the reply message.

Other properties

You can also include user-defined properties in the URL. These properties must be named with a user. prefix. For example:

```
sib:/destination?destinationName=myBus:myDestination & reliability=assured & user.customData=XYZ
```

After the request is sent, the URL itself is available within the message properties, named `inbound.url`.

Chapter 23. Developing Session Initiation Protocol (SIP) applications

This page provides a starting point for finding information about SIP applications, which are Java programs that use at least one Session Initiation Protocol (SIP) servlet written to the JSR 116 specification.

SIP is used to establish, modify, and terminate multimedia IP sessions including IP telephony, presence, and instant messaging.

Developing SIP applications

A SIP application is a set of SIP servlets packaged in a SIP application archive file (SAR).

About this task

A SIP servlet is an application component managed by the SIP container that performs SIP signaling. The programming and deployment models are analogous to web servlets and therefore will be mapped to the WebSphere administrative model accordingly. It is possible to include web servlets in a SAR file (along with the required web.xml deployment descriptor) to create what is known as a converged application. See JSR 116 for details on SIP applications, servlets, converged applications, and status codes.

Developing SIP applications that support PRACK

A SIP response to an INVITE request can be final or provisional. Final responses are always sent reliably, but provisional responses typically are not. For cases where you need to send a provisional response reliably, you can use the PRACK (Provisional response acknowledgement) method.

Before you begin

For you to be able to develop applications that support PRACK, the following criteria must be met:

- The client that sends the INVITE request must put a 100rel tag in the Supported or the Require header to indicate that the client supports PRACK.
- The SIP servlet must respond by invoking the sendReliably() method instead of the send() method to send the response.

About this task

PRACK is described in the following standards:

- RFC 3262 (“Reliability of Provisional Responses in the Session Initiation Protocol (SIP)”), which extends RFC 3261 (“SIP: Session Initiation Protocol”), adding PRACK and the option tag 100rel.
- Section 6.7.1 (“Reliable Provisional Responses”) of JSR 116 (“SIP Servlet API Version 1.0”).

Procedure

- For an application acting as a proxy, do this:
 - Make your application generate and send a reliable provisional response for any INVITE request that has no tag in the To field.
- For an application acting as a user agent client (UAC), do this:
 - Make your application add the 100rel tag to outgoing INVITE requests. The option tag must appear in either the Supported header or the Require header.
 - Within your application's doProvisionalResponse(...) method, prepare the application to create and send PRACK requests for incoming reliable provisional responses. The application must create the PRACK request on the response's dialog through a SipSession.createRequest(...) method, and it must set the RACK header according to RFC 3262 Section 7.2 (“RACK”).

- The application that acts as an UAC will not receive doPrack() methods. The UAC sends INVITE and receives Reliable responses. When the UAC receives the Reliable response, it sends PRACK a request to the UAS and receives a 200 OK on the PRACK so it should next implement doResponse() in order to receive it.
- For an application acting as a user agent server (UAS), do this:
 - If an incoming INVITE request requires the 100rel tag, trying to send a 101-199 response unreliably by using the send() method causes an Exception.
 - Make the application declare a SipErrorListener to receive noPrackReceived() events when a reliable provisional response is not acknowledged within $64 * T1$ seconds, where T1 is a SIP timer. Within the noPrackReceived() event processing, the application should generate and send a 5xx error response for the associated INVITE request per JSR 116 Section 6.7.1.
 - Make the application have at most one outstanding, unacknowledged reliable provisional response. Trying to send another one before the first's acknowledgement results in an Exception.
 - Make sure that the application enforces the RFC 3262 offer/answer semantics surrounding PRACK requests containing session descriptions. Specifically, a servlet must not send a 2xx final response if any unacknowledged provisional responses contained a session description.

Setting up SIP application composition

The JSR 116 standard for SIP applications states in section 2.4 that multiple applications may be invoked for the same SIP request. The process of setting up applications to comply with this standard is called application composition.

About this task

Application composition requires that implementations use a cascaded services model. The cascaded services model requires that service applications triggered on the same host are triggered in sequence, as if the triggering occurred on different hosts. Therefore responses flow upstream and hit applications in the reverse order of the corresponding requests.

The JSR 116 standard does not specify how to implement application composition, thus there are many ways to comply with this standard. For WebSphere Application Server, composition of the application depends on the deployed application order, and on the order of mapping rules within the deployment descriptor of each application.

- For an initial incoming request, the SIP container tries each potential rule in order. When the container finds the n^{th} match, the container invokes the corresponding servlet.
- If the servlet must proxy the request, the container scans the rules again to search for additional matches. When the container finds the $(n+1)^{th}$ match, the container invokes the corresponding servlet.
- Any servlet in the same application as the previously invoked servlet is excluded from the matching process. No servlet can be invoked twice for the same SIP request.

You can specify load on start-up priority. The `<load-on-startup>` in the `sip.xml` defines the order in which servlets are initialized on startup. If this value is lower than zero, the servlets are initialized when the first request is matched to them according to matching rule and composition order. Zero is a legitimate weight for startup initialization order. If this tag does not exist or if it contains a negative value, the servlet does not initialize at startup.

You should also add `<load-on-startup>` to the same tag in the `web.xml` if you are changing it manually. It is the `WebContainer` that loads servlets (and siplets), and it looks only at the `web.xml`. When deploying a SAR, only the `sip.xml` needs to be changed. The `web.xml` is automatically constructed correctly after deployment.

The load-on-startup tag embedded in the SIP deployment descriptor tag for a servlet dictates the order that the application is loaded on start up of the server. It does not dictate the order that an application gets called when the application is a member of an application composition chain that matches rules to process a new message coming in.

The starting weight for applications and their modules is specified in the deployment.xml file. The order in which modules pickup requests on composition is evaluated by applications weight first and then modules weight. The following steps can be completed in any order to specify applications weight or modules weight from the administrative console.

Procedure

1. To specify the applications (EARs) weight, expand **Enterprise Applications** > *applicationName* > **Startup Behavior** and set the startup order.
2. To specify the modules (WARs) weight, expand **Enterprise Applications** > *applicationName* > **Manage Modules** and set the starting weight.
3. Restart the changed applications.

Example

Specifying load-on-startup priority example:

sip.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE sip-app
PUBLIC "-//Java Community Process//DTD SIP Application 1.0//EN"
"http://www.jcp.org/dtd/sip-app_1_0.dtd">
<sip-app>
  <display-name>SIPSampleProxy</display-name>

  <servlet>
    <servlet-name>SIPSampleProxy</servlet-name>
    <servlet-class>sipes.test.container.proxy.SIPSampleProxy</servlet-class>
    <load-on-startup>1</load-on-startup>
  </servlet>

  <servlet-mapping>
    <servlet-name>SIPSampleProxy</servlet-name>
    <pattern>
      <equal>
        <var>request.uri.user</var>
        <value>SIPSampleProxy</value>
      </equal>
    </pattern>
  </servlet-mapping>

  <proxy-config>
    <sequential-search-timeout>1000</sequential-search-timeout>
  </proxy-config>
  <session-config>
    <session-timeout>12</session-timeout>
  </session-config>
</sip-app>
```

web.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE web-app PUBLIC "-//Sun Microsystems, Inc.//DTD Web Application 2.3//EN" "http://java.sun.com/dtd/web-app_2_3.dtd">
<web-app id="WebApp">
  <display-name>SIPSampleProxy</display-name>
  <servlet>
    <servlet-name>SIPSampleProxy</servlet-name>
    <display-name>SIPSampleProxy</display-name>
    <servlet-class>sipes.test.container.proxy.SIPSampleProxy</servlet-class>
  </servlet>
  <servlet-mapping>
    <servlet-name>SIPSampleProxy</servlet-name>
    <url-pattern>/SIPSampleProxy</url-pattern>
  </servlet-mapping>
  <welcome-file-list>
    <welcome-file>index.html</welcome-file>
    <welcome-file>index.htm</welcome-file>
    <welcome-file>index.jsp</welcome-file>
    <welcome-file>default.html</welcome-file>
  </welcome-file-list>
```

```

<welcome-file>default.htm</welcome-file>
<welcome-file>default.jsp</welcome-file>
</welcome-file-list>
</web-app>

```

Specifying starting weight example:

The following example is for a stand-alone server.

deployment.xml

```

<?xml version="1.0" encoding="UTF-8" ?>
- <appdeployment:Deployment xmi:version="2.0" xmlns:xmi="http://www.omg.org/XMI"
  xmlns:appdeployment="http://www.ibm.com/websphere/appserver/schemas/5.0/appdeployment.xmi"
  xmi:id="Deployment_1137951186883">
- <deployedObject xmi:type="appdeployment:ApplicationDeployment" xmi:id="ApplicationDeployment_1137951186883"
  deploymentId="0" startingWeight="1" binariesURL="$(APP_INSTALL_ROOT)/OrangeNode08Cell/SipContainerTestSuite.ear"
  useMetadataFromBinaries="false" enableDistribution="true" createMBeansForResources="true" reloadEnabled="false"
  appContextIDForSecurity="href:OrangeNode08Cell/SipContainerTestSuite"
  filePermission=".*\.dll=755#.*\.so=755#.*\.a=755#.*\.sl=755" allowDispatchRemoteInclude="false"
  allowServiceRemoteInclude="false">
  <targetMappings xmi:id="DeploymentTargetMapping_1137951186883" enable="true" target="ServerTarget_1137951186883" />
  <classloader xmi:id="ClassLoader_1137951186883" mode="PARENT_FIRST" />
- <modules xmi:type="appdeployment:WebModuleDeployment" xmi:id="WebModuleDeployment_1137951186883"
  deploymentId="1" startingWeight="10000" uri="sipunit.war">
  <targetMappings xmi:id="DeploymentTargetMapping_1137951186884" target="ServerTarget_1137951186883" />
  <classloader xmi:id="ClassLoader_1137951186884" /> </modules>
  <properties xmi:id="Property_1137951186883" name="validateinstall" value="warn" /> </deployedObject>
  <deploymentTargets xmi:type="appdeployment:ServerTarget" xmi:id="ServerTarget_1137951186883"
  name="server1" nodeName="OrangeNode10" /> </appdeployment:Deployment>

```

SIP servlets

This topic describes SIP servlets.

The SIP Servlet 1.0 specification (JSR 116) is standardized through Java Specification Request (JSR) 116. The idea behind the specification is to provide a Java application programming interface (API) similar to HTTP servlets, which provides an easy-to-use SIP programming model. Like the popular HTTP servlet programming model, some flexibility is limited to optimize ease-of-use and time-to-value.

However, the SIP Servlet API is different in many ways from HTTP servlets because the protocol is so different. While SIP is a request-response protocol, there is not necessarily only one response to every one request. This complexity and a need for a high performing solution meant that it was easier to make the SIP servlets natively asynchronous. Also, unlike HTTP servlets, the programming model for SIP servlets sought to make client requests easy to create alongside the other logic being written because many applications act as a client or proxy to other servers or proxies.

SipServlet requests

Like HTTP servlets, each SIP servlet extends a base `javax.servlet.sip.SipServlet` class. All messages come in through the service method, which you can extend. However, because there is not a one-to-one mapping of requests to responses in SIP, the suggested practice is to extend the `doRequest` or `doResponse` methods instead. When extending the `doRequest` or `doResponse` methods, it is important to call the extended method for the processing to complete.

Each request method, which the specification must support, has a `doxxx` method just like HTTP. In HTTP, methods such as `doGet` and `doPost` exist for GET and POST requests. In SIP, `doInvite`, `doAck`, `doOptions`, `doBye`, `doCancel`, `doRegister`, `doSubscribe`, `doNotify`, `doMessage`, `doInfo`, and `doPrack` methods exist for each SIP request method.

Unlike an HTTP servlet, SIP servlets have methods for each of the response types that are supported. So, SIP servlets include the `doProvisionalResponse`, `doSuccessResponse`, `doRedirectResponse`, and `doErrorResponse` responses. Specifically, the provisional responses (1xx responses) are used to indicate status, the success responses (2xx responses) are used to indicate a successful completion of the transaction, the redirect responses (3xx responses) are used to redirect the client to a moved resource or entity, and the error responses (4xx, 5xx, and 6xx responses) are used to indicate a failure or a specific

error condition. These types of response messages are similar to HTTP, but because the SIP Servlet programming model includes a client programming model, it is necessary to have responses handled programmatically as well.

Clarifications of JSR 116

JSR 289 has made some clarifications to JSR 116, as follows:

- JSR 289 Section 4.1.3: Contact Header Field
- JSR 289 Section 5.2: Implicit Transaction State
- JSR 289 Section 5.8: Accessibility of SIP Servlet Messages

SIP SipServletRequest and SipServletResponse classes

The SipServletRequest and SipServletResponse classes are similar to the HttpServletRequest and HttpServletResponse classes.

SipServletRequest and SipServletResponse classes

Each class gives you the capability to access the headers in the SIP message and manipulate them. Because of the asynchronous nature of the requests and responses, this class is also the place to create new responses for the requests. When you extend the doInvite method, only the SipServletRequest class is passed to the method. To send a response to the client, you must call the createResponse method on the Request object to create a response. For example:

```
protected void doInvite(SipServletRequest req) throws
    javax.servlet.ServletException, java.io.IOException {

    //send back a provisional Trying response
    SipServletResponse resp = req.createResponse(100);
    resp.send();
}
```

Because of their asynchronous nature, SIP servlets can seem complicated. However, something as simple as the previous code sample sends a response to a client.

Here is a more complex example of a SIP servlet. With the following method included in a SIP servlet, the servlet blocks all of the calls that do not come from the example.com domain.

```
protected void doInvite(SipServletRequest req) throws
    javax.servlet.ServletException, java.io.IOException {

    //check to make sure that the URI is a SIP URI
    if (req.getFrom().getURI().isSipURI()){
        SipURI uri = (SipURI)req.getFrom().getURI();
        if (!uri.getHost().equals("example.com")) {
            //send forbidden response for calls outside domain
            req.createResponse(SipServletResponse.SC_FORBIDDEN).send();
            return;
        }
    }
    //proxy all other requests on to their original destination
    req.getProxy().proxyTo(req.getRequestURI());
}
```

SIP SipSession and SipApplicationSession classes

Possibly the most complex portions of the SIP Servlet 1.0 specification are the SipSession and SipApplicationSession classes.

SIP SipSession and SipApplicationSession classes

Both of these classes have some useful purposes and can act as the primary place to store data in applications that are designed for distributed or highly available environments.

The SipSession class is the best representative of a specific point-to-point communication between two entities and is the closest to the HttpSession object. Because historically no proxying or forking existed for the HTTP request in HTTP servlets, the need for something higher than a single point-to-point session did not exist. However, even HTTP users can see the growing need for this type of function since portlets began essentially forking HTTP requests. The SIP users expect the proxying and forking activities that require multiple layers of SIP session management. The SipSession class is the lowest point-to-point layer.

The SipApplicationSession class represents the higher layer of SIP session management. One SipApplicationSession class can own one or more SipSession objects. However, each SipSession class can be related to one SipSession object only. The SipApplicationSession class also supports the attachment of any number of other protocol sessions. Currently, only HTTP sessions are supported by any implementations. The SipApplicationSession class has a getSessions method, which takes the requested protocol type as an argument.

You might find it useful for many applications to combine HTTP and SIP. For example, you might use this approach to tie together HTTP and SIP sessions to monitor a phone call or to start a phone call through a rich HTTP graphical user interface.

Example: SIP servlet simple proxy

This is a servlet example of a simple proxy.

Simple proxy

```
import java.io.IOException;

import javax.servlet.Servlet;
import javax.servlet.ServletException;
import javax.servlet.sip.Proxy;
import javax.servlet.sip.SipFactory;
import javax.servlet.sip.SipServlet;
import javax.servlet.sip.SipServletRequest;
import javax.servlet.sip.SipServletResponse;
import javax.servlet.sip.SipSession;
import javax.servlet.sip.SipURI;
import javax.servlet.sip.URI;

public class SimpleProxy extends SipServlet implements Servlet {

    final static private String SHUTDOWN_KEY = new String("shutdown");
    final static private String STATE_KEY = new String("state");
    final static private int INVITE_RECEIVED = 1;

    /* (non-Java-doc)
     * @see javax.servlet.sip.SipServlet#SipServlet()
     */
    public SimpleProxy() {
        super();
    }

    /* (non-Javadoc)
     * @see javax.servlet.sip.SipServlet#doInvite(javax.servlet.sip.SipServletRequest)
     */
    protected void doInvite(SipServletRequest request) throws ServletException,
        IOException {

        //log("SimpleProxy: doInvite: TOP");

        try {
            if (request.isInitial() == true)
            {
                // This should cause the sip session to be created. This sample only uses the session on receiving
                // a BYE but the Tivoli performance viewer can be used to track the creation of calls by viewing the
```

```

// active session count.
Integer state = new Integer(INVITE_RECEIVED);
SipSession session = request.getSession();
session.setAttribute(STATE_KEY, state);
    log("SimpleProxy: doInvite: setting attribute");

Proxy proxy = request.getProxy();

SipFactory sipFactory = (SipFactory) getServletContext().getAttribute(SIP_FACTORY);
    if (sipFactory == null) {
        throw new ServletException("No SipFactory in context");
    }

String callingNumber = request.getTo().toString();
if (callingNumber != null)
{
    String destStr = format_lookup(callingNumber);
    URI dest = sipFactory.createURI(destStr);

    //log("SimpleProxy: doInvite: Proxying to dest URI =" + dest.toString());

    if (((SipURI)request.getRequestURI()).getTransportParam() != null)
        ((SipURI)dest).setTransportParam(((SipURI)request.getRequestURI()).getTransportParam());

    proxy.setRecordRoute(true);
    proxy.proxyTo(dest);
}
else
{
    //log("SimpleProxy: doInvite: Request is invalid. Did not contain a To: field.");
    SipServletResponse sipresponse = request.createResponse(400);
    sipresponse.send();
}
else
{
    //log("SimpleProxy: doInvite: target refresh, let container handle invite");
    super.doInvite(request);
}
}
catch (Exception e){
    e.printStackTrace();
}
}

/* (non-Javadoc)
 * @see javax.servlet.sip.SipServlet#doResponse(javax.servlet.sip.SipServletResponse)
 */
protected void doResponse(SipServletResponse response) throws ServletException,
    IOException {
    super.doResponse(response);

    // Example of using the session object to store session state.
    SipSession session = response.getSession();
    if (session.getAttribute(SHUTDOWN_KEY) != null)
    {
        //log("SimpleProxy: doResponse: invalidating session");
        session.invalidate();
    }
}

/* (non-Javadoc)
 * @see javax.servlet.sip.SipServlet#doBye(javax.servlet.sip.SipServletRequest)
 */
protected void doBye(SipServletRequest request) throws ServletException,
    IOException {

```

```

SipSession session = request.getSession();
session.setAttribute(SHUTDOWN_KEY, new Boolean(true));

    //log("SimpleProxy: doBye: invalidate session when responses is received.");
super.doBye(request);
}

protected String format_lookup(String toFormat){
int start_index = toFormat.indexOf('<') + 1;
int end_index = toFormat.indexOf('>');

if(start_index == 0){
    //don't worry about it
}
if(end_index == -1){
    end_index = toFormat.length();
}

return toFormat.substring(start_index, end_index);
}
}

```

Example: SIP servlet SendOnServlet class

The SendOnServlet class is a simple SIP servlet that would perform the basic function of being called on each INVITE and sending the request on from there.

SendOnServlet class

Function could easily be inserted to log this invite request or reject the INVITE based on some specific criteria.

```

package com.example;
import java.io.IOException;
import javax.servlet.sip.*;
import java.servlet.ServletException;
public class SendOnServlet extends SipServlet {
    public void doInvite(SipServletRequest req)
        throws ServletException, java.io.IOException {
        //send on the request
        req.getProxy().proxyTo(req.getRequestURI);
    }
}

```

The doInvite method could be altered to do something such as reject the invite for some specific criteria simply. In the following example, all requests from domains outside of example.com will be rejected with a Forbidden response.

```

    public void doInvite(SipServletRequest req)
throws ServletException, java.io.IOException {
if (req.getFrom().getURI().isSipURI()){
    SipURI uri = (SipURI)req.getFrom.getURI();
    if (!uri.getHost().equals("example.com")) {
        //send forbidden response for calls outside domain
req.createResponse(SipServletResponse.SC_FORBIDDEN, "Calls outside example.com not accepted").send();
return;
    }
}
//proxy all other requests on to their original destination
req.getProxy().proxyTo(req.getRequestURI());
}

```

SendOnServlet deployment descriptor:

```

<sip-app>
    <display-name>Send-on Servlet</display-name>
    <servlet>

```

```

    <servlet-name>SendOnServlet</servlet-name>
    <servlet-class>com.example.SendOnServlet</servlet-class>
</servlet>

<servlet-mapping>
  <servlet-name>SendOnServlet</servlet-name>
  <pattern>
    <equal>
      <var>request.method</var>
      <value>INVITE</value>
    </equal>
  </pattern>
</servlet-mapping>
</sip-app>

```

Example: SIP servlet Proxy servlet class

Proxy servlet class

After the initial INVITE, this application will be called on every subsequent SIP message. For each Request and Response, this class will simply print out the action and who it is to or from.

```

package com.example;
import java.io.IOException;
import javax.servlet.sip.*;
import java.servlet.ServletException;
public class ProxyServlet extends SipServlet {
    public void doInvite(SipServletRequest req)
        throws ServletException, java.io.IOException {
        //get the Proxy
        Proxy p=req.getProxy();
        //turn on supervised mode so that all events come through us
        //The default on this is true but it is set to emphasize the function.
        p.setSupervised(true);
        //set record route so we see the ACK, BYE, and OK
        p.setRecordRoute(true);
        //proxy on the request
        p.proxyTo(req.getRequestURI());
    }
    public void doRequest(SipServletRequest req)
        throws ServletException, java.io.IOException {
        System.out.println(req.getMethod()+" Request from "+req.getFrom().getDisplayName());
        super.doRequest(req);
    }
    public void doResponse(SipServletResponse resp)
        throws ServletException, java.io.IOException {
        System.out.println(resp.getReasonPhrase()+" Response from "+resp.getTo().getDisplayName());
        super.doResponse(resp);
    }
}

```

Proxy deployment descriptor

```

<sip-app>
  <display-name>ProxyServlet</display-name>
  <servlet>
    <servlet-name>ProxyServlet</servlet-name>
    <servlet-class>com.example.ProxyServlet</servlet-class>
  </servlet>

  <servlet-mapping>
    <servlet-name>ProxyServlet</servlet-name>
    <pattern>
      <equal>
        <var>request.method</var>
        <value>INVITE</value>
      </equal>
    </pattern>
  </servlet-mapping>
</sip-app>

```

```
        </equal>
    </pattern>
</servlet-mapping>
</sip-app>
```

JSR 289 overview

Version 8.5 includes support for SIP Servlet Specification 1.1, also referred to as Java Specification Request (JSR) 289.

The SIP Servlet Specification provides the Java API standards for Session Initiation Protocol (SIP). JSR 289 is an update to the existing SIP Servlet specification that addresses new requirements determined by industry users.

SIP is a signaling protocol used for creating, modifying, and terminating IP communication sessions such as telephony and presence applications. SIP is not limited to voice communication and can mediate any type of communication session, such as multimedia.

The following is a brief description of new features available in the JSR 289 specification.

- Application router for application selection
Application routing enables developers to build complex services out of smaller applications. On initial requests the container calls the application router to determine which application to invoke based on the type of request. The application router is the central hub for selecting application order. See the topic on configuring a SIP application router for more information.
- Annotation-based programming
Annotations provide a fast way to develop applications by embedding metadata directly in applications. For example, you can use the `@SipServlet` annotation to indicate that a class is a SIP servlet. The `@SipApplication` is a package level annotation. All servlets in the package belong to the same application unless the servlet uses `@SipServlet(applicationName)`. For more information on annotations, see section 18 of the JSR 289.
- Converged applications
JSR 289 provides a new, standardized mechanism for building converged applications. A converged application contains SIP servlet components and other Java EE components, like HTTP servlets and enterprise beans. The specification includes two new classes to support convergence.
 - `ConvergedHttpSession` is an extension to `HttpSession` for converged applications.
 - `SipSessionUtil` handles session management for converged applications.For more information on converged applications, see section 13 of the JSR 289.
- Back-to-back user agent (B2BUA) APIs
JSR 289 simplifies the B2BUA pattern in applications with the use of the B2BUA helper class. The B2BUA is a frequently used application pattern. The B2BUA acts as an endpoint for two or more dialogs and forwards requests and responses between those dialogs. The B2BUA helper has the ability to create a copy of an incoming request. It also automatically maintains links between sessions on both sides of the B2BUA. For more information on B2BUAs, see section 12 of the JSR 289.

Note: Support for the Session Initiation Protocol (SIP) session key-based targeting mechanism that is described in JSR 289 section 15.11.2 is only supported in stand-alone environments. The session key-based targeting mechanism is not supported in clustered environments. Alternatively, you can use one of the other targeting mechanisms that are described in JSR 289 within a clustered environment:

- Encode the URI mechanism that is described in section 15.11.3.
- Join and replace the targeting mechanism that is described in section 15.11.4.

SIP application router:

The SIP application router is used by the SIP container to select the order in which applications are run within the container.

The SIP container can invoke multiple applications in order to deploy a complete service or function. This modular and compositional approach makes it easier for application developers to develop new applications. The modular applications can be more easily combined and managed, while individual application implementations remain independent.

The application router is responsible for selecting the correct applications in the correct order to service an incoming message. An application router is required for a container to function, but it is a separate logical entity from the container. The application router is based on the JSR 289 specification. See the specification for more details about the application router function.

The default application router (DAR) can be configured with a standard configuration file, which is supplied to the container through a SIP container custom property, as defined in JSR 289. The DAR configuration file can also be uploaded in the administrative console for each target of the DAR.

Application routing, also referred to as application composition, can be handled in a number of ways:

- Specify the order in which the applications should run using the administrative console.
- Upload a custom application router implementation class either by specifying the path of the Java archive (JAR) file containing the application router implementation and provider through the console or adding it to the class path. A specific provider can be defined with a SIP container custom property.
- Configure the DAR by uploading its properties file and providing its location through a system property.
- Use an interactive wizard to generate a DAR configuration file.

Restriction: WebSphere Application Server has a default way of sorting the order of SIP applications invocation using the Startup behavior settings. The sorting order is based on the application weight. This weighting policy only applies if you do not specify a DAR property file and no custom application router has been associated with the server or cluster.

Note: If CEA features are used, the CEA system application requires special consideration when enabled on the same server or cluster as a custom application router. To deploy an application router and still maintain the capabilities of the CEA system application, use one of the following two options:

- Only enable CEA on an isolated server or cluster that includes no custom application router.
- Make sure the custom application router routes all CEA specific messages to the CEA system application. To do this, the developer of the application router must check the mappings that are defined in the sip.xml file associated with the CEA system application. The sip.xml file associated with the CEA system application can be found in the directory path at *app_server_root/systemApps*.

The following information explains how to configure a custom application router to route to the commsvc system application. The examples show a custom application router configuration with and without the commsvc application.

First, here is an example configuration without commsvc:

```
INVITE: ("TestB2bua", "DAR:To", "NEUTRAL", "", "NO_ROUTE", "0")
```

The first element after the INVITE is the display name of the test application, and this one-line application router routes b2bua calls to the application successfully. With the preceding application router configured on the SIP container, however, CEA Web collaboration attempts fail.

To enable routing to the CEA system application, just clone the routing element and change the application name in the second element instance:

```
INVITE: ("TestB2bua", "DAR:To", "NEUTRAL", "", "NO_ROUTE", "0"), ("commsvc", "DAR:To", "NEUTRAL", "", "NO_ROUTE", "0")
```

This action ensures that CEA messages are routed correctly.

Tuning considerations using the JSR 289 Application Router with multiple applications:

This topic describes performance adjustments and considerations using the JSR 289 Application Router™ with multiple applications.

Note: This topic references one or more of the application server log files. As a recommended alternative, you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log`, `SystemErr.log`, `trace.log`, and `activity.log` files on distributed and IBM i systems. You can also use HPEL in conjunction with your native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

When you deploy more than one application, you might see the following errors in the log files when heavy SIP protocol traffic exists for a single application server or cluster of servers:

- Unexpected and excessive SIP application 503 Server Unavailable error messages
- Proxy and Server overload errors

Note: These error messages do not occur when you deploy one application. The proxy server and Session Initiation Protocol (SIP) containers are not synchronized when they are tracking the amount of messages that are flowing through the system. Using the application router, multiple messages might be routed between applications. These messages cause container message counters to increment even though the messages do not flow through the proxy server.

You can diagnose this problem when you have the following conditions:

- Heavy SIP protocol traffic exists.
- Multiple applications are deployed on a single node or cluster.

Check the proxy server, the application server `SystemOut.log` log files, or both for an unexpected overload condition that is detected at the proxy server, the application server, or both. Also, look for 503 Server unavailable messages that are logged from the SIP application.

Resolving the problem

Messages are shared between applications at the SIP container before they are sent to the proxy server. To avoid these error messages and a decrease in SIP performance, tune the SIP containers to consider the additional SIP messages that are generated when using the application router with multiple applications. Complete the following steps in the administrative console to tune the SIP containers:

1. Expand **Servers > Server Types** and click **WebSphere application servers > server_name**
2. Under **Container Settings**, expand **SIP Container Settings** and click **SIP container**.
3. Increase the **Maximum messages per averaging period** value to compensate for the anticipated increase in messages that are generated by the SIP application router.
4. Increase the **Maximum application sessions** value to compensate for the increased **Maximum messages per averaging period** value.

The proxy server cannot detect the amount of messages that are generated at the server. However, modifications to the following settings might increase the messaging capacity at the containers for the number of applications that are deployed per container.

Table 79. DAR and CAR SIP container tuning values.

This table lists the DAR and CAR SIP container tuning values for the number of applications that are deployed per container.

SIP Container	Single Deployed SIP Application	Three Deployed SIP Applications
Maximum messages per averaging period	value = 26640	value = 79920
Maximum application sessions	value = 36000	value = 96000

Note: The values for the **Maximum messages per averaging period** and **Maximum application sessions** fields depend on the processing power, memory, and the deployed application. Use the values for these fields as listed in the SIP container settings topic and adjust them to meet the needs of your environment.

Developing applications that use the Asynchronous Invocation API

You can use the Asynchronous Invocation API to transfer events that require processing in the context of a Session Initiation Protocol (SIP) application session to any server in a cluster based on the related application session ID. The Asynchronous Invocation API transfers the event task to the correct server.

Before you begin

Read the API documentation for information on the following asynchronous work classes:

- `com.ibm.websphere.sip.AsynchronousWork`
- `com.ibm.websphere.sip.AsynchronousWorkListener`

For more information about the API classes, see the Reference section in the information center and click APIs - Application Programming Interfaces to view a list of the product API specifications.

About this task

When running code outside of a SIP thread, application developers can use the Asynchronous Invocation API to create an object, and configure the server to run that object either on a different thread in the same container, or on a different server, if that is where the session exists.

The following example shows the class structure for the `AsynchronousWork` class, which is the abstract base class that is extended when using the API.

```
public abstract class AsynchronousWork implements Serializable
{
    private String sessionId;
    public AsynchronousWork(String sessionId)
    {
        this.sessionId = sessionId;
        ....
    }
    public void dispatch (AsynchronousWorkListener listener)
    {
        ....
    }
    public abstract Serializable doAsyncTask();
}
```

Procedure

1. Extend the abstract class `AsynchronousWork` with the SIP related code. The extended implementation of the `doAsyncTask()` method is invoked on the target server that contains the `SipApplicationSession`, and whose ID was set in the constructor that implements the `AsynchronousWork` class. The implementation class must pass the session ID to the base class by calling `super` in the constructor.

```

public class MyClass extends AsynchronousWork
{
String _sessionId;

public MyClass(String sessionId) {
super(sessionId);
_sessionId = sessionId;
}

// This code is invoked on the target machine or thread
public Serializable doAsyncTask() {
// Application code goes here; for instance:
appSession = sessionUtils.getApplicationSession(_sessionId);
appSession.createRequest().....

Serializable myResponse = new MyResponse();
myResponse.setStatus(200);
return (myResponse);
}
}

```

2. To receive information about the task completion, implement the `AsynchronousWorkListener` class, as in the following example. The code in these methods are invoked on the source server.

```

public class MyListener implements AsynchronousWorkListener
{
public void workCompleted(Serializable myResponse)
{
....
}
public void workFailed(int reasonCode, String reason)
{
}
}

```

3. To invoke the asynchronous call; for example, when you receive the proprietary message, use this sample code as an example.

```

public void onMyMessage()
{
// Obtain the session ID from the message or
// somewhere else
String sessionId = obtainIdFromMessage();

// Create the runnable
MyClass myClass = new MyClass(sessionId);

// Create the listener
MyListener myListener = new MyListener();

// Dispatch it
myClass.dispatch(myListener);
}

```

Results

The SIP container ensures the task is invoked in the correct server and on the correct thread, so that the application can avoid synchronization on the session level.

Asynchronous Invocation API

Use the Asynchronous Invocation API to transfer events that require processing in a Session Initiation Protocol (SIP) application session to any server in a cluster based on an application session ID.

The Asynchronous Invocation API, also referred to as the asynchronous work dispatcher, can transfer events that require processing in the context of a SIP application session to any server in a cluster, using

the related application session ID. These transfers are usually triggered by events that cause a state change to SIP sessions that reside on another server. The asynchronous work dispatcher transfers the event task to the correct server to be run.

In Websphere Application Server, all related SIP messages are delivered to the same server in the cluster, and sessions always reside in the same SIP container. To prevent synchronicity issues and locking, tasks in the same application session cannot be processed simultaneously (that is, on different threads or processes), which limits handling of certain types of events.

For more in-depth information about SIP sessions and SIP application sessions and their relationship, see Section 6 of Java Specification Request (JSR) 289.

The following two scenarios are resolved by implementing the Asynchronous Invocation API.

1. Two requests related to the same SIP application session are simultaneously run on two different threads. For example, a Java EE (J2EE) applications working with a message-driven bean (MDB) can retrieve an event to send a SIP message on a certain SIP application session. At the same time, the SIP container receives an incoming SIP message on another session that is connected to the same application session and handles that on a different thread. It would be necessary to synchronize the session access to avoid race conditions and to ensure that all session attributes are synchronized. To employ the locking mechanism in this case would not be effective, because the SIP application session might contain multiple SIP sessions.
2. A server that does not own a certain SIP application session receives a request, through non-SIP protocol, to send a message in the context of that session. For example, a Web service that is initiating SIP dialogs can reside in a server different from the server that owns the SIP application session it must use.

The Asynchronous Invocation API ensures that the specific application code is run on the correct server and correct thread according to the SIP application session ID.

The Asynchronous Invocation API provides the following benefits:

1. No more than two servers are involved in the asynchronous invocation process: one is the server that retrieves the work task, and the other is the target server that handles the SIP application session for that task and to which the task will be transferred.
2. The asynchronous invocation allows working in a thread-safe manner. This approach ensures that only one thread processes the messages related to the SIP application session. Thus, there is no need to synchronize access to the session.
3. The asynchronous invocation provides a scalable solution. There is no performance impact when more servers are added to the cluster.
4. Cross-server invocation is used only when required, which results in better performance.

Chapter 24. Developing Spring applications

This page provides a starting point for finding information about how to develop Spring applications that can run successfully in a WebSphere Application Server environment.

The Spring Framework is an open source project that provides a framework for simple Java objects that enables them to use the Java EE container through wrapper classes and XML configuration.

Configuring access to a Spring application data source

You can use WebSphere Application Server to manage access to a data source for a Spring application.

About this task

For a Spring application to access a data source, such as a Java Database Connectivity (JDBC) data source, the application must use a resource provider that is managed by the WebSphere Application Server. For more information about Spring applications and the Spring Framework see the following topics:

- Spring Framework
- Data access and the Spring Framework

Procedure

1. During development, configure the WAR module with a resource reference. For example:

```
<resource-ref>
  <res-ref-name>jdbc/springdb</res-ref-name>
  <res-type>javax.sql.DataSource</res-type>
  <res-auth>Container</res-auth>
  <res-sharing-scope>Shareable</res-sharing-scope>
</resource-ref>
```

2. For Enterprise JavaBeans (EJB) Java archive (JAR) files, declare the same resource reference in each EJB that needs to access the data source. Use one of the following steps:

- Declare a data source proxy bean. In the Spring application configuration, declare a proxy bean that references a resource provider that the application server manages. Set the value of the `jndiName` property to `java:comp/env/` followed by the value of `res-ref-name` property that you declared in the resource reference. For example:

```
<bean id="wasDataSource" class="org.springframework.jndi.JndiObjectFactoryBean">
  <property name="jndiName" value="java:comp/env/jdbc/springdb"/>
  <property name="lookupOnStartup" value="false"/>
  <property name="cache" value="true"/>
  <property name="proxyInterface" value="javax.sql.DataSource"/>
</bean>
```

- Alternatively, for Spring Framework Version 2.5 or later, use the `<j2ee:jndi-lookup/>` approach. Set the value of the `jndi-name` property to the value of the `res-ref-name` property that you declared in the resource reference, and the value of the `resource-ref` property to `true`. For example:

```
<jee:jndi-lookup id=" wasDataSource "
  jndi-name="jdbc/springdb"
  cache="true"
  resource-ref="true"
  lookup-on-startup="false"
  proxy-interface="javax.sql.DataSource"/>
```

The Spring application can then use the data source proxy bean as appropriate.

3. When the application is deployed to an application server, configure a resource provider and resource data source that the Spring application resource reference can use.

Results

The resource reference that is declared in the deployment descriptor of the module will be bound to the configured data source of the application server during deployment.

Chapter 25. Developing Transactions

This page provides a starting point for finding information about Java Transaction API (JTA) support. Applications running on the server can use transactions to coordinate multiple updates to resources as one unit of work, such that all or none of the updates are made permanent.

The product provides advanced transactional capabilities to help application developers avoid custom coding. It provides support for the many challenges related to integrating existing software assets with a Java EE environment.

More introduction...

Developing components to use transactions

These topics provide information about developing WebSphere application components to use transactions

About this task

The way that applications use transactions depends on the type of application component, as follows:

- A session bean can either use container-managed transactions (where the bean delegates management of transactions to the container) or bean-managed transactions (component-managed transactions where the bean manages transactions itself).
- Entity beans use container-managed transactions.
- Web components (servlets) and application client components use component-managed transactions.

Use the following tasks to develop WebSphere application components that use transactions:

Procedure

- Configure transactional deployment attributes. This task determines whether EJB components use container- or bean-managed transactions by setting an appropriate value on the Transaction type deployment attribute. You can also configure other transactional deployment descriptor attributes.
- Use component-managed transactions. If you want a session bean, web component, or application client component to manage its own transactions, you must write the code that explicitly demarcates the boundaries of a transaction. There are some limitations to the transaction support available to application client components, as described in the topic about client support for transactions.

Configuring transactional deployment attributes

You can configure the transactional deployment descriptor attributes associated with an EJB or web module, to enable an enterprise application to use transactions.

Before you begin

You must have an enterprise archive (EAR) file for an application component that can be deployed in the application server.

About this task

You can configure the deployment attributes of an application by using an assembly tool.

You can use Rational Application Developer, or an equivalent tool, to configure the deployment attributes of an application.

To use Rational Application Developer to set transactional attributes in the deployment descriptor for an application component (enterprise bean or servlet), complete the following steps.

Procedure

1. Start the assembly tool. For more information, refer to the Rational Application Developer information.
2. Create or edit the application EAR file. For example, to change attributes of an existing application, use the Import wizard to import the EAR file into the assembly tool. To start the Import wizard:
 - a. Click **File > Import > EAR file**.
 - b. Click **Next**, then select the EAR file.
 - c. Click **Finish**.
3. In the Project Explorer view of the Java EE perspective, right-click the component instance, then click **Open With > Deployment Descriptor Editor**. To locate the component instance, use the appropriate step:
 - For a session bean, expand **EJB Modules > ejb_module_instance > Deployment Descriptor > Session Beans**, then select the bean instance.
 - For a servlet, expand **Web Modules > web_application > Deployment Descriptor > web component**, then select the servlet instance.

A property dialog notebook for the deployment descriptor of the component is displayed in the property pane.

4. Optional: For session beans only, set the “Transaction type” attribute, which defines the transactional manner in which the container invokes a method. You can set this attribute to Container or Bean, as follows:
 - To use container-managed transactions, set the attribute to Container.
 - To use bean-managed transactions, set the attribute to Bean.
5. In the deployment descriptor notebook, select the **Bean** tab. Optionally, in the WebSphere Extensions section, configure the Local Transaction attributes. To enable management of local transaction containments, configure the following component extensions attributes. These attributes configure, for the component, the behavior of the local transaction containment (LTC) environment that the container establishes whenever a global transaction is not present.

Boundary

This setting specifies the containment boundary at which all contained resource manager local transactions (RMLTs) must be completed. Possible values are BeanMethod or ActivitySession.

- BeanMethod: This is the default value. If you select this option, RMLTs must be resolved within the same bean method in which they were started.
- [For EJB components only] ActivitySession: RMLTs must be resolved within the scope of any ActivitySession in which they were started or, if no ActivitySession context is present, within the same bean method in which they were started.

Note: The ActivitySession option is not supported in the web container.

Resolver

This setting specifies the component responsible for initiating and ending RMLTs. Possible values are Application or ContainerAtBoundary.

- Application: This is the default value. The application is responsible for starting RMLTs and for completing them within the local transaction containment (LTC) boundary. Any RMLTs that are not completed by the end of the LTC boundary are cleaned up by the container according to the value of the Unresolved action attribute.
- ContainerAtBoundary: The container is responsible for starting RMLTs and for completing them within the LTC boundary. The container begins an RMLT when a connection is first used within the LTC scope, and completes it automatically at the end of the LTC scope. If Boundary is set to ActivitySession, the RMLTs are enlisted as ActivitySession resources and directed to complete by the ActivitySession. If Boundary is set to BeanMethod, the RMLTs are committed at the end of the method by the container.

Unresolved action

Specifies the direction that the container requests RMLTs to take, if those transactions are unresolved at the end of the LTC boundary scope and the Resolver is set to Application. Possible values are Rollback or Commit.

- Rollback: This is the default value. At end of the LTC boundary scope, the container instructs all unresolved RMLTs to roll back.
- Commit: At the end of the LTC boundary scope, the container instructs all unresolved RMLTs to commit. The container instructs the RMLTs to commit only in the absence of an un-handled exception. If the application method that is running in the local transaction context ends with an exception, any unresolved RMLTs are rolled back by the container. This is the same behavior as for global transactions.

Shareable

Specifies whether the component can share an LTC. A new LTC is started only if a shareable LTC does not already exist. Applications that use shareable LTCs cannot explicitly commit or roll back resource manager connections that are used in a shareable LTC (although they can use connections that have an autoCommit capability).

If an application starts any non-autocommit work in an LTC for which the Resolver attribute is set to Application, and the Shareable attribute is set to true, an exception is thrown at run time. For example, on a JDBC Connection, non-autocommit work is work that the application performs after using the setAutoCommit(false) method to switch off the autocommit option on the connection. Enterprise beans that use bean managed transactions (BMT) cannot be assembled with the Shareable attribute set on the LTC configuration.

You must specify the **Shareable** attribute for all components that share the LTC. The component that creates the shareable LTC determines the other properties of the shared LTC, for example the value of the Resolver attribute.

6. In the WebSphere Extensions section, configure the Global Transaction attributes. These attributes configure, for the component, behavior in the presence of a global transaction.

Component Transaction Timeout

For enterprise beans that use container-managed transactions only, specifies the transaction timeout, in seconds, for any new global transaction that the container starts on behalf of the enterprise bean. For transactions started on behalf of the component, the Component Transaction Timeout setting overrides the default total transaction lifetime timeout that is configured in the transaction service settings for the application server.

The following attributes enable WS-AtomicTransaction and WS-BusinessActivity support for JAX-RPC applications only:

Use Web Services Atomic Transaction

For enterprise beans only, when this attribute is selected, if the application component makes any web service requests, any transaction context is propagated with the web service requests in accordance with the WebSphere WS-AtomicTransaction support described in Web Services Atomic Transaction support in the application server. When this attribute is not selected, web service requests do not carry transaction context.

Send Web Services Atomic Transaction on requests

For web components only, when this attribute is selected, if the application component makes any web service requests, any transaction context is propagated with the web service requests in accordance with the WebSphere WS-AtomicTransaction support described in Web Services Atomic Transaction support in the application server. When this attribute is not selected, web service requests do not carry transaction context.

Execute using Web Services Atomic Transaction on incoming requests

For web components only, when this attribute is selected, Web application components are prepared to run under a received WS-AtomicTransaction context. A web application component can run under a received WS-AtomicTransaction context in a similar way to an enterprise bean deployed with a container transaction type of Supports. When this attribute is not selected, the container of the web application component suspends any received

transaction context, in a similar way to the behavior of an EJB container for an enterprise bean deployed with a container transaction type of NotSupported.

If your application uses JAX-WS, enable support for WS-AtomicTransaction or WS-BusinessActivity by creating a policy set, adding the WS-Transaction policy type to the policy set, and attaching the policy set to the service or client.

If a policy set that is attached to a client includes the WS-Transaction policy type, any active global transaction context is propagated with a Web service request, in a similar way to the deployment descriptors Use Web Services Atomic Transaction and Send Web Services Atomic Transaction on requests, described earlier in this topic. Also, when the WS-Transaction policy type is included, the service runs under any received WS-AtomicTransaction context, in a similar way to the deployment descriptor Execute using Web Services Atomic Transaction on incoming requests, described earlier in this topic.

7. For EJB components only, for container-managed transactions, configure how the container manages the transaction boundaries when delegating a method invocation to the business method of an enterprise bean:
 - a. In the deployment descriptor notebook, select the **Assembly** tab. The Container Transactions section displays a table of the methods for enterprise beans.
 - b. For each method of the enterprise bean, set the container transaction type to an appropriate value. The default value for the container transaction type is Required, meaning that the method invocation occurs in the context of a transaction. This transaction is either the (local or remote) client component transaction or, if the client component does not run in a transaction, a new transaction started by the component container.

If the application uses ActivitySessions, how the container manages transaction boundaries when delegating a method invocation depends on both the container transaction type that you set in this task, and the ActivitySession kind attribute, which is described in “Setting EJB module ActivitySession deployment attributes” on page 4. For more detail about the relationship between these two properties, see ActivitySession and transaction container policies in combination.

8. For web services applications that use a SOAP/JMS binding and participates in WS-AtomicTransactions, set the container transaction type of the message-driven bean named “JMS router MDB” to a value of NotSupported, as described in the previous step. Web service applications that use a SOAP/JMS binding include a router message-driven bean named “JMS router MDB” in the assembled EAR. If a web service uses a SOAP/JMS binding and participates in WS-AtomicTransactions, as described in Web Services Atomic Transaction support in the application server, set the container transaction type of the “JMS router MDB” to a value of NotSupported.

For web services applications that use a SOAP/HTTP binding and participate in WS-AtomicTransactions, you do not have to do this.

9. For client application components only, if required, enable support for transaction demarcation by the client. In the deployment descriptor notebook, select the **Allow JTA demarcation** check box. This option directs the client container to bind the Java Transaction API (JTA) UserTransaction interface into JNDI at java:comp/UserTransaction for the client component. There are constraints on transaction support in the client container, which are described in Client support for transactions.
10. Save your changes to the deployment descriptor.
 - a. Close the deployment descriptor editor.
 - b. When prompted, click **Yes** to save changes to the deployment descriptor.
11. Verify the archive files. For more information about verifying files by using Rational Application Developer, refer to the Rational Application Developer information.
12. From the menu of the project, click **Deploy** to generate EJB deployment code.
13. Optional: Test your completed module on an application server installation. Right-click a module, click **Run on Server**, and follow the instructions in the resulting wizard.

Important: Use the **Run On Server** option for unit testing only. The assembly tool controls the application server installation, and when an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use the **Run On Server** option on production servers.

What to do next

After assembling your application, use a systems management tool, for example the administrative console, to deploy the EAR file onto the application server that is to run the application.

Using component-managed transactions

You can enable a session bean, servlet, or application client component to use component-managed transactions, to manage its own transactions directly instead of letting the container manage the transactions.

About this task

Note: Entity beans cannot manage transactions (so cannot use bean-managed transactions).

To enable a session bean, servlet, or application client component to use component-managed transactions, complete the following steps:

Procedure

1. For session beans, set the **Transaction type** attribute in the component deployment descriptor to **Bean**, as described in “Configuring transactional deployment attributes” on page 857.
2. For application client components, enable support for transaction demarcation by setting the **Allow JTA Demarcation** attribute in the component deployment descriptor, as described in “Configuring transactional deployment attributes” on page 857.
3. Write the component code to actively manage transactions.

For stateful session beans, a transaction started in a given method does not have to be completed (that is, committed or rolled back) before completing that method. The transaction can be completed at a later time, for example on a subsequent call to the same method, or even within a different method. However, it is usually preferable to construct the application so that a transaction is begun and completed within the same method call, because it simplifies application debugging and maintenance.

The following code extract shows the standard code required to obtain an object encapsulating the transaction context, and involves the following steps:

- Create a `javax.transaction.UserTransaction` object by calling a lookup on `java:comp/UserTransaction`.
- Use the `UserTransaction` object to demarcate the boundary of a transaction by using transaction methods such as `begin` and `commit`, as needed. If an application component begins a transaction, it must also complete that transaction by invoking either the `commit` method or the `rollback` method.

```
...
import javax.transaction.*;
import javax.naming.InitialContext;
import javax.naming.NamingException;
...
public float doSomething(long arg1) throws NamingException {
    InitialContext initCtx = new InitialContext();
    UserTransaction userTran = (UserTransaction)initCtx.lookup(
        "java:comp/UserTransaction");
    ...
    //Use userTran object to call transaction methods
    userTran.begin ();
    //Do transactional work
    ...
    userTran.commit ();
}
```

```
} ...  
}  
}
```

Using one-phase and two-phase commit resources in the same transaction

Use these topics to help you coordinate the use of a single one-phase commit capable resource with any number of two-phase commit capable resources in the same global transaction.

About this task

You can coordinate the use of a single one-phase commit capable resource with any number of two-phase commit capable resources in the same global transaction. You can have multiple interactions that involve the one-phase commit resource in the same transaction, but only one such resource can be involved. This coordination is enabled by the *last participant support*.

At transaction commit, the two-phase commit resources are prepared first using the two-phase commit protocol, and if this is successful the one-phase commit-resource is then called to commit. The two-phase commit resources are then committed or rolled back depending on the response of the one-phase commit resource.

For more information about using one-phase and two-phase commit resources within the same transaction, see the following topics:

Procedure

- “Coordination of access to one-phase commit and two-phase commit capable resources in the same transaction” on page 864
- “Assembling an application to use one-phase and two-phase commit resources in the same transaction”
- Configuring an application server to log heuristic reporting

Assembling an application to use one-phase and two-phase commit resources in the same transaction

Use this task to assemble an application to use one-phase and two-phase commit resources in the same transaction.

Before you begin

This task description assumes that you have an EAR file for an application component that can be deployed in WebSphere Application Server. For more details about assembling applications, see the topic about assembling applications.

About this task

To enable an application to use one-phase and two-phase commit capable resources in the same transaction, you must configure the deployment attributes of the application to accept the heuristic hazard, that is, the increased risk of an heuristic outcome. You can configure the deployment attributes of an application by using an assembly tool.

You can also configure an application to accept the heuristic hazard after deployment, by using the administrative console and the Last participant support extension settings. Alternatively, you can configure the transaction service for an application server to accept the heuristic hazard.

This topic describes the use of Rational Application Developer to configure the deployment attributes of an application.

To configure an application to indicate that you accept the increased risk of an heuristic outcome, complete the following steps:

Procedure

1. Start the assembly tool. For more information, refer to the Rational Application Developer information.
2. Create or edit the application EAR file.

Note: Ensure that you set the target server as WebSphere Application Server Version 7.0.

For example, to change attributes of an existing application, use the Import wizard to import the EAR file into the assembly tool. To start the Import wizard:

- a. Click **File > Import > EAR file**.
 - b. Click **Next**, then select the EAR file.
 - c. In the Target server field, select WebSphere Application Server v7.0.
 - d. Click **Finish**.
3. In the Project Explorer view of the Java EE perspective, complete the following steps:
 - a. Expand the Enterprise Application instance.
 - b. Right click on the Deployment Descriptor.
 - c. Click **Open With > Deployment Descriptor Editor**.

A property dialog notebook for the component is displayed in the property pane.

4. Complete the following steps to display the Extended Services tab.
 - a. Close the Enterprise Application Deployment Descriptor editor.
 - b. In the toolbar, select **Windows > Preferences**.
 - c. In the left pane, select **Capabilities**.
 - d. In the right pane, expand **Advanced Java EE** and select the **WebSphere PME Development** option.
 - e. Click **Apply**.
 - f. Open the Enterprise Application Deployment Descriptor editor.
5. On the Extended Services tab, in the Last Participant Support section, select the **Last participant support** check box.
6. Save your changes to the deployment descriptor.
 - a. Close the Deployment Descriptor Editor.
 - b. When prompted, click **Yes** to save changes to the deployment descriptor.
7. Verify the archive files. For more information about verifying files using Rational Application Developer, refer to the Rational Application Developer information.
8. From the popup menu of the project, click **Deploy** to generate EJB deployment code.
9. Optional: Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard.

Important: Use **Run On Server** only for unit testing. The assembly tool controls the WebSphere Application Server installation and, when an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use the **Run On Server** option on production servers.

What to do next

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that is to run the application; for example, using the administrative console, as described in the topic about deploying and administering enterprise applications.

Last participant support extension settings:

Use this page to configure settings for last participant support. Last participant support is an extension to the transaction service that enables a single one-phase resource to participate in a two-phase transaction with one or more two-phase resources. Values on this panel are ignored if you select **Use configuration information in binary** on the Application binaries panel.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > application_name**. Under **Detailed Properties**, click **Last participant support extension**.

Accept heuristic hazard:

Specifies whether an application accepts the possibility of a heuristic hazard occurring in a two-phase transaction that contains a one-phase resource.

Information	Value
Default	Cleared
Range	Selected The application accepts the increased risk of an heuristic outcome.
	Cleared The application does not accept the increased risk of an heuristic outcome.

Coordination of access to one-phase commit and two-phase commit capable resources in the same transaction

Last participant support enables the use of a single one-phase commit capable resource with any number of two-phase commit capable resources in the same global transaction. You can have multiple interactions that involve the one-phase commit resource in the same transaction, but only one such resource can be involved.

At transaction commit, the two-phase commit resources are prepared first using the two-phase commit protocol, and if this is successful, the one-phase commit-resource is then called to commit. The two-phase commit resources are then committed or rolled back, depending on the response of the one-phase commit resource.

Last participant support introduces an increased risk of an heuristic outcome to the transaction. That is, the transaction manager cannot be sure that all resources were completed in the same direction (either committed or rolled back). For this reason, to enable an application to coordinate access to one-phase and two-phase commit capable resources in the same transaction, you configure the application to accept the heuristic hazard, that is, accept the increased risk of an heuristic outcome.

An heuristic outcome occurs if the transaction service (JTS) receives no response from the commit one-phase flow on the one-phase commit resource. In this situation, the transaction service cannot determine whether changes for the one-phase commit resource were committed or rolled back, so cannot drive reliably the correct outcome of the global transaction on the other two-phase commit resources.

You can configure the transaction service for an application server to accept the heuristic hazard, or you can configure applications individually to accept the heuristic hazard. You can configure applications individually either when they are assembled, or after they are deployed.

You can configure the transaction service for an application server to indicate whether or not to log that it is about to commit the one-phase commit resource. This does not reduce the heuristic hazard, but ensures that any failure, and subsequent recovery, of the application server during the one-phase commit phase occurs with knowledge of whether or not the one-phase commit resource was asked to commit:

- If the one-phase commit resource was asked to commit, a heuristic outcome is reported to the activity log.
- If the one-phase commit resource was not asked to commit, then the transaction is rolled back consistently.

Transaction exceptions that involve both one-phase and two-phase commit resources

The exceptions that can be thrown by transactions that involve one-phase and two-phase commit resources are the same as those that can be thrown by transactions involving only two-phase commit resources.

The exceptions that can occur are listed in the application programming interface (API) reference information in the WebSphere Application Server information center.

Last Participant Support: Resources for learning:

Use the links in this topic to find relevant supplemental information about Last Participant Support. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Chapter 26. Developing web applications

This page provides a starting point for finding information about web applications, which are comprised of one or more related files that you can manage as a unit, including:

- HTML files
- Servlets can support dynamic web page content, provide database access, serve multiple clients at one time, and filter data.
- Java ServerPages (JSP) files enable the separation of the HTML code from the business logic in web pages.

IBM extensions to the JSP specification make it easy for HTML authors to add the power of Java technology to web pages, without being experts in Java programming. More introduction...

Developing web applications

Learn about selecting tools for developing web applications.

Before you begin

Design a web application and the required components.

About this task

There are two basic approaches to selecting tools for developing web applications:

- You can use one of the available integrated development environments (IDEs). IDE tools automatically generate significant parts of the servlet and JavaServer Pages (JSP) code, and Hypertext Markup Language (HTML) files. They also contain integrated tools for packaging and testing the web application components.
- If you decide to develop web components without an IDE, you need at least an ASCII text editor. You can also use tools available in the Java SE Development Kit 6 and in this product to assemble, test, and deploy the Web application components.

The following steps support the second approach, development without an IDE.

Procedure

1. If necessary, migrate any pre-existing code to the required version of the servlet and JSP specification.
2. Write and compile the components of the web application. To access classes that were extended, compile your code using the `-classpath` option on the `javac` compiler. This option allows you to reference the `j2ee.jar` file in the product directory:
 -  `app_server_root/dev/JavaEE`
 -  For example, to compile a servlet for WebSphere Application Server on i5/OS, specify:

```
javac -J-Djava.version=1.5 -classpath app_server_root/dev/JavaEE/j2ee.jar MyServlet.java
```
3. Optionally disable JavaServer Pages (JSP) runtime compilation, if necessary.

What to do next

Assemble the application components in one or more web modules.

Developing servlets

Developing servlets with WebSphere Application Server extensions

Use this task to provide a summary of the WebSphere Application Server extensions that you can use to develop servlets.

About this task

Several WebSphere Application Server extensions are provided for enhancing your servlets. This task provides a summary of the extensions that you can utilize.

Procedure

1. Review the supported specifications.

Create Java components, referring to the Servlet specifications.

The application server includes its own packages that extend and add to the Java Servlet Application Programming Interface (API). These extensions and additions make it easier to manage session states, create personalized Web pages, generate better servlet error reports, and access databases. Locate the API documentation for the application server APIs in the *app_server_root/web/apidocs* directory for the default installation. All of the public Application Server APIs are located in the `com.ibm.websphere` packages, however, `com.ibm.websphere.servlet` package is specific to the product servlet APIs.

2. Use your favorite integrated development environment (IDE), or a text editor, to develop or migrate code artifacts that meet the specifications.
3. Test the code artifacts.

What to do next

Assemble your code artifacts into a web module using assembly tools as a prerequisite to deploying the code to the application server.

Configuring page list servlet client configurations:

You can define PageListServlet configuration information in the IBM Web Extensions file. The IBM Web Extensions file is created and stored in the web applications archive (WAR) file by an assembly tool.

About this task

Attention: The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 8.5 and will be removed in a future release. Re-architect your legacy applications to use `javax.servlet.filter` classes instead of `com.ibm.servlet` classes. Starting from the Servlet 2.3 specification, `javax.servlet.filter` classes you can intercept requests and examine responses. You can also use `javax.servlet.filter` classes to achieve chaining functionality, as well as embellishing or truncating responses.

To configure and implement page lists:

Procedure

1. To configure page list information, use the Add Markup Language entry dialog of an assembly tool. On the Servlets tab of a web deployment descriptor editor, select a servlet and click **Add** under WebSphere Extensions.
2. Add the `callPage()` method to your servlet to invoke a JavaServer Page (JSP) file in response to a client request.

The PageListServlet has a `callPage()` method that invokes a JSP file in response to the HTTP request for a page in a page list. The `callPage()` method can be invoked in one of the following ways:

- `callPage(String pageName, HttpServletRequest request, HttpServletResponse response)`

where the method arguments are:

pageName

A page name defined in the PageListServlet configuration

request

The HttpServletRequest object

response

The HttpServletResponse object

- `callPage(String mlName, String pageName, HttpServletRequest request, HttpServletResponse response)`

where the method arguments are:

mlName A markup language type

pageName

A page name defined in the PageListServlet configuration

request

The HttpServletRequest object

response

The HttpServletResponse object

3. Use the PageList Servlet client type detection support to determine the markup language type a calling client requires for the response.

Extending PageListServlet

The following example shows how a servlet extends the PageListServlet class and determines the markup-language type required by the client. The servlet then uses the `callPage` method to call an appropriate JavaServer Pages (JSP) file. In this example, the JSP file that provides the correct markup-language for the response is *Hello.page*.

```
public class HelloPervasiveServlet extends PageListServlet implements Serializable
{
    /*
    * doGet -- Process incoming HTTP GET requests
    */
    public void doGet(HttpServletRequest request, HttpServletResponse response)
    throws IOException, ServletException
    {
        // This is the name of the page to be called:
        String pageName = "Hello.page";

        // First check if the servlet was invoked with a queryString that contains
        // a markup-language value.
        // For example, if this is how the servlet is invoked:
        // http://localhost/servlets/HelloPervasive?mlname=VXML
        // then use the following method:
        String mlname= getMLNameFromRequest(request);

        // If no markup language type is provided in the queryString,
        // then try to determine the client
        // Type from the request, and use the markup-language name configured in
        // the client_types.xml file.
        if (mlName == null)
        {
            mlName = getMLTypeFromRequest(request);
        }
        try
        {
            // Serve the request page.
            callPage(mlName, pageName, request, response);
        }
        catch (Exception e)
        {
        }
    }
}
```

```

        handleError(mlName, request, response, e);
    }
}

```

Page lists:

Page lists allow you to avoid hard-coding Uniform Resource Locators (URLs) in servlets and JSP files. A page list specifies the location where a request is to be forwarded, but automatically customizes that location depending on the MIME type of the servlet. Use these properties to specify a markup language and an associated MIME type. For the given MIME type, you also specify a set of pages to invoke.

Note: The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 8.5 and will be removed in a future release. Re-architect your legacy applications to use `javax.servlet.filter` classes instead of `com.ibm.servlet` classes. Starting from the Servlet 2.3 specification, `javax.servlet.filter` classes you can intercept requests and examine responses. You can also use `javax.servlet.filter` classes to achieve chaining functionality, as well as embellishing or truncating responses.

The following list of classes are deprecated:

- `com.ibm.servlet.ClientList`
- `com.ibm.servlet.ClientListElement`
- `com.ibm.servlet.MLNotFoundException`
- `com.ibm.servlet.PageListServlet`
- `com.ibm.servlet.PageNotFoundException`

WebSphere Application Server supplies the `PageListServlet` servlet, which you can use to call a JavaServer Pages (JSP) file by name based on the configuration data in the `client_types.xml` file. This file maps a JSP file to a Uniform Resource Identifier (URI). When the URI is invoked, it specifies another JSP file in a web module. This support allows you to access multiple URLs without hard-coding them in your servlets.

You can also logically group page lists according to the markup language type, such as, Hypertext Markup Language (HTML) or Wireless Markup Language (WML). This allows applications that use servlets to extend the `PageListServlet` servlet, to call JSP files which return the proper markup-language type for the client request. For example, a request that originates from a PDA device requires WML data. The application server sends the request to a servlet that extends the `PageListServlet` servlet, and the servlet calls a JSP file that returns a WML response.

Client type detection support:

In addition to providing the page list mapping capability, the `PageListServlet` also provides Client Type Detection support. A servlet determines the markup language type that a calling client needs in the response, using the configuration information in the `client_types.xml` file.

Client type detection support allows a servlet, extending the `PageListServlet`, to call an appropriate JavaServer Pages (JSP) file. The servlet invokes the `callPage` method, which calls a JSP file based on the markup-language type of the request.

The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 8.5 and will be removed in a future release. Re-architect your legacy applications to use `javax.servlet.filter` classes instead of `com.ibm.servlet` classes.

The client_types.xml file:

The `client_types.xml` file provides client type detection support for servlets extending `PageListServlet`. Using the configuration data in the `client_types.xml` file, servlets can determine the language type that calling clients require for the response.

Attention: The `PageListServlet` custom extension is deprecated in WebSphere Application Server Version 8.5 and will be removed in a future release. Re-architect your legacy applications to use `javax.servlet.filter` classes instead of `com.ibm.servlet` classes.

The client type detection support allows servlets to call appropriate JavaServer Pages (JSP) files with the `callPage` method. Servlets select JSP files based on the `markup-language` type of the request.

Servlets must use the following version of the `callPage` method to determine the markup language type required by the client:

```
callPage(String mlName, String pageName, HttpServletRequest request,
         HttpServletResponse response)
```

where the arguments are:

- `mlName` - a markup language type
- `pageName` - a page name defined in the `PageListServlet` configuration
- `request` - the `HttpServletRequest` object
- `response` - the `HttpServletResponse` object

Review the Extending the `PageListServlet` code example in the Extending the `PageListServlet` topic, to see how the `callPage` method is invoked by a servlet.

In the example, the client type detection method, `getMLTypeFromRequest(HttpServletRequest request)`, provided by the `PageListServlet`, inspects the `HttpServletRequest` object request headers, and searches for a match in the `client_types.xml` file.

The client type detection method does the following:

- Uses the input `HttpServletRequest` and the `client_types.xml` file, to check for a matching HTTP request name and value.
- Returns the `markup-language` value configured for the `<client-type>` element, if a match is found.
- If multiple matches are found, this method returns the `markup-language` for the first `<client-type>` element for which a match is found.
- If no match is found, returns the value of the `markup-language` for the default page defined in the `PageListServlet` configuration.

Location

 The `client_types.xml` file is located in the `/properties` directory.

Usage notes

Review the answers to the following usage questions:

- Is this file read-only?
No
- Is this file updated by a product component?
No
- If so, what triggers its update?
This file is created and updated manually by users.
- How and when are the contents of this file used?

Servlets that extending the `PageListServlet` servlet use this file to determine the language type that calling clients require for the response.

Sample file entry

```
<?xml version="1.0" >
<!DOCTYPE clients [
<!ELEMENT client-type (description, markup-language,request-header+)>
<!ELEMENT description (#PCDATA)>
<!ELEMENT markup-language (#PCDATA)>
<!ELEMENT request-header (name, value)>
<!ELEMENT clients (client-type+)>
<!ELEMENT name (#PCDATA)>
<!ELEMENT value (#PCDATA)>]>
<clients>
  <client-type>
    <description>IBM Speech Client</description>
    <markup-language>VXML</markup-language>
    <request-header>
      <name>user-agent</name>
      <value>IBM VoiceXML pre-release version 000303</value>
    </request-header>
    <request-header>
      <name>accept</name>
      <value>text/vxml</value>
    </request-header>
  </client-type>
  <client-type>
    <description>WML Browser</description>
    <markup-language>WML</markup-language>
    <request-header>
      <name>accept</name>
      <value>text/x-wap.wml</value>
    </request-header>
    <request-header>
      <name>accept</name>
      <value>text/vnd.wap.xml</value>
    </request-header>
  </client-type>
</clients>
```

The *client_types.xml* file:

The `client_types.xml` file provides client type detection support for servlets extending `PageListServlet`. Using the configuration data in the `client_types.xml` file, servlets can determine the language type that calling clients require for the response.

Attention: The `PageListServlet` custom extension is deprecated in WebSphere Application Server Version 8.5 and will be removed in a future release. Re-architect your legacy applications to use `javax.servlet.filter` classes instead of `com.ibm.servlet` classes.

The client type detection support allows servlets to call appropriate JavaServer Pages (JSP) files with the `callPage` method. Servlets select JSP files based on the markup-language type of the request.

Servlets must use the following version of the `callPage` method to determine the markup language type required by the client:

```
callPage(String mlName, String pageName, HttpServletRequest request,
         HttpServletResponse response)
```

where the arguments are:

- `mlName` - a markup language type
- `pageName` - a page name defined in the `PageListServlet` configuration
- `request` - the `HttpServletRequest` object

- response - the `HttpServletResponse` object

Review the Extending the `PageListServlet` code example in the Extending the `PageListServlet` topic, to see how the `callPage` method is invoked by a servlet.

In the example, the client type detection method, `getMLTypeFromRequest(HttpServletRequest request)`, provided by the `PageListServlet`, inspects the `HttpServletRequest` object request headers, and searches for a match in the `client_types.xml` file.

The client type detection method does the following:

- Uses the input `HttpServletRequest` and the `client_types.xml` file, to check for a matching HTTP request name and value.
- Returns the markup-language value configured for the `<client-type>` element, if a match is found.
- If multiple matches are found, this method returns the markup-language for the first `<client-type>` element for which a match is found.
- If no match is found, returns the value of the markup-language for the default page defined in the `PageListServlet` configuration.

Location

 The `client_types.xml` file is located in the `/properties` directory.

Usage notes

Review the answers to the following usage questions:

- Is this file read-only?
No
- Is this file updated by a product component?
No
- If so, what triggers its update?
This file is created and updated manually by users.
- How and when are the contents of this file used?

Servlets that extending the `PageListServlet` servlet use this file to determine the language type that calling clients require for the response.

Sample file entry

```
<?xml version="1.0" >
<!DOCTYPE clients [

    <markup-language>VXML</markup-language>
    <request-header>
      <name>user-agent</name>
      <value>IBM VoiceXML pre-release version 000303</value>
    </request-header>
    <request-header>
      <name>accept</name>
      <value>text/vxml</value>
    </request-header>
  </client-type>
</clients>
```

```

</client-type>
<client-type>
  <description>WML Browser</description>
  <markup-language>WML</markup-language>
<request-header>
  <name>accept</name>
  <value>text/x-wap.wml</value>
</request-header>
<request-header>
  <name>accept</name>
  <value>text/vnd.wap.xml</value>
</request-header>
</client-type>
</clients>

```

Java Servlet 3.0 considerations:

When using Servlet 3.0 web modules, keep in mind the following features.

Java Servlet 3.0 has many, new powerful features. Some of these features are not fully documented in the Servlet 3.0 specification or they entail trade-offs. Consider the following topics to make best use of the new features.

Annotations

Java Servlet 3.0 annotations are picked up in Servlet 2.5 web modules, which can include exposing a servlet on the web. Use caution when upgrading prerequisites of an older application, because the new annotations are processed and the prerequisites JAR file might include annotations that you do not want applied.

File upload

When using the file upload (multipart forms) support that is new to Servlet 3.0, the default location for writing files is the same as the value of the `javax.servlet.context.tempdir` servlet context attribute. For example, `C:\opt\WAS\profiles\node1\temp\node1\server1\fragmentTest\fragmentTest24.war` is produced for a configuration with the following attributes:

- `profile home=C:\opt\WAS\profiles\node1`
- `server name=server1`
- `enterprise application name=fragmentTest`
- `web module name=fragmentTest24.war`

Relative paths are also relative to this default location.

You can change the value of the `javax.servlet.context.tempdir` servlet context attribute to be relative to a different directory by setting the `com.ibm.websphere.servlet.temp.dir` system property. This system property affects all applications on a server-wide basis. For example, if you set `com.ibm.websphere.servlet.temp.dir` to `/foo`, the application temp directory is `/foo/node1/server1/fragmentTest/fragmentTest24.war`. If you want to change the value at an application level, use the `scratchdir` JavaServer Pages (JSP) attribute. View the JSP engine configuration parameters topic for more information about the `scratchdir` attribute.

Programmatic or dynamic HTTP session configuration

Programmatic HTTP session configuration enables an application to modify the session configuration in use, either through `web.xml` file configuration or through API method calls. After the application starts, a dynamically modified cookie name cannot be changed. For security purposes, administrators can disable programmatic session configuration for particular cookies that can be shared between applications.

Generally, it is safe to modify the cookie configuration, if the application uses a unique cookie name or path. You can change the default cookie path for each application to use the context root through the session management.

Important: Changing the path can affect certain IBM extensions, such as session sharing or the `IBMSessionExt.invalidateAll` method that rely on using one cookie for multiple applications.

Dynamic cookies have the following impact on intermediary services:

- An enterprise proxy automatically retrieves a dynamic cookie when an application starts and uses the cookie for session affinity.
- A DMZ proxy in low or medium secure mode also automatically retrieves a dynamic cookie when an application starts. For a DMZ proxy in high secure mode, the retrieval is not automatic; the application must be running before the target routing information is exported.
- A web server plug-in cannot obtain the dynamic cookie automatically because it does not communicate with application servers for configuration information. You must start the application, generate the plug-in configuration, propagate the configuration to the plug-in, and then reload the configuration for the plug-in to obtain the cookie.

Servlet 3.0 programmatic configuration:

The configuration methods, `addListener`, `addFilter`, and `addServlet` are introduced in the Servlet 3.0 specification.

The methods for Servlet 3.0 are part of the `ServletContext` interface. You can call these methods from either a `ServletContainerInitializer` or a `ServletContextListener`.

addListener

The `addGlobalListener` method is deprecated in WebSphere Application Server Version 8.5. It is replaced with the `addListener` method.

- Use the following method to add the listener with the given class name to this servlet context:

```
void addListener(java.lang.String className)
```

- Use the following method to add the given listener to this servlet context:

```
<T extends java.util.EventListener> void addListener(T t)
```

- Use the following method to add a listener of the given class type to this servlet context:

```
void addListener(java.lang.Class<? extends java.util.EventListener> listenerClass)
```

The given listener class must implement one or more of the following interfaces:

- `ServletContextAttributeListener`
- `ServletRequestListener`
- `ServletRequestAttributeListener`
- `HttpSessionListener`
- `HttpSessionAttributeListener`

addFilter

The `addMappingFilter` method is deprecated in WebSphere Application Server Version 8.5. It is replaced with the `addFilter` method. This method adds the filter with the given name, description, and class name to the Web application context. The registered filter might be further configured using the returned `FilterRegistration` object.

- Use the following method to add the filter with the given name and class type to this servlet context:

```
addFilter(java.lang.String filterName, java.lang.Class<? extends Filter> filterClass)
```

- Use the following method to register the given filter instance with this servlet context under the given `filterName`:

```
addFilter(java.lang.String filterName, Filter filter)
```

- Use the following method to add the filter with the given name and class name to this servlet context:

```
addFilter(java.lang.String filterName, java.lang.String className)
```

addServlet

The `addServlet` methods dynamically adds servlets to a `servletContext`. These methods will add the servlet with the given parameters to the web application context. The registered servlet might be further configured using the returned `ServletRegistration` object.

- Use the following method to add the filter with the given name and class type to this servlet context:

```
addFilter(java.lang.String filterName, java.lang.Class<? extends Filter> filterClass)
```

- Use the following method to register the given filter instance with this servlet context under the given `filterName`:

```
addFilter(java.lang.String filterName, Filter filter)
```

- Use the following method to add the filter with the given name and class name to this servlet context:

```
addFilter(java.lang.String filterName, java.lang.String className)
```

ServletContainerInitializer

When you configure a JAR file for a shared library and a `ServletContainerInitializer` is discovered within the JAR, the `ServletContainerInitializer` is invoked for every application that the shared library associates with.

Deprecated classes in Servlet 3.0

The following classes are deprecated from `com.ibm.websphere.servlet.context.IBMServletContext`:

- `public void addDynamicServlet(String servletName, String servletClass, String mappingURI, Properties initParameters) throws ServletException, java.lang.SecurityException;`
- `public void removeDynamicServlet(String servletName) throws java.lang.SecurityException`

There is no replacement for the `removeDynamicServlet` method because removing a servlet can lead to timing issues if a request was servicing that servlet at the same time. The `addServlet` and `createServlet` methods replace the `addDynamicServlet` method.

Initial parameters for servlets settings:

Use this page to specify initial parameters that are passed to the `init` method of web module servlet filters. You can specify initial parameter values for servlets in web modules during or after installation of an application onto a WebSphere Application Server deployment target. The `<param-value>` values specified in `<init-param>` statements in the `web.xml` file of web modules are used by default.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *application_name* > Init parameters for servlets**. This page is the same as the `Init parameters for servlets` in each web module panel on the application installation and update wizards.

Module:

Specifies the name of a module in the application that you are installing or that you are viewing after installation.

URI:

Specifies the location of the module relative to the root of the application (EAR file).

Servlet:

Specifies a unique name for the servlet within the application.

A *servlet* is a Java program that uses the Java Servlet Application Programming Interface (API). You must package servlets in a Web archive (WAR) file or web module for deployment to an application server. Servlets run on a Java-enabled web server and extend the capabilities of a web server, similar to the way applets run on a browser and extend the capabilities of a browser.

Name:

Specifies the name of the initial parameter passed to the init method of the web module servlet filter.

The following example servlet filter statement in a web.xml file specifies an initial parameter name of attribute:

```
<init-param>
  <param-name>attribute</param-name>
  <param-value>tests.Filter.DoFilter_Filter.SERVLET_MAPPED</param-value>
</init-param>
```

Value:

Specifies the value assigned to an initial parameter passed to the init method of the web module servlet filter.

The following example servlet filter statement in a web.xml file specifies an initial parameter value of tests.Filter.DoFilter_Filter.SERVLET_MAPPED for the init parameter attribute:

```
<init-param>
  <param-name>attribute</param-name>
  <param-value>tests.Filter.DoFilter_Filter.SERVLET_MAPPED</param-value>
</init-param>
```

Description:

Specifies information on the initial parameter.

Servlet filtering:

Servlet filtering provides a new type of object called a filter that can transform a request or modify a response.

You can chain filters together so that a group of filters can act on the input and output of a specified resource or group of resources.

Filters typically include logging filters, image conversion filters, encryption filters, and Multipurpose Internet Mail Extensions (MIME) type filters (functionally equivalent to the servlet chaining). Although filters are not servlets, their life cycle is very similar.

Filters are handled in the following manner:

1. The web container determines whether it needs to construct a `FilterChain` containing the `LoggingFilter` for the requested resource.
The `FilterChain` begins with the invocation of the `LoggingFilter` and ends with the invocation of the requested resource.
2. If other filters need to go in the chain, the web container places them after the `LoggingFilter` and before the requested resource.

3. The web container then instantiates and initializes the `LoggingFilter` (if it was not done previously) and invokes its `doFilter(FilterConfig)` method to start the chain.
4. The `LoggingFilter` preprocesses the request and response objects and then invokes the filter chain `doFilter(ServletRequest, ServletResponse)` method.
This method passes the processing to the next resource in the chain, the requested resource.
5. Upon return from the filter chain `doFilter(ServletRequest, ServletResponse)` method, the `LoggingFilter` performs post-processing on the request and response object before sending the response back to the client.

Java Servlet Specification 2.4 enables you to define a new `<dispatcher>` element in the deployment descriptor with possible values such as `REQUEST`, `FORWARD`, `INCLUDE`, `ERROR`, instead of invoking filters with `RequestDispatcher`.

Java Servlet Specification 3.0 enables you to define a new `<dispatcher>` element in the deployment descriptor with possible values such as `ASYNC`, `REQUEST`, `FORWARD`, `INCLUDE`, `ERROR`, instead of invoking filters with `RequestDispatcher`.

For example:

```
<filter-mapping>
<filter-name>Logging Filter</filter-name>
<url-pattern>/products/*</url-pattern>
<dispatcher>FORWARD</dispatcher>
<dispatcher>REQUEST</dispatcher>
</filter-mapping>
```

This indicates that the filter should be applied to requests directly from the client as well as forward requests. Adding the `INCLUDE` and `ERROR` values also indicates that the filter should additionally be applied for included requests and `<error-page>` requests. If you do not specify any `<dispatcher>` elements, then the default is `REQUEST`.

Filter, FilterChain, FilterConfig classes for servlet filtering

The following interfaces are defined as part of the `javax.servlet` package:

- `Filter` interface - methods: `doFilter`, `getFilterConfig`, `setFilterConfig`
- `FilterChain` interface - methods: `doFilter`
- `FilterConfig` interface - methods: `getFilterName`, `getInitParameter`, `getInitParameterNames`, `getServletContext`

The following classes are defined as part of the `javax.servlet.http` package:

- `HttpServletRequestWrapper` - methods: See the Servlet 2.4 Specification
- `HttpServletResponseWrapper` - methods: See the Servlet 2.4 Specification

autoRequestEncoding and autoResponseEncoding:

Starting with WebSphere Application Server Version 5, the web container no longer automatically sets request and response encodings, and response content types. Programmers are expected to set these values using available methods in the Servlet 2.3 specification or later. If programmers choose not to use the character encoding methods, they can specify the **`autoRequestEncoding`** and **`autoResponseEncoding`** extensions, which enable the application server to set the encoding values and content type.

The values of the **`autoRequestEncoding`** and **`autoResponseEncoding`** extensions are either `true` or `false`. The default value for both extensions is `false`. If the value is `false` for both **`autoRequestEncoding`** and **`autoResponseEncoding`**, then the request and response character encoding is set to the Servlet Specification default, which is ISO-8859-1. Also, if the value is set to `false` for a response, the web

container cannot set a response content type. Different character encodings are possible if the client defines character encoding in the request header, or if the code includes the `setCharacterEncoding(String encoding)` method.

If the `autoRequestEncoding` value is set to `true`, and the client did not specify character encoding in the request header, and the code does not include the `setCharacterEncoding(String encoding)` method, the web container tries to determine the correct character encoding for the request parameters and data.

Use an assembly tool to change the default values for the `autoRequestEncoding` and `autoResponseEncoding` extensions.

The web container performs each step in the following list until a match is found:

- Looks at the character set (charset) in the **Content-Type** header.
- Attempts to map the server's locale to a character set using defined properties.
- Attempts to use the `DEFAULT_CLIENT_ENCODING` system property, if one is set.
- Uses the ISO-8859-1 character encoding as the default.

If the `autoResponseEncoding` value is set to `true`, and the client did not specify character encoding in the request header, and the code does not include the `setCharacterEncoding(String encoding)` method, the web container does the following:

- Attempts to determine the response content type and character encoding from information in the request header.
- Uses the ISO-8859-1 character encoding as the default.

Application life cycle listeners and events:

With application life cycle listeners and events, which are now part of the Servlet API, you can notify interested listeners when servlet contexts and sessions change. For example, you can notify users when attributes change and if sessions or servlet contexts are created or destroyed.

The life cycle listeners give the application developer greater control over interactions with `ServletContext` and `HttpSession` objects. Servlet context listeners manage resources at an application level. Session listeners manage resources that are associated with a series of requests from a single client. Listeners are available for life cycle events and for attribute modification events. The listener developer creates a class that implements the `javax.listener` interface, corresponding to the listener functionality that you want.

At application startup time, the container uses introspection to create an instance of your listener class and registers it with the appropriate event generator.

When a servlet context is created, the `contextInitialized` method of your listener class is invoked, which creates the database connection for the servlets in your application to use if this context is for your application. All servlet context listeners are notified of context initialization before any servlet in the web application is initialized.

When the servlet context is destroyed, your `contextDestroyed` method is invoked, which releases the database connection, if this context is for your application. You must destroy all servlets before any servlet context listeners are notified of context destruction.

Notifications to session listeners precede notifications to context listeners.

Listener classes for servlet context and session changes

The following methods are defined as part of the `javax.servlet.ServletContextListener` interface:

- `void contextInitialized(ServletContextEvent)`

Notification that the web application is ready to process requests. Place code in this method to see if the created context is for your web application and if it is, allocate a database connection and store the connection in the servlet context.

- `void contextDestroyed(ServletContextEvent)`

Notification that the servlet context is about to shut down. Place code in this method to see if the created context is for your web application and if it is, close the database connection stored in the servlet context.

The following methods are defined as part of the `javax.servlet.ServletRequestListener` interface:

- `public void requestInitialized(ServletRequestEvent re)`
 - Notification that the request is about to come into scope
 - A request is defined as coming into scope when it is about to enter the first filter in the filter chain that processes the request.
- `public void requestDestroyed(ServletRequestEvent re)`
 - Notification that the request is about to go out of scope
 - A request is defined as going out of scope when it exits the last filter in its filter chain.

The following listener interfaces are defined as part of the `javax.servlet` package:

- `ServletContextListener`
- `ServletContextAttributeListener`

The following filter interface is defined as part of the `javax.servlet` package:

- `FilterChain` interface - methods: `doFilter()`

The following event classes are defined as part of the `javax.servlet` package:

- `ServletContextEvent`
- `ServletContextAttributeEvent`

The following interfaces are defined as part of the `javax.servlet.http` package:

- `HttpSessionListener`
- `HttpSessionAttributeListener`
- `HttpSessionActivationListener`

The following event class is defined as part of the `javax.servlet.http` package:

- `HttpSessionEvent`

Example: Creating a servlet context listener with `com.ibm.websphere.DBConnectionListener.java`

The following example shows how to create a servlet context listener:

```
package com.ibm.websphere;

import java.io.*;
import javax.servlet.*;

public class DBConnectionListener implements ServletContextListener
{
    // implement the required context init method
    void contextInitialized(ServletContextEvent sce)
    {
    }

    // implement the required context destroy method
    void contextDestroyed(ServletContextEvent sce)
    {
    }
}
```

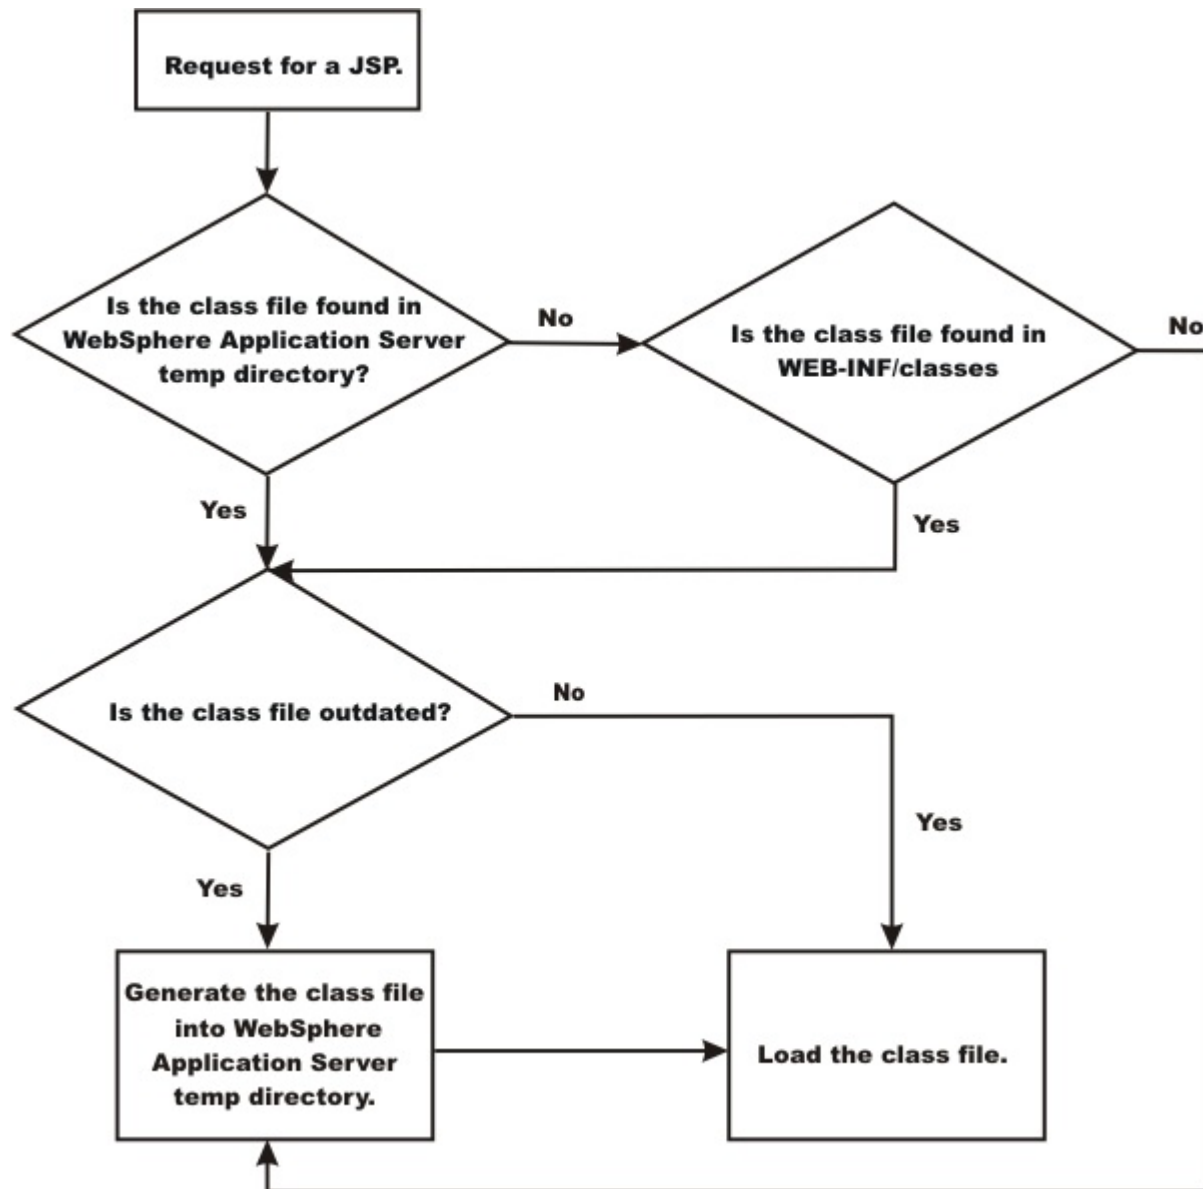

Developing JSP files

Learn about JSP files.

JSP class file generation

At runtime, the WebSphere Application Server JavaServer Pages (JSP) engine loads JSP class files from either the WebSphere Application Server temp directory or a web module's WEB-INF/classes directory. The JSP engine first searches for a class file in the temp directory and then it searches in the web module's WEB-INF/classes directory.

In a default installation, the WebSphere Application Server temp directory is typically *profile_root/temp*. Figure 1 shows the processing logic of the JSP engine at runtime.

The batch compiler supports the generation of class files in both the WebSphere Application Server temp directory and a web module's WEB-INF/classes directory, depending on the type of batch compiler target. In addition, the batch compiler enables the generation of class files into any directory on the filesystem, outside of the target application. Generating class files into a web module's WEB-INF/classes directory

enables you to deploy the web module as a self-contained web application archive (WAR) file, or a WAR file inside an enterprise archive (EAR) file. The following table shows the batch compiler's behavior when compiling class files.

Table 80. Batch compiler behavior. Batch compiler behavior when compiling class files

	ear.path or war.path supplied	enterpriseApp.name supplied
<i>compileToDir</i> not supplied; <i>compileToWebInf</i> not supplied, or is true	The class files are compiled into the web module's WEB-INF/classes directory.	The class files are compiled into the web module's WEB-INF/classes directory.
<i>compileToDir</i> not supplied; <i>compileToWebInf</i> is false	The class files are compiled into the web module's WEB-INF/classes directory.	The class files are compiled into the WebSphere Application Server temp directory, usually <i>profile_root/temp</i> .
<i>compileToDir</i> is supplied; <i>compileToWebInf</i> not supplied, or is either true or false	The class files are compiled into the directory indicated by <i>compileToDir</i> .	The class files are compiled into the directory indicated by <i>compileToDir</i> .

Web container configuration for JavaServer Pages static file access

The web container searches for static files and JavaServer Pages (JSP) files in up to four different locations, depending on application configuration. This search is relevant to finding the appropriate resource to serve an inbound request and for results returned from the following APIs:

```
URL ServletContext.getResource(String path)
Set ServletContext.getResourcePaths(String path)
```

Attention: Static files are only searched when the **fileServing** property is enabled and the application does not include a `/*` servlet mapping. Also, JSP files include files with the following extensions, in addition to any other patterns that are defined in the `web.xml` file

- .jsp
- .jspx
- .jsw
- .jsv

The four locations, in priority order, are as follows:

Application WAR directory

The web container first searches the application WAR directory for a requested resource. However, you cannot serve resources under the WEB-INF or META-INF directories for inbound requests, although they are accessible using the `getResource()` and `getResourcePaths()` methods.

Pre-fragment document roots

The web container searches any application defined pre-fragment document roots second. Define a pre-fragment document root in the `ibm-web-ext.xmi` file, located in the WEB-INF directory for the application. Define a pre-fragment document root for static files or JSP files, as follows:

```
Static files:
<fileServingAttributes xmi:id="<user-provided name>"
  name="preFragmentExtendedDocumentRoot"
  value="<user provided value>"/>
```

```
JSP files:
<jspAttributes xmi:id="<user provided name>" name="preFragmentExtendedDocumentRoot"
  value="<user provided value>"/>
```

The *<user provided name>* is a comma-separated list of directories that can include JAR or ZIP files from which static files or JSP files can be accessed. The list can be fully qualified or relative to the application ear directory. The attributes can be specified with identical values. Further, you can specify the same values by different applications.

Attention: Pre-fragment document roots is a new function in WebSphere Application Server Version 8.5.

META-INF/resources directories of fragments under the WEB-INF/Lib directory in the application WAR file

After searching pre-fragment document roots, the web container searches web fragments. A web fragment comprises a JAR file in an application WEB-INF/lib directory. The JAR might include static resources in a META-INF/resources directory that are defined within the JAR file. To prevent the web container from searching META-INF/resources directories, set the `com.ibm.ws.webcontainer.SkipMetaInfResourcesProcessing` web container custom property to `true`. The default value for the custom property is `false`.

```
com.ibm.ws.webcontainer.SkipMetaInfResourcesProcessing = true
```

Attention: META-INF/resources directories of fragments under the WEB-INF/Lib directory in the application WAR file is a new function in WebSphere Application Server Version 8.5.

Extended document roots

Finally, the web container searches any application defined as extended document roots. Extended document roots were available in previous releases and are defined in the `ibm-web-ext.xml` file, which is located in the application WEB-INF directory. Define extended document root for static files or JSP files, as follows:

```
Static files:  
<fileServingAttributes xmi:id="<user provided name>" name="extendedDocumentRoot"  
  value="<user provided value>"/>
```

```
JSP files:  
<jspAttributes xmi:id="<user provided name>" name="extendedDocumentRoot"  
  value="<user provide value>"/>
```

```
com.ibm.ws.webcontainer.SkipMetaInfResourcesProcessing = true
```

The *<user provided name>* is a comma-separated list of directories that can include JAR or ZIP files from which static files or JSP files can be accessed. The list can be fully qualified, or relative to the application EAR directory. You can specify both attributes with identical values. Also, different applications can specify the same values.

Attention: You might set the `com.ibm.ws.webcontainer.ServeWelcomeFileFromExtendedDocumentRoot` custom property to `true` to enable serving static welcome pages from a static file extended document root. The default value for the custom property is `false`.

```
com.ibm.ws.webcontainer.ServeWelcomeFileFromExtendedDocumentRoot = true
```

When the `com.ibm.ws.webcontainer.ServeWelcomeFileFromExtendedDocumentRoot` property is set to `true`, the web container searches in a static file extended document root for a static welcome file to serve for a request comprising a valid partial URL. For example, if a request specifies only the application context, and a welcome file is specified as `index.html`, the property must be set if `index.html` is to be served from a static file extended document.

```
com.ibm.ws.webcontainer.enablepartialurltoextendeddocumentroot = true
```

The default value is **false**.

If this property is set to **true**, the web container includes the contents of a static file extended document root when determining whether an inbound request is for a valid partial URL. For example, if a request specifies a URL that ends with `/<application context>/<text>` and `<text>` does not map to a servlet or static file, the web container considers this URL a valid partial URL only if `<text>` is a valid directory of the application. As a result if directory `<text>` exists only in a static file extended document root, this property must be set for the URI to be considered a valid partial URI.

Important: These properties are not required for static file pre-fragment document roots. Also, when determining a valid partial URL, the web container does not consider JSP pre-fragment and extended document roots.

Packages and directories for generated .java and .class files

By default, the .java files for all JavaServer Pages (JSP) files are generated with the package statement, `package com.ibm._jsp;`. The JSP engine's class loader knows how to load JSP classes when they are all in the same package. The .java files are located in the filesystem within a directory structure mirroring the JSP source directory structure.

If the JSP engine configuration parameter **useFullPackageNames** is set to true, the .java files are generated with the package statement

```
Package _ibmjsp.<directory structure in which the jsp is located>;
```

The usage of full package names enables the configuration of a JSP as a servlet in the `web.xml` file. Refer to the JSP class loading settings topic for more information. The table later in this section gives examples of packages and directory structures for generated .java and .class files.

Table 81. Packages and directory structures for generated .java and .class files. Examples of packages and directory structures for generated .java and .class files.

Directory		File name		Location of .java or .class files in file system
JSP file	default	useFullPackageNames=true	default	useFullPackageNames=true
/myJsp.jsp	com.ibm._jsp	_ibmjsp	/	/_ibmjsp
/jspFiles/jspOne.jsp	com.ibm._jsp	_ibmjsp.jspFiles	/jspFiles	/_ibmjsp/jspFiles
/dir with spaces/jspTwo.jsp	com.ibm._jsp	_ibmjsp.dir_20_with_20_spaces	/dir with spaces	/_ibmjsp/dir_20_with_20_spaces

Generated .java files:

When the JSP engine's **keepgenerated** configuration parameter is set to true, the .java file that is generated for JavaServer Pages (JSP) is retained. The .java file contains information that is useful in debugging.

Dependency information

In the .java file, immediately following the class declaration, an array of dependent files is defined, if the source JSP has any dependencies. There are three types of files that are tracked as dependencies:

1. Files that are statically included in the JSP

2. Tag files that are used by the JSP, but only tag files that are not in Java Archive (JAR) files
3. TLD files that are used by the JSP, but only TLDs that are not in JAR files

This array is always generated, but the JSP engine uses it, in determining whether a JSP needs to be recompiled, only when the trackDependencies parameter is set to true.

In the example below, three JSP fragments, one TLD and one tag file are dependencies of the JSP jsp1.jsp. There are three parts to each array entry:

1. The path to the dependency, relative to the web module's context root. For example: /dir1/frag1.jspf
2. The long value representing the time the file was last modified. For example: 1082407108000
3. The String representation of the long value. For example: Mon Apr 19 16:38:28 EDT 2004

```
public final class _jsp1 extends com.ibm.ws.jsp.runtime.HttpJspBase
    implements com.ibm.ws.jsp.runtime.JspClassInformation {

Version, JSP engine options, and WEB.XML information

The generated .java source contains a comment that lists information about the file which is located at the bottom of the generated file. This information includes:

- The date and time the .java file was generated
- The version, build number and build date of the WebSphere Application Server on which the .java file was generated
- The values of the JSP engine configuration parameters that were in effect when the file was generated
- The values of any <jsp-config> elements in the web.xml file that pertained to the source JSP file.

```
/*
profile_root/installedApps/MyCell/sampleApp.ear/examples.war/WEB-INF/classes/_ibmjsp/_jsp1.java
was generated @ Wed May 03 10:05:56 EDT 2006IBM WebSphere Application Server - ND, 6.1.0.0
Build Number: o0441.04
Build Date: 05/01/06*****
```

The JSP engine configuration parameters were set as follows:

```
classDebugEnabled = [false]

```

JSP batch compilation

As an IBM enhancement to JavaServer Pages (JSP) support, IBM WebSphere Application Server provides a batch JSP compiler that allows JSP page compilation before application deployment. The batch compiler validates the syntax of JSP pages, translates the JSP pages into Java source files, and compiles the Java source files into Java servlet class files. The batch compiler also validates tag files and generates their Java implementation classes.

Batch compilation of JSP pages in a predeployed application simplifies the deployment process and improves the runtime performance of JSP page by eliminating first-request compilations. The batch compiler also operates on enterprise applications that have been deployed into WebSphere Application Server.

The JSP batch compiler works on web modules that support Servlet 2.2 and later. The batch compiler works on JSP pages written to the JSP 2.1 specification or previous specifications back to JSP 1.0. It recognizes a Servlet 2.5 or later deployment descriptor, `web.xml`, and can use any `jsp-config` elements that it may contain. In a Servlet 2.3 (JSP 1.2) or Servlet 2.2 (JSP 1.1) deployment descriptor the batch compiler recognizes and uses any `taglib` elements that the descriptor may contain.

Batch compiling makes the first request for a JSP page much faster because the JSP page is already translated and compiled into a servlet. Batch compiling is also useful as a fast way to resynchronize all of the JSP pages for an application.

The batch compiler supports the generation of class files in both the WebSphere Application Server `temp` directory and a web module's `WEB-INF/classes` directory, depending on the type of batch compiler target. In addition, the batch compiler enables generation of class files into any directory on the filesystem, outside the target application. Generating class files into a web module's `WEB-INF/classes` directory enables the web module to be deployed as a self-contained WAR file, or a WAR inside an EAR.

Also, you can use shared libraries with the JSP batch compiler. When you use the JSP batch compiler, you must either add the JAR to the WAR in the `<WEB-INF>/lib` directory, or add the JAR to the JVM class path to use shared libraries.

 You can use the pre-touch tool for batch compilation, which can compile and load JSP class files into the application server JVM. This tool offers improved performance over the JSP batch compiler on iSeries servers. Refer to the Pre-touch tool for compiling and loading JSP files article for more information.

JSPBatchCompiler command:

The batch compiler validates the syntax of JavaServer Pages, translates the JSP pages into Java source files, and compiles the Java source files into Java Servlet class files. The batch compiler also validates tag files and generates their Java implementation classes. Use this function to batch compile your JSP files and thereby enable faster responses to the initial client requests for the JSP files on your production web server.

The batch compiler can be executed against compressed or expanded enterprise archive (EAR) files and web application archive (WAR) files, as well as enterprise applications and web modules that have been deployed into WebSphere Application Server. When the target is a deployed enterprise application, the server does not need to be running to execute the batch compiler. If the batch compiler is executed while the target server is running, the server is not aware of an updated class file and does not load that class file unless the enterprise application is restarted. When the target is a compressed EAR file or WAR file, the batch compiler must expand it before executing.

Processing of web modules

The batch compiler operates on one web module at a time. If the target is either an EAR file or an installed enterprise application that contains more than one web module, the batch compiler operates on each web module individually. This is done because JSP pages are configured on a web module basis, through the web module's web.xml deployment descriptor file. Within a web module, the batch compiler processes one directory at a time. It validates and translates each JSP page individually, and then invokes the Java compiler for the entire group of generated Java sources files in that directory. If one JSP page fails during the Java compilation phase, the Java compiler might not create class files for most or all of the JSP pages that successfully compiled in that directory.

JSP file extensions

The batch compiler uses four things to determine what file extensions it should process:

1. Standard JSP file extensions
 - *.jsp
 - *.jspx
 - *.jsw
 - *.jsv
2. The url-pattern property of the jsp-property-group elements in the deployment descriptor file in Servlet 2.4 web modules
3. The `jsp.file.extensions` JSP engine configuration parameter (for pre-Servlet 2.4 web modules)
4. The batch compiler configuration parameter `jsp.file.extensions`

The standard extensions are always used by the batch compiler. If the web module contains a Servlet 2.4 deployment descriptor, the batch compiler also processes any url-patterns found within the jsp-config element. If the batch compiler target contains the JSP engine configuration parameter `jsp.file.extensions`, then those extensions are also processed. If the batch compiler configuration parameter `jsp.file.extensions` is present, the extensions given are also processed and will override the JSP engine configuration parameter `jsp.file.extensions`.

It is a good idea to give JSP 'fragments' an extension that is not processed by the batch compiler. Statically-included fragments that do not stand alone generate translation or compilation errors if processed. The JSP 2.0 Specification suggests that you use the extension `.jspxf` for such files.

Batch compiler command

 The `JspBatchCompiler` script for running the batch compiler from the Qshell command line is found in the `app_server_root/bin` directory. An Ant task is also available for executing the batch compiler using Ant. See the topic, [Batch Compiler Ant Task](#) for additional information.

The batch compiler target is the only required parameter. The target is one of `-ear.path`, `-war.path` or `-enterpriseapp.name`.

```
JspBatchCompiler -ear.path | -war.path | -enterpriseapp.name <name>
  [-response.file <filename>]
  [-webmodule.name <name>]
  [-filename <jsp name | directory name>]
  [-recurse <true | false>]
  [-config.root <path>]
  [-cell.name <name>]
  [-cluster.name <name>] [-node.name <name>]
  [-server.name <name>]
  [-profileName <name>]
  [-extractToDir <path>]
  [-compileToDir <path>]
  [-compileToWebInf <true | false>]
  [-compileToWebInf <true | false>]
  [-compileAfterFailure <true | false>]
  [-translate <true | false>]
  [-compile <true | false>]
  [-removeTempDir <true | false>]
  [-forceCompilation <true | false>]
  [-useFullPackageNames <true | false>]
  [-trackDependencies <true | false>]
  [-createDebugClassfiles <true | false>]
  [-keepgenerated <true | false>]
  [-keepGeneratedclassfiles <true | false>]
  [-usePageTagPool <true | false>]
  [-useThreadTagPool <true | false>]
  [-classloader.parentFirst <true | false>]
  [-classloader.singleWarClassLoader <true | false>]
  [-additional.classpath <classpath to additional JAR files and classes>]

  [-verbose <true | false>]
  [-deprecation <true | false>]
  [-javaEncoding <encoding>]
  [-jdkSourceLevel <13 | 14 | 15 | 16 | 17>]
  [-compilerOptions <space-separated list of java compiler options>]
  [-useJikes <true | false>]
  [-jsp.file.extensions <file extensions to process>]
  [-log.level <SEVERE | WARNING | INFO | CONFIG | FINE | FINER | FINEST | OFF>]
```

IBM i

*** See `batchcompiler.properties.default` in `app_server_root/bin` for more information. ***

*** See `JspCBuild.xml` in `app_server_root/bin` for information about the public WebSphere Ant task `JspC`. ***

The batch compiler is aware of three groups of configuration parameters:

1. JSP engine configuration parameters for a web module.
Refer to the JSP engine configuration parameters topic.
2. Batch compiler response file configuration parameters.
These are the parameters that are found in a batch compiler response file. See `-response.file`, below.
3. Batch compiler command line configuration parameters.
These are the parameters entered on the command line when running the batch compiler.

The batch compiler looks at all three groups of configuration parameters in order to determine which value for a parameter is used when compiling JSP pages. When resolving the value for a given parameter, the precedence is:

1. If the parameter is found on the command line, its value is used.
2. If the parameter is not found on the command line, the batch compiler looks for the parameter in a response file named on the command line.

3. If no response file is named, or if the parameter is not found therein, the batch compiler looks for the parameter in the web module's JSP engine configuration parameters.

If a configuration parameter is not found among these three groups, then a default value is used. The default values for the configuration parameters are given below along with the description of the parameters.

With one exception, these parameters are not case sensitive; `-profileName` is case sensitive. If the values specified for these arguments are comprised of two or more words separated by spaces, you must add quotation marks around the values.

The batch compiler does not create, or set the values of, equivalent JSP engine parameters. This means that if a JSP page in a deployed Web module is modified and is recompiled by the JSP engine at run time, the JSP engine's configuration parameters will determine the engine's behavior. For example, if you use the batch compiler to compile a web module and you use the `-useFullPackageNames true` option, the JSP files will be compiled to support that option. But the JSP engine parameter `useFullPackageNames` must also be set to `true` in order for the JSP runtime to be able to load the compiled JSP pages. If JSP pages are modified in a deployed web module, then the engine's parameters should be set to the same values used in batch compilation.

To use the JSP batch compiler, enter one of the following commands on a single line at an operating system command prompt.:

- *ear.path* | *war.path* | *enterpriseapp.name*

Represents the full path to a single compressed or expanded enterprise application archive (EAR) file or web application archive (WAR) file, or the name of the deployed enterprise application that you want to compile. For example:

```
– IBM i JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear
– IBM i JspBatchCompiler -war.path /home/wasuser/wars/examples.war
– IBM i JspBatchCompiler -enterpriseapp.name myEnterpriseApp -webmodule.name my.war
  -filename mydirectory/main.jsp
```

- *response.file*

Specifies the path to a file that contains configuration parameters used by the batch compiler. The *response.file* is used only if it is given on the command line; it is ignored if it is present in a response file.

IBM i The template response file, `batchcompiler.properties.default`, is found in the `app_server_root/properties` directory. Copy this template to create your own response files containing defaults for the parameters in which you are interested. You can configure all the required and optional parameters, except the *response.file* in a response file. For example: `JspBatchCompiler -response.file /home/wasuser/myproject/batchc.props`

Default : null

- *webmodule.name*

Represents the name of the specific web module that you want to batch compile. If this argument is not set, all web modules in the enterprise application are compiled. This parameter is used only when *ear.path* or *enterpriseapp.name* is given. This parameter is useful when JSP pages in a specific web module within a deployed enterprise application need to be regenerated, because all shared library dependencies are picked up.

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -webmodule.name myWebModule.war`

Default: All web modules in an EAR file or enterprise application are compiled if this parameter is not given.

- *filename*

Represents the name of a single JSP file that you want to compile. If this argument is not set, all files in the web module are compiled. Alternatively, if *filename* is set to the name of a directory, only the JSP files in that directory and that directory's child directories are compiled. The name is relative to the context root of the web module.

Example 1: If you want to compile the file, *myTest.jsp*, and it is found in */subdir/myJSPs*, you would enter *-filename /subdir/myJSPs/myTest.jsp*.

Example 2: If you want to compile all JSP files in */subdir/myJSPs* and its child directories, you would enter *-filename subdir/myJSPs*.

Default: All JSP files in the web module are compiled. Entering *-filename /* is equivalent to the default.

- *recurse*

Determines whether subdirectories beneath the target directory are processed. This parameter is used only when the *filename* parameter is given. Set value to *false* to process only the directory named *filename* parameter; and not its subdirectories.

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -filename /subdir1 -recurse false`.

Default: *true*; All directories beneath the target directory are processed.

- *config.root*

Specifies the location of the WebSphere Application Server configuration directory. This parameter is used only when *enterpriseapp.name* is given.

 Default: *profile_root/config*

- *cell.name*

Specifies the name of the cell in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

Default: The default is obtained from the profile script that is used. The symbolic name of this variable is *WAS_CELL*.

- *cluster.name*

Specifies the name of the cluster in which the application is deployed. This parameter provides the batch compiler with access to cluster scoped shared libraries, and is used only when *enterpriseapp.name* is given.

Default: The default is obtained from the profile script that is used. The symbolic name of this variable is *WAS_CLUSTER*.

- *node.name*

Specifies the name of the node in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

Default: The default is obtained from the profile script that is used. The symbolic name of this variable is *WAS_NODE*.

- *server.name*

Represents the name of the server in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

Default: *server1*

- *profileName*

Specifies the name of the profile you want to use. This parameter is used only when the *enterpriseapp.name* or *-ear.path* is given.

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -profileName AppServer-3`

 Default: The default profile is used. This is obtained from the `setupCmdLine` script in the `app_server_root/bin` directory. The symbolic name is *DEFAULT_PROFILE_SCRIPT*.

- *extractToDir*

Specifies the directory into which predeployed enterprise archive (EAR) files and web application archive (WAR) files will be extracted before the batch compiler operates on them. This parameter is ignored when *enterpriseapp.name* is given. The *extractToDir* parameter is used as described in the table below.

 Example: `JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -extractToDir /home/wasuser/mytempdir`.

Use-case: You must extract a compressed archive before it is batch compiled. You can also extract an expanded archive to a new directory as well. In both cases, extraction leaves the original archive untouched, which may be useful while development is underway.

Table 82. *extractToDir*. Default values

	Expanded archive	Compressed archive
<i>extractToDir</i> supplied	The batch compiler extracts the archive to <i>extractToDir</i> before operating on it. If a file or directory of the same name as the archive already exists in the <i>extractToDir</i> , the batch compiler removes the archive completely before extracting that archive. If the batch compiler exits with no errors, it compresses the archive in place in the <i>extractToDir</i> , even if the original EAR file or WAR file was expanded. If errors are encountered during compilation, the EAR file or WAR file is left in the expanded state even if the original EAR file or WAR file was compressed.	
<i>extractToDir</i> not supplied	The batch compiler operates on the EAR file or WAR file in place (does not extract it to another directory) and the archive remains expanded after the batch compiler finishes.	The batch compiler extracts the archive to the directory returned by the JVM property "java.io.tmpdir". The rest of the behavior described above, when <i>extractToDir</i> is supplied, is the same in this case.

The default is *server1*.

- *compileToDir*

Specifies the directory into which JSP pages are translated into Java source files and compiled into class files. This directory can be anywhere on the filesystem, but the batch compiler's default behavior is usually adequate. The batch compiler's behavior when compiling class files is described in the table below

IBM i Example:: `JspBatchCompiler -enterpriseApp.name sampleApp -compileToDir /home/wasuser/myTargetDir`

Use-case: This parameter enables you to generate the Java and class files into a directory outside of the target, which may be useful if you want to compare the newly generated files with their previous versions which remain untouched within the target.

IBM i

Table 83. *compileToDir*. Default values

	ear.path or war.path supplied	enterpriseApp.name supplied
<i>compileToDir</i> not supplied; <i>compileToWebInf</i> not supplied, or is true	The class files are compiled into the web module's WEB-INF/classes directory	The class files are compiled into the web module's WEB-INF/classes directory.
<i>compileToDir</i> not supplied; <i>compileToWebInf</i> is false	The class files are compiled into the web module's WEB-INF/classes directory.	The class files are compiled into the WebSphere Application Server temp directory (usually <i>profile_root/temp</i>).
<i>compileToDir</i> is supplied; <i>compileToWebInf</i> not supplied, or is either true or false	The class files are compiled into the directory indicated by <i>compileToDir</i> .	The class files are compiled into the directory indicated by <i>compileToDir</i> .

- *compileToWebInf*

Specifies whether the target directory for the compiled JSP class files should be the web module's WEB-INF/classes directory. This parameter is used only when *enterpriseApp.name* is given, and it is overridden by *compileToDir* if *compileToDir* is given.

The batch compiler's default behavior is to compile to the web module's WEB-INF/classes directory. The batch compiler's behavior when compiling class files is described in the table above.

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -compileToWebInf false`.

Use-case: Set this parameter to false when *enterpriseApp.name* is supplied and you want the class files to be compiled to the WebSphere Application Server temp directory instead of the web module's WEB-INF/classes directory. Recommendation: if this parameter is set to false, set *forceCompilation* to true if there are any JSP class files in the WEB-INF/classes directory.

Default: true; see the table above.

- *compileAfterFailure*

Specifies whether the JDK JSP batch compiler continues to compile the other JavaServer Pages (JSP) files in the current directory if one or more of the JavaServer Pages (JSP) files in that directory cannot be compiled. Typically when one of the files cannot be compiled, the JSP batch compiler skips all of the remaining JSPs in that directory, and starts to compile the files in the next directory.

If you set this parameter to true, you must also specify the `useJDKCompiler` parameter and set that parameter to true.

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -useJDKCompiler true -compileAfterFailure false`.

Use-case: Set this parameter to true if you want the JSP batch compiler compile the other JavaServer Pages (JSP) files in the current directory even if one or more of the JSP files in that directory cannot be compiled.

Default: false

- *forceCompilation*

Specifies whether the batch compiler is forced to recompile all JSP resources regardless or whether the JSP page is outdated.

 Example: `JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -forceCompilation true`.

Use-case: Especially useful when creating an archive for deployment, to make sure all JSP classes are up to date.

Default: false

- *useFullPackageNames*

Specifies whether the batch compiler generates full package names for JSP classes. The default is to generate all JSP classes in the same package. The JSP engine's class loader knows how to load JSP classes when they are all in the same package. The default has the benefit of generating smaller file-system paths. Full package names have the benefit of enabling the configuration of precompiled JSP class files as servlets in the `web.xml` file without use of the `jsp-file` attribute, resulting in a single class loader (the web application's class loader) being used to load all such JSP classes. Similarly, when the JSP engine's configuration attributes `useFullPackageNames` and `disableJspRuntimeCompilation` are both true, a single class loader is used to load all JSP classes, even if the JSP pages are not configured as servlets in the `web.xml` file.

When `useFullPackageNames` is set to true, the batch compiler generates a file called `generated_web.xml` in the web module's `WEB-INF` directory. This file contains servlet configuration information for each JSP page that is successfully translated and compiled. The information can optionally be copied into the web module's `web.xml` file so that the JSP pages are loaded as servlets by the web container. Note that if a JSP page is configured as a servlet in this way, no reloading of the JSP page is done at run time if the JSP page is modified. This is because the JSP page is treated as a regular servlet and requests for it do not pass through the JSP engine.

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -useFullPackageNames true`

Use-case: Enables JSP classes to be loaded by a single class loader.

Default: false

- *removeTempDir*

Specifies whether the web module's temp directory is removed. The batch compiler by default generates JSP class files into a web module's `WEB-INF/classes` directory. JSP class files are generated into the temp directory at run time if a JSP page is modified and JSP reloading is enabled. By batch compiling all the JSP pages in a web module and also removing the temp directory, disk resources are preserved. You can only use the `removeTempDir` parameter when `-enterpriseApp.name` is given.

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -removeTempDir true`.

Use-case: Free up disk space by clearing out a web application's temp directory.

Default: false

- *translate*
 Specifies whether JSP pages are translated and compiled. Set `translate` to `false` if you do not want JSP pages to be translated and compiled. You must use this option in conjunction with `-removeTempDir` to tell the batch compiler to remove only the `temp` directory and to do no further processing.
 Example: `JspBatchCompiler -enterpriseApp.name sampleApp -translate false -removeTempDir true`.
 Use-case: Free up disk space by clearing out a web application's `temp` directory, without invoking JSP processing.
 Default: `true`
- *compile*
 Specifies whether JSP pages go through the Java compilation phase. Set `compile` to `false` if you do not want JSP pages to go through the Java compilation phase.
 Example: `JspBatchCompiler -enterpriseApp.name sampleApp -compile false`
 Use-case: If you only want JSP pages to be syntax-checked, set `-compile` to `false`. You can set `-keepgenerated` to `true` if you want to see the `.java` files that are generated during the translation phase.
 Default: `true`
- *trackDependencies*
 Specifies whether the batch compiler recompiles a JSP page when any of its dependencies have changed, even if the JSP page itself has not changed. Tracking dependencies incurs a significant runtime performance penalty because the JSP Engine checks the filesystem on every request to a JSP page to see if any of its dependencies have changed. The dependencies tracked by WebSphere Application Server are :
 1. Files statically included in the JSP page
 2. Tag files used by the JSP page (excluding tag files that are in JAR files)
 3. TLD files used by the JSP page (excluding TLD files that are in JAR files)

IBM i Example: `JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -trackDependencies true`.

 Use-case: Useful in a development environment.
 Default: `false`
- *createDebugClassfiles*
 Specifies whether the batch compiler generates class files that contain SMAP information, as per JSR 45, Debugging support for Other Languages.
 Example: `JspBatchCompiler -enterpriseApp.name sampleApp -createDebugClassfiles true`
 Use-case: Use this parameter when you want to be able to debug JSP pages in your JSR 45-compliant IDE.
 Default: `false`
- *keepgenerated*
 Specifies whether the batch compiler saves or erases the generated Java source files created during the translation phase.
 If set to `true`, WebSphere Application Server saves the generated `.java` files used for compilation on your server. By default, this argument is set to `false` and the `.java` files are erased after the class files have compiled.

IBM i Example: `JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -keepgenerated true`

 Use-case: Use this parameter when you want to review the Java code generated by the batch compiler.
 Default: `false`
- *keepGeneratedclassfiles*
 Specifies whether the batch compiler saves or erases the class files generated during the compilation of Java source files.

IBM i Example: `JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -keepGeneratedclassfiles false -keepgenerated false`

Use-case: Set this parameter to false if you only want to see if there are any translation or compilation errors in your JSP pages. If paired with `-keepgenerated false`, this parameter results in all generated files being removed before the batch compiler completes.

Default: true

- *usePageTagPool*

Enables or disables the reuse of custom tag handlers on an individual JSP page basis.

IBM i Example: `JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -usePageTagPool true`

Use-case: Use this parameter to enable JSP-page-based reuse of tag handlers.

Default: false

- *useThreadTagPool*

Enables or disables the reuse of custom tag handlers on a per request thread basis per web module.

IBM i Example: `JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -useThreadTagPool true`

Use-case: Use this parameter to enable web module-based reuse of tag handlers.

Default: false

- *classloader.parentFirst*

Specifies the search order for loading classes by instructing the batch compiler to search the parent class loader prior to application class loader. This parameter is only used when *ear.path* or *enterpriseApp.name* is given.

IBM i Example: `JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -classloader.parentFirst false`

Use-case: Set this parameter to false when your web module contains a JAR file that is also found in the server lib directory, and you want your web module's JAR file to be picked up first.

Default: true

- *classloader.singleWarClassLoader*

Specifies whether to use one class loader per enterprise archive (EAR) file or one class loader per web application archive (WAR) file. Used only when *ear.path* or *enterpriseApp.name* is given.

IBM i Example: `JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -classloader.singleWarClassLoader true`

Use-case: Set this parameter to true when a Web module depends on JAR files and classes in another web module in the same enterprise application.

Default: false; One class loader is created per WAR file with no visibility of classes in other web modules.

- *additional.classpath*

Specifies additional class path entries to be used when parsing and compiling JSP pages. This parameter is used only when *war.path* is given. When *war.path* is the target, WebSphere Shared Libraries are not picked up by the batch compiler. Therefore, if your WAR file relies on, for example, a JAR file that is configured in WebSphere Application Server as a shared library, then use this option to point to that JAR file. In addition, if you give *war.path* and also use the *-extractToDir* parameter, then any JAR files that are in the WAR file's manifest class-path is not added to the class path (since the WAR file has now been extracted by itself outside the EAR file in which it resides). Use *-additional.classpath* in this case to point to the necessary JAR files. Add the full path to needed resources, separated by your system-dependent path separator.

IBM i Example: `JspBatchCompiler -war.path /home/wasuser/myproject/examples.war -additional.classpath /home/wasuser/myJars/someJar.jar:/home/wasuser/myClasses`

Use-case: Use this parameter to add to the class path JAR files and classes outside of your WAR file. At run time, these same JAR files and classes have to be made available through the standard WebSphere Application Server configuration mechanisms.

Default: null

- *verbose*

Specifies whether the batch compiler should generate verbose output while compiling the generated sources.

IBM i Example: `JspBatchCompiler -war.path /home/wasuser/myproject/examples.war -verbose true`

Use-case: Set this parameter to true when you want to see Java compiler class loading and other messages.

Default: false

- *deprecation*

Indicates the compiler should generate deprecation warnings while compiling the generated sources.

IBM i Example: `JspBatchCompiler -war.path /home/wasuser/myproject/examples.war -deprecation true`

Use-case: Set this parameter to true when you want to see Java compiler deprecation messages.

Default: false

- *javaEncoding*

Specifies the encoding that will be used when the .java file is generated, and when it is compiled by the Java compiler. When `-javaEncoding` is set, that encoding is passed to the java compiler via the `-encoding` argument. Note that encoding is not supported by Jikes.

IBM i Example: `JspBatchCompiler -war.path/home/wasuser/myproject/examples.war -javaEncoding Shift-JIS`

Use-case: Set this parameter when the page encoding of your JSP pages is not UTF-8 compatible.

Default value: UTF-8.

- *jdkSourceLevel*

This JSP engine parameter was introduced in WebSphere Application Server version 6.1 to support JDK 5. Use this parameter instead of the `compileWithAssert` parameter, although `compile WithAssert` still works in version 6.1.

The default value for this parameter is 16. This parameter requires regeneration of Java source. The following are `jdkSourceLevel` parameter values:

- 13 - This value will disable all new language features of JDK 1.4, JDK 5.0, JDK 6.0, and JDK 7.0.
- 14 - This value will enable the use of the assertion facility and will disable all new language features of JDK 5.0, JDK 6.0, and JDK 7.0.
- 15 - This value will enable the use of the assertion facility and will disable all new language features of JDK 6.0 and JDK 7.0.
- 16 - This value will enable the use of the assertion facility and will disable all new language features of JDK 7.0.
- 17 - This value will enable the use of the new features of JDK 7.0.

Example: `JspBatchCompiler -war.path c:\myproject\examples.war -jdkSourceLevel 14`

Use-case: Set this parameter when you want to enable or disable the language features of JDK 1.4 , JDK 5.0, JDK 6.0, and JDK 7.0

Default value: 16

- *compilerOptions*

Specifies a list of strings to be passed on the Java compiler command. This is a space-separated list of the form "arg1 arg2 argn".

IBM i Example: `JspBatchCompiler -war.path /home/wasuser/myproject/examples.war -compilerOptions "-bootclasspath <path>"`

Use-case: Use this parameter if you need Java compiler arguments other than verbose, deprecation and Assert facility support.

Default: null

- *useJikes*

Specifies whether Jikes should be used for compiling Java sources. NOTE: Jikes is not shipped with WebSphere Application Server.

 Example: `JspBatchCompiler -ear.path /home/wasuser/myproject/sampleApp.ear -useJikes true`

Use-case: Set this parameter to true in order for the batch compiler to use Jikes as the Java compiler.

Default value: false

- *jsp.file.extensions*

Specifies the file extensions to be processed by the batch compiler. This is a semicolon- or colon-separated list of the form “*.ext1;*.ext2:*.extn”. Note that this parameter is not necessary for Servlet 2.4 web applications because the url-pattern property of the jsp-property-group elements in the deployment descriptor can be used to identify extensions that should be treated as JSP pages.

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -jsp.file.extensions *jspz;*.jspx`

Use-case: Use this parameter to add additional extensions to the be processed by the batch compiler.

Default: null. See section, “JSP file extensions”, in this topic for additional information.

- *log.level*

Specifies the level of logging that is directed to the console during batch compilation. Values are SEVERE | WARNING | INFO | CONFIG | FINE | FINER | FINEST | OFF

Example: `JspBatchCompiler -enterpriseApp.name sampleApp -log.level FINEST`

Use-case: Set this parameter higher or lower to control logging output. FINEST generates the most output useful for debugging.

Default: CONFIG

Batch compiler ant task:

The ant task **JspC** exposes all the batch compiler configuration options. It runs the batch compiler under the covers. It is backward compatible with the WebSphere Application Server 5.x version of the **JspC** ant task. The following table lists all of the ant task attributes and their batch compiler equivalents.

Table 84. Ant task attributes and their batch compiler equivalents. JspC attributes and the equivalent batch compiler parameters.

JspC attribute	Equivalent batch compiler parameter
earPath	-ear.path
warPath	-war.path
src	-war.path
Same as warPath, for backward compatibility	
enterpriseAppName	-enterpriseapp.name
responseFile	-response.file
webmoduleName	-webmodule.name
fileName	-filename -config.root
configRoot	-config.root
cellName	-cell.name
nodeName	-node.name
serverName	-server.name
profileName	-profileName
extractToDir	-extractToDir

Table 84. Ant task attributes and their batch compiler equivalents (continued). JspC attributes and the equivalent batch compiler parameters.

JspC attribute	Equivalent batch compiler parameter
compileToDir	-compileToDir -compileToDir
same as compileToDir, for backward compatibility	
compileToWebInf	-compileToWebInf
compilerOptions	-compilerOptions
recurse	-recurse
removeTempDir	-removeTempDir
translate	-translate
compile	-compile
forceCompilation	-forceCompilation
useFullPackageNames	-useFullPackageNames
trackDependencies	-trackDependencies
createDebugClassfiles	-createDebugClassfiles
keepgenerated	-keepgenerated
keepGeneratedclassfiles	-keepGeneratedclassfiles
usePageTagPool	-usePageTagPool
useThreadTagPool	-useThreadTagPool
classloaderParentFirst	-classloader.parentFirst
classloaderSingleWarClassLoader	-classloader.singleWarClassLoader
additionalClasspath	-additional.classpath
classpath	-additional.classpath
same as additionalClasspath, for backward compatibility	
verbose	-verbose
deprecation	-deprecation
javaEncoding	-javaEncoding
compileWithAssert	-compileWithAssert
useJikes	-useJikes
jspFileExtensions	-jsp.file.extensions
logLevel	-log.level
wasHome	none
Classpathref	none
jdkSourceLevel	-jdkSourceLevel

Below is an example of a build script with multiple targets, each with different attributes. The following commands are used to launch the script:

On Windows:

```
ws_ant -Dwas.home=%WAS_HOME% -Dear.path=%EAR_PATH% -Dextract.dir=%EXTRACT_DIR%
ws_ant jspc2 -Dwas.home=%WAS_HOME% -Dapp.name=%APP_NAME% -Dwebmodule.name=%MOD_NAME%
ws_ant jspc3 -Dwas.home=%WAS_HOME% -Dapp.name=%APP_NAME% -Dwebmodule.name=%MOD_NAME% -Ddir.name=%DIR_NAME%
```

On UNIX or i5/OS:

```
ws_ant -Dwas.home=$WAS_HOME -Dear.path=$EAR_PATH -Dextract.dir=$EXTRACT_DIR
ws_ant jspc2 -Dwas.home=$WAS_HOME -Dapp.name=$APP_NAME -Dwebmodule.name=$MOD_NAME
ws_ant jspc3 -Dwas.home=$WAS_HOME -Dapp.name=$APP_NAME -Dwebmodule.name=$MOD_NAME -Ddir.name=$DIR_NAME
```

Example build.xml file using the JspC task

```
<project name="JSP Precompile" default="jspc1" basedir=". ">
  <taskdef name="wsjspc" classname="com.ibm.websphere.ant.tasks.JspC"/>
  <target name="jspc1" description="example using a path to an EAR, and extracting the EAR to a directory">
    <wsjspc wasHome="${was.home}">
```

```

        earpath="${ear.path}"
        forcecompilation="true"
        extractToDir="${extract.dir}"
        useThreadTagPool="true"
        keepgenerated="true"
    />
</target>
<target name="jspc2" description="example using an enterprise app and webmodule">
  <wsjspc wasHome="${was.home}"
    enterpriseAppName="${app.name}"
    webmoduleName="${webmodule.name}"
    removeTempDir="true"
    forcecompilation="true"
    keepgenerated="true"
  />
</target>
<target name="jspc3" description="example using an enterprise app, webmodule and specific directory">
  <wsjspc wasHome="${was.home}"
    enterpriseAppName="${app.name}"
    webmoduleName="${webmodule.name}"
    fileName="${dir.name}"
    recurse="false"
    forcecompilation="true"
    keepgenerated="true"
  />
</target>
</project>

```

Pre-touch tool for compiling and loading JSP files:

When enabled, the pre-touch mechanism causes all JavaServer Pages (JSP) files to be compiled within the web module for which they are configured. You can also configure some or all JSP files to be class loaded and JIT-compiled.

To enable the pre-touch mechanism, use Rational Application Developer to specify the following JSP attributes, which are Assembly Property Extensions for your web module:

- **prepareJSPs (Required)**

When this attribute is present, all JSP files are compiled at application server startup. This activity runs in a separate thread, allowing the application server to finish other startup actions in parallel. The numeric attribute value represents the minimum size in kilobytes that a JSP file must be in order to also be class loaded and JIT-compiled. The default is 0, which causes all JSP files to be class loaded and JIT-compiled.

Note: JSP file compilation is different from JIT compilation. JSP compilation generates bytecodes, whereas JIT translates the bytecodes into machine code at run time.

- **prepareJSPAttribute (Optional)**

The pre-touch mechanism compiles and JIT-compiles JSP files by directly invoking the JSP service method, thus making the JSP file susceptible to incurring exceptions because it is called out of context. Such exceptions are avoided by immediately checking the value of this attribute, causing a quick exit from the service method when the JSP was prepared by this tool. This attribute value is added as a request parameter and is composed of alphanumeric characters that your JSP files do not expect to use during normal initiation.

- **prepareJSPThreadCount (Optional)**

Set this numeric attribute to the number of threads that you would like this mechanism to start up to compile your JSP files. Since a thread makes use of just one processor, multi-processor systems may better utilize this pre-touch mechanism by specifying a value greater than 1. The default setting for this attribute is 1, representing the number of threads that are created to perform pre-touch processing for this web module.

- **prepareJSPClassload (Optional)**

Set this attribute to either a whole number or the word *changed*. By entering *changed*, only those JSP files that have been updated or not previously touched, for example, those JSP files that need to be converted from a .jsp file to a .java file, are class loaded. By entering a numerical value, for example, 1000, the pre-touch tool starts class loading at the 1000th JSP that it processes and all subsequent JSP files. This is convenient in the event that the application server is stopped when starting the pre-touch tool. You can then check the server logs to see how many JSP files have been processed and update the prepareJSPClassload value accordingly to avoid duplicating work. If a JSP file is not class loaded, it cannot be JIT compiled. As a result, if a JSP file does not satisfy the requirements of the prepareJSPClassload attribute, but satisfies the requirements of the prepareJSPs attribute, the JSP file is compiled if it has been updated, but is not class loaded or JIT compiled.

Batch compiler class path:

The batch compiler builds its class path as shown in the table later in this topic. When the batch compiler target is a web application archive (WAR) file and war.path is supplied, the configuration additional.classpath parameter is used to give extra class path information.

Table 85. Batch compiler. Batch compiler target.

Location added to class path	enterpriseapp.name	ear.path	war.path
WebSphere Application Server JAR files and classes	yes	yes	yes
JAR files listed in manifest class path for a web module	yes	yes	yes, when the target WAR is inside an EAR and -extractToDir is not used; otherwise, no.
Shared libraries	yes	no	no
Web module JAR files and classes	yes	yes	yes
additional.classpath parameter to batch compiler	no	no	yes

Global tag libraries (deprecated)

JavaServer Pages (JSP) tag libraries contain classes for common tasks such as processing forms and accessing databases from JSP files.

Tag libraries encapsulate, as simple tags, core functionality common to many web applications. The Java Standard Tag Library (JSTL) supports common programming tasks such as iteration and conditional processing, and provides tags for:

- manipulating XML documents
- supporting internationalization
- using Structured Query Language (SQL)

Tag libraries also introduce the concept of an expression language to simplify page development, and include a version of the JSP expression language.

A tag library has two parts - a Tag Library Descriptor (TLD) file and a Java archive (JAR) file.

tsx:dbconnect tag JavaServer Pages syntax (deprecated):

Use the <tsx:dbconnect> tag to specify information needed to make a connection to a database through Java DataBase Connectivity (JDBC) or Open Database Connectivity (ODBC) technology.

Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The `<tsx:dbconnect>` syntax does not establish the connection. Use the `<tsx:dbquery>` and `<tsx:dbmodify>` syntax instead to reference a `<tsx:dbconnect>` tag in the same JavaServer Pages (JSP) file to establish the connection.

When the JSP file compiles into a servlet, the Java processor adds the Java coding for the `<tsx:dbconnect>` syntax to the servlet `service()` method, which means a new database connection is created for each request for the JSP file.

This section describes the syntax of the `<tsx:dbconnect>` tag.

```
<tsx:dbconnect id="connection_id"
  userid="db_user" passwd="user_password"
  url="jdbc:subprotocol:database"
  driver="database_driver_name"
  jndiname="JNDI_context/logical_name">
</tsx:dbconnect>
```

where:

- **id**

Represents a required identifier. The scope is the JSP file. This identifier is referenced by the connection attribute of a `<tsx:dbquery>` tag.

- **userid**

Represents an optional attribute that specifies a valid user ID for the database that you want to access. Specify this attribute to add the attribute and its value to the request object.

Although the `userid` attribute is optional, you must provide the user ID. See `<tsx:userid>` and `<tsx:passwd>` for an alternative to hard coding this information in the JSP file.

- **passwd**

Represents an optional attribute that specifies the user password for the `userid` attribute. (This attribute is not optional if the `userid` attribute is specified.) If you specify this attribute, the attribute and its value are added to the request object.

Although the `passwd` attribute is optional, you must provide the password. See `<tsx:userid>` and `<tsx:passwd>` for an alternative to hard coding this attribute in the JSP file.

- **url and driver**

Represents a required attribute if you want to establish a database connection. You must provide the URL and driver.

The application server supports connection to JDBC databases and ODBC databases.

- For a JDBC database, the URL consists of the following colon-separated elements: `jdbc`, the subprotocol name, and the name of the database to access. An example for a connection to the Sample database included with IBM DB2 is:

```
url="jdbc:db2:sample"
driver="com.ibm.db2.jdbc.app.DB2Driver"
```

- For an ODBC database, use the Sun JDBC-to-ODBC bridge driver included in their Java2 Software Developers Kit (SDK) or another vendor's ODBC driver.

The `url` attribute specifies the location of the database. The `driver` attribute specifies the name of the driver to use in establishing the database connection.

If the database is an ODBC database, you can use an ODBC driver or the Sun JDBC-to-ODBC bridge. If you want to use an ODBC driver, refer to the driver documentation for instructions on specifying the database location with the `url` attribute and the driver name.

If you use the bridge, the `url` syntax is `jdbc:odbc:database`. An example follows:

```
url="jdbc:odbc:autos"
driver="sun.jdbc.odbc.JdbcOdbcDriver"
```

Note: To enable the application server to access the ODBC database, use the ODBC Data Source Administrator to add the ODBC data source to the System DSN configuration. To access the ODBC Administrator, click the ODBC icon on the Windows NT Control Panel.

- **jndiname**

Represents an optional attribute that identifies a valid context in the application server Java Naming and Directory Interface (JNDI) naming context and the logical name of the data source in that context. The web administrator configures the context using an administrative client such as the WebSphere Administrative Console.

If you specify the `jdiname` attribute, the JSP processor ignores the `driver` and `url` attributes on the `<tsx:dbconnect>` tag.

An empty element (such as `<url></url>`) is valid.

dbquery tag JavaServer Pages syntax (deprecated):

Use the `<tsx:dbquery>` tag to establish a connection to a database, submit database queries, and return the results set.

Support for `tsx` tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the `tsx` tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The `<tsx:dbquery>` tag does the following:

1. References a `<tsx:dbconnect>` tag in the same JavaServer Pages (JSP) file and uses the information the tag provides to determine the database URL and driver. You can also obtain the user ID and password from the `<tsx:dbconnect>` tag if those values are provided in the `<tsx:dbconnect>` tag.
2. Establishes a new connection
3. Retrieves and caches data in the results object.
4. Closes the connection and releases the connection resource.

This section describes the syntax of the `<tsx:dbquery>` tag.

```
<%-- SELECT commands and (optional) JSP syntax can be placed within the tsx:dbquery. --%>
<%-- Any other syntax, including HTML comments, are not valid. --%>
<tsx:dbquery id="query_id" connection="connection_id" limit="value" >
</tsx:dbquery>
```

where:

- **id**

Represents the identifier of this query. The scope is the JSP file. Use `id` to reference the query. For example, from the `<tsx:getProperty>` tag, use `id` to display the query results.

The `id` is a `tsx` reference to the bean and can be used to retrieve the bean from the page context. For example, if `id` is named `mySingleDBBean`, instead of using:

```
– if (mySingleDBBean.getValue("UISEAM",0).startsWith("N"))
```

use:

```
– com.ibm.ws.webcontainer.jsp.tsx.db.QueryResults bean =
  (com.ibm.ws.webcontainer.jsp.tsx.db.QueryResults)pageContext. findAttribute("mySingleDBBean"); if
  (bean.getValue("UISEAM",0).startsWith("N")). . .
```

The bean properties are dynamic and the property names are the names of the columns in the results set. If you want different column names, use the SQL keyword for specifying an alias on the `SELECT` command. In the following example, the database table contains columns named `FNAME` and `LNAME`, but the `SELECT` statement uses the `AS` keyword to map those column names to `FirstName` and `LastName` in the results set:

```
Select FNAME, LNAME AS FirstName, LastName from Employee where FNAME='Jim'
```

- **connection**

Represents the identifier of a `<tsx:dbconnect>` tag in this JSP file. The `<tsx:dbconnect>` tag provides the database URL, driver name, and optionally, the user ID and password for the connection.

- **limit**

Represents an optional attribute that constrains the maximum number of records returned by a query. If this attribute is not specified, no limit is used. In such a case, the effective limit is determined by the number of records and the system caching capability.

- **SELECT command and JSP syntax**

Represents the only valid SQL command, SELECT. The `<tsx:dbquery>` tag must return a results set. Refer to your database documentation for information about the SELECT command. See other articles in this section for a description of JSP syntax for variable data and inline Java code.

dbmodify tag JavaServer Pages syntax (deprecated):

The `<tsx:dbmodify>` tag establishes a connection to a database and then adds records to a database table.

Support for `tsx` tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the `tsx` tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The `<tsx:dbmodify>` tag does the following:

1. References a `<tsx:dbconnect>` tag in the same JavaServer Pages (JSP) file and uses the information provided by that tag to determine the database URL and driver.
Note: You can also obtain the user ID and password from the `<tsx:dbconnect>` tag if those values are provided in the `<tsx:dbconnect>` tag.
2. Establishes a new connection.
3. Updates a table in the database.
4. Closes the connection and releases the connection resource.

This section describes the syntax of the `<tsx:dbmodify>` tag.

```
<%-- Any valid database update commands can be placed within the DBMODIFY tag. -->
<%-- Any other syntax, including HTML comments, are not valid. -->
<tsx:dbmodify connection="connection_id">
</tsx:dbmodify>
```

where:

- **connection**
Represents the identifier of a `<tsx:dbconnect>` tag in this JSP file. The `<tsx:dbconnect>` tag provides the database URL, driver name, and (optionally) the user ID and password for the connection.
- **Database commands**
Represents valid database commands. Refer to your database documentation for details

In the following example, a new employee record is added to a database. The values of the fields are based on user input from this JavaServer Pages (JSP) file and referenced in the database commands using the `<tsx:getProperty>` tag.

```
<tsx:dbmodify connection="conn" >
insert into EMPLOYEE
  (EMPNO,FIRSTNME,MIDINIT,LASTNAME,WORKDEPT,EDLEVEL)
values
('<tsx:getProperty name="request" property=request.getParameter("EMPNO") />',
'<tsx:getProperty name="request" property=request.getParameter("FIRSTNME") />',
'<tsx:getProperty name="request" property=request.getParameter("MIDINIT") />',
'<tsx:getProperty name="request" property=request.getParameter("LASTNAME") />',
'<tsx:getProperty name="request" property=request.getParameter("WORKDEPT") />',
'<tsx:getProperty name="request" property=request.getParameter("EDLEVEL") />')
</tsx:dbmodify>
```

tsx:getProperty tag JavaServer Pages syntax and examples (deprecated):

The `<tsx:getProperty>` tag gets the value of a bean to display in a JavaServer Pages (JSP) file.

Note: Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

This IBM extension of the Sun JSP `<jsp:getProperty>` tag implements all of the `<jsp:getProperty>` function and adds the ability to introspect a database bean created using the IBM extension `<tsx:dbquery>` or `<tsx:dbmodify>`.

Note: You cannot assign the value from this tag to a variable. The value, generated as output from this tag, displays in the browser window.

This section describes the syntax of the `<tsx:getProperty>` tag:

```
<tsx:getProperty name="bean_name"
  property="property_name" />
```

where:

- **name**

Represents the name of the bean declared by the `id` attribute of a `<tsx:dbquery>` syntax within the JSP file. Refer to the `<tsx:dbquery>` article for an explanation. The value of this attribute is case-sensitive.

- **property**

Represents the property of the bean to access for substitution. The value of the attribute is case-sensitive and is the locale-independent name of the property.

Tag example:

```
<tsx:getProperty name="userProfile" property="username" />
```

tsx:userid and tsx:passwd tag JavaServer Pages syntax (deprecated):

With the `<tsx:userid>` and `<tsx:passwd>` tags, you do not have to hard code a user ID and password in the `<tsx:dbconnect>` tag.

Note: Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

Use the `<tsx:userid>` and `<tsx:passwd>` tags to accept user input for the values and then add that data to the request object. You can access the request object with a JavaServer Pages (JSP) file, such as the `JSPEmployee.jsp` example that requests the database connection.

You must use `<tsx:userid>` and `<tsx:passwd>` tags within a `<tsx:dbconnect>` tag.

This section describes the syntax of the `<tsx:userid>` and `<tsx:passwd>` tags.

```
<tsx:dbconnect id="connection_id"
  <font color="red"><userid></font>
  <tsx:getProperty name="request" property=request.getParameter("userid") />
  <font color="red"></userid></font>
  <font color="red"><passwd></font>
  <tsx:getProperty name="request" property=request.getParameter("passwd") />
  <font color="red"></passwd></font>
  url="protocol:database_name:database_table"
  driver="JDBC_driver_name">
</tsx:dbconnect>
```

where:

- `<tsx:getProperty>`

Represents the syntax as a mechanism for embedding variable data.

- **userid**
Represents a reference to the request parameter that contains the user ID. You must add the parameter to the request object that passes to this JSP file. You can set the attribute and its value in the request object, using an HTML form or a URL query string to pass the user-specified request parameters.
- **passwd**
Represents a reference to the request parameter that contains the password. Add the parameter to the request object that passes to this JSP file. You can set the attribute and its value in the request object, using an HTML form or a URL query string, to pass user-specified values.

tsx:repeat tag JavaServer Pages syntax (deprecated):

The `<tsx:repeat>` tag repeats a block of HTML tagging.

Support for `tsx` tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the `tsx` tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

Use the `<tsx:repeat>` syntax to iterate over a database query results set. The `<tsx:repeat>` syntax iterates from the start value to the end value until one of the following conditions is met:

- The end value is reached.
- An exception is thrown.

If an exception of the types **ArrayIndexOutOfBoundsException** or **NoSuchElementException** is created before a block completes, output is written only for the iterations up to and not including the iteration during which the exception was created. All other exceptions results in no output being written for that tag instance.

This section describes the syntax of the `<tsx:repeat>` tag:

```
<tsx:repeat index="name" start="starting_index" end="ending_index">
</tsx:repeat>
```

where:

- **index**
Represents an optional name used to identify the index of this repeat block. The scope of the index is NESTED. Its type must be integer.
- **start**
Represents an optional starting index value for this repeat block. The default is 0.
- **end**
Represents an optional ending index value for this repeat block. The maximum value is 2,147,483,647. If the value of the end attribute is less than the value of the start attribute, the end attribute is ignored.

Combining `tsx:repeat` and `tsx:getProperty` JavaServer Pages tags (deprecated)

Support for `tsx` tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the `tsx` tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The following code snippet shows you how to code these tags:

```
<tsx:repeat>
<tr>
  <td><tsx:getProperty name="empqs" property="EMPNO" />
  <tsx:getProperty name="empqs" property="FIRSTNAME" />
  <tsx:getProperty name="empqs" property="WORKDEPT" />
```

```

        <tsx:getProperty name="empqs" property="EDLEVEL" />
    </td>
</tr>
</tsx:repeat>

```

Example: Using `tsx:repeat` JavaServer Pages tag to iterate over a results set (deprecated):

The `<tsx:repeat>` tag iterates over a results set. The results set is contained within a bean. The bean can be a static bean, for example, a bean created by using the IBM WebSphere Studio database wizard, or a dynamically generated bean, for example, a bean generated by the `<tsx:dbquery>` syntax.

Note: Support for `tsx` tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the `tsx` tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The following table is a graphic representation of the contents of a bean called, *myBean*:

Table 86. Graphic representation of *myBean*.. *myBean* contents.

Column	col1	col2	col3
row0	friends	Romans	countrymen
row1	bacon	lettuce	tomato
row2	May	June	July

Some observations about the bean:

- The column names in the database table become the property names of the bean. The `<tsx:dbquery>` section describes a technique for mapping the column names to different property names.
- The bean properties are indexed. For example, `myBean.get(Col1(row2))` returns May.
- The query results are in the rows. The `<tsx:repeat>` tag iterates over the rows, beginning at the start row.

The following table compares using the `<tsx:repeat>` tag to iterate over a static bean, versus a dynamically generated bean:

Table 87. Static Bean and <tsx:repeat> Bean example. Use this table to compare the two beans.

Static Bean Example	<tsx:repeat> Bean Example
<pre>myBean.class // Code to get a connection // Code to get the data Select * from myTable; // Code to close the connection JSP file <tsx:repeat index=abc> <tsx:getProperty name="myBean" property="coll(abc)" /> </tsx:repeat></pre> <p>Note:</p> <ul style="list-style-type: none"> • The bean (myBean.class) is a static bean. • The method to access the bean properties is myBean.get(<i>property(index)</i>). • You can omit the property index, in which case the index of the enclosing <tsx:repeat> tag is used. You can also omit the index on the <tsx:repeat> tag. • The <tsx:repeat> tag iterates over the bean properties row by row, beginning with the start row. 	<pre>JSP file <tsx:dbconnect id="conn" userid="alice"passwd="test" url="jdbc:db2:sample" driver="COM.ibm.db2.jdbc.app.DB2Driver"> </tsx:dbconnect > <tsx:dbquery id="dynamic" connection="conn" > Select * from myTable; </tsx:dbquery> <tsx:repeat index=abc> <tsx:getProperty name="dynamic" property="coll(abc)" /> </tsx:repeat></pre> <p>Note:</p> <ul style="list-style-type: none"> • The bean (dynamic) is generated by the <tsx:dbquery> tag and does not exist until the syntax executes. • The method to access the bean properties is dynamic.getValue(<i>property, index</i>). • You can omit the property index, in which case the index of the enclosing <tsx:repeat> tag is used. You can also omit the index on the <tsx:repeat> tag. • The <tsx:repeat> tag syntax iterates over the bean properties row by row, beginning with the start row.

Implicit and explicit indexing

Examples 1, 2, and 3 show how to use the <tsx:repeat> tag. The examples produce the same output if all indexed properties have 300 or fewer elements. If there are more than 300 elements, Examples 1 and 2 display all elements, while Example 3 shows only the first 300 elements.

Example 1 shows *implicit indexing* with the default start and default end index. The bean with the smallest number of indexed properties restricts the number of times the loop repeats.

```
<table>
<tsx:repeat>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="city" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="address" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="telephone" />
  </tr></td>
</tsx:repeat>
</table>
```

Example 2 shows indexing, starting index, and ending index:

```
<table>
<tsx:repeat index=myIndex start=0 end=2147483647>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=city(myIndex) />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=address(myIndex) />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=telephone(myIndex) />
  </tr></td>
</tsx:repeat>
</table>
```

Example 3 shows *explicit indexing* and ending index with implicit starting index. Although the index attribute is specified, you can still implicitly index the indexed property city because the (myIndex) tag is not required.

```
<table>
<tsx:repeat index=myIndex end=299>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="city" /t>
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="address(myIndex)" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="telephone(myIndex)" />
  </tr></td>
</tsx:repeat>
</table>
```

Nesting <tsx:repeat> blocks

You can nest <tsx:repeat> blocks. Each block is separately indexed. This capability is useful for interleaving properties on two beans, or properties that have subproperties. In the example, two <tsx:repeat> blocks are nested to display the list of songs on each compact disc in the user's shopping cart.

```
<tsx:repeat index=cdindex>
  <h1><tsx:getProperty name="shoppingCart" property=cds.title /></h1>
  <table>
  <tsx:repeat>
    <tr><td><tsx:getProperty name="shoppingCart" property=cds(cdindex).playlist />
    </td></tr>
  </tsx:repeat>
  </table>
</tsx:repeat>
```

Developing JSF files

Learn about JSF files.

JavaServer Faces

JavaServer Faces (JSF) is a user interface framework or application programming interface (API) that eases the development of Java-based web applications.

WebSphere Application Server supports JavaServer Faces 2.0 at a runtime level. The JSF runtime also:

- Makes it easy to construct a user interface from a set of reusable user interface components
- Simplifies migration of application data to and from the user interface
- Helps manage user interface state across server requests
- Provides a simple model for wiring client-generated events to server-side application code
- Supports custom user interface components to be easily build and reused

Both the Sun Reference Implementation and Apache MyFaces implementation are shipped with the product.

The Apache MyFaces JSF Implementation provides the foundation of the code used for the JSF support in WebSphere Application Server. The version of the JSF runtime provided by the Application Server resides in the normal runtime library location and is available to all web applications that use JSF APIs. Loading the JSF servlet works in the same manner as if the run time was packaged with the web application. The bundled version includes enhancements for better integration with the built-in annotation scanning and other runtime components of WebSphere Application Server.

The specification-related classes (javax.faces.*) for JSF and the IBM modified version of the Apache MyFaces JSF Implementation and the JSF Sun reference implementation are packaged in the Application Server run time.

Typically, web applications that use this API/Framework embed the JSF API and implementation Java archive (JAR) files within their web application archive (WAR) file. This practice is not required when these web applications are deployed and run within WebSphere Application Server. Only the removal of these JAR files along with any JSTL JAR files from the WAR file is required. However, because JavaServer Faces 2.0 is a part of the Java Platform, Enterprise Edition (Java EE) platform, a web application does not need to bundle a JavaServer Faces implementation when it runs on a web container that is Java EE technology compliant. If a JavaServer Faces implementation is bundled with a web application, it is ignored as the JavaServer Faces implementation provided by the platform always takes precedence.

The JSF run time for WebSphere Application Server does not support the use of a single class loader for the entire application. This support is not available when the application contains multiple web modules and one of those modules is a JSF module. A single class loader for the entire application is not supported because the FacesConfig initialization requires a single class loader for each JSF module to perform the initialization. Therefore, you must use multiple class loaders when the application contains multiple web modules and at least one JSF module.

For using different implementations of JSF, the WebSphere Application Server JSF engine determines if the SUN RI or Apache MyFaces is used from the application server run time. After the JSF engine determines the implementation that is used, the correct listener class is registered with the web container. You do not need to add the `com.sun.faces.ConfigureListener` or the `org.apache.myfaces.StartupConfigureListener` to the `web.xml` file.

If you want to use a third party JSF implementation that is not shipped with the product, leave the configuration set to MyFaces, add the third party listener to the `web.xml` file that is required and add the third party implementation JAR files to the web module as an isolated shared library. Using an isolated shared library, the web application version of the JSF or JSTL classes load before the Application Server.

JavaServer Faces widget library (JWL)

JavaServer Faces widget library (JWL) is an IBM JSF-based web widget library that integrates widgets from a number of sources. The IBM JSF-based web widget library is deprecated, however, you can obtain the latest version from Rational Application Developer version 6 to work with JSF 1.2.

JWL includes the JSF components from Rational Application Developer except for the base JSF components, which are included in the Application Server run time. This includes the IBM extended JSF components and the extended FacesClient Component. JWL also extends JSF with client-side features for rich browser-based experiences in the form of the FacesClient Component.

Important: JWL is not supported in pages using the JSF 2.0 Facelets format.

Note: You must update the JavaServer Faces widget library (JWL) libraries in JavaServer Faces Web projects that are developed using Rational® Application Developer, Version 7.x with the latest updates from Rational Application Developer before deploying WebSphere® Application Server. Update Rational Application Developer with the latest updates, and update the JWL libraries in the `WEB_PROJECT/WEB-INF/lib` folder.

JWL Java archive files

JWL is packaged into two Java archive (JAR) files, `odc-jsf.jar` and `jsf-ibm.jar`, which are located in the `${WAS_HOME}\optionalLibraries\IBM\jwl\2.0` directory.

To include JWL in your application, you can use the JWL shared library named `JWLLib`, which is created at installation time. To assign the library to an application, see the topic, [Using installed optional packages](#).

Configuring Portlet Bridge for JavaServer Faces

Use this task to configure IBM Portlet Bridge for JavaServer Faces (JSF) 2.0.

About this task

Portlet Bridge for JavaServer Faces is available as Version 8.0.0.2.

Procedure

1. Open the portlet.xml file and modify the portlet class for JSF 2.0 portlet bridge, as follows:

```
<portlet-class>com.ibm.faces20.portlet.FacesPortlet</portlet-class>
<init-param>
  <name>com.ibm.faces.portlet.page.view</name>
  <value>/TestProjectView.xhtml</value>
</init-param>
```

2. Open the faces-config.xml file and add the JSF 2.0 portlet bridge variable resolver, view handler, and resource handler entry

```
<application>
  <variable-resolver>com.ibm.faces20.portlet.PortletVariableResolver</variable-resolver>
  <view-handler>com.ibm.faces20.portlet.FaceletPortletViewHandler</view-handler>
  <resource-handler>com.ibm.faces20.portlet.httpbridge.PortletResourceHandler</resource-handler>
</application>
```

What to do next

If the portlet project has a custom portlet class, these changes are also necessary:

- Point the portlet-class entry in the portlet.xml file to the particular custom portlet class used.
- Modify the portlet class to extend the com.ibm.faces20.portlet.FacesPortlet class from the IBM Portlet Bridge for JSF 2.0.

Configuring JavaServer Faces implementation

Use this task to specify which JavaServer Faces implementation to use. You can use Apache MyFaces 2.0 or the SUN Reference Implementation 1.2 of JSF, or your own implementation.

Before you begin

Ensure that your application is configured for JavaServer Faces (JSF) using the specific web.xml context parameters for the implementation that you have chosen.

Attention: The JSF implementation is a server-wide configuration setting. Thus, if you have multiple applications which require different JSF implementations, you must separate the applications into different application servers or clusters, and specify the implementation by following the steps in this topic for each application server or cluster. Alternatively, you can use an isolated shared library, as described for third-party JSF implementations, as follows.

About this task

Note: The Application Server JSF engine determines if the SUN Reference Implementation (RI) 1.2 or Apache MyFaces 2.0 is used from the Application Server run time. If either is used, the correct listener class is registered with the web container. You do not need to add the com.sun.faces.ConfigureListener or the org.apache.myfaces.StartupConfigureListener to your web.xml file.

Be Aware: If you want to use a third-party JSF implementation that is not shipped with the product, then:

- Keep the configuration set to MyFaces.
- Add the third-party listener to the web.xml file that is required.
- Add the third-party implementation Java archive (JAR) files to the application as an isolated shared library and associate it with your application.

You can also configure the JSF implementation on the Provide JSP reloading options for web modules panel for application installation and update wizards.

Procedure

Configure the server or cluster to use the JSF implementation that you want. You can do this task using the administrative console or the wsadmin tool.

- In the administrative console panel, click **Applications > Application Types > WebSphere enterprise applications > *application_name* > JSP and JSF options**

Select one of the following implementations:

- Sun Reference Implementation 1.2 - Select this option to use the Sun Reference Implementation 1.2 JSF implementation.
 - MyFaces 2.0 - Select this option to use the MyFaces 2.0 JSF implementation. This option is the default JSF implementation.
- Using the wsadmin tool:

- An example of setting a single server to use the Sun RI 1.2 JSF implementation:

```
wsadmin>set server [$AdminConfig list ApplicationServer *server1*]
server1(cells/myNode01Cell/nodes/myNode01/servers/server1|server.xml#ApplicationServer_1183122130078)
wsadmin>$AdminConfig modify $server {{jsfProvider SunRI1.2}}
```

```
wsadmin>$AdminConfig save
```

- An example of setting a cluster to use the MyFaces 2.0 JSF implementation:

```
wsadmin>set cluster [$AdminConfig list ServerCluster]
cluster1(cells/myNode01Cell/nodes/myNode01/clusters/cluster1|cluster.xml#ServerCluster_1173916133721)
wsadmin>$AdminConfig modify $cluster {{jsfProvider MyFaces}}
```

```
wsadmin>$AdminConfig save
```

Results

What to do next

Configure JSF engine parameters as necessary.

Configuring JSF engine parameters:

About this task

WebSphere Application Server does not support the modification of deployment descriptor extension parameters through the administrative console or through administrative scripting.

To add, change or delete JSF engine configuration parameters, complete the following steps:

Procedure

1. Open the WEB-INF/web.xml file. 

JSF engine configuration parameters are stored in a web module's configuration directory or in a web module's binaries directory in the WEB-INF/web.xml file. Open the WEB-INF/web.xml file from:

- The configuration directory, as in the following example: *profile_root/config/cells/cellName/applications/enterpriseAppName/deployments/deployedName/webModuleName/WEB-INF/web.xml*
 - The binaries directory if an application was deployed into WebSphere Application Server with the flag "Use Binary Configuration" set to true. An example of a binaries directory is: *profile_root/installedApps/nodeName/applicationName.ear/applicationName.war/WEB-INF/web.xml*
2. Edit the WEB-INF/web.xml file.
 - To add configuration parameters, use the following format:

```

    <context-param>
      <description>descriptive text</description>
      <param-name>parameter name</param-name>
      <param-value>parameter value</param-value>
    </context-param>

```

- To delete configuration parameters, either delete the line from the file, or enclose the statement with `<!-- -->` tags.

3. Save the file.

4. Restart the Enterprise Application. It is not necessary to restart the server for parameter changes to take effect. However, some JSP engine configuration parameters affect the Java source code that is generated for a JSP. If such a parameter is changed, then you must retranslate the JSP files in the web module to regenerate Java source. You can use the batch compiler to retranslate all JSP files in a web module. The batch compiler uses the JSP engine configuration parameters that you have set in the `web.xml` file, unless you specifically override them. The JSP engine configuration topic identifies the parameters that affect the generated Java source.

Example

The following is a sample of the `WEB-INF/web.xml` file.

```

<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns="http://java.sun.com/xml/ns/javaee" xmlns:web="http://java.sun.com/xml/ns/javaee/web-app_2_5.xsd"
  xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/web-app_2_5.xsd"
  id="WebApp_ID" version="2.5">
  <display-name>Servlet 2.5 example</display-name>
  <welcome-file-list>
    <welcome-file>index.html</welcome-file>
    <welcome-file>index.htm</welcome-file>
    <welcome-file>index.jsp</welcome-file>
    <welcome-file>default.html</welcome-file>
    <welcome-file>default.htm</welcome-file>
    <welcome-file>default.jsp</welcome-file>
  </welcome-file-list>
  <context-param>
    <param-name>javax.faces.CONFIG_FILES</param-name>
    <param-value>/WEB-INF/faces-config.xml</param-value>
  </context-param>
  <context-param>
    <param-name>javax.faces.STATE_SAVING_METHOD</param-name>
    <param-value>server</param-value>
  </context-param>
  <context-param>
    <param-name>com.ibm.ws.jsf.LOAD_FACES_CONFIG_AT_STARTUP</param-name>
    <param-value>>true</param-value>
  </context-param>
  <servlet>
    <servlet-name>Faces Servlet</servlet-name>
    <servlet-class>javax.faces.webapp.FacesServlet</servlet-class>
  </servlet>
  <servlet-mapping>
    <servlet-name>Faces Servlet</servlet-name>
    <url-pattern>/faces/*</url-pattern>
  </servlet-mapping>
  <servlet-mapping>
    <servlet-name>Faces Servlet</servlet-name>
    <url-pattern>*.faces</url-pattern>
  </servlet-mapping>
</web-app>

```

JSF engine configuration parameters:

In WebSphere Application Server, you can configure the JavaServer Faces (JSF) engine configuration parameters for optimal performance in a production server environment and for the needs of developers in a development environment.

The JSF engine parameters are case-sensitive. If the value specified for a parameter is composed of two or more words separated by spaces, you must add quotation marks around the value.

JSF options using SUN RI

Table 88. JSF options using SUN RI. The table shows SUN RI parameter names, descriptions and default values.

SUN RI parameter name	Description	Default value
com.sun.faces.numberOfViewsInSession	Specifies the number of views that are stored in the session when Server-Side State Saving is used. If set to true while client-side state saving is being used, reduces the number of bytes sent to the client by compressing the state before it is encoded and written as a hidden field.	15
com.sun.faces.numberOfLogicalViews	Specifies the number of logical views that are stored in the session when Server-Side State Saving is used.	15
com.sun.faces.enableHighAvailability	If set to true while server-side state saving is used, a serialized representation of the view is stored on the server. This provides failover and server clustering support.	false
com.sun.faces.injectionProvider	Defines an injection provider that is used for JSF annotations.	
com.sun.faces.serializationProvider	Defines a serialization provider that is used for serializing JSF objects into session.	
com.sun.faces.responseBufferSize	Define the size of the response buffer for a JSF response.	1048
com.sun.faces.clientStateWriteBufferSize		8192
com.sun.faces.expressionFactory	Specifies the default EL Expression Factory to use.	org.apache.el.ExpressionFactoryImpl
com.sun.faces.clientStateTimeout	The timeout value used for client side state saving. When the value set has been reached then the state is lost.	infinite
com.sun.faces.displayConfiguration		false
com.sun.faces.validateXml	When set to true, tag library XML files and faces configuration XML files using schema are validated during application start.	false
com.sun.faces.verifyObjects		false
com.sun.faces.forceLoadConfiguration		false
com.sun.faces.disableVersionTracking		false
com.sun.faces.enableHtmTagLibValidator		false
com.sun.faces.prerefXHTML		false
com.sun.faces.compressViewState		true
com.sun.faces.compressJavaScript		true
com.sun.faces.sendPoweredByHeader		true
com.sun.faces.enableJSStyleHiding		false
com.sun.faces.writeStateAtFormEnd		true
com.sun.faces.enableLazyBeanValidation		true
com.sun.faces.enableLoadBundle11Compatibility		false
com.sun.faces.enableRestoreView11Compatibility		false
com.sun.face.serializeServerState		false
com.ibm.ws.jsf.JSP_UPDATE_CHECK	This parameter monitors Faces JavaServer Pages (JSP) files for modifications and synchronizes a running server with the changes without restarting the server. If this parameter is set to false or removed from the deployment descriptor, any changes made to Faces JSP files might not be seen by the server until it is restarted. Set this parameter to true while developing and debugging the Faces JSP files to improve the performance of the development environment.	
com.ibm.ws.jsf.JSF_IMPL_CHECK	Set the com.ibm.ws.jsf.JSF_IMPL_CHECK parameter to true to check at application restart if the SUN RI and MyFaces implementations were switched. If the implementation has switched, then the runtime removes any generated JSP files from the temp directory and the JSP file is retranslated the next time it is requested.	

Table 88. JSF options using SUN RI (continued). The table shows SUN RI parameter names, descriptions and default values.

SUN RI parameter name	Description	Default value
com.ibm.ws.jsf.associateLabelWithId	<p>The com.ibm.ws.jsf.associateLabelWithId custom property changes the rendering behavior for both the <h:selectOneRadio> and <h:selectManyCheckbox> components. The label no longer wraps the input element. Instead, each input element has a unique ID and the label is associated with that ID used for that attribute. Define and set the com.ibm.ws.jsf.associateLabelWithId context parameter to true in the web.xml file.</p> <p>Use the following code as an example.</p> <pre><context-param> <description> Set to true to explicitly associate labels with their input elements for select one radio buttons and select many check box lists. </description> <param-name>com.ibm.ws.jsf.associateLabelWithId </param-name> <param-value>true</param-value> </context-param></pre>	
com.ibm.ws.jsf.disableEnqueuedMessagesWarning	<p>The com.ibm.ws.jsf.disableEnqueuedMessagesWarning custom property disables the FacesMessage(s) have been enqueued, but may not have been displayed warning message. When this property is set to true in the web.xml file, this warning message is not included in the SystemOut.log file .</p> <p>gotcha: This context parameter only applies to JSF applications that use the Sun Reference Implementation (RI) for JSF implementation.</p> <p>Note: This topic references one or more of the application server log files. As a recommended alternative, you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using SystemOut.log , SystemErr.log, trace.log, and activity.log files on distributed and IBM i systems. You can also use HPEL in conjunction with your native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.</p> <p>Use the following code as an example of how to define and set the com.ibm.ws.jsf.disableEnqueuedMessagesWarning context parameter to true in the web.xml file.</p> <pre><context-param> <description> Set to true to disable the following warning message: FacesMessage(s) have been enqueued, but might not have been displayed </description> <param-name> com.ibm.ws.jsf.disableEnqueuedMessagesWarning </param-name> <param-value>true</param-value> </context-param></pre>	
com.ibm.ws.jsf.disableStylePassthroughForCheckboxList	<p>This custom property prevents passing the style information into the items in the check box list. This property defaults to false to maintain the current behavior. Define and set the com.ibm.ws.jsf.disableStylePassthroughForCheckboxList context parameter to true in the web.xml file prevent passing style information into items in the check box list. Use the following code as an example.</p> <pre><context-param> <description> Set to true if style information should not be passed into items of check box list </description> <param-name> com.ibm.ws.jsf.disableStylePassthroughForCheckboxList </param-name> <param-value>true</param-value> </context-param></pre>	

Table 88. JSF options using SUN RI (continued). The table shows SUN RI parameter names, descriptions and default values.

SUN RI parameter name	Description	Default value
com.ibm.ws.jsf.DISABLE_UIDATA_NESTED_CHECK	<p>The com.ibm.ws.jsf.DISABLE_UIDATA_NESTED_CHECK custom property determines whether unique IDs are generated for UIData components that are nested inside iterator components that are not UIData components. When this property is set to true in the web.xml file, unique IDs are generated for UIData components even if they are nested inside iterator components that are not UIData components.</p> <p>When this property is set to false, if a JSF dataTable component is nested within a component that does not extend UIData, such as the Java Widget Library (JWL) dataIterator component, the IDs that are generated for the rows do not increment properly. This situation can result in duplicate IDs being assigned to multiple JSF components.</p> <p>Use the following code as an example of how to define and set the com.ibm.ws.jsf.DISABLE_UIDATA_NESTED_CHECK context parameter to true in the web.xml file.</p> <pre><context-param> <description> Set to true to enable unique IDs to be generated for UIData components even if they are nested inside iterator components that are not UIData components. </description> <param-name> com.ibm.ws.jsf.DISABLE_UIDATA_NESTED_CHECK </param-name> <param-value>true</param-value> </context-param></pre>	
com.ibm.ws.jsf.loadExternalDtd	<p>When parsing the faces-config.xml file from included libraries, the Faces configuration parser attempts to load the DTD even when validation is disabled. The Faces configuration parser uses a SAXParser to read the faces-config.xml. The default behavior of the SAXParser parser is to always load the DTD even if validation is disabled. This behavior can lead to errors initializing the Faces Servlet on systems isolated from the internet.</p> <p>In your web.xml file, set the com.ibm.ws.jsf.loadExternalDtd context parameter to false to have the Faces configuration parser set the "http://apache.org/xml/features/nonvalidating/load-external-dtd" feature to false.</p> <pre><context-param> <description> When set to false, this property sets a feature on the SAX parser to prevent loading the external DTD. </description> <param-name>com.ibm.ws.jsf.loadExternalDtd</param-name> <param-value>>false</param-value> </context-param></pre>	
enableRestoreView11Compatibility	<p>A JSF 1.2 application might create the ViewExpiredException exception under load when using the Sun Reference Implementation. If your view is not found in session, you can use a compatibility mode in JSF to create a new view. This can have adverse behaviors because it is a new view and items that are usually in the view, such as state, will no longer be available. Use the following code as an example to set the com.sun.faces.enableRestoreView11Compatibility context parameter to true in the web.xml file. This is only applicable when the Sun Reference Implementation is in use.</p> <pre><context-param> <param-name> com.sun.faces.enableRestoreView11Compatibility </param-name> <param-value>true</param-value> </context-param></pre>	
enableViewStateIdRendering	<p>The com.sun.faces.enableViewStateIdRendering custom property controls the rendering of the id attribute of the javax.faces.ViewState hidden field. Use the following code as an example to set the com.sun.faces.enableViewStateIdRendering context parameter to true in the web.xml file.</p> <pre><context-param> <param-name>com.sun.faces.enableViewStateIdRendering </param-name> <param-value>true</param-value> </context-param></pre>	

JSF options for MyFaces

Table 89. JSF options for MyFaces. The table shows JSF parameter names, descriptions and default values.

JSF parameter name	Description	Default value
org.apache.myfaces.RESOURCE_VIRTUAL_PATH		/faces/myFacesExtensionResource

Table 89. JSF options for MyFaces (continued). The table shows JSF parameter names, descriptions and default values.

JSF parameter name	Description	Default value
org.apache.myfaces.PRETTY_HTML	If this value is true, rendered HTML code is formatted so that it is human-readable. Additional line separators and white space are written that do not influence the HTML code.	true
org.apache.myfaces.ALLOW_JAVASCRIPT	This parameter tells MyFaces if javascript code is allowed in the rendered HTML output. If javascript is allowed, command_link anchors have javascript code that submits the corresponding form. If javascript is not allowed, the state saving information and nested parameters are added as URL parameters.	true
org.apache.myfaces.DETECT_JAVASCRIPT		false
org.apache.myfaces.AUTO_SCROLL	If true, a javascript function is rendered that can restore the former vertical scroll on every request. This feature is convenient if you have pages with long lists and you do not want the browser page to jump to the top of the page if you trigger a link or button action that stays on the same page.	false
org.apache.myfaces.ADD_RESOURCE_CLASS		org.apache.myfaces.renderkit.html.util.DefaultAddResource
org.apache.myfaces.CHECK_EXTENSIONS_FILTER	This parameter checks for a properly-configured Extensions-Filter if it is needed by the web application.	true
org.apache.myfaces.COMPRESS_STATE_IN_SESSION	Set this option to true to compress the serialized state before it is written to the session. If this option is set to false, the state is not compressed. This option is only applicable if the state saving method is set to server and if org.apache.myfaces.SERIALIZE_STATE_IN_SESSION is set to true.	true
org.apache.myfaces.NUMBER_OF_VIEWS_IN_SESSION	Defines the number of the latest views that are stored in session. This option is only applicable if the state saving method is set to server.	20
org.apache.myfaces.READONLY_AS_DISABLED_FOR_SELECTS		true
org.apache.myfaces.SERIALIZE_STATE_IN_SESSION	Set this option to true to serialize the state to a byte stream before it is written to the session. If this option is set to false, the state is not serialized to a byte stream. This option is only applicable if the state saving method is set to server.	true
org.apache.myfaces.STRICT_JSF_2_CC_EL_RESOLVER	Ensures that, when a getType() is called over the source EL expression, components working with chained EL expressions can use the metadata information that composite:attribute added. Setting this property to true disables this function.	false
com.ibm.ws.jsf.disablealternatefacesconfigsearch	Disables MyFaces searching for META-INF/*.faces-config.xml for only the web application that this context parameter is set on. If the context parameter and the web container custom property are set, the context parameter takes precedence.	false

Table 89. JSF options for MyFaces (continued). The table shows JSF parameter names, descriptions and default values.

JSF parameter name	Description	Default value
org.apache.el.parser.COERCE_TO_ZERO	<p>Allows for the expression language (EL) that WebSphere Application Server uses to coerce null and empty string integer values to a 0 value or for NOT allowing a coerce to a 0 value and retaining the null or empty string integer. The default is true and permits a null or empty string integer value to be coerced to a 0 value.</p> <p>Important: In order to keep a null value from being coerced to a 0 value in a MyFaces application, the following context parameter in the web.xml of the application: should be set to ensure that all possible instances of an empty or null value are inhibited from being coerced to zero.</p> <pre><context-param> <param-name>javax.faces. INTERPRET_EMPTY_STRING_SUBMITTED_VALUES_AS_NULL </param-name> <param-value>true</param-value> </context-param></pre> <p>You set the org.apache.el.parser.COERCE_TO_ZERO property using the administrative console.</p> <ol style="list-style-type: none"> 1. Expand Servers > Select WebSphere Application Servers > Click on the appropriate server from the list. 2. Under Server Infrastructure, expand Java and Process Management > Click on Process definition. 3. Under Additional Properties, click Java virtual Machine. 4. Under Additional Properties, click Custom properties. 5. Click New and add the org.apache.el.parser.COERCE_TO_ZERO property with the value of false if you do NOT want a null value coerced to zero. 6. Click Save to save the change and restart the WebSphere Application Server to ensure the change takes place. 	true
org.apache.myfaces.DEBUG_PHASE_LISTENER	Enables the DebugPhaseListener in the Development Project Stage.	true

JSF options using SUN RI or MyFaces

The following options are valid for both the SUN RI and the MyFaces implementations.

Table 90. JSF options using SUN RI or MyFaces. The table shows JSF parameter names, descriptions and default values.

JSF parameter name	Description	Default value
javax.faces.STATE_SAVING_METHOD	Specifies the location where state information is saved. Valid values are 'server', which is saved in HttpSession, and 'client', which is saved as a hidden field in the form.	server
javax.faces.CONFIG_FILES	Use this parameter to specify a comma-delimited list of context-relative resource paths under which the JSF implementation looks for application configuration resources before loading a configuration resource named /WEB-INF/facesconfig.xml, if a resource exists.	n/a
javax.faces.DEFAULT_SUFFIX	Specifies the default suffix for extension-mapped resources that contain JSF components.	.jsp
javax.faces.LIFECYCLE_ID	Use this parameter to configure an alternate life cycle ID.	n/a

Table 90. JSF options using SUN RI or MyFaces (continued). The table shows JSF parameter names, descriptions and default values.

JSF parameter name	Description	Default value
com.ibm.ws.jsf.JSF_IMPL_CHECK	Specifies that the JSP files in a web module must be recompiled when the application is restarted because the implementation of JSF that is used has changed. After the application is restarted, the next time a JSP file is accessed for this module the JSP file is recompiled against the selected implementation of JSF specified in the administration console. Subsequent calls to the JSP file do not recompile. The default setting for this option is false. Use this option for development and not in a production environment.	n/a

Sun RI context parameters that have an equivalent behavior in MyFaces

Table 91. Sun RI context parameters and equivalent MyFaces behavior. The table shows SUN RI parameters names and MyFaces equivalent.

SUN RI parameter name	Description	RI default	MyFaces equivalent	MyFaces default
com.sun.faces.numberOfViewsInSession	Defines the maximum number of serialized views stored in the session. Works with server state saving.	15	org.apache.myfaces.NUMBER_OF_VIEWS_IN_SESSION	20
com.sun.faces.compressViewState	When true the view is compressed after it is serialized and before base64 encoded. Works with client state saving. As of 1.2_09, this option also affects server-side state saving when com.sun.faces.serializeServerState is set to true (this has a large impact of the size of the state in the session when using this option, at the expense of more CPU.)	true	org.apache.myfaces.COMPRESS_STATE_IN_CLIENT for client-side state saving or org.apache.myfaces.COMPRESS_STATE_IN_SESSION for server-side state saving	false for client-side state saving, true for server-side state saving
com.sun.faces.validateXml	When true JSF validates the configuration files.	false	org.apache.myfaces.VALIDATE	false
com.sun.faces.injectionProvider	This parameter specifies a class that implements the InjectionProvider.	n/a	injection provider is provided by the WebSphere Application Server run time	n/a
com.sun.faces.serializationProvider	This parameter specifies a class that implements the SerializationProvider SPI. This implementation represents a hook the JSF implementation uses to enable using alternate Serialization implementations.	n/a	org.apache.myfaces.SERIAL_FACTORY - class must implement org.apache.myfaces.shared_impl.util.serial.SerialFactory SPI instead of com.sun.faces.spi.SerializationProvider	n/a
com.sun.faces.enabledJSStyleHiding	If true, inline JavaScript rendered by the HTML ResponseWriter implementation is rendered so that the script is hidden from older browser implementations.	false	org.apache.myfaces.WRAP_SCRIPT_CONTENT_WITH_XML_COMMENT_TAG	true
com.sun.faces.serializeServerState	If enabled the component state (not the tree) is serialized before being stored in the session. This might be desirable for applications that have issues with view state being sensitive to model changes.	false	org.apache.myfaces.SERIALIZE_STATE_IN_SESSION	true

Defining an extension for the registry filter

The registry filter specifies if an extensions is applicable to all registry instances or to specified instances.

Before you begin

You must have an extensible application to define an extension for the registry filter.

About this task

Complete the following steps to filter out extensions for an application.

Procedure

1. Define an extension for the registry filter extension point for a named registry instance in the `plugin.xml` file.

```
<extension point="org.eclipse.extensionregistry.RegistryFilter">
  <filter name="AdminConsole*"
    class="com.ibm.ws.admin.AdminConsoleExtensionFilter"/>
</extension>
```

2. Add the filter implementation to the application by creating a class to implement the `com.ibm.workplace.extension.IExtensionRegistryFilter` interface.

```
package com.ibm.ws.admin;
import com.ibm.workplace.extension.IExtensionRegistryFilter;
public class AdminConsoleExtensionFilter implements IExtensionRegistryFilter {
    :
}
```

3. The extensible application declares the registry name by defining an extension for the `RegistryInstance` extension point. This way, the registry can prepare an `IExtensionRegistry` instance and put it in JNDI in advance.

```
<extension point="org.eclipse.extensionregistry.RegistryInstance">
  <registry name="AdminConsole"/>
</extension>
```

4. The extensible application obtains a named instance of the registry to activate any associated filters:

```
InitialContext ic = new InitialContext();
String lookupName = "services/extensionregistry/AdminConsole";
IExtensionRegistry reg = (IExtensionRegistry)ic.lookup(lookupName);
```

Application extension registry

WebSphere Application Server has enabled the Eclipse extension framework for applications to use. Applications are extensible when they contain a defined extension point and provide the extension processing code for the extensible area of the application.

An application can be plugged in to another extensible application by defining an extension that adheres to what the target extension point requires. The extension point can find the newly added extension dynamically and the new function is seamlessly integrated in the existing application. It works on a cross Java Platform, Enterprise Edition (Java EE) module basis. The application extension registry uses the Eclipse plug-in descriptor format and application programming interfaces (APIs) as the standard extensibility mechanism for WebSphere applications. Developers that build WebSphere application modules can use WebSphere Application Server extensions to implement their functionality to an extensible application, which defines an extension point. This is done through the application extension registry mechanism.

The architecture of extensible Java EE applications follow a modular design to add new functional modules or to replace an existing module, particularly by those outside of its core development team. Each module is a pluggable unit, or plug-in that is either deployed into the portal or removed from the Java EE application using a deployment tool that is based upon standard Java EE and portal web module deployment tooling. A plug-in module describes where it is extensible and what capability it provides to other plug-ins in the `plugin.xml` file. The `plugin.xml` manifest file can be created with a simple text editor or in Eclipse's Plug-in Development Environment (PDE), which provides a simplified view of the same underlying XML data.

WebSphere Application Server implementations to the Eclipse model

Some minor differences exist in the WebSphere Application Server implementation of this architecture because of platforms, specifically, Eclipse Workbench or Java 2 Platform, Enterprise Edition (Java EE). The highlights of the WebSphere Application Server implementation include:

- Implementing all of the extension registry-related interfaces from Eclipse 3.6 and later.
- The identical `plugin.xml` syntax, however, some attributes are not used, for example, `<runtime>`.
- The discovery and addition of plug-ins to the registry, when the containing Java EE module starts, and plug-ins are dismissed and removed from the registry when the containing Java EE module stops.
- Access to an `IExtensionRegistry` object is through the Java Naming and Directory Interface (JNDI), instead of by using the `Platform.getExtensionRegistry` method in the Eclipse Workbench.
- Filtering capability is available by providing a filter implementation and using a named registry instance that finds and invokes the filter as necessary. See the developer API documentation for the `IExtensionRegistryFilter` interface for more details.

Available Eclipse 3.6 interfaces

The following Eclipse 3.6 and later interfaces are available on WebSphere Application Server:

- Extension registry API
- Extension point API
- Extension API
- Configuration element API
- Registry change listener API
- Registry change event API
- Extension delta API
- Status API

The following interfaces are recognized and processed the same as in Eclipse:

- Executable extension API
- Executable extension factory API

Application extension registry filtering

The extension registry exposes the registry filter extension point. The registry filter removes elements within the extension registry for client applications. Extensions that are attached to the registry filter extension point and that also implement this interface are called as necessary when a client operates on a named registry instance that matches the target specification.

You can create a filter extension for all registry instances or for named instances that are specified by the extension. In the first case, the filter is applied to all instances of the extension registry, and all client applications use the filter without requesting the filter. In the latter case, a client application must predefine the registry name by defining an extension, called *RegistryInstance*, which is another extension point that is exposed by the extension registry. After the registry name is defined, the client can obtain the named registry instance and use that registry instance. The filter extension is invoked by the named registry instance as necessary.

Registry filter API

Supported arguments include:

```
org.eclipse.core.runtime.IExtension[]  
doFilter(org.eclipse.core.runtime.IExtension[] extensions)
```

This code returns an array of `IExtension` objects that are included in the valid extension list.

Registry instance extension point

The extension registry exposes the *RegistryInstance*. The instance name is declared in the application's `plugin.xml` file, and the application requests an registry instance for that name at runtime.

plugin.xml file

A plug-in is described in an XML manifest file, called `plugin.xml`, which is part of the plug-in deployment files. The manifest file tells the portal application's runtime what it needs to know to register and activate the plug-in. The manifest file essentially serves as the contract between the pluggable component and the portal application's runtime. Although the WebSphere Application Server `plugin.xml` closely follows the one provided for the Eclipse workbench, it does diverge from the Eclipse workbench in several places as outlined below.

Location

The `plugin.xml` file must reside in the `WEB-INF` directory under the context of the hierarchy of directories that exist for a web application or when included in the Web application archive file.. The `plugin.xml` file must reside in the root directory when the `plugin.xml` file is placed in an Enterprise JavaBeans Java archive (JAR) file or shared library JAR file. The extension registry service includes the `plugin.xml` file as the participating components are loaded and started on the application server.

Usage notes

- Is this file read-only?

No

- Is this file updated by a product component?

???

- If so, what triggers its update?

Rational Application Developer updates the `web.xml` file when you assemble web components into a web module, or when you modify the properties of the web components or the web module.

- How and when are the contents of this file used?

WebSphere Application Server functions use information in this file during the configuration and deployment phases of web application development.

- The manifest markup definitions below make use of various naming tokens and identifiers. To eliminate ambiguity, the following are productions rules for these naming conventions. In general, all identifiers are case-sensitive.

```
SimpleToken := sequence of characters from ('a-z','A-Z','0-9')
ComposedToken := SimpleToken | (SimpleToken '.' ComposedToken)
PlugInId := ComposedToken
PlugInPrereq := PlugInId
ExtensionId := SimpleToken
ExtensionPointId := SimpleToken
ExtensionPointReference := ExtensionPointId | (PlugInId '.' ExtensionPointId)
```

Sample file entry

The entire plug-in manifest DTD is as follows. XML Schema is not used to define the manifest since the current Eclipse tooling for plug-in's requires a DTD. The XML DTD construction rule `element*` means zero or more occurrences of the element; `element?` means zero or one occurrence of the element; and `element+` means one or more occurrences of the element.

```
<?xml encoding="US-ASCII"?>

<!ELEMENT plugin (requires?, extension-point*, extension*)>
<!ATTLIST plugin
  name CDATA #IMPLIED
  id CDATA #REQUIRED
  version CDATA #REQUIRED
  provider-name CDATA #IMPLIED
```

```

>
<!ELEMENT requires (import+)>
<!ELEMENT import EMPTY>
<!ATTLIST import
  plugin CDATA #REQUIRED
  version CDATA #IMPLIED
  match (exact | compatible | greaterOrEqual) #IMPLIED
>
<!ELEMENT extension-point EMPTY>
<!ATTLIST extension-point
  name CDATA #IMPLIED
  id CDATA #REQUIRED
  schema CDATA #IMPLIED
>
<!ELEMENT extension ANY>
<!ATTLIST extension
  point CDATA #REQUIRED
  id CDATA #IMPLIED
  name CDATA #IMPLIED
>

```

WebSphere Application Server differences

The `plugin.xml` file closely follows the `plugin.xml` file provided for the Eclipse workbench. However it diverges within the following elements.

The plugin element

The plugin element provided in this manifest does not contain class attributes. The class attribute is unnecessary since the plug-in mechanism does not require the plug-in developer to extend or use any specific classes as is required by the Eclipse workbench. Also, the plugin element does not contain a runtime element since standards such as J2EE that already define the location of runtime libraries for the applications.

The import element

The `requires` element does not contain export attribute since J2EE modules are encouraged to be self-contained to improve manageability. In addition to eliminating the export attribute, the `match` attribute has an option for a greater than or equal to match for versions (`greaterOrEqual`).

The extension-point element

The extension-point element has the `name` attribute as optional since it has no real use in this J2EE implementation.

you can find details regarding the plug-in manifest in the Eclipse documentation, under Platform Plug-In Developer Guide>Other reference information>Plug-in manifest.

The following is an example of how adding a link to an existing page can be accomplished by an extension point. The plug-in manifest of this plug-in declares an extension point (`linkExtensionPoint`) and an extension to this extension point (`linkExtension`). The plug-in declaring the extension point does not need to be the plug-in that implements the extension point. Another plug-in can also define an extension to the link extension point in its plug-in manifest by including the contents of the `<extension>` and `</extension>` tags in its manifest.

```

<?xml version="1.0"?>
<!--the plugin id is derived from the vendor domain name -->
<plugin
  id="com.ibm.ws.console.core"
  version="1.0.0"
  provider-name="IBM WebSphere">

  <!--declaration of prerequisite plugins-->
  <requires>
    <import plugin="com.ibm.data" version="2.0.1" match="compatible"/>
    <import plugin="com.ibm.resources" version="3.0" match="exact"/>

```

```

</requires>

<!--declaration of link extension point -->
<extension-point
  id="linkExtensionPoint"
  schema="/schemas/linkSchema.xsd"/>

<!--declaration of an extension to the link extension point -->
<extension
  point="com.ibm.ws.console.core.linkExtensionPoint"
  id="linkExtension">

  <link
    label="Example.displayName"
    actionView="com.ibm.ws.console.servermanagement.forwardCmd.do?
      forwardName=example.config.view&
      lastPage=ApplicationServer.config.view">
  </link>
</extension>
</plugin>

```

Contexts and Dependency Injection (CDI)

Learn about Contexts and Dependency Injection (CDI).

Developing applications that use Contexts and Dependency Injection (CDI)

Use this task to provide a summary of the WebSphere Application Server extensions that you can use to develop servlets.

About this task

Several WebSphere Application Server extensions are provided for enhancing your servlets. This task provides a summary of the extensions that you can use.

Procedure

1. Review the supported specifications.
Create Java™ components, referring to the CDI specifications. Place a beans.xml file in the WEB-INF directory of the WAR module, or META-INF directory of a JAR file, so the container identifies it as a bean deployment archive.
2. Use your favorite integrated development environment (IDE), or a text editor, to develop or migrate code artifacts that meet the specifications.
3. Test the code artifacts.

What to do next

Assemble your code artifacts into a web module using assembly tools as a prerequisite to deploying the code to the application server.

Contexts and Dependency Injection (CDI)

Contexts and Dependency Injection for the Java EE platform (CDI) is a JSR 299 implementation that is based on Apache OpenWebBeans.

CDI is activated in an application by the presence of a beans.xml file inside that module, as defined by the JSR 299 specification. You can find the beans.xml file in the WEB-INF directory of a web archive (WAR) or META-INF directory of other types of archives. When activated, the container provides services such as:

- Context management
- Type-safe dependency injection: A CDI-managed bean is instantiated and injected as needed.

- Decorators, which implement one or more bean interfaces and can contain business logic. Decorators are disabled by default. You can have multiple decorators per bean and order is defined by the beans.xml file.
- Interceptor bindings. Interceptors, which are enabled manually in the beans.xml file, are bound using an interceptor binding type.
- Event model
- Integration into JavaServer Faces (JSF) and JavaServer Pages (JSP) files using the Expression Language (EL)

The specification-related API classes for JSR 299 and JSR 330 and IBM modified implementation classes that are based on Apache OpenWebBeans are packaged with the application server runtime environment.

Although the WebSphere Application Server CDI implementation is based on Apache OpenWebBeans, there are some changes and additions on top of OpenWebBeans to support integration with the server run time:

- Integration with other Java Platform, Enterprise Edition (Java EE) containers in WebSphere Application Server that support injectable components.
- ScannerService implementation that uses the WebSphere Application Server byte code scanner.
- Direct use of WebSphere Application Server Enterprise JavaBeans (EJB) metadata for determining EJB types.
- Automatic registration of Servlet Listeners, Filters, Interceptors for CDI applications so these no longer must be added by each application.
- WebSphere Application Server-specific implementations of many OpenWebBeans Service Programming Interfaces (SPI), such as ResourceInjectionService, TransactionService, failover service, and so on.

Important: Container-managed transactions and security are not provided by CDI.

Contexts and Dependency Injection custom properties:

WebSphere Application Server Contexts and Dependency Injection (CDI) implementation is based on OpenWebBeans, which is configurable through the openwebbeans.properties file.

To specify CDI custom properties, place the openwebbeans.properties file inside the META-INF/openwebbeans directory of your application. Properties that are not listed below, such as those that control the lifecycle and services, should remain at the default value for the application server. See the following list of some of the available CDI custom properties:

org.apache.webbeans.conversation.Conversation.periodicDelay:

Specifies a delay in milliseconds. Use the conversation periodic delay custom property to search for and delete unused conversations.

Value	Default
integer	15000

org.apache.webbeans.application.jsp:

Specifies that an application is a full JavaServer Pages (JSP) application. Specify true if you want to add the JSP ELResolver class to the application.

Value	Default
true	true

org.apache.webbeans.useOwbSpecificXmlConfig:

Specify true if you want to use OpenWebBeans-specific beans.xml files for the application. The default value is false, which is the portable specification beans.xml format.

Value	Default
true	false

org.apache.webbeans.fieldInjection.useOwbSpecificInjection:

Specify true if you want to use OpenWebBeans-specific injection for the application. The default value is false, which is the portable specification behavior.

Value	Default
true	false

org.apache.webbeans.application.useJSF2Extensions:

Specify true to enable JavaServerFaces (JSF) 2.0-based CDI extensions.

Value	Default
true	false

org.apache.webbeans.application.supportsConversation:

Specify true to support conversation scopes in the application.

Value	Default
true	true

CDI integration with JavaServer Faces:

Contexts and Dependency Injection (CDI) primarily integrates with JavaServer Faces (JSF) through the Expression Language (EL). It enables CDI beans to be exposed through the unified EL-to-JSF components. It also provides a built-in context for conversation scope that is active during standard JSF life cycle phases.

As part of the WebSphere Application Server integration with CDI containers, several JSF components are automatically registered for CDI applications, including:

- EL Resolver
- Phase Listener
- View Handler
- Application Factory

Only the default JSF implementation (based on MyFaces) is supported for use with CDI.

Contexts and Dependency Injection (CDI) integration with EJB container:

The CDI specification enhances the EJB component model with contextual life cycle management.

Relationship of the CDI to the EJB specification

The EJB specification defines a programming model for application components that access transactional resources in a multi-user environment. Concerns, such as role-based security, transaction demarcation, concurrency, and scalability are specified declaratively using annotations and XML deployment descriptors that are enforced by the EJB container at run time. EJB components might be stateful, but are not by nature, contextual.

The following session bean instances are obtained using dependency injection:

- Contextual
- Bound to a life cycle context
- Available to other instances that launch in that context
- Container creates an instance when needed
- Container destroys an instance when context ends

The WebSphere Application Server CDI container performs dependency injection on all session and message-driven bean instances, even instances that are not contextual instances. WebSphere Application Server CDI supports injection of CDI beans inside enterprise beans and vice versa.

Usage

Note: Use the following best practices when injecting enterprise beans:

- Use the `@Inject` method for contextual injection of local session beans.
- Use the `@EJB` method for remote session beans

See the following examples of using the `@EJB` method in CDI:

Define producers making the EJB available for non-contextual injection:

```
@Produces @EJB PaymentService paymentService;
```

Consume the injected types in other CDI beans:

```
@Inject PaymentService myPaymentService
```

Practical considerations

You can define CDI-style interceptors with interceptor bindings and decorators enterprise beans. Interceptors are declared using `@Interceptors` methods or in `ejb-jar.xml` files, which are called before interceptors and are declared using interceptor bindings. Interceptors are called before decorators.

WebSphere Application Server supports failover (activation and passivation) of CDI beans and enterprise beans, along with their interceptors and decorators. EJB failover support with CDI only works for stateful session beans and requires the same configuration as stateful session bean failover. See the stateful session bean failover for the EJB container topic for more information. Configure EJB failover with web HTTP session failover. See the “Configuring for database session persistence” and the “Configuring memory-to-memory replication for the peer-to-peer mode (default memory-to-memory replication)” topics for more information. Except for abstract decorators, failover services are based on current WebSphere Application Server failover providers. Web session failover and EJB stateful session bean failover and configured separately.

When a contextual (`@Injected`) instance of an EJB container is destroyed as a result of going out of scope, and if the underlying EJB container was not already removed by direct invocation of a `remove` method by the application, the WebSphere Application Server CDI container removes the stateful session bean.

The WebSphere Application Server CDI container removes the stateful session bean when:

- You use the `@Inject` method to create a contextual injection instance and that instance in an EJB container is destroyed as a result of going out of scope.
- The underlying EJB container was not already removed by direct invocation of a remove method by the application.

You must also consider the scope and state propagation of CDI beans. The request and application scope CDI beans maintain state in their respective contexts across the web and EJB containers. For instance, a request-scoped CDI bean injected in a servlet holds its state when a business method on stateful session enterprise bean accesses the same request-scoped bean.

Developing servlet applications using asynchronous request dispatcher

Developing servlet applications using asynchronous request dispatcher

Web modules can dispatch requests concurrently on separate threads. Requests can be dispatched by the server or client.

Before you begin

For additional information about the `AsyncRequestDispatcherConfig` and the `AsyncRequestDispatcher` interfaces, review the `com.ibm.websphere.webcontainer.async` package in the application programming interfaces (API) documentation. The generated API documentation is available in the information center table of contents from the path [Reference > APIs - Application Programming Interfaces](#).

Review the asynchronous request dispatcher application (ARD) design considerations topic before completing the following steps.

About this task

Concurrent dispatching can improve servlet response time. If operations are dependant on each other, do not enable asynchronous request dispatching, therefore, select Disabled. Concurrent dispatching might result in errors when operations are dependant. Select Server side to enable the server to aggregate requests dispatched concurrently. Select Client side to enable the client to aggregate requests dispatched concurrently.

Procedure

1. Logically separate resource intensive operations.
2. Develop servlets that use an asynchronous request dispatcher to include these operations.
3. Enable asynchronous request dispatching on an application server.
4. Deploy the application in an application server that has asynchronous request dispatching enabled.
5. Select an aggregation type for the application that needs ARD.
6. Optional: Configure the `AsyncRequestDispatcherWorkManager` work manager that is used for the request dispatch threads.
7. Restart the application server.

What to do next

Restart the modified applications if already installed or start newly installed applications to enable ARD on each application.

Assembling web applications

Assembling web applications

Assemble a web module to contain servlets, JavaServer Pages (JSP) files, and related code artifacts. (Group enterprise beans, client code, and resource adapter code in separate modules). After assembling a web module, you can install it as a stand-alone application or combine it with other modules into an enterprise application.

Before you begin

This topic assumes that you have created and unit tested Servlets and JavaServer Pages (JSP) files and other web components that you want to assemble in an enterprise application and deploy onto an application server.

About this task

Use an assembly tool to assemble a web module in any of the following ways:

- Import an existing web module (WAR file).
- Create a new web module.
- Copy code artifacts (such as servlets) from one web module into a new web module.

Although you can input various properties for web archives, available properties are specific to the Servlet, JSP, and Java Platform, Enterprise Edition (Java EE) specification level.

Procedure

1. Start an assembly tool.
2. If you have not done so already, configure the assembly tool for work on Java EE modules. Ensure that **J2EE** and **Web** capabilities are enabled.
3. Migrate WAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an assembly tool. To migrate files, import your WAR files to the assembly tool.
4. Create a new web module.
5. Copy code artifacts (such as servlets) from one web module into a new web module.

Results

A web project is migrated or created. Files for the Web project are shown in the Project Explorer view under **Enterprise Applications** and **Web Projects**.

What to do next

You can now deploy your web project to an application server.

web.xml file

The web.xml file provides configuration and deployment information for the web components that comprise a web application.

The Java Servlet specification defines the web.xml deployment descriptor file in terms of an XML schema document. For backwards compatibility, any web.xml file that is written to Servlet 2.2 or above that worked in previous versions of WebSphere Application Server are supported by the web container.

If you use Rational Application Developer Version 6 to create your portlets, you must remove the following reference to the std-portlet.tld from the web.xml file:

```

<taglib id="PortletTLD">
  <taglib-uri>http://java.sun.com/portlet</taglib-uri>
  <taglib-location>/WEB-INF/tld/std-portlet.tld</taglib-location>
</taglib>

```

Location

The web.xml file must reside in the WEB-INF directory under the context of the hierarchy of directories that exist for a web application.

IBM i For example, if the application is client.war, then the web.xml file is placed in the *profile_root/installedApps/cellName/client.ear/client.war/WEB-INF* directory (in a default installation), where the edition is either base or WebSphere Application Server, Network Deployment, depending on which edition you are using.

Usage notes

- Is this file read-only?

No

- Is this file updated by a product component?

This file is updated by the assembly tool.

- If so, what triggers its update?

The assembly tool updates the web.xml file when you assemble web components into a web module, or when you modify the properties of the web components or the web module.

- How and when are the contents of this file used?

WebSphere Application Server functions use information in this file during the configuration and deployment phases of web application development.

Sample file entry

Note: The web.xml file does not represent the entire configuration that is available for the web application. There are other servlets filters, and listeners that can be defined using programmatic configurations, annotations, and web fragments.

Note: Marking the web application metadata complete will prevent annotations and web fragments from being able to configure components.

```

<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_9" version="3.0" xmlns="http://java.sun.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://java.sun.com/xml/ns/javaee
  http://java.sun.com/xml/ns/javaee/web-app_3_0.xsd">
  <display-name>Servlet 3.0 application</display-name>
  <filter>
    <filter-name>ServletMappedDoFilter_Filter</filter-name>
    <filter-class>tests.Filter.DoFilter_Filter</filter-class>
    <init-param>
      <param-name>attribute</param-name>
      <param-value>tests.Filter.DoFilter_Filter.SERVLET_MAPPED</param-value>
    </init-param>
  </filter>
  <filter-mapping>
    <filter-name>ServletMappedDoFilter_Filter</filter-name>
    <url-pattern>/DoFilterTest</url-pattern>
    <dispatcher>REQUEST</dispatcher>
  </filter-mapping>
  <filter-mapping>
    <filter-name>ServletMappedDoFilter_Filter</filter-name>
    <url-pattern>/IncludedServlet</url-pattern>
    <dispatcher>INCLUDE</dispatcher>
  </filter-mapping>
  <filter-mapping>
    <filter-name>ServletMappedDoFilter_Filter</filter-name>

```

```

    <url-pattern>ForwardedServlet</url-pattern>
    <dispatcher>FORWARD</dispatcher>
</filter-mapping>
</listener>
<listener-class>tests.ContextListener</listener-class>
</listener>
<listener>
    <listener-class>tests.ServletRequestListener.RequestListener</listener-class>
</listener>
<servlet>
    <servlet-name>welcome</servlet-name>
    <servlet-class>WelcomeServlet</servlet-class>
</servlet>
<servlet>
    <servlet-name>ServletErrorPage</servlet-name>
    <servlet-class>tests.Error.ServletErrorPage</servlet-class>
</servlet>
<servlet>
    <servlet-name>IncludedServlet</servlet-name>
    <servlet-class>tests.Filter.IncludedServlet</servlet-class>
</servlet>
<servlet>
    <servlet-name>ForwardedServlet</servlet-name>
    <servlet-class>tests.Filter.ForwardedServlet</servlet-class>
</servlet>
<servlet-mapping>
    <servlet-name>welcome</servlet-name>
    <url-pattern>/hello.welcome</url-pattern>
</servlet-mapping>
<servlet-mapping>
    <servlet-name>ServletErrorPage</servlet-name>
    <url-pattern>/ServletErrorPage</url-pattern>
</servlet-mapping>
<servlet-mapping>
    <servlet-name>IncludedServlet</servlet-name>
    <url-pattern>/IncludedServlet</url-pattern>
</servlet-mapping>
<servlet-mapping>
    <servlet-name>ForwardedServlet</servlet-name>
    <url-pattern>/ForwardedServlet</url-pattern>
</servlet-mapping>
<welcome-file-list>
    <welcome-file>hello.welcome</welcome-file>
</welcome-file-list>
<error-page>
    <exception-type>java.lang.ArrayIndexOutOfBoundsException</exception-type>
    <location>/ServletErrorPage</location>
</error-page>
    <error-page>
        <error-code>404</error-code>
        <location>/error404.html</location>
    </error-page>
</web-app>

```

Note: For each `<error-page>` declaration, select either `<exception-type>` or `<error-code>`, but not both. The `<location>` tag is required.

File serving

In file serving, web applications can serve static file types, such as HTML. File-serving attributes are used by the servlet that implements file-serving behavior.

The file-serving behavior is implemented by setting the `fileservingenabled` property to true when configuring the web module.

Example attributes:

bufferSize

Sets buffer size that is used for serving static files.

extendedDocumentRoot

Enables you to configure an application with one or more directory paths from which you can serve static files and Java ServerPages (JSP) files. You can use this attribute when an application requires access to files that exist outside of the application web application archive (WAR) directory. For example, if several applications require access to a set of common files, you can place the common files in a directory to which you can link each application as an extended document root directory.

Use this attribute in addition to the contextRoot attribute.

You can also use this attribute to define a WebSphere variable on multiple nodes to the appropriate directory.

Example:

```
<fileServingEnabled="true">
<fileServingAttributes xmi:id="FileServingAttribute_1" name="extendedDocumentRoot"
  value="{MY_CUSTOM_VARIABLE}"/>
```

where *MY_CUSTOM_VARIABLE* is the WebSphere variable that you want to define on multiple nodes.

For more information, see JSP engine configuration parameters.

file.serving.patterns.allow

Specifies that only files matching the specified pattern are served.

file.serving.patterns.deny

Specifies that files that match the specified file pattern are denied

Configuring JavaServer Faces implementation

Configuring JavaServer Faces implementation

Use this task to specify which JavaServer Faces implementation to use. You can use Apache MyFaces 2.0 or the SUN Reference Implementation 1.2 of JSF, or your own implementation.

Before you begin

Ensure that your application is configured for JavaServer Faces (JSF) using the specific web.xml context parameters for the implementation that you have chosen.

Attention: The JSF implementation is a server-wide configuration setting. Thus, if you have multiple applications which require different JSF implementations, you must separate the applications into different application servers or clusters, and specify the implementation by following the steps in this topic for each application server or cluster. Alternatively, you can use an isolated shared library, as described for third-party JSF implementations, as follows.

About this task

Note: The Application Server JSF engine determines if the SUN Reference Implementation (RI) 1.2 or Apache MyFaces 2.0 is used from the Application Server run time. If either is used, the correct listener class is registered with the web container. You do not need to add the com.sun.faces.ConfigureListener or the org.apache.myfaces.StartupConfigureListener to your web.xml file.

Be Aware: If you want to use a third-party JSF implementation that is not shipped with the product, then:

- Keep the configuration set to MyFaces.
- Add the third-party listener to the web.xml file that is required.

- Add the third-party implementation Java archive (JAR) files to the application as an isolated shared library and associate it with your application.

You can also configure the JSF implementation on the Provide JSP reloading options for web modules panel for application installation and update wizards.

Procedure

Configure the server or cluster to use the JSF implementation that you want. You can do this task using the administrative console or the wsadmin tool.

- In the administrative console panel, click **Applications > Application Types > WebSphere enterprise applications > *application_name* > JSP and JSF options**

Select one of the following implementations:

- Sun Reference Implementation 1.2 - Select this option to use the Sun Reference Implementation 1.2 JSF implementation.
- MyFaces 2.0 - Select this option to use the MyFaces 2.0 JSF implementation. This option is the default JSF implementation.

- Using the wsadmin tool:

- An example of setting a single server to use the Sun RI 1.2 JSF implementation:

```
wsadmin>set server [$AdminConfig list ApplicationServer *server1*]
server1(cells/myNode01Cell/nodes/myNode01/servers/server1|server.xml#ApplicationServer_1183122130078)
wsadmin>$AdminConfig modify $server {{jsfProvider SunRI1.2}}
```

```
wsadmin>$AdminConfig save
```

- An example of setting a cluster to use the MyFaces 2.0 JSF implementation:

```
wsadmin>set cluster [$AdminConfig list ServerCluster]
cluster1(cells/myNode01Cell/nodes/myNode01/clusters/cluster1|cluster.xml#ServerCluster_1173916133721)
wsadmin>$AdminConfig modify $cluster {{jsfProvider MyFaces}}
```

```
wsadmin>$AdminConfig save
```

Results

What to do next

Configure JSF engine parameters as necessary.

Developing session management in servlets

About this task

This information, combined with the coding example `SessionSample.java`, provides a programming model for implementing sessions in your own servlets.

Procedure

1. Get the `HttpSession` object.

To obtain a session, use the `getSession` method of the `javax.servlet.http.HttpServletRequest` object in the Java Servlet 3.0 API.

When you first obtain the `HttpSession` object, the Session Management facility uses one of three ways to establish tracking of the session: cookies, URL rewriting, or Secure Sockets Layer (SSL) information.

Note: Session tracking using the SSL ID is deprecated in WebSphere Application Server version 7.0. You can configure session tracking to use cookies or modify the application to use URL rewriting

Assume the Session Management facility uses cookies. In such a case, the Session Management facility creates a unique session ID and typically sends it back to the browser as a *cookie*. Each subsequent request from this user (at the same browser) passes the cookie containing the session ID, and the Session Management facility uses this ID to find the user's existing HttpSession object.

In Step 1 of the code sample, the Boolean(create) is set to true so that the HttpSession object is created if it does not already exist. (With the Servlet 2.3 API and later, the javax.servlet.http.HttpServletRequest.getSession() method with no boolean defaults to true and creates a session if one does not already exist for this user.)

2. Store and retrieve user-defined data in the session.

After a session is established, you can add and retrieve user-defined data to the session. The HttpSession object has methods similar to those in java.util.Dictionary for adding, retrieving, and removing arbitrary Java objects.

In Step 2 of the code sample, the servlet reads an integer object from the HttpSession, increments it, and writes it back. You can use any name to identify values in the HttpSession object. The code sample uses the name sessiontest.counter.

Because the HttpSession object is shared among servlets that the user might access, consider adopting a site-wide naming convention to avoid conflicts.

3. (Optional) Output an HTML response page containing data from the HttpSession object.

4. Provide feedback to the user that an action has taken place during the session. You may want to pass HTML code to the client browser indicating that an action has occurred. For example, in step 3 of the code sample, the servlet generates a web page that is returned to the user and displays the value of the sessiontest.counter each time the user visits that web page during the session.

5. (Optional) Notify Listeners. Objects stored in a session that implement the javax.servlet.http.HttpSessionBindingListener interface are notified when the session is preparing to end and become invalidated. This notice enables you to perform post-session processing, including permanently saving the data changes made during the session to a database.

6. End the session. You can end a session:

- Automatically with the Session Management facility if a session is inactive for a specified time. The administrators provide a way to specify the amount of time after which to invalidate a session.
- By coding the servlet to call the invalidate() method on the session object.

Example

```
import java.io.*;
import java.util.*;
import javax.servlet.*;
import javax.servlet.http.*;

public class SessionSample extends HttpServlet {
    public void doGet (HttpServletRequest request, HttpServletResponse response)
        throws ServletException, IOException {

        // Step 1: Get the Session object

        boolean create = true;
        HttpSession session = request.getSession(create);

        // Step 2: Get the session data value

        Integer ival = (Integer)
            session.getAttribute ("sessiontest.counter");
        if (ival == null) ival = new Integer (1);
        else ival = new Integer (ival.intValue () + 1);
        session.setAttribute ("sessiontest.counter", ival);

        // Step 3: Output the page
```

```

        response.setContentType("text/html");
        PrintWriter out = response.getWriter();
        out.println("<html>");
        out.println("<head><title>Session Tracking Test</title></head>");
        out.println("<body>");
        out.println("<h1>Session Tracking Test</h1>");
        out.println ("You have hit this page " + ival + " times" + "<br>");
        out.println ("Your " + request.getHeader("Cookie"));
        out.println("</body></html>");
    }
}

```

Assembling so that session data can be shared

By default, the session management facility supports session scoping by web module in accordance with the Servlet 2.3 and later API specification. Only servlets in the same web module can access the data associated with a particular session. However, you can use the `IBMApplicationSession` object or the IBM extension, shared session context, to share data outside of the web module scope.

About this task

The `IBMApplicationSession` object is a parent session object that can be retrieved by a web module's session and can share session attributes across all of the web modules in a business-level application. The default scope of the business-level application is the enterprise application. The shared session context option extends the scope of the session attributes as well. Using the shared session context extension, there is only one session object for the entire business-level application or for the default enterprise application.

If you are using a shared session for a business-level application, then the class files for all objects placed in the session must exist in an isolated shared library and be common among all applications.

The benefit to using the `IBMApplicationSession` method is that each web module can maintain its own session as well as have a reference to the shared session.

If you're migrating an application from a previous version of the product, the `IBMApplicationSession` method requires a change to the application logic of the application.

Restriction: To use a shared session, you must install all applications within a business-level application on a given server. You cannot split up the enterprise application by servers. For example, you cannot use this option when one enterprise application in "BLA1" is installed on one server and a second enterprise application also in "BLA1" is installed on a different server. In such split installations, applications might share session attributes across web modules using distributed sessions, but session data integrity is lost when concurrent access to a session is made in different web modules. It also severely restricts use of some session management features, like `TIME_BASED_WRITES`.

For enterprise applications on which this shared session context extension is enabled, the session management configuration on the web module inside the enterprise application is ignored. Then session management configuration defined on enterprise application is used if session management is overwritten at the enterprise application level. Otherwise, the session management configuration on the web container is used. If using multiple enterprise applications within a business-level application, the session management configuration must be common among all applications and web modules within this business-level application.

`HttpSession` listeners that are defined in all the web modules inside the business-level application or enterprise application are invoked for session events. The order of listener invocation is not guaranteed.

Complete the following to share session data across the business-level application.

Procedure

1. Complete the following to share session data using the `IBMApplicationSession` object within the application code.
 - a. Retrieve the session object

```
HttpSession session = request.getSession();
```
 - b. Cast this object to an `IBMSession` object and call the `getIBMApplicationSession` method.

```
IBMApplicationSession appSession = ((IBMSession)session).getIBMApplicationSession();
```
 - c. Use the `appSession` like a normal session object.
2. Do the following to share session data using the Shared session context extension.
 - a. Start an assembly tool.
 - b. In the assembly tool, right-click the application (EAR file) that you want to share and click **Open With > Deployment Descriptor Editor**.
 - c. In the application deployment descriptor editor of the assembly tool, select **Shared session context** under WebSphere Extensions. Make sure the class definition of attributes put into session are available to all web modules in the enterprise application. The shared session context does not fully meet the requirements of the specifications.
 - d. Save the application (EAR) file. In the assembly tool, after you close the application deployment descriptor editor, confirm that you want to save changes made to the application.

Chapter 27. Developing web services

This page provides a starting point for finding information about web services.

Web services are self-contained, modular applications that can be described, published, located, and invoked over a network. They implement a services oriented architecture (SOA), which supports the connecting or sharing of resources and data in a very flexible and standardized manner. Services are described and organized to support their dynamic, automated discovery and reuse.

Using JAXB for XML data binding

Java Architecture for XML Binding (JAXB) is a Java technology that provides an easy and convenient way to map Java classes and XML schema for simplified web services development. JAXB provides the `xjc` schema compiler, the `schemagen` schema generator and a runtime framework to support marshalling and unmarshalling of XML documents to and from Java objects.

About this task

JAXB is an XML-to-Java binding technology that enables transformation between schema and Java objects and between XML instance documents and Java object instances. JAXB technology consists of a runtime API and accompanying tools that simplify access to XML documents. You can use JAXB APIs and tools to establish mappings between Java classes and XML schema. An XML schema defines the data elements and structure of an XML document. JAXB technology provides tooling to enable you to convert your XML documents to and from Java objects. Data stored in an XML document is accessible without the need to understand the XML data structure.

JAXB is the default data binding technology used by the Java API for XML Web Services (JAX-WS) tooling and implementation within this product. You can develop JAXB objects to use within your JAX-WS applications. You can also use JAXB independently of the JAX-WS programming model as a convenient way to leverage the XML data binding technology to manipulate XML within your Java applications.

Note: This version of the application server supports the JAXB 2.2 specification. JAX-WS 2.2 requires JAXB 2.2 for data binding. JAXB 2.2 provides minor enhancements to its annotations for improved schema generation and better integration with JAX-WS.

Note: The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

JAXB provides the `xjc` schema compiler tool, the `schemagen` schema generator tool, and a runtime framework. The `xjc` schema compiler tool enables you to start with an XML schema definition (XSD) to create a set of JavaBeans that map to the elements and types defined in the XSD schema. You can also start with a set of JavaBeans and use the `schemagen` schema generator tool to create the XML schema. After using either the schema compiler or the schema generator command-line tools, you can convert your XML documents both to and from Java objects and use the resulting Java classes to assemble a web services application.

In addition to using the tools from the command-line, you can invoke these JAXB tools from within the Ant build environments. Use the `com.sun.tools.xjc.XJCTask` Ant task from within the Ant build environment to invoke the `xjc` schema compiler tool. Use the `com.sun.tools.xjc.SchemaGenTask` Ant task from within the Ant build environment to invoke the `schemagen` schema generator tool. These Ant tasks require that the `com.ibm.jaxb.tools.jar` and the `com.ibm.jaxws.tools.jar` files be in the classpath.

JAXB annotated classes and artifacts contain all the information that the JAXB runtime API needs to process XML instance documents. The JAXB runtime API enables marshaling of JAXB objects to XML files and unmarshaling the XML document back to JAXB class instances. The JAXB binding package, `javax.xml.bind`, defines the abstract classes and interfaces that are used directly with content classes. In addition the package defines the marshal and unmarshal APIs.

You can optionally use JAXB binding customizations to override the default generated type mappings. You can customize JAXB bindings using inline annotations in the source schema, or by using an external bindings customization file to pass your customizations to the JAXB binding compiler, `xjc`, to control the Java type mappings. Alternatively, you can add Java annotations to existing Java classes to pass to the schema generator, `schemagen`, to control the schema or XML type mappings. See the JAXB specification for information regarding binding customization options and Java annotations.

Using JAXB, you can manipulate data objects in the following ways:

Procedure

- Generate an XML schema from a Java class. Use the schema generator `schemagen` command to generate an XML schema from Java classes.
- Generate Java classes from an XML schema. Use the schema compiler `xjc` command to create a set of JAXB-annotated Java classes from an XML schema.
- Marshal and unmarshal XML documents. After the mapping between XML schema and Java classes exists, use the JAXB binding runtime to convert XML instance documents to and from Java objects.

Results

You now have JAXB objects that your Java application can use to manipulate XML data.

Using JAXB schemagen tooling to generate an XML schema file from a Java class

Use Java Architecture for XML Binding (JAXB) `schemagen` tooling to generate an XML schema file from Java classes.

Before you begin

Identify the Java classes or a set of Java objects to map to an XML schema file.

About this task

Use JAXB APIs and tools to establish mappings between Java classes and XML schema. XML schema documents describe the data elements and relationships in an XML document. After a data mapping or binding exists, you can convert XML documents to and from Java objects. You can now access data stored in an XML document without the need to understand the data structure.

To develop web services using a bottom-up development approach starting from existing JavaBeans or enterprise beans, use the `wsgen` tool to generate the artifacts for Java API for XML-Based Web Services (JAX-WS) applications. After the Java artifacts for your application are generated, you can create an XML schema document from an existing Java application that represents the data elements of a Java application by using the JAXB schema generator, `schemagen` command-line tool. The JAXB schema generator processes either Java source files or class files. Java class annotations provide the capability to customize the default mappings from existing Java classes to the generated schema components. The XML schema file along with the annotated Java class files contain all the necessary information that the JAXB runtime requires to parse the XML documents for marshaling and unmarshaling.

You can create an XML schema document from an existing Java application that represents the data elements of a Java application by using the JAXB schema generator, **schemagen** command-line tool. The JAXB schema generator processes either Java source files or class files. Java class annotations provide the capability to customize the default mappings from existing Java classes to the generated schema components. The XML schema file along with the annotated Java class files contain all the necessary information that the JAXB runtime requires to parse the XML documents for marshaling and unmarshaling.

Note: The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are located in the `app_server_root\bin\` directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the `app_server_root\bin\` directory.

Note: This product supports the JAXB 2.2 specification. JAX-WS 2.2 requires JAXB 2.2 for data binding.

JAXB provides compilation support to enable you to configure the **schemagen** schema generator so that it does not automatically generate a new schema. This is helpful if you are using a common schema such as the World Wide Web Consortium (W3C), XML Schema, Web Services Description Language (WSDL), or WS-Addressing and you do not want a new schema generated for a particular package that is referenced. The `location` attribute on the `@XmlSchema` annotation causes the **schemagen** generator to refer to the URI of the existing schema instead of generating a new one.

In addition to using the **schemagen** tool from the command-line, you can invoke this JAXB tool from within the Ant build environments. Use the `com.sun.tools.jxc.SchemaGenTask` Ant task from within the Ant build environment to invoke the **schemagen** schema generator tool. To function properly, this Ant task requires that you invoke Ant using the `ws_ant` script.

Note: When running the **schemagen** tool, the schema generator does not correctly read the `@XmlSchema` annotations from the package-info class file to derive targetNamespaces. Instead of using the `@XMLSchema` annotation, use one of the following methods:

- Provide a package-info.java file with the `@XmlSchema`; for example:

```
schemagen sample.Address sample\package-info.java
```

- Use the `@XmlType` annotation namespace attribute to specify a namespace; for example:

```
@XmlType(namespace="http://myNameSpace")
```

Procedure

1. Locate the Java source files or Java class files to use in generating an XML schema file. Ensure that all classes referenced by your Java class files are contained in the classpath or are provided to the tool using the `-classpath/-cp` options.
2. Use the JAXB schema generator, **schemagen** command to generate an XML schema. The schema generator is located in the `app_server_root\bin\` directory.

```
app_server_root/bin/schemagen myObj1.java myObj2.java
```

The parameters, myObj1.java and myObj2.java, are the names of the Java files containing the data objects. If myObj1.java or myObj2.java refer to Java classes that are not passed into the **schemagen** command, you must use the -cp option to provide the classpath location for these Java classes. Read about the **schemagen** command to learn more about this command and additional options that you can specify.

3. (Optional) Use JAXB program annotations defined in the javax.xml.bind.annotations package to customize the JAXB XML schema mappings.
4. (Optional) Configure the location property on the @XmlSchema annotation to indicate to the schema compiler to use an existing schema rather than generating a new one. For example,

```
@XmlSchema(namespace="foo")
package foo;
@XmlType
class Foo {
    @XmlElement Bar zot;
}
@XmlSchema(namespace="bar",
    location="http://example.org/test.xsd")
package bar;
@XmlType
class Bar {
    ...
}
<xs:schema targetNamespace="foo">
<xs:import namespace="bar"
    schemaLocation="http://example.org/test.xsd"/>
<xs:complexType name="foo">
<xs:sequence>
<xs:element name="zot" type="bar:Bar" xmlns:bar="bar"/>
</xs:sequence>
</xs:complexType>
</xs:schema>
```

the location="http://example.org/test.xsd" indicates the location on the existing schema to the **schemagen** tool and a new schema is not generated.

Results

Now that you have generated an XML schema file from Java classes, you are ready to marshal and unmarshal the Java objects as XML instance documents.

Note: The schemagen command does not differentiate the XML namespace between multiple @XMLType annotations that have the same @XMLType name defined within different Java packages. When this scenario occurs, the following error is produced:

```
Error: Two classes have the same XML type name ...
Use @XmlType.name and @XmlType.namespace to assign different names to them...
```

This error indicates you have class names or @XMLType.name values that have the same name, but exist within different Java packages. To prevent this error, add the @XML.Type.namespace class to the existing @XMLType annotation to differentiate between the XML types.

Example

The following example illustrates how JAXB tooling can generate an XML schema file from an existing Java class, Bookdata.java.

1. Copy the following Bookdata.java file to a temporary directory.

```
package generated;

import javax.xml.bind.annotation.XmlAccessType;
import javax.xml.bind.annotation.XmlAccessorType;
import javax.xml.bind.annotation.XmlAttribute;
import javax.xml.bind.annotation.XmlElement;
import javax.xml.bind.annotation.XmlType;
import javax.xml.datatype.XMLGregorianCalendar;

@XmlAccessorType(XmlAccessType.FIELD)
@XmlType(name = "bookdata", propOrder = {
    "author",
```

```

        "title",
        "genre",
        "price",
        "publishDate",
        "description"
    })
    public class Bookdata {

        @XmlElement(required = true)
        protected String author;
        @XmlElement(required = true)
        protected String title;
        @XmlElement(required = true)
        protected String genre;
        protected float price;
        @XmlElement(name = "publish_date", required = true)
        protected XMLGregorianCalendar publishDate;
        @XmlElement(required = true)
        protected String description;
        @XmlAttribute
        protected String id;

        public String getAuthor() {
            return author;
        }
        public void setAuthor(String value) {
            this.author = value;
        }
        public String getTitle() {
            return title;
        }

        public void setTitle(String value) {
            this.title = value;
        }

        public String getGenre() {
            return genre;
        }

        public void setGenre(String value) {
            this.genre = value;
        }

        public float getPrice() {
            return price;
        }

        public void setPrice(float value) {
            this.price = value;
        }

        public XMLGregorianCalendar getPublishDate() {
            return publishDate;
        }

        public void setPublishDate(XMLGregorianCalendar value) {
            this.publishDate = value;
        }

        public String getDescription() {
            return description;
        }

        public void setDescription(String value) {
            this.description = value;
        }

        public String getId() {
            return id;
        }

        public void setId(String value) {
            this.id = value;
        }
    }
}

```

2. Open a command prompt.

3. Run the schemagen schema generator tool from the directory where you copied the Bookdata.java file.

`app_server_root/bin/schemagen Bookdata.java`

4. The XML schema file, schema1.xsd is generated:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<xs:schema version="1.0" xmlns:xs="http://www.w3.org/2001/XMLSchema">
  <xs:complexType name="bookdata">
    <xs:sequence>
      <xs:element name="author" type="xs:string"/>
      <xs:element name="title" type="xs:string"/>
      <xs:element name="genre" type="xs:string"/>
      <xs:element name="price" type="xs:float"/>
      <xs:element name="publish_date" type="xs:anySimpleType"/>
      <xs:element name="description" type="xs:string"/>
    </xs:sequence>
    <xs:attribute name="id" type="xs:string"/>
  </xs:complexType>
</xs:schema>
```

Refer to the JAXB Reference implementation documentation for additional information about the **schemagen** command.

Using JAXB xjc tooling to generate JAXB classes from an XML schema file

Use Java Architecture for XML Binding (JAXB) xjc tooling to compile an XML schema file into fully annotated Java classes.

Before you begin

Develop or obtain an XML schema file.

About this task

Use JAXB APIs and tools to establish mappings between an XML schema and Java classes. XML schemas describe the data elements and relationships in an XML document. After a data mapping or binding exists, you can convert XML documents to and from Java objects. You can now access data stored in an XML document without the need to understand the data structure.

To develop web services using a top-down development approach starting with an existing Web Services Description Language (WSDL) file, use the **wsimport** tool to generate the artifacts for your Java API for XML-Based Web Services (JAX-WS) applications when starting with a WSDL file. After the Java artifacts for your application are generated, you can generate fully annotated Java classes from an XML schema file by using the JAXB schema compiler, **xjc** command-line tool. The resulting annotated Java classes contain all the necessary information that the JAXB runtime requires to parse the XML for marshaling and unmarshaling. You can use the resulting JAXB classes within Java API for XML Web Services (JAX-WS) applications or other Java applications for processing XML data.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are located in the `app_server_root\bin\` directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the `app_server_root\bin\` directory.

Note: This product supports the JAXB 2.2 specification. JAX-WS 2.2 requires JAXB 2.2 for data binding.

In addition to using the `xjc` tool from the command-line, you can invoke this JAXB tool from within the Ant build environments. Use the `com.sun.tools.xjc.XJCTask` Ant task from within the Ant build environment to invoke the `xjc` schema compiler tool. To function properly, this Ant task requires that you invoke Ant using the `ws_ant` script.

Note: If you are using the `xjc` Ant task, you must use the `destDir` parameter to specify the destination directory instead of the `target` option. Specifying the `target` option when using the `xjc` Ant task causes an error.

Procedure

1. Use the JAXB schema compiler, `xjc` command to generate JAXB-annotated Java classes. The schema compiler is located in the `app_server_root\bin\` directory. The schema compiler produces a set of packages containing Java source files and JAXB property files depending on the binding options used for compilation.
2. (Optional) Use custom binding declarations to change the default JAXB mappings. Define binding declarations either in the XML schema file or in a separate bindings file. You can pass custom binding files by using the `-b` option with the `xjc` command.
3. Compile the generated JAXB objects. To compile generated artifacts, add the Thin Client for JAX-WS with WebSphere Application Server to the classpath.

Results

Now that you have generated JAXB objects, you can write Java applications using the generated JAXB objects and manipulate the XML content through the generated JAXB classes.

Example

The following example illustrates how JAXB tooling can generate Java classes when starting with an existing XML schema file.

1. Copy the following `bookSchema.xsd` schema file to a temporary directory.

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema">
  <xsd:element name="CatalogData">
    <xsd:complexType >
      <xsd:sequence>
        <xsd:element name="books" type="bookdata" minOccurs="0"
          maxOccurs="unbounded"/>
      </xsd:sequence>
    </xsd:complexType>
  </xsd:element>
  <xsd:complexType name="bookdata">
    <xsd:sequence>
      <xsd:element name="author" type="xsd:string"/>
      <xsd:element name="title" type="xsd:string"/>
      <xsd:element name="genre" type="xsd:string"/>
      <xsd:element name="price" type="xsd:float"/>
      <xsd:element name="publish_date" type="xsd:dateTime"/>
      <xsd:element name="description" type="xsd:string"/>
    </xsd:sequence>
    <xsd:attribute name="id" type="xsd:string"/>
  </xsd:complexType>
</xsd:schema>
```

2. Open a command prompt.
3. Run the JAXB schema compiler, `xjc` command from the directory where the schema file is located. The `xjc` schema compiler tool is located in the `app_server_root\bin\` directory.

Running the `xjc` command generates the following JAXB Java files:

```
generated\Bookdata.java
generated\CatalogData.java
generated\ObjectFactory.java
```

4. Use the generated JAXB objects within a Java application to manipulate XML content through the generated JAXB classes.

Refer to the JAXB Reference implementation documentation for additional information about the `xjc` command.

Using the JAXB runtime to marshal and unmarshal XML documents

Use the Java Architecture for XML Binding (JAXB) run time to manipulate XML instance documents.

Before you begin

Use JAXB to generate Java classes from an XML schema with the schema compiler, `xjc` command or to generate an XML schema from a Java class with the schema generator, `schemagen` command.

About this task

Use JAXB APIs and tools to establish mappings between an XML schema and Java classes. After data bindings exist, use the JAXB binding runtime API to convert XML instance documents to and from Java objects. Data stored in an XML document is accessible without the need to understand the data structure. JAXB annotated classes and artifacts contains all the information that the JAXB runtime API needs to process XML instance documents. The JAXB runtime API enables marshaling of JAXB objects to XML and unmarshaling the XML document back to JAXB class instances.

Procedure

- Marshal JAXB objects to XML instance documents.

Use the JAXB runtime API to marshal or convert JAXB object instances into an XML instance document.

1. Instantiate your JAXB classes.
2. Invoke the JAXB marshaller.

This example demonstrates how to instantiate the generated JAXB objects within an application and use the `JAXBContext` class and the JAXB runtime marshaller APIs to marshal the JAXB objects into XML instances.

```
JAXBContext jc = JAXBContext.newInstance("myPackageName");
//Create marshaller
Marshaller m = jc.createMarshaller();
//Marshal object into file.
m.marshal(myJAXBObject, myOutputStream);
```

The JAXB Reference Implementation introduces additional vendor specific marshaller properties such as namespace prefix mapping, indentation, and character escaping control that are not defined by the JAXB specification. Use these properties to specify additional controls of the marshaling process. These properties operate with the JAXB Reference Implementation only and might not with other JAXB providers. Additional information regarding the vendor specific properties is located in the Java Architecture for XML Binding JAXB RI Vendor Extensions Runtime Properties specification.

- Unmarshal XML files to JAXB objects.

Use the JAXB runtime API to unmarshal or convert an XML instance document to JAXB object instances.

1. Obtain an existing XML instance document.
2. Invoke the JAXB unmarshaller.

This example demonstrates a program that reads an XML document and unmarshals or converts the XML document into JAXB object instances. Use the `JAXBContext` class and JAXB runtime `Unmarshaller` APIs to unmarshal the XML document.

```
JAXBContext jc = JAXBContext.newInstance("myPackageName");
//Create unmarshaller
Unmarshaller um = jc.createUnmarshaller();
//Unmarshal XML contents of the file myDoc.xml into your Java
object instance.
MyJAXBObject myJAXBObject = (MyJAXBObject)
um.unmarshal(new java.io.FileInputStream( "myDoc.xml" ));
```

Results

You can now marshal JAXB Java classes, and unmarshal XML data using the JAXB binding framework. Refer to the JAXB Reference implementation documentation for additional information about the marshal and unmarshal runtime APIs

Note: If Java 2 Security is enabled, wrap your `JAXBContext.newInstance()`, `Unmarshaller.unmarshal()` and, `Marshaller.marshal()` method calls within a `AccessController.doPrivileged` method to avoid a security exception.

xjc command for JAXB applications

Use the Java Architecture for XML Binding (JAXB) tools to generate Java classes from an XML schema with the `xjc` schema compiler tool.

JAXB is an XML-to-Java binding technology that enables transformation between schema and Java objects and between XML instance documents and Java object instances. JAXB technology consists of a runtime API and accompanying tools that simplify access to XML documents. You can use JAXB APIs and tools to establish mappings between Java classes and XML schema. An XML schema defines the data elements and structure of an XML document. JAXB technology provides a runtime environment to enable you to convert your XML documents to and from Java objects. Data stored in an XML document is accessible without the need to understand the XML data structure.

You can generate fully annotated Java classes from an XML schema file by using the JAXB schema compiler, `xjc` command-line tool. Use the `xjc` schema compiler tool to start with an XML schema definition (XSD) to create a set of JavaBeans that map to the elements and types defined in the XSD schema. Once the mapping between XML schema and Java classes exists, XML instance documents can be converted to and from Java objects through the use of the JAXB binding runtime API. The resulting annotated Java classes contains all the necessary information that the JAXB runtime requires to parse the XML for marshaling and unmarshaling. You can use the resulting JAXB classes within Java API for XML Web Services (JAX-WS) applications or in your non-JAX-WS Java applications for processing XML data.

Note: The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are located in the `app_server_root\bin\` directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the `app_server_root\bin\` directory.

In addition to using the `xjc` tool from the command line, you can invoke this JAXB tool from within the Ant build environments. Use the `com.sun.tools.xjc.XJCTask` Ant task from within the Ant build environment to invoke the `xjc` schema compiler tool. To function properly, this Ant task requires that you invoke Ant using the `ws_ant` script.

Note: If you are using the `xjc` Ant task, you must use the `destdir` parameter to specify the destination directory instead of the `target` option. Specifying the `target` option when using the `xjc` Ant task causes an error.

Syntax

The command-line syntax is:

```
IBM i  
app_server_root/bin/xjc [options] <schema_file/URL/directory_or_jar> ...[-b<binding_information>] ...
```

If a directory is specified, all schema files in the directory are compiled.

Parameters

The schema file/URL JAR file name or location of the directory is the only parameter that is required. The following parameters are optional for the `xjc` command:

- b <file_name or directory>**
Specifies the external JAX-WS or JAXB binding files. You can specify multiple JAX-WS and JAXB binding files by using the `-b` option; however, each file must be specified with its own `-b` option. If a directory is specified, `**/*.xjb` is searched.
- catalog <file_name>**
Specifies the catalog file to resolve external entity references. It supports the TR9401, XCatalog, and the OASIS XML Catalog formats.
- classpath <path>**
Specifies the location of the class files.
- d <directory>**
Specifies where to place the generated output files.
- dtd**
Specifies to treat the input as XML Document Type Definition (DTD). This option is unsupported and experimental.
- extension**
Specifies whether to enable custom extensions for functionality not specified by the JAXB specification. Use of the extensions can result in applications that are not portable or do not interoperate with other implementations.
- help**
Displays the help menu.
- httpproxy <[user[:password]@]<proxyhost>:<proxyport>>**
Specifies an HTTP or HTTPs proxy.
- httpproxyfile <file_name>**
This parameter is similar to the `-httpproxy` parameter, but takes the argument in a file to protect the password.
- no-header**
Specifies to suppress the generation of a file header with a timestamp.
- npa**
Specifies to suppress the generation of the `**/package-info.java` package level annotation.
- nv**
Specifies to not perform a strict validation of the input schemas.

- p <package_name>**
Specifies a target package.
- quiet**
Specifies to suppress the output from the `xjc` tool.
- relaxng**
Specifies to treat the input as REgular LAnguage for XML Next Generation (RELAX NG). This option is unsupported and experimental.
- readOnly**
Specifies that the generated files are in read-only mode.
- relaxng-compact**
Specifies to treat the input as REgular LAnguage for XML Next Generation (RELAX NG) compact syntax. This option is unsupported and experimental.
- target <version>**
Specifies to generate output to conform to the specified level of the JAX-WS specification. Specify 2.0 or 2.1 for the tool to generate compliant code for the JAXB 2.0 or JAX-WS 2.1 specification respectively. Specify 2.1 for the tool to generate compliant code for the JAXB 2.1 specification. The default target version is 2.2 and generates compliant code for the JAXB 2.2 specification.
- verbose**
Specifies to output messages about what the compiler is doing.
- version**
Prints the version information. If you specify this option, only the version information is output and typical command processing does not occur.
- wsdl**
Specifies to treat the input as a Web Services Description Language (WSDL) file and compile schemas inside the WSDL. This option is unsupported and experimental.
- xmlschema**
Specifies to treat the input as a World Wide Web Consortium (W3C) XML schema. This value is the default.

schemagen command for JAXB applications

Use the schema generator tool, `schemagen`, to generate an XML schema using Java Architecture for XML Binding (JAXB).

Use JAXB APIs and tools to establish mappings between an XML schema and Java classes. XML schemas describe the data elements and relationships in an XML document. After a data mapping or binding exists, you can convert XML documents to and from Java objects. You can now access data stored in an XML document without the need to understand the data structure.

You can generate a schema file from Java classes using the `schemagen` schema generator tool to create the XML schema. After the mapping between XML schema and Java classes exists, XML instance documents can be converted to and from Java objects through the use of the JAXB binding runtime API. The resulting Java classes contain all the necessary information that the JAXB run time requires to parse the XML for marshaling and unmarshaling. You can use the JAXB classes within Java API for XML Web Services (JAX-WS) applications or in your non-JAX-WS Java applications for processing XML data.

Note: The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are located in the `app_server_root\bin` directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the `app_server_root\bin` directory.

Note: When running the `schemagen` tool to process JavaBeans, the schema generator will not automatically process the `@XmlSchema` annotations from existing `package-info.class` files to derive target namespaces. To assure that the `schemagen` tool processes namespace values correctly, use one of the following methods:

- Explicitly specify the `package-info.java` source file in the `schemagen` invocation; for example:

```
schemagen sample.Address sample\package-info.java
```

- Use the `@XmlType` annotation namespace attribute within your JavaBeans to specify a namespace; for example:

```
@XmlType(namespace="http://myNameSpace")  
public class Address {...}
```

In addition to using the `schemagen` tool from the command line, you can invoke this JAXB tool from within the Ant build environments. Use the `com.sun.tools.jxc.SchemaGenTask` Ant task from within the Ant build environment to invoke the `schemagen` schema generator tool. To function properly, this Ant task requires that you invoke Ant using the `ws_ant` script.

Syntax

The command-line syntax is:

```
app_server_root/bin/schemagen [options] <java_files>
```

Parameters

The following parameters are optional for the `schemagen` command:

-classpath <path>

Specifies the location of the Java source or class files.

-cp <path>

Specifies the location of the Java source or class files.

-d <path>

Specifies where to place the processor and the generated Java class files.

-episode<file_name>

Specifies to generate an episode file for separate compilation.

-encoding <encoding>

Specifies to use encoding when invoking the `-apt` or `-javac` tool. This property is applicable for JAXB 2.2 and later.

-help

Displays the help menu.

-version

Prints the version information. If you specify this option, only the version information is output and typical command processing does not occur.

Developing JAX-WS web services (bottom-up)

Setting up a development environment for web services

The application server provides command-line tools to develop web services clients and implementations that are based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. You must set up your development environment before you start developing web services.

Before you begin

Before you can set up a web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information on installing the application server, read about installing your application server environment.

About this task

Set up a web services development environment by completing the following actions.

Procedure

Set up the environment.

 Run the **setupCmdLine** script on the Qshell command line from the `./profile_root/bin` directory.

Results

You have set up an environment so that you can develop Web services.

What to do next

Implement web services applications. See the task overview for implementing web services applications information to learn about how to develop and implement a Java EE web service.

Developing JAX-WS web services with annotations

Java API for XML-Based Web Services (JAX-WS) supports two different service endpoint implementations types, the standard web service endpoint interface and a new Provider interface to enable services to work at the XML message level. By using annotations on the service endpoint implementation or client, you can define the service endpoint as a web service.

Before you begin

Set up a development environment for web services.

About this task

This task is a required step to develop JAX-WS web services.

JAX-WS technology supports the implementation of web services based on both the standard service endpoint interface and a new Provider interface. JAX-WS endpoints are like the endpoint implementations in the Java API for XML-based RPC (JAX-RPC) specification. Unlike JAX-RPC, the requirement for a service endpoint interface (SEI) is optional for JAX-WS web services. JAX-WS services that do not have an associated SEI are regarded as having an implicit SEI; whereas services that have an associated SEI

are regarded as having an explicit SEI. The service endpoint interfaces required by JAX-WS are also more generic than the service endpoint interfaces required by JAX-RPC. With JAX-WS, the SEI is not required to extend the `java.rmi.Remote` interface as required by the JAX-RPC specification.

The JAX-WS programming model also uses support for annotating Java classes with metadata to define a service endpoint implementation as a web service and define how a client can access the web service. JAX-WS supports annotations based on the Metadata Facility for the Java Programming Language (JSR 175) specification, the Web Services Metadata for the Java Platform (JSR 181) specification and annotations defined by the JAX-WS 2.0 (JSR 224) specification, which includes Java Architecture for XML Binding (JAXB) annotations. Using annotations, the service endpoint implementation can independently describe the web service without requiring a WSDL file. Annotations can provide all the WSDL information necessary to configure your service endpoint implementation or web services client. You can specify annotations on the service endpoint interface used by the client and the server, or on the server-side service implementation class.

For details regarding the supported standards and specifications, see the web services specifications and API documentation.

When developing a JAX-WS web service starting from existing Java classes, known as the bottom-up approach, you must annotate the class with either the `@WebService` (`javax.jws.WebService`) annotation or `@WebServiceProvider` (`javax.xml.ws.Provider`) annotation to initially define the class as a web service. The `@WebService` annotation defines the service as an SEI-based endpoint, while the `@WebServiceProvider` annotation defines the service as a Provider-based endpoint.

Develop SEI-based JAX-WS web services

For an SEI-based endpoint, the service endpoint interface (SEI), whether it is a Java class or a Java interface, declares the business methods provided by a particular web service. The only methods that a web services client can invoke on a JAX-WS endpoint are the business methods that are defined in the explicit or implicit SEI.

All SEI-based endpoints are required to have the `@WebService` annotation included on the implementation class. If the service implementation uses an explicit SEI, then that interface must be referenced by the `endpointInterface` attribute on the `@WebService` annotation. If the service implementation does not use an explicit SEI, then the service is described implicitly by the implementation class and is an implicit SEI.

Develop JAX-WS web services using the Provider interface

The JAX-WS programming model introduces the Provider interface for Provider endpoints, `javax.xml.ws.Provider`, as the dynamic alternative to SEI-based endpoints. The Provider interface supports a more messaging-oriented approach to web services. With the Provider interface, you can create a Java class that implements a simple interface to produce a generic service implementation class. The Provider interface defines one method, the `invoke` method, which uses generics to control both the input and output types when working with various messages or message payloads. All Provider endpoints must be annotated with the `@WebServiceProvider` (`javax.xml.ws.WebServiceProvider`) annotation. A service implementation cannot specify the `@WebService` annotation if it implements the `javax.xml.ws.Provider` interface.

Starting with WebSphere Application Server Version 7.0 and later, Java EE 5 application modules (web application modules version 2.5 or above, or EJB modules version 3.0 or above) are scanned for annotations to identify JAX-WS services and clients. However, pre-Java EE 5 application modules (web application modules version 2.4 or before, or EJB modules version 2.1 or before) are not scanned for JAX-WS annotations, by default, for performance considerations. In the Version 6.1 Feature Pack for Web Services, the default behavior is to scan pre-Java EE 5 web application modules to identify JAX-WS services and to scan pre-Java EE 5 web application modules and EJB modules for service clients during application installation. Because the default behavior for WebSphere Application Server Version 7.0 and later is to not scan pre-Java EE 5 modules for annotations during application installation or server startup,

to preserve backward compatibility with the feature pack from previous releases, you must configure either the `UseWSFEP61ScanPolicy` property in the `META-INF/MANIFEST.MF` of a web application archive (WAR) file or EJB module or define the Java virtual machine custom property, `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy`, on servers to request scanning during application installation and server startup. To learn more about annotations scanning, see the JAX-WS annotations information.

Procedure

1. Determine if you want to define your web services using SEI endpoints or the Provider interface. If you prefer a high-level Java-centric abstraction that hide the details of converting between Java objects and their XML representation, consider using SEI-based endpoints to develop your web services. However, if you prefer that your web service operate more at the XML message level, consider using Provider-based endpoints.
2. Annotate the service endpoints.
 - a. Annotate the SEI-based endpoint with the `javax.jws.WebService` annotation.
 - For an SEI-based endpoint, annotate the implementation class with the `javax.jws.WebService` annotation. You can choose to explicitly reference a service endpoint interface by defining the `@WebService.endpointInterface` attribute, which specifies this endpoint is an explicit SEI. In this case, the Java interface that is referenced must also contain the `javax.jws.WebService` annotation. If the `endpointInterface` attribute is not defined or is empty, the implementation bean is considered an implicit SEI. You can add the `@WebMethod` annotation to methods of a service endpoint interface to customize the Java-to-WSDL mappings. All public methods are considered exposed methods regardless of whether the `@WebMethod` annotation is specified. It is incorrect to have an `@WebMethod` annotation on a service endpoint interface that contains the `exclude` attribute.
 - If you use an implicit SEI, you can apply more granular control on how the methods are exposed through selective use of the `@WebMethod` annotation. For a more detailed explanation, see the exposing methods in SEI-based JAX-WS web services information.
 - b. Annotate the Provider-based endpoint with the `javax.xml.ws.WebServiceProvider` annotation.
 - For a Provider-based endpoint, annotate the implementation class with the `javax.xml.ws.WebServiceProvider` annotation. This annotation must be specified only on a class that implements a strongly typed `javax.xml.ws.Provider` interface class such as `Provider<Source>` or `Provider<SOAPMessage>`, in contrast to a class that is unbounded, such as `Provider<T>`. A strongly typed class is one that is associated with a specific input and output Java type, such as `Source` or `SOAPMessage`, for example.
3. Understand and apply best practices for exposing methods as operations in SEI-based JAX-WS web services.

```
@WebServiceProvider(  
    serviceName="StringProviderService",  
    wsdlLocation="META-INF/echostring.wsdl",  
    targetNamespace="http://stringprovider.sample.test.org")
```

- (optional) According to the JAX-WS 2.2 specification, if you are defining a Provider-based endpoint so that the Provider implementation returns a null value, no response is needed. If the `javax.xml.ws.WebServiceProvider` annotation does not specify a WSDL, and the `Provider` `invoke()` method returns a null value, the default behavior of the JAX-WS runtime environment is to return a response that consists of a `SOAPEnvelope` that contains an empty `SOAPBody`. You can set the `JVM` property, `jaxws.provider.interpretNullAsOneway`, to `true` if you want the JAX-WS runtime environment to interpret this scenario as a request-only operation and not return a response.

Because of ambiguity across multiple web services specifications regarding which methods are exposed as web services operations for SEI-based endpoints, you can ensure consistent behavior by following best practices, regardless of the JAX-WS implementation that you use.

Results

You have defined the service endpoint implementation that represents the web services application. See the JAX-WS annotations documentation to learn more about the supported JAX-WS annotations.

Sample JavaBeans service endpoint implementation and interface

The following example illustrates a simple explicit JavaBeans service endpoint implementation and the associated service endpoint interface:

```
/** This is an excerpt from the service implementation file, EchoServicePortTypeImpl.java.
package com.ibm.was.wssample.echo;
import java.io.ByteArrayInputStream;
import java.io.ByteArrayOutputStream;

import javax.xml.bind.JAXBContext;
import javax.xml.bind.Marshaller;
import javax.xml.bind.Unmarshaller;
import javax.xml.transform.stream.StreamSource;

@javax.jws.WebService(serviceName = "EchoService", endpointInterface =
"com.ibm.was.wssample.echo.EchoServicePortType", targetNamespace="http://com.ibm.was/wssample/echo/",
portName="EchoServicePort")
public class EchoServicePortTypeImpl implements EchoServicePortType {

    public EchoServicePortTypeImpl() {
    }

    public String echo(String obj) {
        String str;
        ....
        str = obj;
        ....

        return str;
    }
}

/** This is a sample EchoServicePortType.java service interface. */

import javax.jws.WebMethod;
import javax.jws.WebService;
import javax.xml.ws.*;

@WebService(name = "EchoServicePortType", targetNamespace = "http://com.ibm.was/wssample/echo/",
wsdlLocation="WEB-INF/wsdl/Echo.wsdl")
public interface EchoServicePortType {

    /** ...the method process ...*/
    @WebMethod
}

```

The following example illustrates a simple Provider service endpoint interface for a Java class:

```
package javax.xml.ws.provider;

import javax.xml.ws.Provider;
import javax.xml.ws.WebServiceProvider;
import javax.xml.transform.Source;

@WebServiceProvider()
public class SourceProvider implements Provider<Source> {

    public Source echo(Source data) {
        return data;
    }
}

```

In the Provider implementation example, the `javax.xml.transform.Source` type is specified in the generic `<Source>` method. The generic `<Source>` method specifies that both the input and output types are `Source` objects.

What to do next

Develop Java artifacts for JAX-WS applications from JavaBeans. To learn more, see the generating Java artifacts for JAX-WS applications information.

Directory conventions

References in product information to `app_server_root`, `profile_root`, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

IBM i

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root

The default installation root directory for the Application Client for IBM WebSphere Application Server is the `/QIBM/ProdData/WebSphere/AppClient/V85/client` directory.

app_client_user_data_root

The default Application Client for IBM WebSphere Application Server user data root is the `/QIBM/UserData/WebSphere/AppClient/V85/client` directory.

app_client_profile_root

The default Application Client for IBM WebSphere Application Server profile root is the `/QIBM/UserData/WebSphere/AppClient/V85/client/profiles/profile_name` directory.

app_server_root

The default installation root directory for WebSphere Application Server is the `/QIBM/ProdData/WebSphere/AppServer/V85/Base` directory.

java_home

Table 92. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32-bit IBM Technology for Java	<code>/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit</code>
64-bit IBM Technology for Java	<code>/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit</code>

plugins_profile_root

The default Web Server Plug-ins profile root is the `/QIBM/UserData/WebSphere/Plugins/V85/webserver/profiles/profile_name` directory.

plugins_root

The default installation root directory for Web Server Plug-ins is the `/QIBM/ProdData/WebSphere/Plugins/V85/webserver` directory.

plugins_user_data_root

The default Web Server Plug-ins user data root is the `/QIBM/UserData/WebSphere/Plugins/V85/webserver` directory.

product_library

product_lib

This is the product library for the installed product. The product library for each Version 8.5

installation on the system contains the program and service program objects (similar to .exe, .dll, .so objects) for the installed product. The product library name is QWAS85x (where x is A, B, C, and so on). The product library for the first WebSphere Application Server Version 8.5 product installed on the system is QWAS85A. The *app_server_root/properties/product.properties* file contains the value for the product library of the installation, *was.install.library*, and is located under the *app_server_root* directory.

profile_root

The default directory for a profile named *profile_name* for WebSphere Application Server is the */QIBM/UserData/WebSphere/AppServer/V85/Base/profiles/profile_name* directory.

shared_product_library

The shared product library, which contains all of the objects shared by all installations on the system, is QWAS85. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root

The default user data directory for WebSphere Application Server is the */QIBM/UserData/WebSphere/AppServer/V85/Base* directory.

The profiles and profileRegistry subdirectories are created under this directory when you install the product.

The *user_data_root* directory contains the default locations for WLP_USR_DIR and WLP_OUTPUT_DIR when the Liberty profile is installed. These directories are *user_data_root/wlp/usr* and *user_data_root/wlp/output/servers*, respectively.

web_server_root

The default web server path is */www/web_server_name*.

Exposing methods in SEI-based JAX-WS web services

You can use the `@WebService` and `@WebMethod` annotations on a service endpoint implementation to specify Java methods that you want to expose as Java API for XML-Based Web Services (JAX-WS) web services.

Before you begin

JAX-WS technology enables the implementation of web services based on both the standard service endpoint interface and a Provider interface. When developing a JAX-WS web service starting from existing Java classes, known as the bottom-up approach, you must annotate the class with either the `@WebService` or `@WebServiceProvider` annotation to initially define the class as a web service.

Using the Provider interface is the dynamic approach to defining your JAX-WS services. To use the Provider interface, your class must implement the `javax.xml.ws.Provider` interface, and contain the `@WebServiceProvider` annotation. The Provider interface has one method, the `invoke` method, which uses generics in the Java programming language to control both the input and output types when working with various messages or message payloads.

In contrast, this topic describes how you can use Java annotations to describe your web services using the service endpoint interface (SEI) approach.

About this task

To initially define a web service, annotate the Java class with the `@WebService` annotation. You can also selectively annotate individual methods with the `@WebMethod` annotation to control their exposure as web services operations.

Because of ambiguities across multiple web services specifications regarding how methods are exposed as operations, use the following guidelines to help ensure consistent behavior regardless of the JAX-WS implementation that you use.

- To define a basic web service, annotate the implementation class with the `@WebService` annotation.
- To define your web services using an explicit SEI, explicitly reference a Java interface class using the `endpointInterface` attribute of the `@WebService` annotation.
- Provide a reference to a WSDL file in the `wSDLLocation` attribute of the `@WebService` annotation. By specifying a pre-defined WSDL file, performance is improved. Also, discrepancies between the WSDL file and the annotations are reported to you by the runtime environment.
- When you use an explicit SEI, all public methods in the SEI and inherited classes are always exposed. You only need to add `@WebMethod` annotations if you want to further customize the methods that are already exposed.
- Providing a reference in the `@WebService` annotation to an explicit SEI or to an existing WSDL file helps to remove possible ambiguities when exposing methods.
- If you do not use an explicit SEI, follow these rules to ensure that your methods are exposed consistently:
 - Add an `@WebService` annotation to your implementation class and all its superclasses that contain methods that you want to expose. Adding an `@WebService` annotation to a class exposes all public methods in that class that are not static or final.
 - If you want more granular control to expose only certain methods, use the `@WebMethod` annotation on selected methods. To ensure that a method is exposed, annotate it with the `@WebMethod` annotation. If you want to make sure that a method is not exposed, annotate it with the `@WebMethod(exclude=true)` annotation.

Note:

Behavior change for exposing methods that are not annotated:

The behavior of JAX-WS has changed regarding exposing methods as web services operations. This complies with recent clarifications to JAX-WS specifications.

Applications without an explicit SEI or WSDL that are migrated from prior versions might have additional operations exposed as shown below. You can set a property so the JAX-WS runtime environment uses the legacy behavior. You might need this when migrating applications without a WSDL or an SEI so that additional methods are not exposed.

```
@WebService
public class Foo {
    @WebMethod
    public void a() {} // exposed now, exposed before
    public void b() {} // exposed now, not exposed before
}
```

Using the new interpretation, public methods in an implementation class and its superclasses are only exposed under the following conditions:

- The containing class has an `@WebService` annotation.
- The method does not have an `@WebMethod(exclude=true)` annotation.

Using the legacy interpretation, a method in an implementation class and its superclasses are only exposed under the following conditions:

- The containing class has an `@WebService` annotation.
- The method has no `@WebMethod` annotations AND no other methods have `@WebMethod` annotations.
- The method has an `@WebMethod` or `@WebMethod(exclude=false)` annotation.

To specify that the JAX-WS runtime environment use the legacy `@WebMethod` behavior, configure the `jaxws.runtime.legacyWebMethod=true` property. You can configure this property as a Java Virtual Machine (JVM) system property or as a property in the `META-INF/MANIFEST.MF` file of a web application archive (WAR) file. By default, this property is set to `false` and the application server uses the new behavior.

You might encounter a `WSWS7054E` error message if all of the following conditions are true:

- Your web service application consists of unannotated methods.
- The methods are not meant to be mapped to a web service operation.
- Your application does not reference an SEI nor package a WSDL file.

The error message contains information that is similar to the following text:

```
javax.xml.ws.WebServiceException: WSWS7054E:
The Web Services Description Language (WSDL) file could not be generated for the XXXX Web service implementation
class because of the following error: javax.xml.ws.WebServiceException: Unable to create JAXBContext
```

The JAX-WS tooling complies with the JAX-WS specification with respect to `@WebMethod` mapping principles. This change might affect applications that have been dependent on previously non-compliant default behavior. If your applications package and reference WSDL or an SEI and have ALL methods correctly annotated with the `@WebMethod` exclude flag in the SEI implementation, then this change does not affect you. However, if you are affected, add explicit annotations to your methods to ensure that they are excluded in WSDL generation. For example: `@WebMethod(exclude=true)` Also, you can package a WSDL with your application to eliminate the need for the run time to generate a WSDL on your behalf.

Behavior change for exposing static and final methods:

Static or final methods in a service without an explicit SEI are no longer exposed as web services operations. To expose them, package the WSDL with the application and set `jaxws.runtime.legacyWebMethod=true`.

Procedure

1. Identify the methods that you want to expose as web services operations.
2. Review the rules for exposing methods as operations on classes annotated with the `@WebService` annotation.
3. Use the best practices for applying the `@WebMethod` and `@WebService` annotations in applications without SEIs to appropriately expose methods as operations within your web services.

Results

You have used the `@WebMethod` annotation to specify which methods to expose as web services operations.

Note:

If you have upgraded your application server environment and you are experiencing problems, review the following troubleshooting information.

Client errors indicate a mismatch between the WSDL file and portType when using a JAX-WS tooling version 2.1.6 or higher environment

You might receive a client-side error message like the following message:

```
javax.xml.ws.WebServiceException: The Endpoint validation failed to validate due to the following errors:
:: Invalid Endpoint Interface ::
:: The number of operations in the WSDL portType does not match the number of methods in the SEI or web service
implementation class. wsdl operations = [...] dispatch operations = [....]
```

To correct this problem, you must regenerate client artifacts to match the WSDL file.

Note: Be sure to regenerate your client side artifacts any time you receive an updated WSDL file.

Clients that perform a ?WSDL operation on web services have non-dispatchable operations

After performing a ?WSDL operation, you might receive a WSDL file that contains more operations than the JAX-WS runtime environment can dispatch. If the client tries to invoke any of the non-dispatchable operations, the client receives an error like the following message:

The endpoint reference (EPR) for the Operation not found is `http://localhost:9086/example/BeanImpl2Service` and the WSA Action = `<WSA_action_from_server>`. If this EPR was previously reachable, contact the server administrator.

Clients must only access the operations that the web service intends to expose. You can correct this problem in one of the following ways:

- Modify the `@WebMethod` annotations in the web services application so that the resulting WSDL file exposes the correct set of operations.
- Set the `jaxws.runtime.legacyWebMethod` property to `false` to ensure that all operations in the WSDL are dispatched.

What to do next

Develop Java artifacts for JAX-WS applications from JavaBeans.

JAX-WS annotations

Java API for XML-Based Web Services (JAX-WS) relies on the use of annotations to specify metadata associated with web services implementations and to simplify the development of web services. Annotations describe how a server-side service implementation is accessed as a web service or how a client-side Java class accesses web services.

The JAX-WS programming standard introduces support for annotating Java classes with metadata that is used to define a service endpoint application as a web service and how a client can access the web service. JAX-WS supports the use of annotations based on the Metadata Facility for the Java Programming Language (Java Specification Request (JSR) 175) specification, the Web Services Metadata for the Java Platform (JSR 181) specification and annotations defined by the JAX-WS 2.0 and later (JSR 224) specification which includes JAXB annotations. Using annotations from the JSR 181 standard, you can simply annotate the service implementation class or the service interface and now the application is enabled as a web service. Using annotations within the Java source simplifies development and deployment of web services by defining some of the additional information that is typically obtained from deployment descriptor files, WSDL files, or mapping metadata from XML and WSDL into the source artifacts.

Use annotations to configure bindings, handler chains, set names of portType, service and other WSDL parameters. Annotations are used in mapping Java to WSDL and schema, and at runtime to control how the JAX-WS runtime processes and responds to web service invocations.

For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

Starting with WebSphere Application Server Version 7.0 and later, Java EE 5 application modules (Web application modules version 2.5 or above, or EJB modules version 3.0 or above) are scanned for annotations to identify JAX-WS services and clients. However, pre-Java EE 5 application modules (web application modules version 2.4 or before, or EJB modules version 2.1 or before) are not scanned for JAX-WS annotations, by default, for performance considerations.

In the Version 6.1 Feature Pack for Web Services, the default behavior is to scan pre- Java Platform, Enterprise Edition (Java EE) 5 web application modules to identify JAX-WS services and to scan pre-Java EE 5 web application modules and EJB modules for service clients during application installation. Because the default behavior for WebSphere Application Server Version 7.0 and later is to not scan pre-Java EE 5 modules for annotations during application installation or server startup, to preserve backward compatibility with the feature pack from previous releases, you must configure one of the following properties:

- You can set the `UseSFEP61ScanPolicy` property in the META-INF/MANIFEST.MF of a WAR file or EJB module to true. For example:

```
Manifest-Version: 1.0
UseSFEP61ScanPolicy: true
```

When this property is set to true in the META-INF/MANIFEST.MF file of the module, the module is scanned for JAX-WS annotations regardless of the Java EE version of the module. The default value is false and when the default value is in effect, JAX-WS annotations are only supported in modules whose version is Java EE 5 or later.

- You can set the `com.ibm.websphere.webservices.UseSFEP61ScanPolicy` custom Java virtual machine (JVM) property using the administrative console. See the JVM custom properties documentation for the correct navigation path to use. To request annotation scanning in all modules regardless of their Java EE version, set the custom property `com.ibm.websphere.webservices.UseSFEP61ScanPolicy` to true. You must change the setting on each server that requires a change in the default behavior.

If the property is set within the META-INF/MANIFEST.MF file of the module, this setting takes precedence over the server's custom JVM property. When using either property, you must establish the desired annotation scanning behavior before the application is installed. You cannot dynamically change the scanning behavior once an application is installed. If changes to the behavior are required after your application is installed, you must first uninstall the application, specify the desired scanning behavior using the appropriate property and then install the application again. When federating nodes that have the `com.ibm.websphere.webservices.UseSFEP61ScanPolicy` set to true in the configuration of the servers contained within the node, this property does not affect the deployment manager. You must set the property to true on the deployment manager before the node is federated to preserve the behavior as it was on the node before federation.

Annotations supported by JAX-WS are listed in the table below. The target for annotations is applicable for these Java objects:

- types such as a Java class, enum or interface
- methods
- fields representing local instance variables within a Java class
- parameters within a Java method

Table 93. Web services Metadata Annotations (JSR 181). Describes the supported web services metadata annotations and their associated properties.

Annotation class	Annotation	Properties
javax.jws.WebService	<p>The @WebService annotation marks a Java class as implementing a Web service or marks a service endpoint interface (SEI) as implementing a web service interface.</p> <p>Important:</p> <ul style="list-style-type: none"> A Java class that implements a web service must specify either the <code>@WebService</code> or <code>@WebServiceProvider</code> annotation. Both annotations cannot be present. This annotation is applicable on a client or server SEI or a server endpoint implementation class. If the annotation references an SEI through the <code>endpointInterface</code> attribute, the SEI must also be annotated with the <code>@WebService</code> annotation. See the exposing methods in SEI-based JAX-WS web services information to learn about best practices for using the <code>@WebService</code> and <code>@WebMethod</code> annotations on a service endpoint implementation to specify Java methods that you want to expose as JAX-WS web services. 	<ul style="list-style-type: none"> Annotation target: Type Properties: <ul style="list-style-type: none"> name The name of the <code>wsdl:portType</code>. The default value is the unqualified name of the Java class or interface. (String) targetNamespace Specifies the XML namespace of the WSDL and XML elements generated from the web service. The default value is the namespace mapped from the package name containing the web service. (String) serviceName Specifies the service name of the web service: <code>wsdl:service</code>. The default value is the simple name of the Java class + <code>Service</code>. (String) endpointInterface Specifies the qualified name of the service endpoint interface that defines the services' abstract web service contract. If specified, the service endpoint interface is used to determine the abstract WSDL contract. (String) portName The <code>wsdl:portName</code>. The default value is <code>WebService.name + Port</code>. (String) wsdlLocation Specifies the web address of the WSDL document defining the web service. The web address is either relative or absolute. (String)
javax.jws.WebMethod	<p>The @WebMethod annotation denotes a method that is a web service operation.</p> <p>Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.</p>	<ul style="list-style-type: none"> Annotation target: Method Properties: <ul style="list-style-type: none"> operationName Specifies the name of the <code>wsdl:operation</code> matching this method. The default value is the name of Java method. (String) action Defines the action for this operation. For SOAP bindings, this value determines the value of the SOAPAction header. The default value is the name of Java method. (String) exclude Specifies whether to exclude a method from the web service. The default value is <code>false</code>. (Boolean)

Table 93. Web services Metadata Annotations (JSR 181) (continued). Describes the supported web services metadata annotations and their associated properties.

Annotation class	Annotation	Properties
javax.jws.Oneway	The @Oneway annotation denotes a method as a web service one-way operation that only has an input message and no output message. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	<ul style="list-style-type: none"> • Annotation target: Method • There are no properties on the Oneway annotation.
javax.jws.WebParam	The @WebParam annotation customizes the mapping of an individual parameter to a web service message part and XML element. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	<ul style="list-style-type: none"> • Annotation target: Parameter • Properties: <ul style="list-style-type: none"> - name <p>The name of the parameter. If the operation is remote procedure call (RPC) style and the <code>partName</code> attribute is not specified, then this is the name of the <code>wsdl:part</code> attribute representing the parameter. If the operation is document style or the parameter maps to a header, then <code>-name</code> is the local name of the XML element representing the parameter. This attribute is required if the operation is document style, the parameter style is BARE, and the mode is OUT or INOUT. (String)</p> - partName <p>Defines the name of <code>wsdl:part</code> attribute representing this parameter. This is only used if the operation is RPC style, or the operation is document style and the parameter style is BARE. (String)</p> - targetNamespace <p>Specifies the XML namespace of the XML element for the parameter. Applies only for document bindings when the attribute maps to an XML element. The default value is the <code>targetNamespace</code> for the web service. (String)</p> - mode <p>The value represents the direction the parameter flows for this method. Valid values are IN, INOUT, and OUT. (String)</p> - header <p>Specifies whether the parameter is in a message header rather than a message body. The default value is <code>false</code>. (Boolean)</p>

Table 93. Web services Metadata Annotations (JSR 181) (continued). Describes the supported web services metadata annotations and their associated properties.

Annotation class	Annotation	Properties
<p>javax.jws.WebResult</p>	<p>The @WebResult annotation customizes the mapping of a return value to a WSDL part or XML element.</p> <p>Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.</p>	<ul style="list-style-type: none"> • Annotation target: Method • Properties: <ul style="list-style-type: none"> - name <p>Specifies the name of the return value as it is listed in the WSDL file and found in messages on the wire. For RPC bindings, this is the name of the <code>wstl:part</code> attribute representing the return value. For document bindings, the <code>-name</code> parameter is the local name of the XML element representing the return value. The default value is <code>return</code> for RPC and <code>DOCUMENT/Wrapped</code> bindings. The default value is the method name + <code>Response</code> for <code>DOCUMENT/BARE</code> bindings. (String)</p> <ul style="list-style-type: none"> - targetNamespace <p>Specifies the XML namespace for the return value. This parameter is only used if the operation is <code>RPC</code> style or if the operation is <code>DOCUMENT</code> style and the parameter style is <code>BARE</code>. (String)</p> <ul style="list-style-type: none"> - header <p>Specifies whether the result is carried in a header. The default value is <code>false</code>. (Boolean)</p> <ul style="list-style-type: none"> - partName <p>Specifies the part name for the result with <code>RPC</code> or <code>DOCUMENT/BARE</code> operations. The default value is <code>@WebResult.name</code>. (String)</p>
<p>javax.jws.HandlerChain</p>	<p>The @HandlerChain annotation associates the web service with an externally defined handler chain.</p> <p>You can only configure the server side handler by using the <code>@HandlerChain</code> annotation on the <code>Service Endpoint Interface (SEI)</code> or the server endpoint implementation class.</p> <p>Use one of several ways to configure a client side handler. You can configure a client side handler by using the <code>@HandlerChain</code> annotation on the generated service class or <code>SEI</code>. Additionally, you can programmatically register your own implementation of the <code>HandlerResolver</code> interface on the <code>Service</code>, or programmatically set the handler chain on the <code>Binding</code> object.</p>	<ul style="list-style-type: none"> • Annotation target: Type • Properties: <ul style="list-style-type: none"> - file <p>Specifies the location of the handler chain file. The file location is either an absolute <code>java.net.URL</code> in external form or a relative path from the class file. (String)</p> <ul style="list-style-type: none"> - name <p>Specifies the name of the handler chain in the configuration file. (String)</p>

Table 93. Web services Metadata Annotations (JSR 181) (continued). Describes the supported web services metadata annotations and their associated properties.

<p>Annotation class</p> <p>javax.jws.SOAPBinding</p>	<p>Annotation</p> <p>The @SOAPBinding annotation specifies the mapping of the web service onto the SOAP message protocol.</p> <p>Apply this annotation to a type or methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.</p> <p>The method level annotation is limited in what it can specify and is only used if the <code>style</code> property is <code>DOCUMENT</code>. If the method level annotation is not specified, the @SOAPBinding behavior from the type is used.</p>	<p>Properties</p> <ul style="list-style-type: none"> • Annotation target: Type or Method • Properties: <ul style="list-style-type: none"> - style Defines encoding style for messages sent to and from the web service. The valid values are <code>DOCUMENT</code> and <code>RPC</code>. The default value is <code>DOCUMENT</code>. (String) - use Defines the formatting used for messages sent to and from the web service. The default value is <code>LITERAL</code>. <code>ENCODED</code> is not supported. (String) - parameterStyle Determines whether the method's parameters represent the entire message body or whether parameters are elements wrapped inside a top-level element named after the operation. Valid values are <code>WRAPPED</code> or <code>BARE</code>. You can only use the <code>BARE</code> value with <code>DOCUMENT</code> style bindings. The default value is <code>WRAPPED</code>. (String)
---	---	--

Table 94. JAX-WS Annotations (JSR 224). Describes the supported JAX-WS annotations and their associated properties.

Annotation class	Annotation	Properties
<p>javax.xml.ws.Action</p>	<p>The @Action annotation specifies the WS-Addressing action that is associated with a web service operation.</p> <p>When you use this annotation with a particular method, and generate the corresponding WSDL document, the WS-Addressing Action extension attribute is added to the input and output elements of the WSDL operation that corresponds to that method.</p> <p>To add this attribute to the WSDL operation, you must also specify the @Addressing annotation on the server endpoint implementation class. If you do not want to use the @Addressing annotation you can supply your own WSDL document with the Action attribute already defined.</p>	<ul style="list-style-type: none"> • Annotation target: Method • Properties: <ul style="list-style-type: none"> - fault Specifies the array of FaultAction for the wsdl: fault of the operation. (String) - input Specifies the action for thewsdl:input of the operation. (String) - output Specifies the action for thewsdl:output of the operation. (String)
<p>javax.xml.ws.BindingType</p>	<p>The @BindingType annotation specifies the binding to use when publishing an endpoint of this type.</p> <p>Apply this annotation to a server endpoint implementation class.</p> <p>Important: You can use the @BindingType annotation on the JavaBeans endpoint implementation class to enable MTOM by specifying either javax.xml.ws.soap.SOAPBinding.SOAP11HTTP_MTOM_BINDING or javax.xml.ws.soap.SOAPBinding.SOAP12HTTP_MTOM_BINDING as the value for the annotation.</p>	<ul style="list-style-type: none"> • Annotation target: Type • Properties: <ul style="list-style-type: none"> - value Indicates the binding identifier web address. Valid values are javax.xml.ws.soap.SOAPBinding.SOAP11HTTP_BINDING, javax.xml.ws.soap.SOAPBinding.SOAP12HTTP_BINDING, and javax.xml.ws.http.HTTPBinding.HTTP2HTTP_BINDING. The default value is javax.xml.ws.soap.SOAPBinding.SOAP11HTTP_BINDING. (String)
<p>javax.xml.ws.FaultAction</p>	<p>The @FaultAction annotation specifies the WS-Addressing action that is added to a fault response.</p> <p>This annotation must be contained within an @Action annotation.</p> <p>When you use this annotation with a particular method, the WS-Addressing FaultAction extension attribute is added to the fault element of the WSDL operation that corresponds to that method.</p> <p>To add this attribute to the WSDL operation, you must also specify the @Addressing annotation on the server endpoint implementation class. If you do not want to use the @Addressing annotation you can supply your own WSDL document with the Action attribute already defined.</p>	<ul style="list-style-type: none"> • Annotation target: Method • Properties: <ul style="list-style-type: none"> - value Specifies the action of the wsdl: fault of the operation. (String) - output Specifies the name of the exception class. (String) - className Specifies the name of the class representing the request wrapper. (String)

Table 94. JAX-WS Annotations (JSR 224) (continued). Describes the supported JAX-WS annotations and their associated properties.

Annotation class	Annotation	Properties
<p>javax.xml.ws.RequestWrapper</p>	<p>The @RequestWrapper annotation supplies the JAXB generated request wrapper bean, the element name, and the namespace for serialization and deserialization with the request wrapper bean that is used at runtime.</p> <p>When starting with a Java object, this element is used to resolve overloading conflicts in document literal mode. Only the <code>className</code> attribute is required in this case.</p> <p>Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.</p>	<ul style="list-style-type: none"> • Annotation target: Method • Properties: <ul style="list-style-type: none"> - localName Specifies the local name of the XML schema element representing the request wrapper. The default value is the <code>operationName</code> as defined in <code>javax.jws.WebMethod</code> annotation. (String) - targetNamespace Specifies the XML namespace of the request wrapper method. The default value is the target namespace of the SEI. (String) - className Specifies the name of the class representing the request wrapper. (String) - partName Specifies the name of the <code>wsdl:part</code> attribute that represents the XML schema element for the <code>RequestWrapper</code> class. This property is applicable for JAX-WS 2.2 and later. (String)
<p>javax.xml.ws.ResponseWrapper</p>	<p>The @ResponseWrapper annotation supplies the JAXB generated response wrapper bean, the element name, and the namespace for serialization and deserialization with the response wrapper bean that is used at runtime.</p> <p>When starting with a Java object, this element is used to resolve overloading conflicts in document literal mode. Only the <code>className</code> attribute is required in this case.</p> <p>Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.</p>	<ul style="list-style-type: none"> • Annotation target: Method • Properties: <ul style="list-style-type: none"> - localName Specifies the local name of the XML schema element representing the request wrapper. The default value is the <code>operationName</code> + <code>Response</code>. <code>operationName</code> is defined in <code>javax.jws.WebMethod</code> annotation. (String) - targetNamespace Specifies the XML namespace of the request wrapper method. The default value is the target namespace of the SEI. (String) - className Specifies the name of the class representing the response wrapper. (String) - partName Specifies the name of the <code>wsdl:part</code> attribute that represents the XML schema element for the <code>ResponseWrapper</code> class. This property is applicable for JAX-WS 2.2 and later. (String)

Table 94. JAX-WS Annotations (JSR 224) (continued). Describes the supported JAX-WS annotations and their associated properties.

Annotation class	Annotation	Properties
javax.xml.ws.RespectBinding	<p>The @RespectBinding annotation specifies whether the JAX-WS implementation must use the contents of the <code>wsdl:binding</code> for an endpoint.</p> <p>When this annotation is specified, a check is performed to ensure all required WSDL extensibility elements with the <code>enabled</code> attribute set to <code>true</code> are supported.</p> <p>Apply this annotation to methods on a server endpoint implementation class.</p>	<ul style="list-style-type: none"> • Annotation target: Method • Properties: <ul style="list-style-type: none"> - enabled Specifies whether the <code>wsdl:binding</code> must be used or not. The default value is <code>true</code>. (Boolean)
javax.xml.ws.ServiceMode	<p>The @ServiceMode annotation specifies whether a service provider needs to have access to an entire protocol message or just the message payload.</p> <p>Important: The <code>@ServiceMode</code> annotation is only supported on classes that are annotated with the <code>@WebServiceProvider</code> annotation.</p>	<ul style="list-style-type: none"> • Annotation target: Type • Properties: <ul style="list-style-type: none"> - value Indicates whether the provider class accepts the payload of the message, <code>PAYLOAD</code> or the entire message <code>MESSAGE</code>. The default value is <code>PAYLOAD</code>. (String)
javax.xml.ws.soap.Addressing	<p>The @Addressing annotation specifies that this service wants to enable WS-Addressing support.</p> <p>Apply this annotation to methods on a server endpoint implementation class.</p>	<ul style="list-style-type: none"> • Annotation target: Type • Properties: <ul style="list-style-type: none"> - enabled Specifies if WS-Addressing is enabled or not. The default value is <code>true</code>. (Boolean) - required Specifies that WS-Addressing headers must be present on incoming messages. The default value is <code>false</code>. (Boolean) - responses Specifies the message exchange pattern to use. The default value is <code>Responses.ALL</code>. This property is applicable for JAX-WS 2.2 and later. (String)

Table 94. JAX-WS Annotations (JSR 224) (continued). Describes the supported JAX-WS annotations and their associated properties.

Annotation class	Annotation	Properties
<p>javax.xml.ws.soap.MTOM</p>	<p>The @MTOM annotation specifies whether binary content in the body of a SOAP message is sent using MTOM.</p> <p>Apply this annotation to a service endpoint implementation class.</p>	<ul style="list-style-type: none"> • Annotation target: Class • Properties: <ul style="list-style-type: none"> - enabled Specifies if MTOM is enabled for the JAX-WS endpoint. The default value is <code>true</code>. (Boolean) - threshold Specifies the minimum size for messages that are sent using MTOM. When the message size is less than this specified integer, the message is inlined in the XML document as base64 or hexBinary data. (integer)
<p>javax.xml.ws.WebFault</p>	<p>The @WebFault annotation maps WSDL faults to Java exceptions. It is used to capture the name of the fault during the serialization of the JAXB type that is generated from a global element referenced by a WSDL fault message. It can also be used to customize the mapping of service specific exceptions to WSDL faults.</p> <p>This annotation can only be applied to a fault implementation class on the client or server.</p>	<ul style="list-style-type: none"> • Annotation target: Type • Properties: <ul style="list-style-type: none"> - name Specifies the local name of the XML element that represents the corresponding fault in the WSDL file. The actual value must be specified. (String) - targetNamespace Specifies the namespace of the XML element that represents the corresponding fault in the WSDL file. (String) - faultBean Specifies the name of the fault bean class. (String) - messageName Specifies the name of the wsdl:message attribute that represents the corresponding fault in the WSDL file. This property is applicable for JAX-WS 2.2 and later. (String)

Table 94. JAX-WS Annotations (JSR 224) (continued). Describes the supported JAX-WS annotations and their associated properties.

<p>Annotation class</p> <p>javax.xml.ws.WebServiceProvider</p>	<p>Annotation</p> <p>The @WebServiceProvider annotation denotes that a class satisfies requirements for a JAX-WS Provider implementation class.</p> <p>Important:</p> <ul style="list-style-type: none"> A Java class that implements a web service must specify either the <code>@WebService</code> or <code>@WebServiceProvider</code> annotation. Both annotations cannot be present. The <code>@WebServiceProvider</code> annotation is only supported on the service implementation class. <p>Any class with the <code>@WebServiceProvider</code> annotation must implement the <code>javax.xml.ws.Provider</code> interface.</p>	<p>Properties</p> <ul style="list-style-type: none"> Annotation target: Type Properties: <ul style="list-style-type: none"> - targetNamespace Specifies the XML namespace of the WSDL and XML elements generated from the web service. The default value is the namespace mapped from the package name containing the web service. (String) - serviceName Specifies the service name of the web service: <code>wsdl:service</code>. The default value is the simple name of the Java class + <code>Service</code>. (String) - portName The <code>wsdl:portName</code>. The default value is the name of the class + <code>Port</code>. (String) - wsdlLocation The web address of the WSDL document defining the web service. This attribute is required. (String)
---	---	--

Table 94. JAX-WS Annotations (JSR 224) (continued). Describes the supported JAX-WS annotations and their associated properties.

Annotation class	Annotation	Properties
<p>javax.xml.ws.WebServiceRef</p>	<p>The @WebServiceRef annotation defines a reference to a web service invoked by the client.</p> <p>Note:</p> <ul style="list-style-type: none"> The @WebServiceRef annotation can be used to inject instances of JAX-WS services and ports. The @WebServiceRef annotation is only supported in certain class types. Examples are JAX-WS endpoint implementation classes, JAX-WS handler classes, Enterprise JavaBeans classes, and servlet classes. This annotation is supported in the same class types as the @Resource annotation. See the Java Platform, Enterprise Edition (Java EE) 5 specification for a complete list of supported class types. 	<ul style="list-style-type: none"> Annotation target: Type, Field or Method Properties: <ul style="list-style-type: none"> - name Specifies the JNDI name of the resource. The field name is the default for field annotations. The JavaBeans property name that corresponds to the method is the default for method annotations. You must specify a value for class annotations as there is no default. (String) - type Indicates the Java type of the resource. The field type is the default for field annotations. The type of the JavaBeans property is the default for method annotations. You must specify a value for class annotations as there is no default. (Class) - mappedName Specifies the name to map this resource to. (String) - value Indicates the value of the service class and it is a type that extends <code>javax.xml.ws.Service</code>. This attribute is required when the type of the reference is a service endpoint interface. (Class) - wsdlLocation The web address of the WSDL document defining the web service. This attribute is required. (String) - lookup Specifies the JNDI lookup name for the target web service. This property is applicable for JAX-WS 2.2 and later. (String)
<p>javax.xml.ws.WebServiceRefs</p>	<p>The @WebServiceRefs annotation associates multiple @WebServiceRef annotations with a specific class.</p> <p>Note: The @WebServiceRef annotation is only supported in certain class types. Annotation class	Annotation	Properties
<p>com.ibm.websphere.wsaddressing. Jaxws21. SubmissionAddressing</p>	<p>The @SubmissionAddressing annotation specifies that this service wants to enable WS-Addressing support for the 2004/08 WS-Addressing specification.</p> <p>This annotation is part of the IBM implementation of the JAX-WS 2.1 specification.</p> <p>Apply this annotation to methods on a server endpoint implementation class.</p>	<ul style="list-style-type: none"> • Annotation target: Type • Properties: <ul style="list-style-type: none"> - enabled Specifies if WS-Addressing is enabled or not. The default value is true. (Boolean) - required Specifies that WS-Addressing headers must be present on incoming messages. The default value is false. (Boolean)

Generating Java artifacts for JAX-WS applications

Use Java API for XML-Based Web Services (JAX-WS) tools to generate the necessary JAX-WS and Java Architecture for XML Binding (JAXB) Java artifacts that are needed for JAX-WS web services applications when starting from JavaBeans or enterprise beans components.

Before you begin

To develop a Java API for XML-Based Web Services (JAX-WS) web service application, you must first develop a service endpoint interface (SEI) implementation that explicitly or implicitly describes the SEI.

About this task

When using a bottom-up approach to develop JAX-WS web services, use the **wsgen** command-line tool on the existing service endpoint implementation. The **wsgen** tool processes a compiled service endpoint implementation class as input and generates the following portable artifacts:

- Java Architecture for XML Binding (JAXB) classes that are required to marshal and unmarshal the message contents.
- a Web Services Description Language (WSDL) file if the optional *-wsdl* argument is specified.

Note: The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are located in the *app_server_root\bin* directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root\bin* directory.

You are not required to develop a WSDL file when developing JAX-WS Web services using the bottom-up approach of starting with JavaBeans. The use of annotations provides all of the WSDL information necessary to configure the service endpoint or the client. The application server supports WSDL 1.1 documents that comply with Web Services-Interoperability (WS-I) Basic Profile 1.1 specifications and are either Document/Literal style documents or RPC/Literal style documents. Additionally, WSDL documents with bindings that declare a USE attribute of value LITERAL are supported while the value, ENCODED, is not supported. For WSDL documents that implement a Document/Literal wrapped pattern, a root element is declared in the XML schema and is used as an operation wrapper for a message flow. Separate wrapper element definitions exist for both the request and the response.

To ensure the **wsgen** command does not miss inherited methods on a service endpoint implementation bean, you must either add the `@WebService` annotation to the desired superclass or you can override the inherited method in the implementation class with a call to the superclass method.

Although a WSDL file is typically optional when developing a JAX-WS service implementation bean, it is required if your JAX-WS endpoints are exposed using the SOAP over JMS transport and you are publishing your WSDL file. If you are developing an enterprise JavaBeans service implementation bean that is invoked using the SOAP over JMS transport, and you want to publish the WSDL so that the

published WSDL file contains the fully resolved JMS endpoint URL, then have **wsgen** tool generate the WSDL file by specifying the `-wsdl` argument. In this scenario, you must package the WSDL file with your web service application.

In addition to using the tools from the command-line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsGen` Ant task from within the Ant build environment to invoke the `wsgen` tool. To function properly, this Ant task requires that you invoke Ant using the `ws_ant` script.

Procedure

1. Locate your service endpoint implementation class file.
2. Run the **wsgen** command to generate the portable artifacts. The **wsgen** tool is located in the `app_server_root/bin/` directory.

```
app_server_root/bin/ wsgen [options] service_implementation_class
```

(Optional) Use the following options with the **wsgen** command:

- Use the **-verbose** option to see a list of generated files along with additional informational messages.
- Use the **-keep** option to keep generated Java files.
- Use the **-wsdl** option to generate a WSDL file. If you are developing a service implementation bean that will be invoked using the HTTP transport, then the WSDL file generated by the **wsgen** command-line tool during this step is optional. However, if you are developing a service implementation bean that will be invoked using the SOAP over JMS transport, then the WSDL file generated by the **wsgen** tool during this step is required in subsequent developing JAX-WS applications steps, so it is not optional.

Read about **wsgen** to learn more about this command and additional options that you can specify.

Results

You have the required Java artifacts to create a JAX-WS web service.

Note: The **wsgen** command does not differentiate the XML namespace between multiple XMLType annotations that have the same `@XMLType` name defined within different Java packages. When this scenario occurs, the following error is produced:

```
Error: Two classes have the same XML type name ...  
Use @XmlType.name and @XmlType.namespace to assign different names to them...
```

This error indicates that you have classes or `@XMLType.name` values that have the same name, but exist within different Java packages. To prevent this error, add the `@XMLType.namespace` class to the existing `@XMLType` annotation to differentiate between the XML types.

With JAX-WS applications, the **wsgen** command-line tool might not locate shared class files. You can specify the location of these class files using the `com.ibm.websphere.webservices.wsdl_generation_extra_classpath` custom property. For more information, see the documentation about the Java virtual machine custom properties.

Example

The following example demonstrates how to use the **wsgen** command to process the service endpoint implementation class to generate JAX-WS artifacts. This example EchoService service implementation class uses an explicit JavaBeans service endpoint.

1. Copy the sample `EchoServicePortTypeImpl` service implementation class file and the associated `EchoServicePortType` service interface class file into a directory. The directory must contain a directory tree structure that corresponds to the `com.ibm.was.wssample.echo` package name for the class file.

```

/* This is a sample EchoServicePortTypeImpl.java file.  */
package com.ibm.was.wssample.echo;

@javax.jws.WebService(serviceName = "EchoService", endpointInterface =
"com.ibm.was.wssample.echo.EchoServicePortType",
targetNamespace="http://com/ibm/was/wssample/echo/",
portName="EchoServicePort")

public class EchoServicePortTypeImpl implements EchoServicePortType {

    public EchoServicePortTypeImpl() {
    }

    public String invoke(String obj) {
        System.out.println(">> JAXB Provider Service:
Request received.\n");
        String str = "Failed";
        if (obj != null) {
            try {
                str = obj;
            } catch (Exception e) {
                e.printStackTrace();
            }
        }
        return str;
    }
}

```

```

/* This is a sample EchoServicePortType.java file.  */
package com.ibm.was.wssample.echo;

```

```

import javax.jws.WebMethod;
import javax.jws.WebParam;
import javax.jws.WebResult;
import javax.jws.WebService;
import javax.xml.ws.RequestWrapper;
import javax.xml.ws.ResponseWrapper;

```

```

@WebService(name = "EchoServicePortType", targetNamespace =
"http://com/ibm/was/wssample/echo/",
wsdlLocation="WEB-INF/wsdl/Echo.wsdl")

```

```

public interface EchoServicePortType {

```

```

    /**
     *
     * @param arg0
     * @return
     * returns java.lang.String
     */
    @WebMethod
    @WebResult(name = "response", targetNamespace =
"http://com/ibm/was/wssample/echo/")
    @RequestWrapper(localName = "invoke", targetNamespace =
"http://com/ibm/was/wssample/echo/",
        className = "com.ibm.was.wssample.echo.Invoke")
    @ResponseWrapper(localName = "echoStringResponse",
        targetNamespace = "http://com/ibm/was/wssample/echo/",
        className = "com.ibm.was.wssample.echo.EchoStringResponse")
    public String invoke(
        @WebParam(name = "arg0", targetNamespace =
"http://com/ibm/was/wssample/echo/")
        String arg0);
}

```

2. Run the **wsgen** command from the `app_server_root\bin\` directory. The `-cp` option specifies the location of the service implementation class file. The `-s` option specifies the directory for the generated source files. The `-d` option specifies the directory for the generated output files. When using the `-s` or `-d` options, you must first create the directory for the generated output files.

After generating the Java artifacts using the **wsgen** command, the following files are generated:

```

/generated_source/com/ibm/was/wssample/echo/EchoStringResponse.java
/generated_source/com/ibm/was/wssample/echo/Invoke.java
/generated_artifacts/EchoService.wsdl
/generated_artifacts/EchoService_schema1.xsd
/generated_artifacts/com/ibm/was/wssample/echo/EchoStringResponse.class
/generated_artifacts/com/ibm/was/wssample/echo/Invoke.class

```

The `EchoStringResponse.java` and `Invoke.java` files are the generated Java class files. The compiled versions of the generated Java files are `EchoStringResponse.class` and `Invoke.class` files. The

EchoService.wsdl and EchoService_schema1.xsd files are generated because the -wsdl option was specified.

What to do next

Complete the implementation of your JAX-WS web service application.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

IBM i

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root

The default installation root directory for the Application Client for IBM WebSphere Application Server is the /QIBM/ProdData/WebSphere/AppClient/V85/client directory.

app_client_user_data_root

The default Application Client for IBM WebSphere Application Server user data root is the /QIBM/UserData/WebSphere/AppClient/V85/client directory.

app_client_profile_root

The default Application Client for IBM WebSphere Application Server profile root is the /QIBM/UserData/WebSphere/AppClient/V85/client/profiles/*profile_name* directory.

app_server_root

The default installation root directory for WebSphere Application Server is the /QIBM/ProdData/WebSphere/AppServer/V85/Base directory.

java_home

Table 97. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32-bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit
64-bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit

plugins_profile_root

The default Web Server Plug-ins profile root is the /QIBM/UserData/WebSphere/Plugins/V85/webserver/profiles/*profile_name* directory.

plugins_root

The default installation root directory for Web Server Plug-ins is the /QIBM/ProdData/WebSphere/Plugins/V85/webserver directory.

plugins_user_data_root

The default Web Server Plug-ins user data root is the /QIBM/UserData/WebSphere/Plugins/V85/webserver directory.

product_library

product_lib

This is the product library for the installed product. The product library for each Version 8.5 installation on the system contains the program and service program objects (similar to .exe, .dll, .so objects) for the installed product. The product library name is QWAS85x (where x is A, B, C, and

so on). The product library for the first WebSphere Application Server Version 8.5 product installed on the system is QWAS85A. The `app_server_root/properties/product.properties` file contains the value for the product library of the installation, `was.install.library`, and is located under the `app_server_root` directory.

profile_root

The default directory for a profile named *profile_name* for WebSphere Application Server is the `/QIBM/UserData/WebSphere/AppServer/V85/Base/profiles/profile_name` directory.

shared_product_library

The shared product library, which contains all of the objects shared by all installations on the system, is QWAS85. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root

The default user data directory for WebSphere Application Server is the `/QIBM/UserData/WebSphere/AppServer/V85/Base` directory.

The profiles and profileRegistry subdirectories are created under this directory when you install the product.

The *user_data_root* directory contains the default locations for `WLP_USR_DIR` and `WLP_OUTPUT_DIR` when the Liberty profile is installed. These directories are `user_data_root/wlp/usr` and `user_data_root/wlp/output/servers`, respectively.

web_server_root

The default web server path is `/www/web_server_name`.

wsgen command for JAX-WS applications

The **wsgen** command-line tool generates the necessary artifacts required for Java API for XML Web Services (JAX-WS) applications when starting from Java code. The generated artifacts are Java 5 compliant, making them portable across different Java versions and platforms.

When using a bottoms-up approach to develop JAX-WS web services and you are starting from a service endpoint implementation, use the **wsgen** tool to generate the required JAX-WS artifacts.

Note: The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are located in the `app_server_root\bin\` directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the `app_server_root\bin\` directory.

The **wsgen** tool accepts a properly annotated service endpoint implementation using the `@WebService` annotation as input and generates the following artifacts:

- any additional Java Architecture for XML Binding (JAXB) classes that are required to marshal and unmarshal the message contents.
- a WSDL file if the optional `-wsdl` argument is specified. The **wsgen** tool does not automatically generate the WSDL file.

When using JAX-WS V2.2 tools, `java.lang.RuntimeException` and `java.rmi.RemoteException` references and their subclasses are no longer mapped in the WSDL file. This behavior change complies with the JAX-WS V2.1 specification conformance rule that is described in section 3.7 of the specification. This conformance rule specifies that the `java.lang.RuntimeException` and `java.rmi.RemoteException` classes and their subclasses cannot be treated as service-specific exceptions and mapped in the WSDL file.

In addition to using the tools from the command line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsGen` Ant task from within the Ant build environment to invoke the `wsgen` tool. To function properly, this Ant task requires that you invoke Ant using the `ws_ant` script.

Note: The `wsgen` command does not differentiate the XML namespace between multiple `XMLType` annotations that have the same `@XMLType` name defined within different Java packages. When this scenario occurs, the following error is produced:

```
Error: Two classes have the same XML type name ....
Use @XMLType.name and @XMLType.namespace to assign different names to them...
```

This error indicates you have class names or `@XMLType.name` values that have the same name, but exist within different Java packages. To prevent this error, add the `@XML.Type.namespace` class to the existing `@XMLType` annotation to differentiate between the XML types.

With JAX-WS applications, the `wsgen` command-line tool might not locate shared class files. You can specify the location of these class files using the `com.ibm.websphere.webservices.wsdl_generation_extra_classpath` custom property. For more information, see the documentation about the Java virtual machine custom properties.

Syntax

The command-line syntax is:

```
 app_server_root/bin/wsgen [options] service_implementation_class
```

Parameters

The `service_implementation_class` name is the only parameter that is required. The following parameters are optional for the `wsgen` command:

- classpath <path>**
Specifies the location of the service implementation class.
- cp <path>**
Specifies the location of the service implementation class. This parameter is the same as `-classpath <path>`.
- d <directory>**
Specifies where to place the generated output files.
- extension**
Specifies whether to enable custom extensions for functionality not specified by the JAX-WS specification. Use of the extensions can result in applications that are not portable or do not interoperate with other implementations.
- help**
Displays the help menu.
- keep**
Specifies whether to keep the generated source files.

-r <directory>

This parameter is only used with the `-wsdl` parameter. Specifies where to place the generated WSDL file.

-s <directory>

Specifies the directory to place the generated source files.

-verbose

Specifies to output messages about what the compiler is doing.

-version

Prints the version information. If you specify this option, only the version information is output and normal command processing does not occur.

-wsdl [:protocol]

By default, the `wsgen` tool does not generate a WSDL file. This optional parameter causes `wsgen` to generate a WSDL file and is typically only used to enable a developer to review a WSDL file before the endpoint is deployed. The `protocol` is optional and specifies the protocol used in the `wsdl:binding`. Valid values for `protocol` are `soap 1.1` and `Xsoap 1.2`. The default value is `soap 1.1`. The `Xsoap 1.2` value is not standard and is only used with the `-extension` option.

-servicename <name>

This parameter is only used with the `-wsdl` option. Specifies a `wsdl:service` name to be generated in the WSDL file. For example,

```
-service name "{http://mynamespace/}MyService"
```

-portname

This parameter is only used with the `-wsdl` option. Specifies a `wsdl:port` name to be generated in the WSDL file. For example,

```
-portname "{http://mynamespace/}MyPort"
```

Mapping between Java language, WSDL and XML for JAX-WS applications

Data for Java API for XML Web Services (JAX-WS) applications flows as extensible Markup Language (XML). JAX-WS applications use mappings to describe the data conversion between the Java language and extensible Markup Language (XML) technologies, including XML Schema, Web Services Description Language (WSDL) and SOAP that are supported by the application server.

For web services based on the JAX-WS programming model, mappings between the Java language and XML are specified by the JAX-WS specification and the Java Architecture for XML Binding (JAXB) specification for data bindings. JAX-WS leverages the JAXB API and tools as the binding technology for mappings between Java objects and XML documents. JAX-WS tooling relies on JAXB tooling for default data binding for two-way mappings between Java objects and XML documents.

The JAX-WS specification describes the mapping between Web Services Description Language (WSDL) files and the Java language. The supported mappings include WSDL-to-Java mappings and Java-to-WSDL mappings. WSDL 1.1 is required by the JAX-WS 2.0 specification. You can use annotations to customize the mapping from Java artifacts to their associated WSDL components. Refer to the JAX-WS specification for details describing the WSDL-to-Java mappings and Java-to-WSDL mappings.

Data binding mappings used by the JAX-WS programming model are described by the JAXB specification. Refer to the JAXB specification for details that describe the JAXB mappings for the Java representation of XML content, including the default and custom bindings between XML schema to Java representations.

Enabling MTOM for JAX-WS web services

With Java API for XML-Based Web Services (JAX-WS), you can send binary attachments such as images or files along with web services requests. JAX-WS adds support for optimized transmission of binary data as specified by the SOAP Message Transmission Optimization Mechanism (MTOM) specification.

About this task

JAX-WS supports the use of SOAP Message Transmission Optimized Mechanism (MTOM) for sending binary attachment data. By enabling MTOM, you can send and receive binary data optimally without incurring the cost of data encoding needed to embed the binary data in an XML document.

The application server supports sending attachments using MTOM only for JAX-WS applications. This product also provides the ability to provide attachments with Web Services Security SOAP messages by using the new MTOM and XOP standards.

JAX-WS applications can send binary data as base64 or hexBinary encoded data contained within the XML document. However, to take advantage of the optimizations provided by MTOM, enable MTOM to send binary base64 data as attachments contained outside the XML document. MTOM optimization is not enabled by default. JAX-WS applications require separate configuration of both the client and the server artifacts to enable MTOM support.

Procedure

1. Develop Java artifacts for your JAX-WS application that includes an XML schema or Web Services Description Language (WSDL) file that represents your web services application data that includes a binary attachment.
 - a. If you are starting with a WSDL file, develop Java artifacts from a WSDL file by using the `wsimport` command to generate the required JAX-WS portable artifacts.
 - b. If you are starting with JavaBeans components, develop Java artifacts for JAX-WS applications and optionally generate a WSDL file using the `wsgen` command. The XML schema or WSDL file includes a `xsd:base64Binary` or `xsd:hexBinary` element definition for the binary data.
 - c. You can also include the `xmime:expectedContentTypes` attribute on the element to affect the mapping by JAXB.
2. Enable MTOM on your endpoint implementation class using one of the following methods:
 - Use the `@MTOM` annotation on the endpoint.

To enable MTOM on an endpoint, use the `@MTOM` (`javax.xml.ws.soap.MTOM`) annotation on the endpoint. The `@MTOM` annotation has two parameters, `enabled` and `threshold`. The `enabled` parameter has a boolean value and indicates if MTOM is enabled for the JAX-WS endpoint. The `threshold` parameter has an integer value, that must be greater than or equal to zero. When MTOM is enabled, any binary data whose size, in bytes, exceeds the threshold value is XML-binary Optimized Packaging (XOP) encoded or sent as an attachment. When the message size is less than the threshold value, the message is inlined in the XML document as either base64 or hexBinary data.

The following example snippet illustrates adding the `@MTOM` annotation so that MTOM is enabled for the JAX-WS `MyServiceImpl` endpoint and specifies a threshold value of 2048 bytes:

```
@MTOM(enabled=true, threshold=2048)
@WebService
public class MyServiceImpl {
    ...
}
```

Additionally, you can use the `@BindingType` (`javax.xml.ws.BindingType`) annotation on an endpoint implementation class to specify that the endpoint supports one of the MTOM binding types so that the response messages are MTOM-enabled. The `javax.xml.ws.SOAPBinding` class defines two different constants, `SOAP11HTTP_MTOM_BINDING` and `SOAP12HTTP_MTOM_BINDING` that you can use for the value of the `@BindingType` annotation; for example:

```
// This example is for SOAP version 1.1.
@BindingType(value = SOAPBinding.SOAP11HTTP_MTOM_BINDING)
@WebService
public class MyServiceImpl {
    ...
}
```

```
// This example is for SOAP version 1.2.
@BindingType(value = SOAPBinding.SOAP12HTTP_MTOM_BINDING)
@WebService
public class MyServiceImpl {
    ...
}
```

The presence and value of an `@MTOM` annotation overrides the value of the `@BindingType` annotation. For example, if the `@BindingType` indicates MTOM is enabled, but an `@MTOM` annotation is present with an enabled value of `false`, then MTOM is not enabled.

- Use the `<enable-mtom>` and `<mtom-threshold>` deployment descriptor elements. You can use the `<enable-mtom>` and `<mtom-threshold>` elements within the `<port-component>` element in the `webservices.xml` deployment descriptor as an alternative to using the `@MTOM` annotation on the service endpoint implementation class; for example:

```
<port-component>
  <port-component-name>MyPort1</port-component-name>
  <enable-mtom>true</enable-mtom>
  <mtom-threshold>2048</mtom-threshold>
  <service-impl-bean>
    <servlet-link>MyPort1ImplBean</servlet-link>
  </service-impl-bean>
</port-component>
```

Note: The deployment descriptor elements take precedence over the corresponding attributes in the MTOM annotation. For example, if the `enabled` attribute is set to `true` in the annotation, but the `<enable-mtom>` element is set to `false` in the `webservices.xml` file, MTOM is not enabled for the corresponding endpoint.

3. Enable MTOM on your client to optimize the binary messages that are sent from the client to the server. Use one of the following methods to enable MTOM on your client:

- Enable MTOM on a Dispatch client.

The following examples use SOAP version 1.1.

The first method uses `SOAPBinding.setMTOMEnabled()`; for example:

```
SOAPBinding binding = (SOAPBinding)dispatch.getBinding();
binding.setMTOMEnabled(true);
```

The second method uses `Service.addPort`; for example:

```
Service svc = Service.create(serviceName);
svc.addPort(portName, SOAPBinding.SOAP11HTTP_MTOM_BINDING, endpointUrl);
```

The third method uses `MTOMFeature`; for example:

```
MTOMFeature mtom = new MTOMFeature(true, 2048);
Service svc = Service.create(serviceName);
svc.addPort(portName, SOAPBinding.SOAP11HTTP_BINDING, endpointUrl);
Dispatch<Source> dsp = svc.createDispatch(portName, Source.class, Service.Mode.PAYLOAD, mtom);
```

- Enable MTOM on a Dynamic Proxy client.

```
// Create a BindingProvider bp from a proxy port.
Service svc = Service.create(serviceName);
MtomSample proxy = svc.getPort(portName, MtomSample.class);
BindingProvider bp = (BindingProvider) proxy;

//Enable MTOM using the SOAPBinding.
MtomSample proxy = svc.getPort(portName, MtomSample.class);
BindingProvider bp = (BindingProvider) proxy;
SOAPBinding binding = (SOAPBinding) bp.getBinding();
binding.setMTOMEnabled(true);

//Or, you can enable MTOM with the MTOMFeature.
MTOMFeature mtom = new MTOMFeature();
MtomSample proxy = svc.getPort(portName, MtomSample.class, mtom);
```

- Enable MTOM on your client using the `@MTOM` annotation; for example:

```
public class MyClientApplication {
    // Enable MTOM for a port-component-ref resource injection.
    @MTOM(enabled=true, threshold=1024)
    @WebServiceRef(MyService.class)
    private MyPortType myPort;
    ...
}
```

- Enable MTOM on your client using deployment descriptor elements within a `port-component-ref` element; for example:

```

<service-ref>
  <service-ref-name>service/MyPortComponentRef</service-ref-name>
  <service-interface>com.example.MyService</service-ref-interface>
  <port-component-ref>
    <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
    <enable-mtom>true</enable-mtom>
    <mtom-threshold>1024</mtom-threshold>
  </port-component-ref>
</service-ref>

```

Note: The deployment descriptor elements take precedence over the corresponding attributes in the MTOM annotation. For example, if the enabled attribute is set to true in the annotation, but the <enable-mtom> element is set to false in the deployment descriptor entry for the service-ref of the client, MTOM is not enabled for that service reference.

Results

You have developed a JAX-WS web services server and client application that optimally sends and receives binary data using MTOM.

Example

The following example illustrates enabling MTOM support on both the web services client and server endpoint when starting with an WSDL file.

1. Locate the WSDL file containing an `xsd:base64Binary` element. The following example is a portion of a WSDL file that contains an `xsd:base64Binary` element.

```

<types>
  .....
  <xs:complexType name="ImageDepot">
    <xs:sequence>
      <xs:element name="imageData"
        type="xs:base64Binary"
        mimeType:expectedContentTypes="image/jpeg"/>
    </xs:sequence>
  </xs:complexType>
  .....
</types>

```

2. Run the **wsimport** command from the `app_server_root\bin\` directory against the WSDL file to generate a set of JAX-WS portable artifacts.

Depending on the `expectedContentTypes` value contained in the WSDL file, the JAXB artifacts generated are in the Java type as described in the following table:

Table 98. Mapping of MIME type and Java type. Describes the mapping between MIME types and Java types.

MIME Type	Java Type
image/gif	java.awt.Image
image/jpeg	java.awt.Image
text/plain	java.lang.String
text/xml	javax.xml.transform.Source
application/xml	javax.xml.transform.Source
/	javax.activation.DataHandler

3. Use the JAXB artifacts in the same manner as in any other JAX-WS application. Use these beans to send binary data from both the Dispatch and the Dynamic Proxy client APIs.
4. Enable MTOM on a Dispatch client.

```

//Create the Dispatch instance.
JAXBContext jbc = JAXBContext.newInstance("org.apache.axis2.jaxws.sample.mtom");
Dispatch<Object> dispatch = svc.createDispatch(portName, jbc, Service.Mode.PAYLOAD);

//Enable MTOM.
SOAPBinding binding = (SOAPBinding) dispatch.getBinding();
binding.setMTOMEnabled(true);

```

5. Enable MTOM on a Dynamic Proxy client.

```

//Create the Dynamic Proxy instance.
Service svc = Service.create(serviceName);
MtomSample proxy = svc.getPort(portName, MtomSample.class);

```

```
//Enable MTOM.
    BindingProvider bp = (BindingProvider) proxy;
    SOAPBinding binding = (SOAPBinding) bp.getBinding();
    binding.setMTOMEnabled(true);
```

Now that you have enabled the JAX-WS client for MTOM, messages sent to the server have MTOM enabled. However, for the server to respond back to the client using MTOM, you must enable MTOM on the endpoint.

6. Enable MTOM on the endpoint implementation class.

```
@MTOM(enabled, threshold=4096)
@WebService (endpointInterface="org.apache.axis2.jaxws.sample.mtom.MtomSample")

public class MtomSampleService implements MtomSample {
    ....
}
```

The `jaxax.xml.ws.SOAPBinding` class has a static member for each of the supported binding types. Include either the `SOAP11HTTP_MTOM_BINDING` or the `SOAP12HTTP_MTOM_BINDING` as the value for the `@BindingType` annotation. This value enables all server responses to have MTOM enabled.

When you enable MTOM on the server and the client, the binary data that represents the attachment is included as a Multipurpose Internet Mail Extensions (MIME) attachment to the SOAP message. Without MTOM, the same data is encoded in the format that describes the XML schema, either base64 or hexadecimal encoding, and included inline in the XML document.

This example illustrates an MTOM enabled SOAP version 1.1 message with an attachment. The type and content-type attributes both have the value, `application/xop+xml`, which indicates that the message was successfully optimized using XML-binary Optimized packaging (XOP) when MTOM was enabled. This example demonstrates how the optimized message looks on the wire with MTOM enabled.

```
... other transport headers ...
Content-Type: multipart/related; boundary=MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812;
type="application/xop+xml"; start="
<0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org>; start-info="text/xml"; charset=UTF-8

--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: application/xop+xml; charset=UTF-8; type="text/xml";
content-transfer-encoding: binary
content-id:
    <0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org>

<?xml version="1.0" encoding="UTF-8"?>
    <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
        <soapenv:Header/>
        <soapenv:Body>
            <sendImage xmlns="http://org.apache.axis2/jaxws/sample/mtom">
                <input>
                    <imageData>
                        <xop:Include xmlns:xop="http://www.w3.org/2004/08/xop/include"
href="cid:1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org"/>
                    </imageData>
                </input>
            </sendImage>
        </soapenv:Body>
    </soapenv:Envelope>
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: text/plain
content-transfer-encoding: binary
content-id:
    <1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org>

... binary data goes here ...
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812--
```

In contrast, this example demonstrates a SOAP version 1.1 message on the wire without MTOM enabled. The binary data is included in the body of the SOAP message, and the SOAP message is not optimized.

```
... other transport headers ...
Content-Type: text/xml; charset=UTF-8

<?xml version="1.0" encoding="UTF-8"?>
    <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
        <soapenv:Header/>
        <soapenv:Body>
            <sendImage xmlns="http://org.apache.axis2/jaxws/sample/mtom">
```

```

<input>
  <imageData>R01GAD1 ... more base64 encoded data ... KTJk8giAAA7</imageData>
</input>
</sendImage>
</soapenv:Body>
</soapenv:Envelope>

```

For additional information, refer to the Samples section of the Information Center which includes a sample that demonstrates the use of MTOM with JAX-WS web services.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

IBM i

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root

The default installation root directory for the Application Client for IBM WebSphere Application Server is the `/QIBM/ProdData/WebSphere/AppClient/V85/client` directory.

app_client_user_data_root

The default Application Client for IBM WebSphere Application Server user data root is the `/QIBM/UserData/WebSphere/AppClient/V85/client` directory.

app_client_profile_root

The default Application Client for IBM WebSphere Application Server profile root is the `/QIBM/UserData/WebSphere/AppClient/V85/client/profiles/profile_name` directory.

app_server_root

The default installation root directory for WebSphere Application Server is the `/QIBM/ProdData/WebSphere/AppServer/V85/Base` directory.

java_home

Table 99. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32-bit IBM Technology for Java	<code>/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit</code>
64-bit IBM Technology for Java	<code>/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit</code>

plugins_profile_root

The default Web Server Plug-ins profile root is the `/QIBM/UserData/WebSphere/Plugins/V85/webserver/profiles/profile_name` directory.

plugins_root

The default installation root directory for Web Server Plug-ins is the `/QIBM/ProdData/WebSphere/Plugins/V85/webserver` directory.

plugins_user_data_root

The default Web Server Plug-ins user data root is the `/QIBM/UserData/WebSphere/Plugins/V85/webserver` directory.

product_library

product_lib

This is the product library for the installed product. The product library for each Version 8.5 installation on the system contains the program and service program objects (similar to `.exe`, `.dll`,

.so objects) for the installed product. The product library name is QWAS85x (where x is A, B, C, and so on). The product library for the first WebSphere Application Server Version 8.5 product installed on the system is QWAS85A. The *app_server_root*/properties/product.properties file contains the value for the product library of the installation, was.install.library, and is located under the *app_server_root* directory.

profile_root

The default directory for a profile named *profile_name* for WebSphere Application Server is the /QIBM/UserData/WebSphere/AppServer/V85/Base/profiles/*profile_name* directory.

shared_product_library

The shared product library, which contains all of the objects shared by all installations on the system, is QWAS85. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root

The default user data directory for WebSphere Application Server is the /QIBM/UserData/WebSphere/AppServer/V85/Base directory.

The profiles and profileRegistry subdirectories are created under this directory when you install the product.

The *user_data_root* directory contains the default locations for WLP_USR_DIR and WLP_OUTPUT_DIR when the Liberty profile is installed. These directories are *user_data_root*/wlp/usr and *user_data_root*/wlp/output/servers, respectively.

web_server_root

The default web server path is /www/*web_server_name*.

Enforcing adherence to WSDL bindings in JAX-WS web services

Java API for XML-Based Web Services (JAX-WS) Version 2.1 introduced the concept of *features* as a way to programmatically control specific functions and behaviors. The `RespectBindingFeature` is one of the supported standard features. You can use the `RespectBindingFeature` to control whether a JAX-WS implementation is required to respect the contents of a Web Services Description Language (WSDL) binding that is associated with an endpoint.

About this task

While WSDL documents are often used during the development process, the actual enforcement of the use of the WSDL document specifications, when they are provided, at run time has not been well defined in versions of the JAX-WS specification previous to Version 2.1. The JAX-WS Version 2.1 specification added the feature, `RespectBindingFeature`, to clarify the impact of the `wsdl:binding` in a JAX-WS runtime environment.

Enabling the feature, `RespectBindingFeature`, causes the JAX-WS runtime environment to inspect the `wsdl:binding` for an endpoint at run time to ensure that the binding of service endpoint interface (SEI) parameters and return values is respected. Additionally, this feature ensures that all required `wsdl:binding` extensions are either understood and used by the runtime environment, or the extensions have been explicitly disabled by the application. Your JAX-WS application can disable a specific `wsdl:binding` extension that has a defined `WebServiceFeature` interface by using the appropriate annotation that is associated with that feature, using an API that accepts the `javax.xml.ws.WebServiceFeature` interface, or configuring the deployment descriptors.

When the `RespectBindingFeature` feature is not enabled, which is the default, the runtime environment can choose whether any part of the `wsdl:binding` is enforced.

Procedure

1. Develop Java artifacts for your JAX-WS application that includes a Web Services Description Language (WSDL) file that represents your web services application.

- a. If you are starting with a WSDL file, develop Java artifacts from a WSDL file by using the `wsimport` command to generate the required JAX-WS portable artifacts.
 - b. If you are starting with JavaBeans components, develop Java artifacts for JAX-WS applications and generate a WSDL file using the `wsgen` command.
2. If you want to enable `RespectBindingFeature` on your endpoint implementation class, use one of the following methods:

- Use the `@RespectBinding` annotation on the endpoint.

To enable `RespectBinding` on an endpoint, use the `@RespectBinding` (`javax.xml.ws.RespectBinding`) annotation on the endpoint. The `@RespectBinding` annotation has only one parameter, `enabled`. This parameter is optional. The `enabled` parameter has a Boolean value and indicates if `RespectBindingFeature` is enabled for the JAX-WS endpoint.

The following example snippet illustrates adding the `@RespectBinding` annotation for the JAX-WS `MyServiceImpl` endpoint:

```
@RespectBinding(enabled=true)
@WebService
public class MyServiceImpl {
    ...
}
```

- Use the `<respect-binding>` deployment descriptor element.

You can use the `<respect-binding>` element within the `<port-component>` element in the `webservices.xml` deployment descriptor as an alternative to using the `@RespectBinding` annotation on the service endpoint implementation class; for example:

```
<port-component>
  <port-component-name>MyPort1</port-component-name>
  <respect-binding>
    <enabled>true</enabled>
  </respect-binding>
  <service-impl-bean>
    <servlet-link>MyPort1ImplBean</servlet-link>
  </service-impl-bean>
</port-component>
```

3. If you want to enable `RespectBindingFeature` on your client, use one of the following methods:

- Enable `RespectBindingFeature` on a dispatch client; for example:

```
RespectBindingFeature respectBinding = new RespectBindingFeature();
Service svc = Service.create(serviceName);
svc.addPort(portName, SOAPBinding.SOAP11_HTTP_BINDING, endpointUrl);
Dispatch<Source> dsp = svc.createDispatch(portName, Source.class, Service.Mode.PAYLOAD, respectBinding);
```

- Enable `RespectBindingFeature` on a dynamic proxy client; for example:

```
// Create a dynamic proxy with RespectBinding enabled.
Service svc = Service.create(serviceName);
RespectBindingFeature respectBinding = new RespectBindingFeature();
RespectBindingSample proxy = svc.getPort(portName, RespectBindingSample.class, respectBinding);
```

- Enable `RespectBindingFeature` on your client using the `@RespectBinding` annotation; for example:

```
public class MyClientApplication {
    ...
    // Enable RespectBinding for a port-component-ref resource injection.
    @RespectBinding(enabled=true)
    @WebServiceRef(MyService.class)
    private MyPortType myPort;
    ...
}
```

- Enable `RespectBindingFeature` on your client using deployment descriptor elements within a `port-component-ref` element; for example:

```
<service-ref>
  <service-ref-name>service/MyPortComponentRef</service-ref-name>
  <service-interface>com.example.MyService</service-ref-interface>
  <port-component-ref>
    <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
    <respect-binding>
      <enabled>true</enabled>
    </respect-binding>
  </port-component-ref>
</service-ref>
```

Results

By implementing the feature, `RespectBindingFeature`, you have specified to enforce adherence of the contents of a WSDL binding that is associated with an endpoint for your JAX-WS application.

Developing a `webservices.xml` deployment descriptor for JAX-WS applications

Deployment descriptors are standard text files, formatted using XML and packaged in a web services application. You can optionally use the `webservices.xml` deployment descriptor to augment or override application metadata specified in annotations within Java API for XML-Based Web Services (JAX-WS) web services.

About this task

Similar to Java API for XML-based RPC (JAX-RPC) Web services, you can use deployment descriptors to describe JAX-WS web services. For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

A JAX-WS web service requires that you annotate your Java class with the `javax.jws.WebService` annotation or the `javax.jws.WebServiceProvider` annotation for Provider endpoints. You can use server-side deployment descriptors to override corresponding attributes of the annotation or to enhance information in annotations. There is a defined relationship between the deployment descriptor elements and the `@WebService` and `@WebServiceProvider` annotations. Refer to section 5.3 in the Web Services for Java Platform, Enterprise Edition (Java EE) specification, Version 1.2 for detailed information regarding the deployment descriptor elements and the mapping to the `@WebService` and `@WebServiceProvider` annotation attributes. There are also elements in the `webservice.xml` deployment descriptor that map to other annotations. For example, the deployment descriptor element `<protocol-binding>` maps to the `@BindingType` annotation, and the deployment descriptor element `<enable-mtom>` maps to the `@MTOM` annotation. For more information regarding the web services deployment descriptor elements, see section 7.1 in the Web Services for Java Platform, Enterprise Edition (Java EE) specification.

Procedure

Use assembly tools to generate the `webservice.xml` deployment descriptor.

Results

You have deployment descriptor templates that you can use to override JAX-WS annotation attributes or specify attributes that are not defined by the annotation.

Example

In the following example, the service implementation class for a JAX-WS web service includes the `@WebService` annotation:

```
@WebService(wsdlLocation="http://myhost.com/location/of/the/wsdl/ExampleService.wsdl")
```

The associated `webservices.xml` deployment descriptor specifies a different filename for the WSDL document as follows:

```
<webservices>
<webservice-description>
<webservice-description-name>ExampleService</webservice-description-name>
```

```

<wsdl-file>META-INF/wsdl/ExampleService.wsdl</wsdl-file>
...
</webservice-description>
</webservices>

```

The value that is specified in the deployment descriptor, META-INF/wsdl/ExampleService.wsdl, overrides the annotation value.

What to do next

Configure the webservice.xml deployment descriptor. After you configure the deployment descriptors, you must assemble the Web services application for deployment.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

IBM i

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root

The default installation root directory for the Application Client for IBM WebSphere Application Server is the /QIBM/ProdData/WebSphere/AppClient/V85/client directory.

app_client_user_data_root

The default Application Client for IBM WebSphere Application Server user data root is the /QIBM/UserData/WebSphere/AppClient/V85/client directory.

app_client_profile_root

The default Application Client for IBM WebSphere Application Server profile root is the /QIBM/UserData/WebSphere/AppClient/V85/client/profiles/*profile_name* directory.

app_server_root

The default installation root directory for WebSphere Application Server is the /QIBM/ProdData/WebSphere/AppServer/V85/Base directory.

64-bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit

plugins_profile_root

The default Web Server Plug-ins profile root is the /QIBM/UserData/WebSphere/Plugins/V85/webserver/profiles/*profile_name* directory.

plugins_root

The default installation root directory for Web Server Plug-ins is the /QIBM/ProdData/WebSphere/Plugins/V85/webserver directory.

plugins_user_data_root

The default Web Server Plug-ins user data root is the /QIBM/UserData/WebSphere/Plugins/V85/webserver directory.

product_library

product_lib

This is the product library for the installed product. The product library for each Version 8.5 installation on the system contains the program and service program objects (similar to .exe, .dll, .so objects) for the installed product. The product library name is QWAS85x (where x is A, B, C, and so on). The product library for the first WebSphere Application Server Version 8.5 product installed on the system is QWAS85A. The *app_server_root/properties/product.properties* file contains the value for the product library of the installation, *was.install.library*, and is located under the *app_server_root* directory.

profile_root

The default directory for a profile named *profile_name* for WebSphere Application Server is the */QIBM/UserData/WebSphere/AppServer/V85/Base/profiles/profile_name* directory.

shared_product_library

The shared product library, which contains all of the objects shared by all installations on the system, is QWAS85. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root

The default user data directory for WebSphere Application Server is the */QIBM/UserData/WebSphere/AppServer/V85/Base* directory.

The profiles and profileRegistry subdirectories are created under this directory when you install the product.

The *user_data_root* directory contains the default locations for WLP_USR_DIR and WLP_OUTPUT_DIR when the Liberty profile is installed. These directories are *user_data_root/wlp/usr* and *user_data_root/wlp/output/servers*, respectively.

web_server_root

The default web server path is */www/web_server_name*.

Completing the JavaBeans implementation for JAX-WS applications

After you have developed the Java artifacts necessary to develop a Java API for XML-Based Web Services (JAX-WS) web service, you must complete the JavaBeans implementation to assemble a web application archive (WAR) file. The resulting WAR file contains the JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Generate Java artifacts for JAX-WS applications and optionally generate a WSDL file using the **wsgen** command-line tool. You can also optionally use deployment descriptors to augment or override binding information contained in annotations for JAX-WS web services.

About this task

For JAX-WS applications, complete the JavaBeans implementation by writing your business application.

Procedure

1. Write the JavaBeans implementation. The JavaBeans implementation is not generated by JAX-WS tooling.
2. Compile all the Java classes.

Results

You have now written your JavaBeans implementation to complete your web service application.

What to do next

After completing the JavaBeans implementation, assemble your web services application.

Completing the EJB implementation for JAX-WS applications

After you have developed the Java artifacts necessary to develop a Java API for XML-Based Web Services (JAX-WS) web service, you must complete the Enterprise JavaBeans (EJB) implementation to assemble a Java archive (JAR) file. The resulting JAR file contains the Enterprise JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Generate Java artifacts for JAX-WS applications and optionally generate a WSDL file using the **wsgen** command-line tool. You can also optionally use deployment descriptors to augment or override binding information contained in annotations for JAX-WS web services.

About this task

For JAX-WS applications, complete the enterprise beans implementation by writing your business application.

Procedure

1. Write the enterprise beans implementation. The enterprise beans implementation is not generated by JAX-WS tooling.
2. Compile all the Java classes.

Results

You have now written your enterprise beans implementation to complete your web service application.

What to do next

After completing the enterprise beans implementation, assemble your web services application.

Developing JAX-WS web services with WSDL files (top-down)

Setting up a development environment for web services

The application server provides command-line tools to develop web services clients and implementations that are based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. You must set up your development environment before you start developing web services.

Before you begin

Before you can set up a web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information on installing the application server, read about installing your application server environment.

About this task

Set up a web services development environment by completing the following actions.

Procedure

Set up the environment.

IBM i Run the `setupCmdLine` script on the Qshell command line from the `./profile_root/bin` directory.

Results

You have set up an environment so that you can develop Web services.

What to do next

Implement web services applications. See the task overview for implementing web services applications information to learn about how to develop and implement a Java EE web service.

Generating Java artifacts for JAX-WS applications from a WSDL file

Use JAX-WS tools to generate the Java artifacts that are needed to develop JAX-WS web services when starting with a Web Services Description Language (WSDL) file.

Before you begin

When using a top-down development approach to developing Java API for XML-Based Web Services (JAX-WS) web services by starting with a Web Services Description Language (WSDL) file, you must obtain the Uniform Resource Locator (URL) of the WSDL file.

IBM i If the WSDL file is a local file, the URL looks like this example: `file:/path/file_name.wsdl`.

You can also specify local files using the absolute or relative file system path.

About this task

You can use the JAX-WS tool, `wsimport`, to process a WSDL file and generate portable Java artifacts that are used to create a web service. The portable Java artifacts created using the `wsimport` tool are:

- Service endpoint interface (SEI)
- Service class
- Exception class that is mapped from the `wsdl:fault` class (if any)
- Java Architecture for XML Binding (JAXB) generated type values which are Java classes mapped from XML schema types

Note: The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are located in the `app_server_root\bin\` directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the `app_server_root\bin\` directory.

In addition to using the tools from the command-line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsImport` Ant task from within the Ant build environment to invoke the `wsimport` tool. To function properly, this Ant task requires that you invoke Ant using the `ws_ant` script.

Procedure

Run the `wsimport` command to generate the portable client artifacts. The `wsimport` tool is located in the `app_server_root\bin\` directory.

```
IBM i  
app_server_root/bin/wsimport wsdl_URL
```

(Optional) Use the following options with the `wsimport` command:

- Use the **-verbose** option to see a list of generated files when you run the command.
- Use the **-keep** option to keep generated Java files.
- Use the **-wsdlLocation** option to specify the location of the WSDL file.

Note: A best practice for ensuring that you produce a JAX-WS web services client enterprise archive (EAR) file that is portable to other systems is to package the WSDL document within the application module such as a web services client Java archive (JAR) file or a web application archive (WAR) file. You can specify a relative URI for the location of your WSDL file by using the `-wsdllocation` annotation attribute. For example, if your `MyService.wsdl` file is located in the `META-INF/wsdl/` directory, then run the `wsimport` tool and use the `-wsdllocation` option to specify the value to be used for the location of the WSDL file. This ensures that the generated artifacts contain the correct `-wsdllocation` information needed when the application is loaded into the administrative console; for example:

```
wsimport -keep -wsdllocation=META-INF/wsdl/MyService.wsdl
```

- Use the **-b** option if you are using WSDL or schema customizations to specify external binding files that contain your customizations.

You can customize the bindings in your WSDL file to enable asynchronous mappings or attachments. To generate asynchronous interfaces, add the client-side only customization `enableAsyncMapping` binding declaration to the `wsdl:definitions` element or in an external binding file that is defined in the WSDL file. Use the `enableMIMEContent` binding declaration in your custom client or server binding file to enable or disable the default `mime:content` mapping rules. For additional information on custom binding declarations, see chapter 8 the JAX-WS specification.

Read about the `wsimport` command to learn more about this command and additional options that you can specify.

Results

You have the required Java artifacts to create a JAX-WS web service. To learn more about the usage, syntax, and parameters for the `wsimport` command, see the `wsimport` command for JAX-WS applications documentation.

Example

The following example illustrates how the `wsimport` command is used to process the sample Ping WSDL file to generate portable artifacts.

1. Copy the following `ping.wsdl` WSDL file to a temporary directory.

```
<?xml version="1.0" encoding="UTF-8"?>  
<!--  
 * This program can be used, run, copied, modified and distributed  
 * without royalty for the purpose of developing, using, marketing, or distributing.  
 -->  
<wsdl:definitions xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
```

```

xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
xmlns:tns="http://com.ibm/was/wssample/sei/ping/"
xmlns:xsd="http://www.w3.org/2001/XMLSchema" name="PingService"
targetNamespace="http://com.ibm/was/wssample/sei/ping/"
<wsdl:types>
  <xsd:schema
    targetNamespace="http://com.ibm/was/wssample/sei/ping/"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema">

    <xsd:element name="pingStringInput">
      <xsd:complexType>
        <xsd:sequence>
          <xsd:element name="pingInput" type="xsd:string" />
        </xsd:sequence>
      </xsd:complexType>
    </xsd:element>
  </xsd:schema>
</wsdl:types>
<wsdl:message name="pingOperationRequest">
  <wsdl:part element="tns:pingStringInput" name="parameter" />
</wsdl:message>
<wsdl:portType name="PingServicePortType">
  <wsdl:operation name="pingOperation">
    <wsdl:input message="tns:pingOperationRequest" />
  </wsdl:operation>
</wsdl:portType>
<wsdl:binding name="PingSOAP" type="tns:PingServicePortType">
  <soap:binding style="document"
    transport="http://schemas.xmlsoap.org/soap/http" />
  <wsdl:operation name="pingOperation">
    <soap:operation soapAction="pingOperation" style="document" />
  <wsdl:input>
    <soap:body use="literal" />
  </wsdl:input>
</wsdl:operation>
</wsdl:binding>
<wsdl:service name="PingService">
  <wsdl:port binding="tns:PingSOAP" name="PingServicePort">
    <soap:address
      location="http://localhost:9080/WSSampleSei/PingService" />
  </wsdl:port>
</wsdl:service>
</wsdl:definitions>

```

2. Run the **wsimport** command from the *app_server_root\bin* directory.

IBM i

```
app_server_root/bin/wsimport -keep -verbose ping.wsdl
```

After generating the template files using the **wsimport** command, the following files are generated:

```

com\ibm\was\wssample\sei\ping\ObjectFactory.java
com\ibm\was\wssample\sei\ping\package-info.java
com\ibm\was\wssample\sei\ping\PingServicePortType.java
com\ibm\was\wssample\sei\ping\PingStringInput.java
com\ibm\was\wssample\sei\ping\PingService.java

```

The `ObjectFactory.java` file contains factory methods for each Java content interface and Java element interface generated in the associated ping package. The `package-info.java` file takes the `targetNamespace` value and creates the directory structure. The `PingServicePortType.java` file is the generated service endpoint interface (SEI) class that contains the ping method definition. The `PinStringInput.java` file contains the JAXB generated type values which are Java classes mapped from XML schema types. The `PingService.java` file is the generated service provider class file that is used by the JAX-WS client.

What to do next

Complete the implementation of your web service application by completing the JavaBeans or enterprise beans implementation.

wsimport command for JAX-WS applications

The `wsimport` command-line tool processes an existing Web Services Description Language (WSDL) file and generates the required artifacts for developing Java API for XML-Based Web Services (JAX-WS) web service applications. The generated artifacts are Java 5 compliant, making them portable across different Java versions and platforms.

The `wsimport` command-line tool supports the top-down approach to developing JAX-WS web services. When you start with an existing WSDL file, use the `wsimport` command-line tool to generate the required JAX-WS artifacts.

Note: The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The `wsimport`, `wsgen`, `schemagen` and `xjc` command-line tools are located in the `app_server_root\bin\` directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the `app_server_root\bin\` directory.

The `wsimport` tool reads an existing WSDL file and generates the following artifacts:

- Service Endpoint Interface (SEI) - The SEI is the annotated Java representation of the WSDL file for the web service. This interface is used for implementing JavaBeans endpoints or creating dynamic proxy client instances.
- `javax.xml.ws.Service` extension class - This is a generated class that extends the `javax.xml.ws.Service` class. This class is used to configure and create both dynamic proxy and dispatch instances.
- required data beans, including any Java Architecture for XML Binding (JAXB) beans that are required to model the web service data.

You can package the generated artifacts in a web application archive (WAR) file with the WSDL file and schema documents along with the endpoint implementation to be deployed.

Note: To correctly use the `wsimport` tool, you must adhere to the following requirements:

- You must define all your services within the main WSDL file. Services that are defined within an imported WSDL file are not processed by the `wsimport` tool.
- If you run the `wsimport` tool on a WSDL file that implements a Document or Literal style pattern, the `complexType` elements that define the input and output types must be composed of unique names to prevent naming conflicts in the parameter list for the operation..
- If you run the `wsimport` tool and pass a `?wsdl` Uniform Resource Identifier (URI) as a parameter for a WSDL file, ensure that you are using the actual resolved WSDL URI. The `wsimport` tool correctly resolves the `?wsdl` URI, but other relative URIs that are referenced might not resolve correctly.

In addition to using the tools from the command line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsImport` Ant task from within the Ant build environment to invoke the `wsimport` tool. To function properly, this Ant task requires that you invoke Ant using the `ws_ant` script.

Syntax

The command-line syntax is:

```
IBM i  
app_server_root/bin/wsimport [options] WSDL_URI
```

Parameters

The *WSDL_URI* is the only parameter that is required. The following parameters are optional for the **wsimport** command:

- b <path>**
Specifies the external JAX-WS or JAXB binding files. You can specify multiple JAX-WS and JAXB binding files by using the **-b** option; however, each file must be specified with its own **-b** option.
- B <jaxbOption>**
Specifies to pass this option to the JAXB schema compiler.
- catalog**
Specifies the catalog file to resolve external entity references. It supports the TR9401, XCatalog, and the OASIS XML Catalog formats
- d <directory>**
Specifies where to place the generated output files.
- extension**
Specifies whether to accept custom extensions for functionality that are not specified by the JAX-WS specification. The use of custom extensions can result in applications that are not portable or do not interoperate with other implementations.
- help**
Displays the help menu.
- httpproxy:<host>:<port>**
Specifies an HTTP proxy. The default port value is 8080.
- keep**
Specifies whether to keep the generated source files.
- p <package_name>**
Specifies a target package with this command-line option and overrides any WSDL file and schema binding customization for the package name and the default package name algorithm defined in the JAX-WS specification.
- quiet**
Specifies to suppress the **wsimport** output.
- s <directory>**
Specifies the directory to place the generated source files.
- target <version>>**
Specifies to generate code that is compliant with a specific JAX-WS specification level. Specify version 2.0 or 2.1 to generate code that is compliant with the JAX-WS 2.0 or JAX-WS 2.1 specification respectively. Specifying version 2.1 indicates to generate code that is compliant with the JAX-WS 2.1 specification. The default value is version 2.2 and generates compliant code for the JAXB 2.2 specification.
- verbose**
Specifies to output messages about what the compiler is doing.

-version

Prints the version information. If you specify this option, only the version information is included in the output and normal command processing does not occur.

-wsdlLocation

Specifies the `@WebServiceClient.wsdlLocation` value.

Note: The `wsimport` tool does not set the `@WebService.wsdlLocation` value either by default or when the `-wsdlLocation` attribute is specified. The `wsimport` command-line tool updates the `@WebServiceClient.wsdlLocation` annotation only. You can manually update the `@WebService.wsdlLocation` annotation with a relative URL that specifies the location of the Web Services Description Language (WSDL) file. If the `@WebService.wsdlLocation` annotation is present on an endpoint implementation class, then the value must be a relative URL and the WSDL document that it references must be packaged with the application.

Note: If you specify an HTTPS URL for the `-wsdlLocation` parameter, the `wsimport` tool generates a service class with a no-argument constructor that is not valid. Avoid using the no-argument service constructor to instantiate your service. Instead, pass the HTTPS URL to one of the service class constructors that takes a WSDL URL for an argument; for example:

```
MyService("https://example.ibm.com/My?wsdl");
```

Enabling MTOM for JAX-WS web services

With Java API for XML-Based Web Services (JAX-WS), you can send binary attachments such as images or files along with web services requests. JAX-WS adds support for optimized transmission of binary data as specified by the SOAP Message Transmission Optimization Mechanism (MTOM) specification.

About this task

JAX-WS supports the use of SOAP Message Transmission Optimized Mechanism (MTOM) for sending binary attachment data. By enabling MTOM, you can send and receive binary data optimally without incurring the cost of data encoding needed to embed the binary data in an XML document.

The application server supports sending attachments using MTOM only for JAX-WS applications. This product also provides the ability to provide attachments with Web Services Security SOAP messages by using the new MTOM and XOP standards.

JAX-WS applications can send binary data as base64 or hexBinary encoded data contained within the XML document. However, to take advantage of the optimizations provided by MTOM, enable MTOM to send binary base64 data as attachments contained outside the XML document. MTOM optimization is not enabled by default. JAX-WS applications require separate configuration of both the client and the server artifacts to enable MTOM support.

Procedure

1. Develop Java artifacts for your JAX-WS application that includes an XML schema or Web Services Description Language (WSDL) file that represents your web services application data that includes a binary attachment.
 - a. If you are starting with a WSDL file, develop Java artifacts from a WSDL file by using the `wsimport` command to generate the required JAX-WS portable artifacts.
 - b. If you are starting with JavaBeans components, develop Java artifacts for JAX-WS applications and optionally generate a WSDL file using the `wsgen` command. The XML schema or WSDL file includes a `xsd:base64Binary` or `xsd:hexBinary` element definition for the binary data.
 - c. You can also include the `xmime:expectedContentTypes` attribute on the element to affect the mapping by JAXB.
2. Enable MTOM on your endpoint implementation class using one of the following methods:

- Use the `@MTOM` annotation on the endpoint.

To enable MTOM on an endpoint, use the `@MTOM` (`javax.xml.ws.soap.MTOM`) annotation on the endpoint. The `@MTOM` annotation has two parameters, `enabled` and `threshold`. The `enabled` parameter has a boolean value and indicates if MTOM is enabled for the JAX-WS endpoint. The `threshold` parameter has an integer value, that must be greater than or equal to zero. When MTOM is enabled, any binary data whose size, in bytes, exceeds the threshold value is XML-binary Optimized Packaging (XOP) encoded or sent as an attachment. When the message size is less than the threshold value, the message is inlined in the XML document as either base64 or hexBinary data.

The following example snippet illustrates adding the `@MTOM` annotation so that MTOM is enabled for the JAX-WS `MyServiceImpl` endpoint and specifies a threshold value of 2048 bytes:

```
@MTOM(enabled=true, threshold=2048)
@WebService
public class MyServiceImpl {
    ...
}
```

Additionally, you can use the `@BindingType` (`javax.xml.ws.BindingType`) annotation on an endpoint implementation class to specify that the endpoint supports one of the MTOM binding types so that the response messages are MTOM-enabled. The `javax.xml.ws.SOAPBinding` class defines two different constants, `SOAP11HTTP_MTOM_BINDING` and `SOAP12HTTP_MTOM_BINDING` that you can use for the value of the `@BindingType` annotation; for example:

```
// This example is for SOAP version 1.1.
@BindingType(value = SOAPBinding.SOAP11HTTP_MTOM_BINDING)
@WebService
public class MyServiceImpl {
    ...
}

// This example is for SOAP version 1.2.
@BindingType(value = SOAPBinding.SOAP12HTTP_MTOM_BINDING)
@WebService
public class MyServiceImpl {
    ...
}
```

The presence and value of an `@MTOM` annotation overrides the value of the `@BindingType` annotation. For example, if the `@BindingType` indicates MTOM is enabled, but an `@MTOM` annotation is present with an `enabled` value of `false`, then MTOM is not enabled.

- Use the `<enable-mtom>` and `<mtom-threshold>` deployment descriptor elements.

You can use the `<enable-mtom>` and `<mtom-threshold>` elements within the `<port-component>` element in the `webservices.xml` deployment descriptor as an alternative to using the `@MTOM` annotation on the service endpoint implementation class; for example:

```
<port-component>
  <port-component-name>MyPort1</port-component-name>
  <enable-mtom>true</enable-mtom>
  <mtom-threshold>2048</mtom-threshold>
  <service-impl-bean>
    <servlet-link>MyPort1ImplBean</servlet-link>
  </service-impl-bean>
</port-component>
```

Note: The deployment descriptor elements take precedence over the corresponding attributes in the MTOM annotation. For example, if the `enabled` attribute is set to `true` in the annotation, but the `<enable-mtom>` element is set to `false` in the `webservices.xml` file, MTOM is not enabled for the corresponding endpoint.

3. Enable MTOM on your client to optimize the binary messages that are sent from the client to the server. Use one of the following methods to enable MTOM on your client:

- Enable MTOM on a Dispatch client.

The following examples use SOAP version 1.1.

The first method uses `SOAPBinding.setMTOMEnabled()`; for example:

```
SOAPBinding binding = (SOAPBinding)dispatch.getBinding();
binding.setMTOMEnabled(true);
```

The second method uses `Service.addPort`; for example:

```
Service svc = Service.create(serviceName);
svc.addPort(portName,SOAPBinding.SOAP11HTTP_MTOM_BINDING,endpointUrl);
```

The third method uses MTOMFeature; for example:

```
MTOMFeature mtom = new MTOMFeature(true, 2048);
Service svc = Service.create(serviceName);
svc.addPort(portName, SOAPBinding.SOAP11_HTTP_BINDING, endpointUrl);
Dispatch<Source> dsp = svc.createDispatch(portName, Source.class, Service.Mode.PAYLOAD, mtom);
```

- Enable MTOM on a Dynamic Proxy client.

```
// Create a BindingProvider bp from a proxy port.
Service svc = Service.create(serviceName);
MtomSample proxy = svc.getPort(portName, MtomSample.class);
BindingProvider bp = (BindingProvider) proxy;

//Enable MTOM using the SOAPBinding.
MtomSample proxy = svc.getPort(portName, MtomSample.class);
BindingProvider bp = (BindingProvider) proxy;
SOAPBinding binding = (SOAPBinding) bp.getBinding();
binding.setMTOMEnabled(true);

//Or, you can enable MTOM with the MTOMFeature.
MTOMFeature mtom = new MTOMFeature();
MtomSample proxy = svc.getPort(portName, MtomSample.class, mtom);
```

- Enable MTOM on your client using the @MTOM annotation; for example:

```
public class MyClientApplication {

    // Enable MTOM for a port-component-ref resource injection.
    @MTOM(enabled=true, threshold=1024)
    @WebServiceRef(MyService.class)
    private MyPortType myPort;
    ...
}
```

- Enable MTOM on your client using deployment descriptor elements within a port-component-ref element; for example:

```
<service-ref>
  <service-ref-name>service/MyPortComponentRef</service-ref-name>
  <service-interface>com.example.MyService</service-ref-interface>
  <port-component-ref>
    <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
    <enable-mtom>true</enable-mtom>
    <mtom-threshold>1024</mtom-threshold>
  </port-component-ref>
</service-ref>
```

Note: The deployment descriptor elements take precedence over the corresponding attributes in the MTOM annotation. For example, if the enabled attribute is set to true in the annotation, but the <enable-mtom> element is set to false in the deployment descriptor entry for the service-ref of the client, MTOM is not enabled for that service reference.

Results

You have developed a JAX-WS web services server and client application that optimally sends and receives binary data using MTOM.

Example

The following example illustrates enabling MTOM support on both the web services client and server endpoint when starting with an WSDL file.

1. Locate the WSDL file containing an xsd:base64Binary element. The following example is a portion of a WSDL file that contains an xsd:base64Binary element.

```
<types>
  .....
  <xs:complexType name="ImageDepot">
    <xs:sequence>
      <xs:element name="imageData"
        type="xs:base64Binary"
        xmime:expectedContentTypes="image/jpeg"/>
    </xs:sequence>
  </xs:complexType>
  .....
</types>
```

2. Run the **wsimport** command from the `app_server_root\bin\` directory against the WSDL file to generate a set of JAX-WS portable artifacts.

Depending on the `expectedContentTypes` value contained in the WSDL file, the JAXB artifacts generated are in the Java type as described in the following table:

Table 101. Mapping of MIME type and Java type. Describes the mapping between MIME types and Java types.

MIME Type	Java Type
image/gif	java.awt.Image
image/jpeg	java.awt.Image
text/plain	java.lang.String
text/xml	javax.xml.transform.Source
application/xml	javax.xml.transform.Source
/	javax.activation.DataHandler

3. Use the JAXB artifacts in the same manner as in any other JAX-WS application. Use these beans to send binary data from both the Dispatch and the Dynamic Proxy client APIs.
4. Enable MTOM on a Dispatch client.

```
//Create the Dispatch instance.
JAXBContext jbc = JAXBContext.newInstance("org.apache.axis2.jaxws.sample.mtom");
Dispatch<Object> dispatch = svc.createDispatch(portName, jbc, Service.Mode.PAYLOAD);

//Enable MTOM.
SOAPBinding binding = (SOAPBinding) dispatch.getBinding();
binding.setMTOMEnabled(true);
```

5. Enable MTOM on a Dynamic Proxy client.

```
//Create the Dynamic Proxy instance.
Service svc = Service.create(serviceName);
MtomSample proxy = svc.getPort(portName, MtomSample.class);

//Enable MTOM.
BindingProvider bp = (BindingProvider) proxy;
SOAPBinding binding = (SOAPBinding) bp.getBinding();
binding.setMTOMEnabled(true);
```

Now that you have enabled the JAX-WS client for MTOM, messages sent to the server have MTOM enabled. However, for the server to respond back to the client using MTOM, you must enable MTOM on the endpoint.

6. Enable MTOM on the endpoint implementation class.

```
@MTOM(enabled, threshold=4096)
@WebService (endpointInterface="org.apache.axis2.jaxws.sample.mtom.MtomSample")

public class MtomSampleService implements MtomSample {
    ....
}
```

The `javax.xml.ws.SOAPBinding` class has a static member for each of the supported binding types. Include either the `SOAP11HTTP_MTOM_BINDING` or the `SOAP12HTTP_MTOM_BINDING` as the value for the `@BindingType` annotation. This value enables all server responses to have MTOM enabled.

When you enable MTOM on the server and the client, the binary data that represents the attachment is included as a Multipurpose Internet Mail Extensions (MIME) attachment to the SOAP message. Without MTOM, the same data is encoded in the format that describes the XML schema, either base64 or hexadecimal encoding, and included inline in the XML document.

This example illustrates an MTOM enabled SOAP version 1.1 message with an attachment. The type and content-type attributes both have the value, `application/xop+xml`, which indicates that the message was successfully optimized using XML-binary Optimized packaging (XOP) when MTOM was enabled. This example demonstrates how the optimized message looks on the wire with MTOM enabled.

```
... other transport headers ...
Content-Type: multipart/related; boundary=MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812;
type="application/xop+xml"; start="
<0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org>; start-info="text/xml"; charset=UTF-8

--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
```

```

content-type: application/xop+xml; charset=UTF-8; type="text/xml";
content-transfer-encoding: binary
content-id:
  <0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org>

<?xml version="1.0" encoding="UTF-8"?>
  <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
    <soapenv:Header/>
    <soapenv:Body>
      <sendImage xmlns="http://org.apache.axis2/jaxws/sample/mtom">
        <input>
          <imageData>
            <xop:Include xmlns:xop="http://www.w3.org/2004/08/xop/include"
href="cid:1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org"/>
          </imageData>
        </input>
      </sendImage>
    </soapenv:Body>
  </soapenv:Envelope>
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: text/plain
content-transfer-encoding: binary
content-id:
  <1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org>

... binary data goes here ...
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812--

```

In contrast, this example demonstrates a SOAP version 1.1 message on the wire without MTOM enabled. The binary data is included in the body of the SOAP message, and the SOAP message is not optimized.

```

... other transport headers ...
Content-Type: text/xml; charset=UTF-8

<?xml version="1.0" encoding="UTF-8"?>
  <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
    <soapenv:Header/>
    <soapenv:Body>
      <sendImage xmlns="http://org.apache.axis2/jaxws/sample/mtom">
        <input>
          <imageData>R01GAD1 ... more base64 encoded data ... KTJk8giAA7</imageData>
        </input>
      </sendImage>
    </soapenv:Body>
  </soapenv:Envelope>

```

For additional information, refer to the Samples section of the Information Center which includes a sample that demonstrates the use of MTOM with JAX-WS web services.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

IBM i

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root

The default installation root directory for the Application Client for IBM WebSphere Application Server is the /QIBM/ProdData/WebSphere/AppClient/V85/client directory.

app_client_user_data_root

The default Application Client for IBM WebSphere Application Server user data root is the /QIBM/UserData/WebSphere/AppClient/V85/client directory.

app_client_profile_root

The default Application Client for IBM WebSphere Application Server profile root is the /QIBM/UserData/WebSphere/AppClient/V85/client/profiles/*profile_name* directory.

app_server_root

The default installation root directory for WebSphere Application Server is the /QIBM/ProdData/WebSphere/AppServer/V85/Base directory.

java_home

Table 102. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32-bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit
64-bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit

plugins_profile_root

The default Web Server Plug-ins profile root is the /QIBM/UserData/WebSphere/Plugins/V85/webserver/profiles/*profile_name* directory.

plugins_root

The default installation root directory for Web Server Plug-ins is the /QIBM/ProdData/WebSphere/Plugins/V85/webserver directory.

plugins_user_data_root

The default Web Server Plug-ins user data root is the /QIBM/UserData/WebSphere/Plugins/V85/webserver directory.

product_library

product_lib

This is the product library for the installed product. The product library for each Version 8.5 installation on the system contains the program and service program objects (similar to .exe, .dll, .so objects) for the installed product. The product library name is QWAS85x (where x is A, B, C, and so on). The product library for the first WebSphere Application Server Version 8.5 product installed on the system is QWAS85A. The *app_server_root*/properties/product.properties file contains the value for the product library of the installation, was.install.library, and is located under the *app_server_root* directory.

profile_root

The default directory for a profile named *profile_name* for WebSphere Application Server is the /QIBM/UserData/WebSphere/AppServer/V85/Base/profiles/*profile_name* directory.

shared_product_library

The shared product library, which contains all of the objects shared by all installations on the system, is QWAS85. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root

The default user data directory for WebSphere Application Server is the /QIBM/UserData/WebSphere/AppServer/V85/Base directory.

The profiles and profileRegistry subdirectories are created under this directory when you install the product.

The *user_data_root* directory contains the default locations for WLP_USR_DIR and WLP_OUTPUT_DIR when the Liberty profile is installed. These directories are *user_data_root*/wlp/usr and *user_data_root*/wlp/output/servers, respectively.

web_server_root

The default web server path is /www/*web_server_name*.

Enforcing adherence to WSDL bindings in JAX-WS web services

Java API for XML-Based Web Services (JAX-WS) Version 2.1 introduced the concept of *features* as a way to programmatically control specific functions and behaviors. The RespectBindingFeature is one of the

supported standard features. You can use the `RespectBindingFeature` to control whether a JAX-WS implementation is required to respect the contents of a Web Services Description Language (WSDL) binding that is associated with an endpoint.

About this task

While WSDL documents are often used during the development process, the actual enforcement of the use of the WSDL document specifications, when they are provided, at run time has not been well defined in versions of the JAX-WS specification previous to Version 2.1. The JAX-WS Version 2.1 specification added the feature, `RespectBindingFeature`, to clarify the impact of the `wsdl:binding` in a JAX-WS runtime environment.

Enabling the feature, `RespectBindingFeature`, causes the JAX-WS runtime environment to inspect the `wsdl:binding` for an endpoint at run time to ensure that the binding of service endpoint interface (SEI) parameters and return values is respected. Additionally, this feature ensures that all required `wsdl:binding` extensions are either understood and used by the runtime environment, or the extensions have been explicitly disabled by the application. Your JAX-WS application can disable a specific `wsdl:binding` extension that has a defined `WebServiceFeature` interface by using the appropriate annotation that is associated with that feature, using an API that accepts the `javax.xml.ws.WebServiceFeature` interface, or configuring the deployment descriptors.

When the `RespectBindingFeature` feature is not enabled, which is the default, the runtime environment can choose whether any part of the `wsdl:binding` is enforced.

Procedure

1. Develop Java artifacts for your JAX-WS application that includes a Web Services Description Language (WSDL) file that represents your web services application.
 - a. If you are starting with a WSDL file, develop Java artifacts from a WSDL file by using the `wsimport` command to generate the required JAX-WS portable artifacts.
 - b. If you are starting with JavaBeans components, develop Java artifacts for JAX-WS applications and generate a WSDL file using the `wsgen` command.
2. If you want to enable `RespectBindingFeature` on your endpoint implementation class, use one of the following methods:

- Use the `@RespectBinding` annotation on the endpoint.

To enable `RespectBinding` on an endpoint, use the `@RespectBinding` (`javax.xml.ws.RespectBinding`) annotation on the endpoint. The `@RespectBinding` annotation has only one parameter, `enabled`. This parameter is optional. The `enabled` parameter has a Boolean value and indicates if `RespectBindingFeature` is enabled for the JAX-WS endpoint.

The following example snippet illustrates adding the `@RespectBinding` annotation for the JAX-WS `MyServiceImpl` endpoint:

```
@RespectBinding(enabled=true)
@WebService
public class MyServiceImpl {
    ...
}
```

- Use the `<respect-binding>` deployment descriptor element.

You can use the `<respect-binding>` element within the `<port-component>` element in the `webservices.xml` deployment descriptor as an alternative to using the `@RespectBinding` annotation on the service endpoint implementation class; for example:

```
<port-component>
  <port-component-name>MyPort1</port-component-name>
  <respect-binding>
    <enabled>true</enabled>
  </respect-binding>
  <service-impl-bean>
    <servlet-link>MyPort1ImplBean</servlet-link>
  </service-impl-bean>
</port-component>
```

3. If you want to enable `RespectBindingFeature` on your client, use one of the following methods:

- Enable `RespectBindingFeature` on a dispatch client; for example:

```
RespectBindingFeature respectBinding = new RespectBindingFeature();
Service svc = Service.create(serviceName);
svc.addPort(portName, SOAPBinding.SOAP11_HTTP_BINDING, endpointUrl);
Dispatch<Source> dsp = svc.createDispatch(portName, Source.class, Service.Mode.PAYLOAD, respectBinding);
```

- Enable `RespectBindingFeature` on a dynamic proxy client; for example:

```
// Create a dynamic proxy with RespectBinding enabled.
Service svc = Service.create(serviceName);
RespectBindingFeature respectBinding = new RespectBindingFeature();
RespectBindingSample proxy = svc.getPort(portName, RespectBindingSample.class, respectBinding);
```

- Enable `RespectBindingFeature` on your client using the `@RespectBinding` annotation; for example:

```
public class MyClientApplication {
    // Enable RespectBinding for a port-component-ref resource injection.
    @RespectBinding(enabled=true)
    @WebServiceRef(MyService.class)
    private MyPortType myPort;
    ...
}
```

- Enable `RespectBindingFeature` on your client using deployment descriptor elements within a `port-component-ref` element; for example:

```
<service-ref>
  <service-ref-name>service/MyPortComponentRef</service-ref-name>
  <service-interface>com.example.MyService</service-ref-interface>
  <port-component-ref>
    <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
    <respect-binding>
      <enabled>true</enabled>
    </respect-binding>
  </port-component-ref>
</service-ref>
```

Results

By implementing the feature, `RespectBindingFeature`, you have specified to enforce adherence of the contents of a WSDL binding that is associated with an endpoint for your JAX-WS application.

Developing a `webservices.xml` deployment descriptor for JAX-WS applications

Deployment descriptors are standard text files, formatted using XML and packaged in a web services application. You can optionally use the `webservices.xml` deployment descriptor to augment or override application metadata specified in annotations within Java API for XML-Based Web Services (JAX-WS) web services.

About this task

Similar to Java API for XML-based RPC (JAX-RPC) Web services, you can use deployment descriptors to describe JAX-WS web services. For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

A JAX-WS web service requires that you annotate your Java class with the `javax.jws.WebService` annotation or the `javax.jws.WebServiceProvider` annotation for Provider endpoints. You can use server-side deployment descriptors to override corresponding attributes of the annotation or to enhance information in annotations. There is a defined relationship between the deployment descriptor elements and the `@WebService` and `@WebServiceProvider` annotations. Refer to section 5.3 in the Web Services for Java Platform, Enterprise Edition (Java EE) specification, Version 1.2 for detailed information regarding the deployment descriptor elements and the mapping to the `@WebService` and `@WebServiceProvider` annotation attributes. There are also elements in the `webservice.xml` deployment descriptor that map to other annotations. For example, the deployment descriptor element `<protocol-binding>` maps to the

@BindingType annotation, and the deployment descriptor element <enable-mtom> maps to the @MTOM annotation. For more information regarding the web services deployment descriptor elements, see section 7.1 in the Web Services for Java Platform, Enterprise Edition (Java EE) specification.

Procedure

Use assembly tools to generate the webservice.xml deployment descriptor.

Results

You have deployment descriptor templates that you can use to override JAX-WS annotation attributes or specify attributes that are not defined by the annotation.

Example

In the following example, the service implementation class for a JAX-WS web service includes the @WebService annotation:

```
@WebService(wsdlLocation="http://myhost.com/location/of/the/wsdl/ExampleService.wsdl")
```

The associated webservices.xml deployment descriptor specifies a different filename for the WSDL document as follows:

```
<webservices>
<webservice-description>
<webservice-description-name>ExampleService</webservice-description-name>
<wsdl-file>META-INF/wsdl/ExampleService.wsdl</wsdl-file>
...
</webservice-description>
</webservices>
```

The value that is specified in the deployment descriptor, META-INF/wsdl/ExampleService.wsdl, overrides the annotation value.

What to do next

Configure the webservice.xml deployment descriptor. After you configure the deployment descriptors, you must assemble the Web services application for deployment.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root

The default installation root directory for the Application Client for IBM WebSphere Application Server is the /QIBM/ProdData/WebSphere/AppClient/V85/client directory.

app_client_user_data_root

The default Application Client for IBM WebSphere Application Server user data root is the /QIBM/UserData/WebSphere/AppClient/V85/client directory.

app_client_profile_root

The default Application Client for IBM WebSphere Application Server profile root is the /QIBM/UserData/WebSphere/AppClient/V85/client/profiles/*profile_name* directory.

app_server_root

The default installation root directory for WebSphere Application Server is the /QIBM/ProdData/WebSphere/AppServer/V85/Base directory.

java_home

Table 103. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32-bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit
64-bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit

plugins_profile_root

The default Web Server Plug-ins profile root is the /QIBM/UserData/WebSphere/Plugins/V85/webserver/profiles/*profile_name* directory.

plugins_root

The default installation root directory for Web Server Plug-ins is the /QIBM/ProdData/WebSphere/Plugins/V85/webserver directory.

plugins_user_data_root

The default Web Server Plug-ins user data root is the /QIBM/UserData/WebSphere/Plugins/V85/webserver directory.

product_library

product_lib

This is the product library for the installed product. The product library for each Version 8.5 installation on the system contains the program and service program objects (similar to .exe, .dll, .so objects) for the installed product. The product library name is QWAS85x (where x is A, B, C, and so on). The product library for the first WebSphere Application Server Version 8.5 product installed on the system is QWAS85A. The *app_server_root*/properties/product.properties file contains the value for the product library of the installation, was.install.library, and is located under the *app_server_root* directory.

profile_root

The default directory for a profile named *profile_name* for WebSphere Application Server is the /QIBM/UserData/WebSphere/AppServer/V85/Base/profiles/*profile_name* directory.

shared_product_library

The shared product library, which contains all of the objects shared by all installations on the system, is QWAS85. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root

The default user data directory for WebSphere Application Server is the /QIBM/UserData/WebSphere/AppServer/V85/Base directory.

The profiles and profileRegistry subdirectories are created under this directory when you install the product.

The *user_data_root* directory contains the default locations for WLP_USR_DIR and WLP_OUTPUT_DIR when the Liberty profile is installed. These directories are *user_data_root*/wlp/usr and *user_data_root*/wlp/output/servers, respectively.

web_server_root

The default web server path is /www/*web_server_name*.

Completing the JavaBeans implementation for JAX-WS applications

After you have developed the Java artifacts necessary to develop a Java API for XML-Based Web Services (JAX-WS) web service, you must complete the JavaBeans implementation to assemble a web application archive (WAR) file. The resulting WAR file contains the JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Generate Java artifacts for JAX-WS applications and optionally generate a WSDL file using the **wsgen** command-line tool. You can also optionally use deployment descriptors to augment or override binding information contained in annotations for JAX-WS web services.

About this task

For JAX-WS applications, complete the JavaBeans implementation by writing your business application.

Procedure

1. Write the JavaBeans implementation. The JavaBeans implementation is not generated by JAX-WS tooling.
2. Compile all the Java classes.

Results

You have now written your JavaBeans implementation to complete your web service application.

What to do next

After completing the JavaBeans implementation, assemble your web services application.

Completing the EJB implementation for JAX-WS applications

After you have developed the Java artifacts necessary to develop a Java API for XML-Based Web Services (JAX-WS) web service, you must complete the Enterprise JavaBeans (EJB) implementation to assemble a Java archive (JAR) file. The resulting JAR file contains the Enterprise JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Generate Java artifacts for JAX-WS applications and optionally generate a WSDL file using the **wsgen** command-line tool. You can also optionally use deployment descriptors to augment or override binding information contained in annotations for JAX-WS web services.

About this task

For JAX-WS applications, complete the enterprise beans implementation by writing your business application.

Procedure

1. Write the enterprise beans implementation. The enterprise beans implementation is not generated by JAX-WS tooling.
2. Compile all the Java classes.

Results

You have now written your enterprise beans implementation to complete your web service application.

What to do next

After completing the enterprise beans implementation, assemble your web services application.

Developing JAX-WS clients

Developing a JAX-WS client from a WSDL file

Java API for XML-Based Web Services (JAX-WS) tooling supports generating Java artifacts you need to develop static JAX-WS web services clients when starting with a Web Services Description Language (WSDL) file.

Before you begin

When you use a top-down development approach to developing JAX-WS web services by starting with a WSDL file, you must obtain the Uniform Resource Locator (URL) for the WSDL file.

 If the WSDL file is a local file, the URL looks like this example: `file:/path/file_name.wsdl`.

You can also specify local files using the absolute or relative file system path.

About this task

The static client programming model for JAX-WS is called the dynamic proxy client. The dynamic proxy client invokes a web service based on a service endpoint interface that is provided. After you create the proxy, the client application can invoke methods on the proxy just like a standard implementation of those interfaces. For JAX-WS web service clients using the dynamic proxy programming model, use the JAX-WS tool, **wsimport**, to process a WSDL file and generate portable Java artifacts that are used to create a web service client. Create the following portable Java artifacts using the **wsimport** tool:

- Service endpoint interface (SEI)
- Service class
- Exception class that is mapped from the `wsdl:fault` class (if any)
- Java Architecture for XML Binding (JAXB) generated type values which are Java classes mapped from XML schema types

Note: The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are located in the `app_server_root\bin\` directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the `app_server_root\bin\` directory.

In addition to using the tools from the command-line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsImport` Ant task from within the Ant build

environment to invoke the `wsimport` tool. To function properly, this Ant task requires that you invoke Ant using the `ws_ant` script.

Procedure

Run the `wsimport` command to generate the portable client artifacts. The `wsimport` tool is located in the `app_server_root\bin\` directory.

```
IBM i
app_server_root/bin/wsimport wsdl_URL
```

(Optional) Use the following options with the `wsimport` command:

- Use the **-verbose** option to see a list of generated files when you run the command.
- Use the **-keep** option to keep generated Java files.
- Use the **-wsdlLocation** option to specify the location of the WSDL file.

Note: A best practice for ensuring that you produce a JAX-WS web services client enterprise archive (EAR) file that is portable to other systems is to package the WSDL document within the application module such as a web services client Java archive (JAR) file or a web application archive (WAR) file. You can specify a relative URI for the location of your WSDL file by using the `-wsdllocation` annotation attribute. For example, if your `MyService.wsdl` file is located in the `META-INF/wsdl/` directory, then run the `wsimport` tool and use the `-wsdllocation` option to specify the value to be used for the location of the WSDL file. This ensures that the generated artifacts contain the correct `-wsdllocation` information needed when the application is loaded into the administrative console; for example:

```
wsimport -keep -wsdllocation /META-INF/wsdl/MyService.wsdl
```

- Use the **-b** option if you are using WSDL or schema customizations to specify external binding files that contain your customizations.

You can customize the bindings in your WSDL file to enable asynchronous mappings or attachment files. To generate asynchronous interfaces, add the client-side only customization `enableAsyncMapping` binding declaration to the `wsdl:definitions` element or in an external binding file that is defined in the WSDL file. Use the `enableMIMEContent` binding declaration in your custom client or server binding file to enable or disable the default `mime:content` mapping rules. For additional information on custom binding declarations, see chapter 8 the JAX-WS specification.

Read about the `wsimport` command to learn more about this command and additional options that you can specify.

Results

You have the generated Java artifacts to create a JAX-WS client that can invoke JAX-WS web services. To learn more about the usage, syntax, and parameters for the `wsimport` command, see the `wsimport` command for JAX-WS applications documentation.

Example

The following example illustrates how the `wsimport` command is used to process the sample `ping.wsdl` file to generate portable artifacts.

1. Copy the following `ping.wsdl` file to a temporary directory.

```
<?xml version="1.0" encoding="UTF-8"?>
<!--
 * This program can be used, run, copied, modified and distributed
 * without royalty for the purpose of developing, using, marketing, or distributing.
-->
<wsdl:definitions xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
  xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
  xmlns:tns="http://com.ibm/was/wssample/sei/ping/"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema" name="PingService"
```

```

targetNamespace="http://com/ibm/was/wssample/sei/ping/">
<wsdl:types>
<xsd:schema
targetNamespace="http://com/ibm/was/wssample/sei/ping/"
xmlns:xsd="http://www.w3.org/2001/XMLSchema">

<xsd:element name="pingStringInput">
<xsd:complexType>
<xsd:sequence>
<xsd:element name="pingInput" type="xsd:string" />
</xsd:sequence>
</xsd:complexType>
</xsd:element>
</xsd:schema>
</wsdl:types>
<wsdl:message name="pingOperationRequest">
<wsdl:part element="tns:pingStringInput" name="parameter" />
</wsdl:message>
<wsdl:portType name="PingServicePortType">
<wsdl:operation name="pingOperation">
<wsdl:input message="tns:pingOperationRequest" />

</wsdl:operation>
</wsdl:portType>
<wsdl:binding name="PingSOAP" type="tns:PingServicePortType">
<soap:binding style="document"
transport="http://schemas.xmlsoap.org/soap/http" />
<wsdl:operation name="pingOperation">
<soap:operation soapAction="pingOperation" style="document" />
<wsdl:input>
<soap:body use="literal" />
</wsdl:input>
</wsdl:operation>
</wsdl:binding>
<wsdl:service name="PingService">
<wsdl:port binding="tns:PingSOAP" name="PingServicePort">
<soap:address
location="http://localhost:9080/WSSampleSei/PingService" />
</wsdl:port>
</wsdl:service>
</wsdl:definitions>

```

2. Run the **wsimport** command from the *app_server_root\bin* directory.

```
app_server_root/bin/wsimport -keep -verbose ping.wsdl
```

After generating the template files from the **wsimport** command, the following files are generated:

```

com\ibm\was\wssample\sei\ping\ObjectFactory.java
com\ibm\was\wssample\sei\ping\package-info.java
com\ibm\was\wssample\sei\ping\PingServicePortType.java
com\ibm\was\wssample\sei\ping\PingService.java
com\ibm\was\wssample\sei\ping\PingStringInput.java

```

The `ObjectFactory.java`, `PingService.java`, and `PingServicePortType.java` files are the generated Java class files to use when you package the Java artifacts with your client implementation inside a Java archive (JAR) or a web application archive (WAR) file.

What to do next

Complete the client implementation.

Developing deployment descriptors for a JAX-WS client

Deployment descriptors are standard text files, formatted using XML and packaged in a web services application. You can optionally use the Web Services for Java Platform, Enterprise Edition (Java EE) specification (JSR 109) service reference deployment descriptor to augment or override application metadata specified in annotations within Java API for XML-Based Web Services (JAX-WS) web services client.

Before you begin

You must first generate the web services client artifacts from a Web Services Description Language (WSDL) file using the `wsimport` command.

About this task

You can add `service-ref` entries within the `application-client.xml`, `web.xml`, or `ejb-jar.xml` Java EE deployment descriptors. A `service-ref` entry represents a reference to a web service that is used by a Java EE component in Web, Enterprise JavaBeans (EJB) or application client containers. A `service-ref` entry has a JNDI name that is used to lookup the service. Specifying the `service-ref` entry enables the client applications to locate the service using a JNDI lookup and you can also use these service references for resource injection.

For each `service-ref` entry found in one of the deployment descriptors, the corresponding service object is bound into the JNDI namespace and the port information is included, if specified. The JAX-WS client can now perform a JNDI lookup to retrieve either a JAX-WS service or port instance.

When defining a `service-ref` that represents a JAX-WS service, use the `javax.xml.ws.Service` subclass that is generated by the `wsimport` tool as the `service-interface` value. This is the class that contains the `@WebServiceClient` annotation. When defining a `service-ref` that represents a JAX-WS port, the `service-interface` value is still the `javax.xml.ws.Service` subclass generated by the `wsimport` tool, and the `service-ref-type` value specifies the service endpoint interface (SEI) class used by the port. The SEI class is also generated by `wsimport`, and it is annotated with the `@WebService` annotation.

Procedure

1. Define the `service-ref` entry in your `application-client.xml`, `web.xml`, or `ejb-jar.xml` deployment descriptors.

For example, suppose a web application archive (WAR) file contains a `WEB-INF/web.xml` deployment descriptor that includes the following `service-ref` entries:

```
<service-ref>
  <service-ref-name>service/ExampleService</service-ref-name>
  <service-interface>com.ibm.sample.ExampleService</service-interface>
</service-ref>

<service-ref>
  <service-ref-name>service/ExamplePort</service-ref-name>
  <service-interface>com.ibm.sample.ExampleService</service-interface>
  <service-ref-type>com.ibm.sample.ExamplePort</service-ref-type>
</service-ref>

<service-ref>
  <service-ref-name>service/ExamplePortInjected</service-ref-name>
  <service-interface>com.ibm.sample.ExampleService</service-interface>
  <service-ref-type>com.ibm.sample.ExamplePort</service-ref-type>

  <injection-target>
    <injection-target-class>com.ibm.sample.J2EEClient</injection-target-class>
    <injection-target-name>injectedPort</injection-target-name>
  </injection-target>
</service-ref>
```

In this example, `com.ibm.sample.ExampleService` is a generated JAX-WS service class and this class must be a subclass of `javax.xml.ws.Service`. Additionally, the `ExampleService.getPort()` method returns an instance of `com.ibm.sample.ExamplePort`.

2. Use the deployment descriptors within your web services client application to customize your application. The following code fragments are examples of how your client application can use the `service-ref` entries within the WAR module:

```
import javax.xml.ws.Service;
import com.ibm.sample.ExampleService;
import com.ibm.sample.ExamplePort;

// Create an InitialContext object for doing JNDI lookups.
InitialContext ic = new InitialContext();
```

```

// Client obtains an instance of the generic service class using JNDI.
Service genericService =
(Service) ic.lookup("java:comp/env/service/ExampleService");

// Client obtains an instance of the generated service class using JNDI.
ExampleService exampleService =
(ExampleService) ic.lookup("java:comp/env/service/ExampleService");

// Client obtains an instance of the port using JNDI.
ExamplePort ExamplePort =
(ExamplePort) ic.lookup("java:comp/env/service/ExamplePort");

// The container injects an instance of ExamplePort based on the client deployment descriptor
private ExamplePort injectedPort;

```

Results

You can now use the service references that were defined in the deployment descriptor within your client application. Additionally, you can use deployment descriptors to augment or override information specified by `@WebServiceRef` or `@Resource` annotations.

The `<lookup-name>` deployment descriptor element is new in Java EE 6, and is used to indirectly refer to an already-defined service reference. When the `<lookup-name>` element is used, only the `<service-ref-name>` element may also be specified, and no other child elements of `<service-ref>` may be defined.

The following example shows a `service-ref` entry within a `WEB-INF/web.xml` file which defines a reference to a JAX-WS service, as well as a `service-ref` entry within the same `web.xml` file which defines an indirect reference to the first `service-ref`:

```

<service-ref>
  <service-ref-name>service/ExampleService</service-ref-name>
  <service-interface>com.ibm.sample.ExampleService</service-interface>
  <service-ref-type>com.ibm.sample.ExampleServicePortType</service-ref-type>
  <wsdl-file>WEB-INF/wsdl/ExampleService.wsdl</wsdl-file>
</service-ref>

<service-ref>
  <service-ref-name>service/ExampleService2</service-ref>
  <lookup-name>java:comp/env/service/ExampleService</lookup-name>
</service-ref>

```

Assuming the above `service-refs` are defined in the `WEB-INF/web.xml` file, the client application could perform a JNDI lookup using the name `java:comp/env/service/ExampleService2`, and the result would be a reference to the `ExampleService` service defined in the WSDL document `WEB-INF/wsdl/ExampleService.wsdl`, as defined in the first `service-ref`.

What to do next

Complete the client implementation by writing your client application code that is used to invoke the web service.

Developing a dynamic client using JAX-WS APIs

Java API for XML-Based Web Services (JAX-WS) provides support for the dynamic invocation of service endpoint operations.

About this task

JAX-WS provides a new dynamic Dispatch client API that is more generic and offers more flexibility than the existing Java API for XML-based RPC (JAX-RPC)-based Dynamic Invocation Interface (DII). The Dispatch client interface, `javax.xml.ws.Dispatch`, is an XML messaging oriented client that is intended for advanced XML developers who prefer to work at the XML level using XML constructs. To write a Dispatch client, you must have expertise with the Dispatch client APIs, the supported object types, and knowledge of the message representations for the associated Web Services Description Language (WSDL) file.

The Dispatch API can send data in either PAYLOAD or MESSAGE mode. When using the PAYLOAD mode, the Dispatch client is only responsible for providing the contents of the <soap:Body> and JAX-WS includes the input payload in a <soap:Envelope> element. When using the MESSAGE mode, the Dispatch client is responsible for providing the entire SOAP envelope.

The Dispatch client API requires application clients to construct messages or payloads as XML and requires a detailed knowledge of the message or message payload. The Dispatch client can use HTTP bindings when using Source objects, Java Architecture for XML Binding (JAXB) objects, or data source objects. The Dispatch client supports the following types of objects:

- `javax.xml.transform.Source`: Use Source objects to enable clients to use XML APIs directly. You can use Source objects with SOAP and HTTP bindings.
- JAXB objects: Use JAXB objects so that clients can use JAXB objects that are generated from an XML schema to create and manipulate XML with JAX-WS applications. JAXB objects can only be used with SOAP and HTTP bindings.
- `javax.xml.soap.SOAPMessage`: Use SOAPMessage objects so that clients can work with SOAP messages. You can only use SOAPMessage objects with SOAP version 1.1 or SOAP version 1.2 bindings.
- `javax.activation.DataSource`: Use DataSource objects so that clients can work with Multipurpose Internet Mail Extension (MIME) messages. Use DataSource only with HTTP bindings.

The Dispatch API uses the concept of generics that are introduced in Java SE Runtime Environment (JRE) 6. For each of the `invoke()` methods on the Dispatch interface, generics are used to determine the return type.

Procedure

1. Determine if you want your dynamic client to send data in PAYLOAD or MESSAGE mode.
2. Create a service instance and add at least one port to it. The port carries the protocol binding and service endpoint address information.
3. Create a `Dispatch<T>` object using either the `Service.Mode.PAYLOAD` method or the `Service.Mode.MESSAGE` method.
4. Configure the request context properties on the `javax.xml.ws.BindingProvider` interface. Use the request context to specify additional properties such as enabling HTTP authentication or specifying the endpoint address.
5. Optional: Set the `jaxws.response.throwExceptionIfSOAPFault` property on the RequestContext option for the Dispatch API to `Boolean.TRUE` if you do not want the JAX-WS runtime to throw a `SOAPFaultException`.

The following example illustrates how to specify this property on the RequestContext option for the Dispatch API

```
Dispatch<OMElement> dispatch = service.createDispatch(  
    portName, OMElement.class, Mode.MESSAGE);  
BindingProvider bp = (BindingProvider)dispatch;  
bp.getRequestContext().put(  
    "jaxws.response.throwExceptionIfSOAPFault", Boolean.FALSE);
```

6. Compose the client request message for the dynamic client.
7. Invoke the service endpoint with the Dispatch client either synchronously or asynchronously.
8. Process the response message from the service.

Results

You have developed a dynamic JAX-WS client using the Dispatch API. Refer to Chapter 4, section 3 of the JAX-WS 2.0 specification for more information on using a Dispatch client.

JAX-WS dynamic ports, which are those added using the service method `addPort`, might have additional memory requirements starting in WebSphere Application Server Version 8.0. In previous releases, a single instance of a dynamic port could be shared across multiple service instances. In version 8.x, dynamic

ports are now scoped to the instance of the service that added them. If a JAX-WS client has multiple service instances which refer to a dynamic port of the same name, those instances are no longer shared. This can potentially increase the memory requirements for that client. The memory used by dynamic ports is released when the service instance goes out of scope. However, if you encounter issues related to increased memory usage, it is possible to revert the behavior so that dynamic ports are again shared across service instances. To do this, set the system property `jaxws.share.dynamic.ports.enable` to the value `true`. However, note that doing so can cause some other issues, such as having policy set attachments incorrectly applied across shared dynamic ports. If you set this flag to `true` and encounter some of these issues, then you should remove the flag setting. In previous releases, if a SOAP Action was not provided by the Dispatch client application, the correct SOAP Action was not sent on the outbound message. Instead, the SOAP action was set to an anonymous operation. Starting in WebSphere Application Server Version 8, if the SOAP Action is not provided by the Dispatch client application, the JAX-WS runtime environment parses the outgoing message. It determines the operation being invoked and uses that information to determine the appropriate value for the SOAP Action. The operation resolution of the outbound message is based on the SOAP Body and the message encoding, for example, Doc/Lit/Bare, Doc/Lit/Wrapped. Since this parsing can be expensive, a property can be set. To always disable the parsing, set the property at the System level. To disable parsing on a per-message basis, set the property on the JAX-WS Request Message Context. The property is defined as a constant `org.apache.axis2.jaxws.Constants.DISPATCH_CLIENT_OUTBOUND_RESOLUTION` with a String value of `jaxws.dispatch.outbound.operation.resolution.enable`. The default value of the property is `null` which is interpreted as the String `true`, which enables the outbound operation resolution. Setting the property to `false` disables the outbound operation resolution. If parsing is disabled, then the SOAP Action in the outbound message is set to an anonymous operation as in previous releases. If the client provides a SOAP Action through the JAX-WS `javax.xml.ws.BindingProvider` properties, `SOAPACTION_USE_PROPERTY` and `SOAPACTION_URI_PROPERTY`, then that SOAP Action is used. Therefore, parsing of the outbound message does not occur regardless of the setting of the property. Setting a SOAP Action explicitly by the client is considered a best practice, particularly for performance on the service-provider. This practice prevents the inbound message from being parsed, to be routed to the correct endpoint operation.

Example

The following example illustrates the steps to create a Dispatch client and invoke a sample EchoService service endpoint.

```
String endpointUrl = ...;

QName serviceName = new QName("http://com/ibm/was/wssample/echo/",
    "EchoService");
QName portName = new QName("http://com/ibm/was/wssample/echo/",
    "EchoServicePort");

/** Create a service and add at least one port to it. */
Service service = Service.create(serviceName);
service.addPort(portName, SOAPBinding.SOAP11HTTP_BINDING, endpointUrl);

/** Create a Dispatch instance from a service.*/
Dispatch<SOAPMessage> dispatch = service.createDispatch(portName,
    SOAPMessage.class, Service.Mode.MESSAGE);

/** Create SOAPMessage request. */
// compose a request message
MessageFactory mf = MessageFactory.newInstance(SOAPConstants.SOAP_1_1_PROTOCOL);

// Create a message. This example works with the SOAPPART.
SOAPMessage request = mf.createMessage();
SOAPPART part = request.getSOAPPART();

// Obtain the SOAPEnvelope and header and body elements.
SOAPEnvelope env = part.getEnvelope();
SOAPHeader header = env.getHeader();
SOAPBody body = env.getBody();

// Construct the message payload.
SOAPElement operation = body.addChildElement("invoke", "ns1",
    "http://com/ibm/was/wssample/echo/");
SOAPElement value = operation.addChildElement("arg0");
value.addTextNode("ping");
request.saveChanges();
```

```
/** Invoke the service endpoint. */  
SOAPMessage response = dispatch.invoke(request);  
  
/** Process the response. */
```

Invoking JAX-WS web services asynchronously

Java API for XML-Based Web Services (JAX-WS) provides support for invoking web services using an asynchronous client invocation. JAX-WS provides support for both a callback and polling model when calling web services asynchronously. Both the callback model and the polling model are available on the Dispatch client and the Dynamic Proxy client.

Before you begin

Develop a JAX-WS Dynamic Proxy or Dispatch client. When developing Dynamic Proxy clients, after you generate the portable client artifacts from a Web Services Description Language (WSDL) file using the **wsimport** command, the generated service endpoint interface (SEI) does not have asynchronous methods included in the interface. Use JAX-WS bindings to add the asynchronous callback or polling methods on the interface for the Dynamic Proxy client. To enable asynchronous mappings, you can add the `jaxws:enableAsyncMapping` binding declaration to the WSDL file. For more information on adding binding customizations to generate an asynchronous interface, see chapter 8 of the JAX-WS specification.

Note: When you run the **wsimport** tool and enable asynchronous invocation through the use of the JAX-WS `enableAsyncMapping` binding declaration, ensure that the corresponding response message your WSDL file does not contain parts. When a response message does not contain parts, the request acts as a two-way request, but the actual response that is sent back is empty. The **wsimport** tool does not correctly handle a void response. To avoid this scenario, you can remove the output message from the operation which makes your operation a one-way operation or you can add a `<wsdl:part>` to your message. For more information on the usage, syntax and parameters for the **wsimport** tool, see the **wsimport** command for JAX-WS applications documentation.

About this task

An asynchronous invocation of a web service sends a request to the service endpoint and then immediately returns control to the client program without waiting for the response to return from the service. JAX-WS asynchronous web service clients consume web services using either the callback approach or the polling approach. Using a polling model, a client can issue a request and receive a response object that is polled to determine if the server has responded. When the server responds, the actual response is retrieved. Using the callback model, the client provides a callback handler to accept and process the inbound response object. The `handleResponse()` method of the handler is called when the result is available. Both the polling and callback models enable the client to focus on continuing to process work without waiting for a response to return, while providing for a more dynamic and efficient model to invoke web services. Polling invocations are valid from Enterprise JavaBeans (EJB) clients or Java Platform, Enterprise Edition (Java EE) application clients. Callback invocations are valid only from Java EE application clients.

Using the callback asynchronous invocation model

To implement an asynchronous invocation that uses the callback model, the client provides an `AsyncHandler` callback handler to accept and process the inbound response object. The client callback handler implements the `javax.xml.ws.AsyncHandler` interface, which contains the application code that is run when an asynchronous response is received from the server. The `javax.xml.ws.AsyncHandler` interface contains the `handleResponse(javax.xml.ws.Response)` method that is called after the run time has received and processed the asynchronous response from the server. The response is delivered to the callback handler in the form of a `javax.xml.ws.Response` object. The response object returns the response content when the `get()` method is called. Additionally, if an error was received, then an exception is returned to the client during that call. The response method is then invoked according to the threading model used by

the executor method, `java.util.concurrent.Executor` on the client's `java.xml.ws.Service` instance that was used to create the Dynamic Proxy or Dispatch client instance. The executor is used to invoke any asynchronous callbacks registered by the application. Use the `setExecutor` and `getExecutor` methods to modify and retrieve the executor configured for your service.

Using the polling asynchronous invocation model

Using the polling model, a client can issue a request and receive a response object that can subsequently be polled to determine if the server has responded. When the server responds, the actual response can then be retrieved. The response object returns the response content when the `get()` method is called. The client receives an object of type `javax.xml.ws.Response` from the `invokeAsync` method. That Response object is used to monitor the status of the request to the server, determine when the operation has completed, and to retrieve the response results.

Using an asynchronous message exchange

By default, asynchronous client invocations do not have asynchronous behavior of the message exchange pattern on the wire. The programming model is asynchronous; however, the exchange of request or response messages with the server is not asynchronous. To use an asynchronous message exchange, the `com.ibm.websphere.webservices.use.async.mep` property must be set on the client request context with a boolean value of `true`. When this property is enabled, the messages exchanged between the client and server are different from messages exchanged synchronously. With an asynchronous exchange, the request and response messages have WS-Addressing headers added that provide additional routing information for the messages. Another major difference between asynchronous and synchronous message exchange is that the response is delivered to an asynchronous listener that then delivers that response back to the client. For asynchronous exchanges, there is no timeout that is sent to notify the client to stop listening for a response. To force the client to stop waiting for a response, issue a `Response.cancel()` method on the object returned from a polling invocation or a `Future.cancel()` method on the object returned from a callback invocation. The cancel response does not affect the server when processing a request.

Procedure

1. Determine if you want to implement the callback method or the polling method for the client to asynchronously invoke the web service.
2. (Optional) Configure the client request context. Add the

```
com.ibm.websphere.webservices.use.async.mep
```

property to the request context to enable asynchronous messaging for the web services client. Using this property requires that the service endpoint supports WS-Addressing which is supported by default for the application server. The following example demonstrates how to set this property:

```
Map<String, Object> rc = ((BindingProvider) port).getRequestContext();  
rc.put("com.ibm.websphere.webservices.use.async.mep", Boolean.TRUE);
```

3. To implement the asynchronous callback method, perform the following steps.
 - a. Find the asynchronous callback method on the SEI or `javax.xml.ws.Dispatch` interface. For an SEI, the method name ends in `Async` and has one more parameter than the synchronous method of type `javax.xml.ws.AsyncHandler`. The `invokeAsync(Object, AsyncHandler)` method is the one that is used on the Dispatch interface.
 - b. (Optional) Add the `service.setExecutor` methods to the client application. Adding the executor methods gives the client control of the scheduling methods for processing the response. You can also choose to use the `java.concurrent.Executors` class factory to obtain packaged executors or implement your own executor class. See the JAX-WS specification for more information on using executor class methods with your client.
 - c. Implement the `javax.xml.ws.AsyncHandler` interface. The `javax.xml.ws.AsyncHandler` interface only has the `handleResponse(javax.xml.ws.Response)` method. The method must contain the logic for processing the response or possibly an exception. The method is called after the client run time has received and processed the asynchronous response from the server.
 - d. Invoke the asynchronous callback method with the parameter data and the callback handler.

- e. The `handleResponse(Response)` method is invoked on the callback object when the response is available. The `Response.get()` method is called within this method to deliver the response.
4. To implement the polling method,
 - a. Find the asynchronous polling method on the SEI or `javax.xml.ws.Dispatch` interface. For an SEI, the method name ends in *Async* and has a return type of `javax.xml.ws.Response`. The `invokeAsync(Object)` method is used on the Dispatch interface.
 - b. Invoke the asynchronous polling method with the parameter data.
 - c. The client receives the object type, `javax.xml.ws.Response`, that is used to monitor the status of the request to the server. The `isDone()` method indicates whether the invocation has completed. When the `isDone()` method returns a value of `true`, call the `get()` method to retrieve the response object.
 5. Use the `cancel()` method for the callback or polling method if the client needs to stop waiting for a response from the service. If the `cancel()` method is invoked by the client, the endpoint continues to process the request. However, the wait and response processing for the client is stopped.

Results

You have enabled your JAX-WS web service client to asynchronously invoke and consume web services. See the JAX-WS specification for additional information regarding the asynchronous client APIs.

Example

The following example illustrates a web service interface with methods for asynchronous requests from the client.

```
@WebService
public interface CreditRatingService {
    // Synchronous operation.
    Score getCreditScore(Customer customer);
    // Asynchronous operation with polling.
    Response<Score> getCreditScoreAsync(Customer customer);
    // Asynchronous operation with callback.
    Future<?> getQuoteAsync(Customer customer,
        AsyncHandler<Score> handler);
}
```

Using the callback method

The callback method requires a callback handler that is shown in the following example. When using the callback procedure, after a request is made, the callback handler is responsible for handling the response. The response value is a response or possibly an exception. The `Future<?>` method represents the result of an asynchronous computation and is checked to see if the computation is complete. When you want the application to find out if the request is completed, invoke the `Future.isDone()` method. Note that the `Future.get()` method does not provide a meaningful response and is not similar to the `Response.get()` method.

```
CreditRatingService svc = ...;
Future<?> invocation = svc.getCreditScoreAsync(customerTom,
    new AsyncHandler<Score>() {
        public void handleResponse (
            Response<Score> response)
        {
            score = response.get();
            // process the request...
        }
    }
);
```

Using the polling method

The following example illustrates an asynchronous polling client:

```
CreditRatingService svc = ...;
Response<Score> response = svc.getCreditScoreAsync(customerTom);
while (!response.isDone()) {
```

```

    // Do something while we wait.
}

score = response.get();

```

Implementing extensions to JAX-WS web services clients

WebSphere Application Server provides extensions to web services clients using the Java API for XML-based Web Services (JAX-WS) programming model.

About this task

You can customize web services by using the following extensions to the JAX-WS client programming model.

Procedure

- Set the **JAXWS_OUTBOUND_SOAP_HEADERS** and **JAXWS_INBOUND_SOAP_HEADERS** properties on the request context of the Dispatch or Proxy object to enable a JAX-WS web services client to send or retrieve implicit SOAP headers.

An implicit SOAP header is a SOAP header that is not explicitly defined in the WSDL file. An implicit SOAP header file fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the WSDL file, but the message definition is not referenced by a portType within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

To learn how to modify your client code to send or retrieve transport headers, see the information on sending implicit SOAP headers with JAX-WS or receiving implicit SOAP headers with JAX-WS.

- Set the **REQUEST_TRANSPORT_PROPERTIES** and **RESPONSE_TRANSPORT_PROPERTIES** properties to enable a web services client to send or retrieve transport headers.

Set the properties on the BindingProvider instance.

By modifying your client code to send or retrieve transport headers, you can send or receive specific information within the transport headers of outgoing requests or incoming responses from the server. For requests or responses that use the HTTP transport, the information is sent or retrieved in an HTTP header. Similarly, for a request or response that uses the Java Message Service (JMS) transport, the information is sent or retrieved in a JMS message property.

To learn how to modify your client code to send or retrieve transport headers, see the information on sending transport headers with JAX-WS or retrieving transport headers with JAX-WS.

To learn how to enable a web services client to send or retrieve transport headers, see the transport header properties best practices information.

Example: Using JAX-WS properties to manipulate SOAP headers in a JAX-WS handler

WebSphere Application Server provides extensions to the Java API for XML-Based Web Services (JAX-WS) and Web Services for Java Platform, Enterprise Edition (Java EE) client programming models, including the `jaxws.binding.soap.headers.outbound` and `jaxws.binding.soap.headers.inbound` properties. This example shows how to use these two properties to manipulate SOAP headers in a JAX-WS handler.

The following programming example illustrates how to set two request SOAP headers and retrieve one response SOAP header within a JAX-WS handler context:

```

1 //Create the hashmaps for the outbound soap headers
2 Map<QName, List<String>> outboundHeaders=messageContext.get("jaxws.binding.soap.headers.outbound");
3
4 //Add "AtmUuid1" and "AtmUuid2" to the outbound map
5 List<String> list1 = new ArrayList<String>();
6 list1.add("<AtmUuid1 xmlns=\\"com.rotbank.security\\"><uuid>R0TB-0A01254385FCA09</uuid></AtmUuid1>");
7 List<String> list2 = new ArrayList<String>();
8 list2.add("<AtmUuid2 xmlns=\\"com.rotbank.security\\"><uuid>R0TB-0A01254385FCA09</uuid></AtmUuid2>")

```

```
9  outboundHeaders.put(new QName("com.rotbank.security", "AtmUuid1"), list1);
10 outboundHeaders.put(new QName("com.rotbank.security", "AtmUuid2"), list2);
11 // Set the outbound map on the MessageContext object, which is passed into the JAX-WS handler method
12 messageContext.put("jaxws.binding.soap.headers.outbound", outboundHeaders);
```

On line 2, retrieve the outbound SOAP header map from the MessageContext parameter, which is passed into the JAX-WS handler method.

On lines 5-10, the AtmUuid1 and AtmUuid2 headers elements are added to the outbound map.

On line 12, the outbound map is set on the JAX-WS handler context, which causes the AtmUuid1 and AtmUuid2 headers to be added to the request message. This code is not necessary because the outboundHeaders map is a live map.

JAX-WS handler methods might also retrieve specific headers from the map and remove headers or entire lists of headers, if desired.

Sending implicit SOAP headers with JAX-WS

You can enable an existing Java API for XML-Based Web Services (JAX-WS) web services client to send values in implicit SOAP headers. By modifying your client code to send implicit SOAP headers, you can send specific information within an outgoing web service request.

Before you begin

To complete this task, you need a web services client that you can enable to send implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a portType element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

Using JAX-WS, there is no restriction on types of headers that you can manipulate.

About this task

The client application sets properties on the Dispatch or Proxy object to send and receive implicit SOAP headers.

Procedure

1. Create a `java.util.HashMap<QName, List<String>>` object.
2. Add an entry to the HashMap object for each implicit SOAP header that the client wants to send. The HashMap entry key is the QName of the SOAP header. The HashMap entry value is a `List<String>` object, and each String is the XML text of the entire SOAP header element. By using `List<String>` object, you can add multiple SOAP header elements that each have the same QName object.
3. Set the HashMap object as a property on the request context of the Dispatch or Proxy object. The property name is `com.ibm.wsspi.websvcs.Constants.JAXWS_OUTBOUND_SOAP_HEADERS`. The value of the property is the HashMap.
4. Issue the remote method calls using the Dispatch or Proxy object. The headers within the HashMap object are sent in the outgoing message.

A `WebServiceException` error can occur if any of the following are true:

- The HashMap object contains a key that is not a QName object or if the HashMap object contains a value that is not a List<String> object.
- The String representing an SOAP header is not a compliant XML message.
- The HashMap contains a key that represents a SOAP header that is declared protected by the owning component.

Results

You have a JAX-WS web services client that is configured to send implicit SOAP headers.

Example

The following programming example illustrates how to set two request SOAP headers and retrieve one response SOAP header within a JAX-WS web services request and response context:

```

1 //Create the hashmaps for the outbound soap headers
2 Map<QName, List<String>> outboundHeaders=new HashMap<QName, List<String>>();
3
4 //Add "AtmUuid1" and "AtmUuid2" to the outbound map
5 List<String> list1 = new ArrayList<String>();
6 list1.add("<AtmUuid1 xmlns=\"com.rotbank.security\"><uuid>ROTB-0A01254385FCA09</uuid></AtmUuid1>");
7 List<String> list2 = new ArrayList<String>();
8 list2.add("<AtmUuid2 xmlns=\"com.rotbank.security\"><uuid>ROTB-0A01254385FCA09</uuid></AtmUuid2>");
9 outboundHeaders.put(new QName("com.rotbank.security", "AtmUuid1"), list1);
10 outboundHeaders.put(new QName("com.rotbank.security", "AtmUuid2"), list2);
11 // Set the outbound map on the request context
12 dispatch.getRequestContext().put("jaxws.binding.soap.headers.outbound");
13 // Invoke the remote operation
14 dispatch.invoke(parm1);
15 // Get the inbound header map from the response context
16 Map<QName,List<String>> inboundMap = dispatch.getResponseContext().get("jaxws.binding.soap.headers.outbound");
17 List<String> serverUuidList = inboundMap.get(new QName("com.rotbank.security","ServerUuid"));
18 String text = serverUuidList.get(0);
19 //Note: text now equals a XML object that contains a SOAP header:
21//"<y:ServerUuid xmlns:y=\"com.rotbank.security\"><:uuid>ROTB-0A03519322FSA01
22 </y:uuid></y:ServerUuid.");

```

On line 2, create the outbound SOAP header map.

On lines 5-10, the AtmUuid1 and AtmUuid2 headers elements are added to the outbound map.

On line 12, the outbound map is set on the request context, which causes the AtmUuid1 and AtmUuid2 headers to be added to the request message when the operation is invoked.

On line 14, invoke the remote operation.

On line 15, obtain the outbound header map.

On lines 17-18, the ServerUuid header is retrieved from the response Map. The Map accesses the SOAP header from the response message.

Receiving implicit SOAP headers with JAX-WS

You can enable an existing Java API for XML-Based Web Services (JAX-WS) web services client to receive values from implicit SOAP headers. By modifying your client code to receive implicit SOAP headers, you can receive specific information within an incoming web service response.

Before you begin

To complete this task, you need a web services client that you can enable to receive implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a portType element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

Using JAX-WS, there is no restriction on types of headers that you can manipulate.

About this task

The client application sets properties on the Dispatch or Proxy object to send and receive implicit SOAP headers.

Procedure

1. Issue a remote method call with the Dispatch or Proxy object.
2. Using the property name, `com.ibm.wsspi.websvcs.Constants.JAXWS_INBOUND_SOAP_HEADERS`, retrieve the `Map<QName, List<String>>` from the `ResponseContext` of the Dispatch or Proxy object.
3. From the `Map<QName, List<String>>` value, retrieve a `List<String>` using the `QName` of the SOAP header. If the `List<String>` value is present, that value contains zero or more `String` objects that contain the XML text of the SOAP headers for the corresponding `QName`.

Results

You have a JAX-WS web services client that can receive values from implicit SOAP headers.

Transport header properties best practices

You can set the `REQUEST_TRANSPORT_PROPERTIES` property and `RESPONSE_TRANSPORT_PROPERTIES` property on a Java API for XML-based RPC (JAX-RPC) client Stub, a Call instance, or a Java API for XML-Based Web services (JAX-WS) `BindingProvider`'s `RequestContext` instance to enable a web services client to send or retrieve transport headers.

Note: Use these best practices to enable a Web services client to send or retrieve transport headers.

REQUEST_TRANSPORT_PROPERTIES best practices

Some transport headers such as the HTTP Cookie header and the Cookie2 header contain multiple embedded values. For headers that contain multiple values, the header value must be written in the following way:

- Each `name=value` pair embedded within the header value must be separated by a semi-colon (;).
- Each `name` and its value must be separated by an equal (=) sign.

The following is an example of how the header value must be written:

```
name1=value1;name2=value2;name3=value3
```

The values contained in the user's `Map` might be parsed before being added to the outgoing request if the outgoing request already contains a header identifier that matches one in the `Map`. For certain transport headers that contain multiple embedded values, the header values in the `Map` are parsed into individual `name=value` components. A semi-colon (;) separates the components, for example, `name1=value1;name2=value2`. Each `name=value` is appended to the outgoing header unless:

- The outgoing request header contains a `name` value.

In this case, the `name=value` from the `Map` is silently ignored, preventing a client from overwriting or modifying values for the `name` value that are already set in the outgoing request header by either the server or the web services engine.

- The user's header value contains multiple *name* values.

When the user's header value contains multiple *name* values, the first occurrence of the *name* value is used and the others are silently ignored. For example, if the user's header value contains `name1=value1;name2=value2;name1=value3`, where there are two occurrences of `name1`, the first value, `name1=value1`, is used. The other value, `name1=value3`, is silently ignored.

RESPONSE_TRANSPORT_PROPERTIES best practices

Only the Map keys are used; the Map values are ignored. The values are filled in this Map by retrieving the transport headers, which correspond to the Map keys from the incoming response message. An empty Map causes all of the transport headers and the associated values to be retrieved from the incoming response message.

HTTP headers that are processed under special consideration

The following are HTTP headers that are given special consideration when sending and retrieving HTTP responses and requests.

The values in these headers can be set in a variety of ways. For example, some header values are sent based on settings in a deployment descriptor or binding file. In these cases, the value set through `REQUEST_TRANSPORT_PROPERTIES` overrides the values set any other way.

Table 104. HTTP request and response header values. Values to specify for HTTP headers when sending and retrieving HTTP responses and requests.

Header	Send request	Retrieve response
Transfer-encoding	<ul style="list-style-type: none"> • The transfer-encoding header is ignored for HTTP 1.0. • When using HTTP 1.1, the transfer-encoding header is set to chunked if the value is chunked. 	There is no special processing.
Connection	<ul style="list-style-type: none"> • The connection header is ignored for HTTP 1.0. • When using HTTP 1.1, the following values are set: <ul style="list-style-type: none"> – The connection header is set to "close" if the value is set to "close". – The connection header is set to "keep-alive" if the value is set to "keep-alive". – All other value settings are ignored. 	There is no special processing.
Expect	<ul style="list-style-type: none"> • The expect header is ignored for HTTP 1.0. • When using HTTP 1.1, the following values are set: <ul style="list-style-type: none"> – The connection header is set to "100-continue" if the value is set to "100-continue". – All other value settings are ignored. 	There is no special processing.
Host	Ignored	There is no special processing.
Content-type	Ignored	There is no special processing.
SOAPAction	Ignored	There is no special processing.
Content-length	Ignored	There is no special processing.

Table 104. HTTP request and response header values (continued). Values to specify for HTTP headers when sending and retrieving HTTP responses and requests.

Header	Send request	Retrieve response
Cookie The following is a String constant: com.ibm.websphere.webservices.Constants .HTTP_HEADER_COOKIE	The value is sent on the header if it is structured correctly. See the information in this article for Header value format and Map values.	There is no special processing.
Cookie2 The following is a String constant: com.ibm.websphere.webservices.Constants .HTTP_HEADER_COOKIE2	See the information in the "Cookie" entry.	There is no special processing.
Set-cookie The following is a String constant: com.ibm.websphere.webservices.Constants .HTTP_HEADER_SET_COOKIE	There is no special processing.	If the property MAINTAIN_SESSION is set to true, the entire value is saved into SessionContext.CONTEXT_PROPERTY and is sent on subsequent requests in the Cookie header. See the Cookie entry in this table for more information.
Set-cookie2 The following is a String constant: com.ibm.websphere.webservices.Constants .HTTP_HEADER_SET_COOKIE2	There is no special processing.	If the property MAINTAIN_SESSION is set to true, the entire value is saved into SessionContext.CONTEXT_PROPERTY and is sent on subsequent requests in the Cookie header. See the Cookie entry in this table for more information.

Example client code

The following is an example of how you can code a web services client to send and retrieve transport header values:

```
public class MyApplicationClass {
    // Inject an instance of the service's port-type.
    @WebServiceRef(EchoService.class)
    private EchoPortType port;

    // This method will invoke the web service operation and send and receive transport headers.
    public void invokeService() {

        // Set up the Map that will contain the request headers.
        Map<String, Object>requestHeaders = new HashMap<String, Object>();
        requestHeaders.put("Cookie", "ClientAuthenticationToken=FFEEBCC");
        requestHeaders.put("MyHeaderFlag", new Boolean(true));

        // Set the Map as a property on the RequestContext.
        BindingProvider bp = (BindingProvider) port;
        bp.getRequestContext().put(com.ibm.websphere.webservices.Constants.REQUEST_TRANSPORT_PROPERTIES, requestHeaders);

        // Set up the Map to retrieve transport headers from the response message.
        Map<String, Object>responseHeaders = new HashMap<String, Object>();
        responseHeaders.put("Set-Cookie", null);
        responseHeaders.put("MyHeaderFlag", null);

        // Invoke the web services operation.
        String result = port.echoString("Hello, world!");

        // Retrieve the headers from the response.
        String cookieValue = responseHeaders.get("Set-Cookie");
        String headerFlag = responseHeaders.get("MyHeaderFlag");
    }
}
```

Sending transport headers with JAX-WS

You can enable an existing Java API for XML-Based Web Services (JAX-WS) web services client to send application-defined information along with your web services requests by using transport headers. In addition, you can enable a JAX-WS Web services endpoint to send application-defined information along with the Web services response message by using transport headers.

Before you begin

You need a JAX-WS web services client that you can enable to send transport headers.

Sending transport headers is supported in JAX-WS Web services clients, and is supported for the HTTP and JMS transports. The web services client must call the JAX-WS APIs directly and not through any intermediary layers, such as a gateway function.

About this task

When using the JAX-WS programming model, the client must set a property on the `BindingProvider`'s `RequestContext` object to send values in transport headers with the Web services request message. After you set the property, the values are set in all the requests for subsequent remote method invocations against the `BindingProvider` object until the associated property is set to `null` or the `BindingProvider` object is discarded.

To send values in the transport headers on outbound requests from a JAX-WS Web services client application, modify the client code as follows:

Procedure

1. Create a `java.util.Map` object that contains the transport headers.
2. Add an entry to the `Map` object for each transport header that you want the client to send.
 - a. Set the `Map` entry key to a string that exactly matches the transport header identifier. You can define the header identifier with a reserved header name, such as `Cookie` in the case of HTTP, or the header identifier can be user-defined, such as `MyTransportHeader`. Certain header identifiers are processed in a unique manner, but no other checks are made as to the header identifier value. To learn more about the HTTP header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as `HTTP_HEADER_SET_COOKIE` in the `com.ibm.websphere.webservices.Constants` class.
 - b. Set the `Map` entry value to the value of the transport header. The type of this value can be one of the following data types:
 - `java.lang.String`
 - `java.lang.Integer`
 - `java.lang.Short`
 - `java.lang.Long`
 - `java.lang.Float`
 - `java.lang.Double`
 - `java.lang.Byte`
 - `java.lang.Boolean`
3. Set the `Map` object on the `BindingProvider`'s `RequestContext` using the `com.ibm.websphere.webservices.Constants.REQUEST_TRANSPORT_PROPERTIES` property. When the `REQUEST_TRANSPORT_PROPERTIES` property value is set, that `Map` is used on subsequent invocations to set the header values in the outgoing requests. If the `REQUEST_TRANSPORT_PROPERTIES` property value is set to `null`, no transport properties are sent in outgoing requests. To learn more about these properties, see the transport header properties documentation.
4. Issue remote method calls against the `BindingProvider` instance. The headers and the associated values from the `Map` are added to the outgoing request for each method invocation. If the invocation uses HTTP, then the transport headers are sent as HTTP headers within the HTTP request. If the invocation uses JMS, then the transport headers are sent as JMS message properties.

If the `Constants.REQUEST_TRANSPORT_PROPERTIES` property is not set correctly, you might experience API usage errors that result in a `WebServiceException` error. The following requirements must be met, or the process fails:

 - a. The `Constants.REQUEST_TRANSPORT_PROPERTIES` property value that is set on the `BindingProvider`'s `RequestContext` must be a `java.util.Map` object or `null`.
 - b. Each key in the `Map` must be a `java.util.String` data type.

c. Each value in the Map must be one of the following data types:

- java.lang.String
- java.lang.Integer
- java.lang.Short
- java.lang.Long
- java.lang.Float
- java.lang.Double
- java.lang.Byte
- java.lang.Boolean

Results

You have a JAX-WS web services client that is configured to send transport headers in Web services request messages.

Example

Here is a short programming example that illustrates how request transport headers are sent by a JAX-WS Web services client application:

```
public class MyApplicationClass {
    // Inject an instance of the service's port-type.
    @WebServiceRef(EchoService.class)
    private EchoPortType port;

    // This method will invoke the web service operation and send transport headers on the request.
    public void invokeService() {

        // Set up the Map that will contain the request headers.
        Map<String, Object> requestHeaders = new HashMap<String, Object>();
        requestHeaders.put("MyHeader1", "This is a string value");
        requestHeaders.put("MyHeader2", new Integer(33));
        requestHeaders.put("MyHeader3", new Boolean(true));

        // Set the Map as a property on the RequestContext.
        BindingProvider bp = (BindingProvider) port;
        bp.getRequestContext().put(com.ibm.websphere.webservices.Constants.REQUEST_TRANSPORT_PROPERTIES, requestHeaders);

        // Invoke the web services operation.
        String result = port.echoString("Hello, world!");
    }
}
```

Sending response transport headers from a JAX-WS endpoint: Before you begin

You need a JAX-WS Web services endpoint implementation class that you can enable to send transport headers.

Sending response transport headers from a JAX-WS endpoint is similar to sending request transport headers from a JAX-WS client. It is supported for the HTTP and JMS transports.

About this task

When using the JAX-WS programming model, the endpoint implement class must set a property on the MessageContext to send values in transport headers with the Web services response message.

Procedure

1. Create a java.util.Map object that contains the transport headers.
2. Add an entry (key and value) to the Map object for each transport header that you want to send in the response message. This is similar to the procedure for the client above.

3. Retrieve the `MessageContext` (instance of `javax.xml.ws.handler.MessageContext`) associated with the invocation of the endpoint.
4. Set the `Map` object on the `MessageContext` using the `com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES` property.

Results

You have a JAX-WS Web services endpoint implementation class that is configured to send transport headers in Web services response messages.

Example

Here is a short programming example that illustrates how response transport headers are sent by a JAX-WS Web services endpoint implementation class:

```
@WebService
public class EchoServiceImpl implements EchoServicePortType {

    // Inject an instance of WebServiceContext so we can retrieve
    // the MessageContext for each invocation of this endpoint.
    @Resource
    WebServiceContext ctxt;

    /**
     * Default constructor.
     */
    public EchoServiceImpl() {
        ....
    }

    public String echoString(String input) {
        String result = "Echo result: " + input;

        // Retrieve the MessageContext from the injected WebServiceContext.
        MessageContext mc = ctxt.getMessageContext();

        // Send some headers back in the response message.
        Map<String, Object> responseHeaders = new HashMap<String, Object>();
        responseHeaders.put("MyHeader1", "This is a string response value");
        responseHeaders.put("MyHeader2", new Integer(33));
        responseHeaders.put("MyHeader3", new Boolean(false));

        // Set the response header Map on the MessageContext.
        mc.put(com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES, responseHeaders);

        return result;
    }
}
```

Retrieving transport headers with JAX-WS

You can enable a Java API for XML-Based Web Services (JAX-WS) web services client to retrieve values from transport headers. For a request that uses HTTP, the transport headers are retrieved from HTTP headers found in the HTTP response message. For a request that uses Java Message Service (JMS), the transport headers are retrieved from the JMS message properties found on the JMS response message.

Before you begin

You need a JAX-WS web services client that you can enable to retrieve transport headers.

Retrieving transport headers is supported only by Web services clients, and is supported for the HTTP and JMS transports. The web services client must call the JAX-WS APIs directly and not through any intermediary layers, such as a gateway function.

About this task

When using the JAX-WS programming model, the client must set a property on the `BindingProvider`'s `RequestContext` object to retrieve values from the transport headers. After you set the property, values are read from responses for the subsequent method invocations against that `BindingProvider` object until the associated property is set to `null` or the `BindingProvider` object is discarded.

To retrieve values from the transport headers on inbound responses, modify the client code as follows:

Procedure

1. Create a `java.util.Map` object that will hold the transport headers retrieved from the response message. To retrieve all the transport headers from a response message, leave this `Map` empty.
2. (Optional) Add an entry to the `Map` for each header that you want to retrieve from the incoming response message.
 - a. Set the `Map` entry key to a string that exactly matches the transport header identifier. You can specify the header identifier with a reserved header name, such as `Cookie` in the case of HTTP, or the header identifier can be user-defined, such as `MyTransportHeader`. Certain header identifiers are processed in a unique manner, but no other checks are made to confirm the header identifier value. To learn more about the HTTP header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as `HTTP_HEADER_SET_COOKIE` in the `com.ibm.websphere.webservices.Constants` class. The `Map` entry value is ignored and does not need to be set. An empty `Map`, for example, one that is non-null, but does not contain any keys, causes all the transport headers in the response to be retrieved.
3. Set the `Map` object on the `BindingProvider`'s `RequestContext` using the `com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES` property. When the `Map` is set, the `RESPONSE_TRANSPORT_PROPERTIES` property is used in subsequent invocations to retrieve the headers from the responses. If you set the property to `null`, no headers are retrieved from the response. To learn more about these properties, see the transport header properties documentation.
4. Invoke remote method calls against the `BindingProvider` instance. The values from the specified transport headers are retrieved from the response message and placed in the `Map`.

If the property is not set correctly, you might experience API usage errors that result in a `WebServiceException` error. The following requirements must be met, or the process fails:

- The `Constants.RESPONSE_TRANSPORT_PROPERTIES` property value that is set on the `BindingProvider`'s `RequestContext` instance must be either `null` or an instance of `java.util.Map`.
- All the `Map` keys must be of the `java.lang.String` data type, and the keys must not be null.
- The `Map` may be empty, which means that it contains no entries at all. In this case, all the transport headers will be retrieved from the response message.

Results

You have a JAX-WS web service that can receive transport headers from incoming response messages.

Example

Here is a short programming example that illustrates how response transport headers are retrieved by a JAX-WS Web services client application:

```
public class MyApplicationClass {
    // Inject an instance of the service's port-type.
    @WebServiceRef(EchoService.class)
    private EchoPortType port;

    // This method will invoke the web service operation and retrieve transport headers on the request.
    public void invokeService() {
```

```

// Set up the Map to retrieve our response headers.
Map<String, Object> responseHeaders = new HashMap<String, Object>;
responseHeaders.put("MyHeader1", null);
responseHeaders.put("MyHeader2", null);
responseHeaders.put("MyHeader3", null);

// Set the Map as a property on the RequestContext.
BindingProvider bp = (BindingProvider) port;
bp.getRequestContext().put(com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES, responseHeaders);

// Invoke the web services operation.
String result = port.echoString("Hello, world!");

// Now retrieve our response headers.
Object header1 = responseHeaders.get("MyHeader1");
Object header2 = responseHeaders.get("MyHeader2");
Object header3 = responseHeaders.get("MyHeader3");
}
}

```

Developing JAX-RPC web services

Setting up a development environment for web services

The application server provides command-line tools to develop web services clients and implementations that are based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. You must set up your development environment before you start developing web services.

Before you begin

Before you can set up a web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information on installing the application server, read about installing your application server environment.

About this task

Set up a web services development environment by completing the following actions.

Procedure

Set up the environment.

 Run the `setupCmdLine` script on the Qshell command line from the `./profile_root/bin` directory.

Results

You have set up an environment so that you can develop Web services.

What to do next

Implement web services applications. See the task overview for implementing web services applications information to learn about how to develop and implement a Java EE web service.

Developing a service endpoint interface from JavaBeans for JAX-RPC applications

You must develop a service endpoint interface if you are developing a JAX-RPC web service from a JavaBeans implementation.

Before you begin

You need to set up a development environment for web services and access an existing Java bean web application archive (WAR) file. See the setting up a development environment for web services information.

About this task

This task is a required step in developing a JAX-RPC Web service from a Java bean.

The service endpoint interface defines the methods for particular Java API for XML-based RPC (JAX-RPC) web services. The JavaBeans implementation must implement methods with the same signature as the methods on the service endpoint interface. A number of restrictions apply on which types to use as parameters and results of service endpoint interface methods. These restrictions are documented in the JAX-RPC specification.

You can also create a service endpoint interface by using assembly tools.

Develop a service endpoint interface for a JavaBeans implementation by following the actions listed:

Procedure

1. Create a Java interface that contains the methods to include in the service endpoint interface. If you start with an existing Java interface, remove any methods that do not conform to the JAX-RPC specification.
2. Compile the interface.

Use the name of the service endpoint interface class in the `javac` command for the class to compile.

 Ensure the `j2ee.jar` file is in your class path to compile the interface. The JAR file is located in the `app_server_root/dev/JavaEE` directory path.

Results

You have developed a service endpoint interface that you can use to develop web services.

Example

The following example depicts the `AddressBook` interface:

```
package addr;
public interface AddressBook {
    /**
     * Retrieve an entry from the AddressBook.
     *
     * @param name the name of the entry to look up.
     * @return the AddressBook entry matching name or null if none.
     * @throws java.rmi.RemoteException if communications failure.
     */
    public addr.Address getAddressFromName(java.lang.String name);
}
```

Use the `AddressBook` interface to create the service endpoint interface:

1. Make a copy of the `AddressBook.java` interface and name it `AddressBook_SEI.java`. Use this copy as a template for the service endpoint interface.
2. Compile the interface.

What to do next

Continue to gather the artifacts that are required to develop a web service, including the Web Services Description Language (WSDL) file. You need to develop a WSDL file because it is the engine of a web

service. Without a WSDL file, you do not have a web service. See the developing a WSDL file for JAX-RPC applications information.

Developing a service endpoint interface from enterprise beans for JAX-RPC applications

You can develop a service endpoint interface from an Enterprise JavaBeans (EJB) for JAX-RPC web services.

Before you begin

Set up a development environment for web services. To learn more, see the setting up a development environment for web services information.

Set up a development environment for web services.

This task is a required step in developing a Java API for XML-based RPC (JAX-RPC) web service from an enterprise bean.

The service endpoint interface defines the web services methods. The enterprise beans that implements the web service must implement methods having the same signature as the methods of the service endpoint interface. A number of restrictions exist on which types to use as parameters and results of service endpoint interface methods. These restrictions are documented in the Java API for XML-based remote procedure call (JAX-RPC) specification. See the web services specifications and API documentation to review the JAX-RPC specification along with a complete list of the supported standards and specifications.

The easiest method for creating the service endpoint interface for an EJB web service implementation is from the EJB remote interface.

You can also create a service endpoint interface by using assembly tools..

About this task

Develop a service endpoint interface by following the steps provided in this task section.

Procedure

1. Create a Java interface that contains the methods that you want to include in the service endpoint interface. If you start with an existing Java interface, remove any methods that do not conform to the JAX-RPC specification.
2. Compile the interface.

Use the name of the service endpoint interface class in the **javac** command for the class to compile.

 Ensure that the `j2ee.jar` file is in your CLASSPATH to compile the interface. The JAR file is located in the `app_server_root/dev/JavaEE` directory path.

Results

You have a service endpoint interface that you can use to develop a web service.

Example

This example uses the EJB remote interface, `AddressBook_RI`, to create a service endpoint interface for an EJB implementation that is used as a web service. The following code example illustrates the `AddressBook_RI` remote interface.

```

package addr;
public interface AddressBook_RI extends javax.ejb.EJBObject {
    /**
     * Retrieve an entry from the AddressBook.
     *
     * @param name the name of the entry to look up.
     * @return the AddressBook entry matching name or null if none.
     * @throws java.rmi.RemoteException if communications failure.
     */
    public addr.Address getAddressFromName(java.lang.String name)
        throws java.rmi.RemoteException;
}

```

Use the following steps to create the service endpoint interface with the AddressBook_RI remote interface:

1. Locate a remote interface that has already been created, like the AddressBook_RI.java remote interface.
2. Make a copy of the AddressBook.java remote interface and use it as a template for the service endpoint interface.
3. Compile the AddressBook.java service endpoint interface.

What to do next

Continue gathering the artifacts that are required to develop a web service, including the Web Services Description Language (WSDL) file. You need to develop a WSDL file because it is the engine of a web service; without a WSDL file, you have no web service.

Developing a WSDL file for JAX-RPC applications

You can develop a Web Services Description Language (WSDL) file to describe the characteristics of your Java API for XML-based RPC (JAX-RPC) web services application including where the service resides and how to invoke the service using an XML format.

Before you begin

Depending on your development path, develop a service endpoint interface from a JavaBeans implementation or develop a service endpoint interface from an enterprise bean implementation.

About this task

You need a WSDL file to use web services. You can develop your own WSDL file or get one from a web services provider through email, downloading, or through a Uniform Resource Locator (URL). This documentation assumes you are creating your own.

Develop a WSDL file by following the actions listed:

Procedure

1.  Run the Start Qshell (**STRQSH**) command to start the Qshell.
2.  Update the CLASSPATH environment variable to include the location of the service endpoint interface class and other referenced classes, for example:

```
export -s CLASSPATH=/myapp/myclass.class:/myapp/myjar.jar
```
3. Run the **Java2WSDL seiInterface** command. A WSDL file named *seiInterface.wsdl* is created.
 - Move the WSDL file to the META-INF/wsdl subdirectory if you are using Enterprise JavaBeans (EJB).
 - Move the WSDL file to the WEB-INF/wsdl subdirectory if you are using JavaBeans.
4. Edit the generated WSDL file and inspect the part names. The WSDL parts have names like arg_0_0. Modify the WSDL file to use the actual names of the Java parameters.
5. (Optional) Use the **Java2WSDL** command tool to generate the correct part names of WSDL file. You can automatically generate and set the correct part names by using the **Java2WSDL** command tool. Generating and setting the part names is done by providing additional information to the **Java2WSDL**

command tool in the form of a Java implementation class that implements the same methods as the service endpoint interface and is compiled with debug information turned on. Parameter names are stored in the `.class` file with the debug information. If your implementation class is compiled with debug on, you can use the `Java2WSDL -implClass seiImpl seiInterface` command to generate a WSDL file with the proper part names.

Results

A WSDL file that defines the web services described by the service endpoint interface.

Example

This example uses the JAR file name `AddressBook.jar` that contains a class named `AddressBook.class` class file.

You must add the `AddressBook.jar` file to your `CLASSPATH` to create the WSDL file. The JAR file contains an EJB implementation class that is compiled with debugging information turned on. Run the `Java2WSDL -implClass addr.AddressBookBean addr.AddressBook` command to create the file, `AddressBook.wsdl`.

What to do next

Depending on your development path, develop web services deployment descriptor templates for JavaBeans or develop web services deployment descriptor templates for an enterprise beans implementation.

Java2WSDL command for JAX-RPC applications

The `Java2WSDL` command-line tool maps Java classes to a WSDL file for Java API for XML-based RPC (JAX-RPC) applications.

The `Java2WSDL` command maps a Java class to a Web Services Description Language (WSDL) file by following the Java API for XML-based Remote Procedure Call (JAX-RPC) 1.1 specification.

The `Java2WSDL` command accepts a Java class as input and produces a WSDL file that represents the input class. If a file exists at the output location, it is overwritten. The WSDL file that is generated by the `Java2WSDL` command contains WSDL and XML schema constructs that are automatically derived from the input class. You can override these default values with command-line arguments.

The `Java2WSDL` command is protocol independent; when you run the `Java2WSDL` command, you can specify command-line options that generate both SOAP and non-SOAP protocol bindings in the WSDL file. For each binding that can be generated, the `Java2WSDL` command has a binding generator to generate the WSDL for that binding.

Command line syntax and arguments

The command line syntax is:

```
Java2WSDL [argument...] class
```

The following command-line arguments are supported:

Required arguments

- `class`

Represents the fully qualified name of one of the following Java classes:

- Stateless session Enterprise JavaBeans (EJB) remote interface that extends the `javax.ejb.EJBObject` class
- Service endpoint interface that extends the `java.rmi.Remote` class
- Java beans

The **Java2WSDL** command locates the class in the CLASSPATH variable.

Important arguments

- **-location** *location*

Provides the published location or the Uniform Resource Locator (URL) of the service. If this information is not provided, a warning is issued that indicates that the final published location is not determined yet. The service location is typically overridden when the web service is deployed.

The name after the last backslash is the name of the service port, unless the name is overridden by the **-serviceName** argument. The service port address location attribute is assigned the specified value. Multiple endpoint addresses can be specified. Using the **-location** option is recommended only if a single binding type is required. If multiple binding types are requested, protocol binding-specific location properties are passed over the command line using the **-x** flag.

- **-output** *wsdl-uri*

Indicates the path and file name of the output WSDL file. If not specified, the default `class.wsdl` file is written into the current directory.

- **-input** *wsdl-uri*

Specifies the input WSDL file that is used to build an output WSDL file. Information from an existing WSDL file, is specified in this option and is used with the input Java class to generate the output.

- **-bindingTypes**

Specifies the list of binding types write to the output WSDL file. Each binding generator in the **Java2WSDL** command supports specific binding types. The valid binding type values are `http` (SOAP over HTTP), `jms` (SOAP over JMS) and `ejb` (local or remote EJB invocation). For example, the following command can be used to generate SOAP over HTTP, EJB bindings for the `my.pkg.MySEI` Service Endpoint Interface and the `my.pkg.MyEJBClass` implementation class :

```
java2wsdl -bindingTypes http,ejb -implClass my.pkg.MyEJBClass my.pkg.MySEI
```

The following command is an example of using the **-bindingTypes** option to generate SOAP over HTTP and SOAP over JMS bindings:

```
java2wsdl -bindingTypes http,jms -implClass my.pkg.MyEJBClass my.pkg.MySEI
```

- **-style** *RPC | DOCUMENT*

Specifies the WSDL style to use in the generated WSDL file. To learn more, see the Mapping between Java language, WSDL and XML for JAX-RPC applications information. This argument is used with the **-use** argument.

If `RPC` is specified with **-use ENCODED**, a `style=rpc/use=encoded` WSDL file is generated. If `RPC` is specified with the **-use LITERAL** option, a `style=rpc/use=literal` WSDL file is generated. If `DOCUMENT` is specified with the **-use LITERAL** option, a `style=document/use=literal` WSDL file is generated.

- **-use** *LITERAL | ENCODED*

Specifies which style and use combinations are generated into the WSDL file when used with the **-style** argument. The combinations are `rpc` and `encoded`, `rpc` and `literal`, or `doc` and `literal`. This setting applies to all SOAP bindings. To learn more, see the Mapping between Java language, WSDL and XML for JAX-RPC applications information.

- **-transport** *http | jms*

Generates SOAP bindings for either HTTP (default) or JMS. If JMS is specified, the characters `jms` are appended to the WSDL file name to prevent overwriting an existing WSDL file for another transport. The transport option can be specified only once.

This option is deprecated. The **-bindingTypes** option replaces the **-transport** option, so that you can generate bindings that are non-SOAP specific.

- **-portTypeName** *name*

Specifies the name to use for the portType element. If not specified, the binding name is the port type name.

- **-bindingName** *name*

Specifies the name to use for the binding element. If not specified, the binding name is the port type name.

- `-serviceName` *name*

Specifies the name of the service element.

- `-servicePortName` *name*

Specifies the name of the service. If not specified, the service name is derived from the `-location` argument.

- `-namespace` *targetNamespace*

Indicates the target namespace for the WSDL file being generated. To learn about the algorithm that is used to obtain the default namespace, see the Mapping between Java language, WSDL and XML for JAX-RPC applications information.

- `-PkgtoNS` *package namespace*

Specifies the mapping of a Java package to a namespace. If a package does not have a namespace, the `Java2WSDL` command generates a namespace name. You can repeat the `-PkgtoNS` argument to specify mappings for multiple packages.

- `-extraClasses` *classes*

Specifies other classes that are represented in the WSDL file.

- `-implClass` *impl-class*

The `Java2WSDL` command uses method parameter names to construct the WSDL file message part names. The command automatically obtains the message names from the debug information in the class. If the class is compiled without debug information, or if the class is an interface, the method parameter names are not available. In this case, you can use the `-implClass` argument to provide an alternative class from which to obtain method parameter names. The `impl-class` does not need to implement the class if the class is an interface, but it must implement the same methods as the class.

- `-verbose`

Displays verbose messages.

- `-help`

Displays the help message.

- `-helpX`

Displays the help message for extended options and for various options that are supported by binding generators.

Other arguments

- `-wrapped` *boolean*

Specifies whether to generate the WSDL file according to wrapped rules. This option is valid if use is literal only. The option defaults to `true`.

- `-stopClasses` *parent* [, *parent*]

The `Java2WSDL` command searches inherited classes and interfaces to construct the list of methods for WSDL file operations if the `-all` argument is specified.

The `Java2WSDL` command searches inherited classes and interfaces when generating extended complexTypes. The search stops when a class or an interface is found within a package that begins with `java` or `javax`. You can use the `-stopClasses` argument to define additional classes that cause the search to stop.

- `-methods` *argument*

Specifies a list of method names from the Service Endpoint Interface that must be exposed in the output WSDL file. The list is separated by spaces or commas.

- `-soapAction`

Valid arguments are:

- `DEFAULT`

Sets the `soapAction` field according to the deployment information.

- `NONE`

Sets the soapAction field to double quotes ("").

– OPERATION

Sets the soapAction field to the operation name.

• -outputImpl *impl-wsdl*

Specifies if you want an interface and implementation WSDL file emitted.

• -locationImport *location-uri*

Specifies the location of the interface WSDL file if you use the -outputImpl argument.

• -namespaceImpl *namespace*

Specifies the target namespace for the implementation WSDL file, if you use the -outputImpl argument.

• -MIMEStyle *<style>*

Specifies the Multipurpose Internet Mail Extensions (MIME)- type used to map to Web Services-Interoperability (WS-I) SOAP with attachments reference (wsi:swaRef) for the binding element.

<style> can be one of the following:

– WSDL11 (default): Exclusively map MIME types using WSDL 1.1 standards. If the MIME type cannot map to WSDL 1.1 standards, the command fails.

– AXIS: Map MIME types using AXIS standards, for example image becomes axis:image.

– swaRef: Map MIME types using WSDL 1.1 standards with two caveats:

- DataHandler maps to the wsi:swaRef element instead of an application and octet-stream

- If mapping is illegal through WSDL 1.1, map to the wsi:swaRef element

• -propertiesFile *argument*

Sets existing options, such as -extraClasses, with a properties file instead of with a command line. The following example illustrates the use of this argument:

```
extraClasses=com.ibm.Class1, com.sun.Class2,org.apache.Class3
```

• -voidReturn

Valid arguments are:

– ONEWAY

Methods with void returns are one-way. This argument is the default for a JMS transport.

– TWOWAY

Methods with void returns are two-way. This argument is the default for an HTTP transport.

• -debug

Displays debug messages.

• -property or -x

You can use the -x option to pass command-line options to various binding generators. Use the -x option multiple times on the command line to specify a set of property values to pass to each binding generator method called by the **Java2WSDL** command. You can also use a single -x option to specify multiple properties by separating them with a comma, for example:

```
java2wsdl -x prop1=value1 -x prop2=value2
```

is equivalent to:

```
java2wsdl -x prop1=value1,prop2=value2
```

The -x option provides flexibility to specify each command-line option for each binding generator individually, if required. The value specified in the -x option overrides the value that is specified in the equivalent command-line option if both are specified.

Mapping between Java language, WSDL and XML for JAX-RPC applications

Data for Java API for XML-based Remote Procedure Call (JAX-RPC) applications flows as extensible Markup Language (XML). JAX-RPC applications use mappings to describe the data conversion between the Java language and extensible Markup Language (XML) technologies, including XML Schema, Web Services Description Language (WSDL) and SOAP that are supported by the application server.

For JAX-RPC applications, most of the mappings between the Java language and XML are specified by the JAX-RPC specification. Some mappings that are optional or unspecified in JAX-RPC are also supported. Review the JAX-RPC specification for a complete list of APIs. For a complete list of the supported standards and specifications, see the web services specifications and API documentation.

Notational conventions

Table 105. Namespace conventions. Describes the namespace prefixes and the corresponding namespace used in namespace conventions.

Namespace prefix	Namespace
xsd	http://www.w3.org/2001/XMLSchema
xsi	http://www.w3.org/2001/XMLSchema-instance
soapenc	http://schemas.xmlsoap.org/soap/encoding/
wSDL	http://schemas.xmlsoap.org/wSDL/
wSDLsoap	http://schemas.xmlsoap.org/wSDL/soap/
ns	user-defined namespace
apache	http://xml.apache.org/xml-soap
wasws	http://websphere.ibm.com/webservices/

Detailed mapping information

The following sections identify the supported mappings, including:

- Java-to-WSDL mapping
- WSDL-to-Java mapping
- Mapping between WSDL and SOAP messages

Java-to-WSDL mapping

This section summarizes the Java-to-WSDL mapping rules. The Java-to-WSDL mapping rules are used by the **Java2WSDL** command for *bottom-up processing*. In bottom-up processing, an existing Java service implementation is used to create a WSDL file defining the web service. The generated WSDL file can require additional manual editing for the following reasons:

- Not all Java classes and constructs have mappings to WSDL files. For example, Java classes that do not comply with the Java bean specification rules might not map to a WSDL construct.
- Some Java classes and constructs have multiple mappings to a WSDL file. For example, a `java.lang.String` class can map to either an `xsd:string` or `soapenc:string` construct. The **Java2WSDL** command chooses one of these mappings, but you must edit the WSDL file if a different mapping is required.
- Multiple ways exist to generate WSDL constructs. For example, you can generate the `wSDL:part` in `wSDL:message` with a `type` or `element` attribute. The **Java2WSDL** command makes an informed choice based on the `-style` and `-use` option settings.
- The WSDL file describes the instance data elements sent in the SOAP message. If you want to modify the names or format used in the message, the WSDL file must be edited. For example, the **Java2WSDL** command maps a Java bean property as an XML element. In some circumstances, you might want to change the WSDL file to map the Java bean property as an XML attribute.
- The WSDL file requires editing if header or attachment support is desired.
- The WSDL file requires editing if a multipart WSDL file, using the `wSDL:import` construct, is desired.

For simple services, the generated WSDL file is sufficient. For complicated services, the generated WSDL file is a good starting point. Read about the **Java2WSDL** command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

General issues

- Package to namespace mapping:

The JAX-RPC specification does not indicate the default mapping of Java package names to XML namespaces. The JAX-RPC specification does specify that each Java package must map to a single XML namespace. Likewise, each XML namespace must map to a single Java package. A default mapping algorithm is provided that constructs the namespace by reversing the names of the Java package and adding an `http://` prefix. For example, a package named, `com.ibm.webservice`, is mapped to the XML namespace `http://webservice.ibm.com`.

You can override the default mapping between XML namespaces and Java package names by using the `-NStoPkg` and `-PkgtoNS` options of the `WSDL2Java` and `Java2WSDL` commands.

- Identifier mapping :

Java identifiers are mapped directly to WSDL and XML identifiers.

Java bean property names are mapped to XML identifiers. For example, a Java bean, with `getInfo` and `setInfo` methods, maps to an XML construct with the name, `info`.

The service endpoint interface method parameter names, if available, are mapped directly to the WSDL and XML identifiers. See the information for the `WSDL2Java` command `-implClass` option to learn more.

- WSDL construction summary:

Table 106. Mapping of Java to WSDL or an XML construct. Describes the mapping from a Java construct to the related WSDL and XML construct.

Java construct	WSDL and XML construct
Service endpoint interface	<code>wsdl:portType</code>
Method	<code>wsdl:operation</code>
Parameters	<code>wsdl:input</code> , <code>wsdl:message</code> , <code>wsdl:part</code>
Return	<code>wsdl:output</code> , <code>wsdl:message</code> , <code>wsdl:part</code>
Throws	<code>wsdl:fault</code> , <code>wsdl:message</code> , <code>wsdl:part</code>
Primitive types	<code>xsd</code> and <code>soapenc</code> simple types
Java beans	<code>xsd:complexType</code>
Java bean properties	Nested <code>xsd:elements</code> of <code>xsd:complexType</code>
Arrays	JAX-RPC defined <code>xsd:complexType</code> or <code>xsd:element</code> with a <code>maxOccurs="unbounded"</code> attribute
User defined exceptions	<code>xsd:complexType</code>

- **Binding and service construction**

A `wsdl:binding` that conforms to the generated `wsdl:portType` is generated. A `wsdl:service` containing a port that references the generated `wsdl:binding` is generated. The names of the binding and service are controlled by the `Java2WSDL` command.

- **Style and use**

Use the `-style` and `-use` options to generate different kinds of WSDL files. The four supported combinations are:

- `-style DOCUMENT -use LITERAL`
- `-style RPC -use LITERAL`
- `-style DOCUMENT -use LITERAL -wrapped false`
- `-style RPC -use ENCODED`

The following is a brief description of each combination.

- **DOCUMENT LITERAL:**

The `Java2WSDL` command generates a Web Services - Interoperability (WS-I) specification compliant document-literal WSDL file. The `wsdl:binding` is generated with embedded `style="document"` and `use="literal"` attributes. An `xsd:element` is generated for each service endpoint interface method to describe the request message. A similar `xsd:element` is generated for each service endpoint interface method to describe the response message.

- **RPC LITERAL:**

The `Java2WSDL` command generates a WS-I compliant `rpc-literal` WSDL file. The `wsdl:binding` is generated with embedded `style="rpc"` and `use="literal"` attributes. The `wsdl:message` constructs are generated for the inputs and outputs of each service endpoint interface method. The parameters of the method are described by the part elements within the `wsdl:message` constructs.

- DOCUMENT LITERAL not wrapped:

The **Java2WSDL** command generates a document-literal WSDL file according to the JAX-RPC specification. This WSDL file is not compliant with .NET. The main difference between DOCUMENT LITERAL and DOCUMENT LITERAL not wrapped is the use of `wsdl:message` constructs to define the request and response messages.

- RPC ENCODED:

The **Java2WSDL** command generates an rpc-encoded WSDL file according to the JAX-RPC specification. This WSDL file is not compliant with the WS-I specification. The `wsdl:binding` is generated with embedded `style="rpc"` and `use="encoded"` attributes. Certain soapenc mappings are used to represent types and arrays.

Many Java types map directly to standard XML types. For example, a `java.lang.String` maps to an `xsd:string`. These mappings are described in the JAX-RPC specification.

Java types that cannot be mapped directly to standard XML types are generated in the `wsdl:types` section. A Java class that matches the Java bean pattern is mapped to an `xsd:complexType`. Review the JAX-RPC specification for a description of all the mapping rules. The following example illustrates the mapping for a sample base and derived Java classes.

Java:

```
public abstract class Base {
    public Base() {}
    public int a;           // mapped
    private int b;         // mapped via setter/getter
    private int c;         // not mapped
    private int[] d;       // mapped via indexed setter/getter

    public int getB() { return b; } // map property b
    public void setB(int b) {this.b = b;}

    public int[] getD() { return d; } // map indexed property d
    public void setD(int[] d) {this.d = d;}
    public int getD(int index) { return d[index];}
    public void setB(int index, int value) {this.d[index] = value;}

    public void someMethod() {...} // not mapped
}

public class Derived extends Base {
    public int x;           // mapped
    private int y;         // not mapped
}
```

Mapped to:

```
<xsd:complexType name="Base" abstract="true">
  <xsd:sequence>
    <xsd:element name="a" type="xsd:int"/>
    <xsd:element name="b" type="xsd:int"/>
    <xsd:element name="d" minOccurs="0" maxOccurs="unbounded" type="xsd:int"/>
  </xsd:sequence>
</xsd:complexType>

<xsd:complexType name="Derived">
  <xsd:complexContent>
    <xsd:extension base="ns:Base">
      <xsd:sequence>
        <xsd:element name="x" type="xsd:int"/>
      </xsd:sequence>
    </xsd:extension>
  </xsd:complexContent>
</xsd:complexType>
```

- Unsupported classes:

If a class cannot be mapped to an XML type, the **Java2WSDL** command issues a message and an `xsd:anyType` reference is generated in the WSDL file. In these situations, modify the web service implementation to use the JAX-RPC compliant classes.

WSDL-to-Java mapping

The **WSDL2Java** command generates Java classes using information described in the WSDL file.

General issues:

- Mapping of a namespace to a package:

JAX-RPC does not specify the mapping of XML namespaces to Java package names. JAX-RPC does specify that each Java package map to a single XML namespace. Likewise, each XML namespace must map to a single Java package. A default mapping algorithm omits any protocol from the XML namespace and reverses the names. For example, an XML namespace `http://websphere.ibm.com` becomes a Java package with the name `com.ibm.websphere`.

The default mapping of an XML namespace to a Java package disregards the context-root. If two namespaces are the same up to the first slash, they map to the same Java package. For example, the XML namespaces `http://websphere.ibm.com/foo` and `http://websphere.ibm.com/bar` map to the `com.ibm.websphere` Java package. You can override the default mapping between XML namespaces and Java package names by using the `-NStoPkg` and `-PkgtoNS` options of the `WSDL2Java` and `Java2WSDL` commands.

XML names are much richer than Java identifiers. They can include characters that are not permitted in Java identifiers. See Appendix 20 of the JAX-RPC specification for the rules to map an XML name to a Java identifier.

- Java construction summary:

The following table summarizes the XML to Java construction. See the JAX-RPC specification for a description of these mappings.

Table 107. Mapping of a WSDL or an XML construct to Java. Describes the mapping between constructions for XML and Java.

WSDL and XML construction	Java construction
xsd:complexType	Java bean class, Java exception class, or Java array
nested xsd:element/xsd:attribute	Java bean property
xsd:simpleType (enumeration)	JAX-RPC enumeration class
wSDL:message The method parameter signature typically is determined by the wSDL:message.	Service endpoint interface method signature
wSDL:portType	Service endpoint interface
wSDL:operation	Service endpoint interface method
wSDL:binding	Stub
wSDL:service	Service interface
wSDL:port	Port accessor method in Service interface

- Mapping standard XML types:

- JAX-RPC simple XML types mapping:

Many XML types are mapped directly to Java types. See the JAX-RPC specification for a description of these mappings.

The `WSDL2Java` command generates Java types for the XML schema constructs that are defined in the `wSDL:types` section. The XML schema language is broader than the required or optional subset defined in the JAX-RPC specification. The `WSDL2Java` command supports the required mappings and most of the optional mappings, as well as some XML schema mappings that are not included in the JAX-RPC specification. The `WSDL2Java` command ignores some constructs that it does not support. For example, the command does not support the default attribute. If an `xsd:element` is defined with the default attribute, the default attribute is ignored. In some cases, the command maps unsupported constructs to the Java interface, `javax.xml.soap.SOAPElement`.

The standard Java bean mapping is defined in section 4.2.3 of the JAX-RPC specification. The `xsd:complexType` defines the type. The nested `xsd:elements` within the `xsd:sequence` or `xsd:all` groups are mapped to Java bean properties. For example:

XML:

```
<xsd:complexType name="Sample">
  <xsd:sequence>
    <xsd:element name="a" type="xsd:string"/>
    <xsd:element name="b" maxOccurs="unbounded" type="xsd:string"/>
  </xsd:sequence>
</xsd:complexType>
```

Java:

```
public class Sample {
    // ..
    public Sample() {}

    // Bean Property a
    public String getA()      {...}
    public void  setA(String value) {...}

    // Indexed Bean Property b
    public String[] getB()    {...}
    public String  getB(int index) {...}
    public void    setB(String[] values) {...}
    public void    setB(int index, String value) {...}
}

```

– Mapping of the wsdl:portType construct:

The wsdl:portType construct is mapped to the service endpoint interface. The name of the wsdl:portType construct is mapped to the name of the class of the service endpoint interface.

– Mapping of the wsdl:operation construct:

A wsdl:operation construct within a wsdl:portType is mapped to a method of the service endpoint interface. The name of the wsdl:operation is mapped to the name of the method. The wsdl:operation contains wsdl:input and wsdl:output elements that reference the request and response wsdl:message constructs using the message attribute. The wsdl:operation can contain a wsdl:fault element that references a wsdl:message describing the fault. These faults are mapped to Java classes that extend the exception, java.lang.Exception as discussed in section 4.3.6 of the JAX-RPC specification.

- Effect of document literal wrapped format:

If the WSDL file uses the document literal wrapped format, the method parameters are mapped from the wrapper xsd:element. The document literal wrapped and literal format is automatically detected by the **WSDL2Java** command. The following criteria must be met:

- The WSDL file must have style="document" in its wsdl:binding construct.
- The input and output constructs of the operations within the wsdl:binding must contain soap:body elements that contain use="literal".
- The wsdl:message referenced by the wsdl:operation input construct must have a single part.
- The part must use the element attribute to reference an xsd:element.
- The referenced xsd:element, or wrapper element, must have the same name as the wsdl:operation.
- The wrapper element must not contain any xsd:attributes.

In such cases, each parameter name is mapped from a nested xsd:element contained within wrapper element. The type of the parameter is mapped from the type of the nested xsd:element. For example:

WSDL:

```
<xsd:element name="myMethod">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="param1" type="xsd:string"/>
      <xsd:element name="param2" type="xsd:int"/>
    </xsd:sequence>
  </xsd:complexType>
</xsd:element>
...
<wsdl:message name="response"/>
  <part name="parameters" element="ns:myMethod"/>
</wsdl:message name="response"/>
...
<wsdl:message name="response"/>
...
<wsdl:operation name="myMethod">
  <input name="input" message="request"/>
  <output name="output" message="response"/>
</wsdl:operation>

```

Java:

```
void myMethod(String param1, int param2) ...
```

- Parameter mapping:

If the document and literal wrapped format is not detected, the parameter mapping follows the normal JAX-RPC mapping rules set in section 4.3.4 of the JAX-RPC specification.

Each parameter is defined by a wsdl:message part referenced from the input and output elements.

- A wsdl:part in the request wsdl:message is mapped to an input parameter.
- A wsdl:part in the response wsdl:message is mapped to the return value. If multiple wsdl:parts exist in the response message, they are mapped to output parameters.
 - A Holder class is generated for each output parameter, as discussed in section 4.3.5 of the JAX-RPC specification.
- A wsdl:part that is both the request and response wsdl:message is mapped to an inout parameter.
 - A Holder class is generated for each inout parameter, as discussed in section 4.3.5 of the JAX-RPC specification.
 - The wsdl:operation parameterOrder attribute defines the order of the parameters.

XML:

```
<wsdl:message name="request">
  <part name="param1" type="xsd:string"/>
  <part name="param2" type="xsd:int"/>
</wsdl:message name="request"/>

<wsdl:message name="response"/>
...
<wsdl:operation name="myMethod" parameterOrder="param1, param2">
  <input name="input" message="request"/>
  <output name="output" message="response"/>
</wsdl:operation>
```

Java:

```
void myMethod(String param1, int param2) ...
```

- Mapping of wsdl:binding:

The **WSDL2Java** command uses the wsdl:binding information to generate an implementation-specific client-side stub. WebSphere Application Server uses the wsdl:binding information on the server side to properly deserialize the request, invoke the web service, and serialize the response. The information in the wsdl:binding does not affect the generation of the service endpoint interface, except when the document and literal wrapped format is used, or when MIME attachments are present.

- MIME attachments:

For a WSDL 1.1-compliant WSDL file, the part of an operation message, that is defined in the binding as a MIME attachment, becomes a parameter of the type of the attachment regardless of the part declared. For example:

XML:

```
<wsdl:types>
  <schema ...>
    <complexType name="ArrayOfBinary">
      <restriction base="soapenc:Array">
        <attribute ref="soapenc:arrayType" wsdl:arrayType="xsd:binary[]" />
      </restriction>
    </complexType>
  </schema>
</wsdl:types>

<wsdl:message name="request">
  <part name="param1" type="ns:ArrayOfBinary"/>
</wsdl:message name="request"/>

<wsdl:message name="response"/>
...

<wsdl:operation name="myMethod">
  <input name="input" message="request"/>
  <output name="output" message="response"/>
</wsdl:operation>
...

<binding ...
  <wsdl:operation name="myMethod">
    <input>
      <mime:multipartRelated>
        <mime:part>
          <mime:content part="param1" type="image/jpeg"/>
        </mime:part>
      </mime:multipartRelated>
    </input>
  </wsdl:operation>
</binding>
```

```

    </mime:multipartRelated>
  </input>
  ...
</wsdl:operation>

```

Java:

```
void myMethod(java.awt.Image param1) ...
```

The JAX-RPC specification requires support for the following MIME types:

Table 108. Mapping of MIME type and Java type. Describes the mapping between MIME types and Java types.

MIME type	Java type
image/gif	java.awt.Image
image/jpeg	java.awt.Image
text/plain	java.lang.String
multipart/*	javax.mail.internet.MimeMultipart
text/xml	javax.xml.transform.Source
application/xml	javax.xml.transform.Source

– Mapping of wsdl:service:

The wsdl:service element is mapped to a generated service interface. The generated service interface contains methods to access each of the ports in the wsdl:service element. The generated service interface is discussed in sections 4.3.9, 4.3.10, and 4.3.11 of the JAX-RPC specification.

In addition, the wsdl:service element is mapped to the implementation-specific ServiceLocator class, which is an implementation of the generated service interface.

Read about the **WSDL2Java** command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

Mapping between WSDL and SOAP messages

The WSDL file defines the format of the SOAP message that are transmitted through network connections. The **WSDL2Java** command and the WebSphere Application Server runtime use the information in the WSDL file to ensure that the SOAP message is properly serialized and deserialized.

If a wsdl:binding element indicates that a message is sent using an RPC format, the SOAP message contains an element defining the operation. If a wsdl:binding element indicates that the message is sent using a document format, the SOAP message does not contain the operation element.

If the wsdl:part element is defined using the type attribute, the name and type of the part are used in the message. If the wsdl:part element is defined using the element attribute, the name and type of the element are used in the message. The element attribute is not supported by the JAX-RPC specification when use="encoded".

If a wsdl:binding element indicates that a message is encoded, the values in the message are sent with xsi:type information. If a wsdl:binding element indicates that a message is literal, the values in the message are typically not sent with xsi:type information. For example:

DOCUMENT/LITERAL

WSDL:

```

<xsd:element name="c" type="xsd:int"/>
<xsd:element name="method">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="a" type="xsd:string"/>
      <xsd:element ref="ns:c"/>
    </xsd:sequence>
  </xsd:complexType>
</xsd:element>
...
<wsdl:message name="request">
  <part name="parameters" element="ns:method"/>
</wsdl:message>

```

```

...
<wsdl:operation name="method">
  <input message="request"/>
...

Message:
<soap:body>
  <ns:method>
    <a>ABC</a>
    <c>123</a>
  </ns:method>
</soap:body>

RPC/ENCODED
WSDL:
<xsd:element name="c" type="xsd:int"/>

...
<wsdl:message name="request">
  <part name="a" type="xsd:string"/>
  <part name="b" element="ns:c"/>
</wsdl:message>
...
<wsdl:operation name="method">
  <input message="request"/>
...

Message:
<soap:body>
  <ns:method>
    <a xsi:type="xsd:string">ABC</a>
    <element attribute is not permitted in rpc/encoded mode>
  </ns:method>
</soap:body>

DOCUMENT/LITERAL not wrapped
WSDL:
<xsd:element name="c" type="xsd:int"/>

...
<wsdl:message name="request">
  <part name="a" type="xsd:string"/>
  <part name="b" element="ns:c"/>
</wsdl:message>
...
<wsdl:operation name="method">
  <input message="request"/>
...

...

Message:
<soap:body>
  <a>ABC</a>
  <c>123</a>
</soap:body>

```

Developing JAX-RPC web services deployment descriptor templates for a JavaBeans implementation

Deployment descriptors are standard text files, formatted using XML and packaged in a web services application. Deployment descriptors are required to deploy Java API for XML-based RPC (JAX-RPC) web services that are developed using Web Services for Java Platform, Enterprise Edition (Java EE) technology.

Before you begin

Develop a Web Services Description Language (WSDL) file.

You need a WSDL file to use web services. You can develop your own WSDL file or get one from a web services provider through email, downloading, or through a Uniform Resource Locator (URL). This documentation assumes you are creating your own. See the developing a WSDL file for JAX-RPC applications information.

About this task

Completing this task creates the deployment descriptors used to describe how to map the service implementation to a JavaBeans component for Java API for XML-based RPC (JAX-RPC) applications.

To develop the deployment descriptor templates from a WSDL file, you must obtain the web address of the WSDL file.

If the WSDL file is a local file and you are running on the Windows platform, the web address looks like this example: `file:drive:\path\file_name.wsdl`. If you are using the Linux or Unix platform, the Web address looks like this example: `file:/path/file_name.wsdl`. You can also specify local files using the absolute or relative file system path.

When the web service is a JavaBeans implementation in a web module, the `webservices.xml`, `ibm-webservices-bnd.xmi` and `ibm-webservices.ext.xmi` deployment descriptors and the JAX-RPC mapping file are generated in the WEB-INF subdirectory.

Procedure

Run the **WSDL2Java -verbose -role develop-server -container web -genJava no wsdlURL** command to generate the server deployment descriptor templates and mapping file into the WEB-INF subdirectory. If the **-verbose** option is specified, a list of all the generated files is displayed when the command runs.

Results

You have deployment descriptor templates that are required to implement or use JAX-RPC web services.

Example

The following example uses a WSDL file named `AddressBookJ2WB.wsdl`:

Generate the template files:

```
WSDL2Java -verbose -role develop-server -container web -genJava no AddressBookJ2WB.wsdl
```

The deployment descriptor templates and mapping file are generated into the WEB-INF subdirectory:

```
Parsing XML file: AddressBookJ2WB.wsdl
Generating: WEB-INF\webservices.xml
Generating: WEB-INF\ibm-webservices-bnd.xmi
Generating: WEB-INF\ibm-webservices-ext.xmi
Generating: WEB-INF\AddressBookJ2WB_mapping.xml
```

What to do next

 Now, you need to configure the deployment descriptors so that WebSphere Application Server can process the incoming web services. After you configure the deployment descriptors, you must assemble the web services application for deployment.

WSDL2Java command for JAX-RPC applications:

Run the **WSDL2Java** command-line tool against the WSDL file to create Java APIs and deployment descriptor templates.

A Web Services Description Language (WSDL) file describes a Web service. The Java API for XML-based Remote Procedure Call (JAX-RPC) 1.1 specification defines a Java API mapping that interacts with the web service. The Web Services for Java Platform, Enterprise Edition (Java EE) specification defines deployment descriptors that deploy a web service in a Java EE environment. The **WSDL2Java** command is run against the WSDL file to create Java APIs and deployment descriptor templates according to these specifications.

Note: It is a best practice to use absolute namespaces within your WSDL or schema. By default, the **WSDL2Java** tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the

XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. However, if you have an established WSDL or schema that relies on relative namespaces, under specific conditions you can use the `allowRelativeNamespace` property to disable the relative namespace restrictions in the **WSDL2Java** tool. For additional information, see the property description.

You can convert any relative namespaces to absolute namespaces. The following is an example of a relative namespace:

```
targetNamespace="MyReINamespace"
```

. You can change the relative namespace in this example to an absolute namespace by adding the protocol and base URI information:

```
targetNamespace="http://www.sample.com/MyReINamespace"
```

Command-line syntax

The command-line syntax is:

```
WSDL2Java [arguments] WSDL-URI
```

Required arguments

- **WSDL-URI**
Specifies the location of the input WSDL file using a Universal Resource Identifier (URI). You can also use a regular file path if the WSDL file is on the local file system.

Important arguments

- **-role *Java EE role***
Specifies the Java EE development role that identifies which files to generate. Valid arguments include:
 - **client**
A combination of the `develop-client` and `deploy-client` arguments.
 - **deploy-client**
Generates binding files for client deployment.
 - **deploy-server**
Generates binding files for server deployment.
 - **develop-client (default)**
Generates files for client development.
 - **develop-server**
Generates files for server development.
 - **server**
A combination of the `develop-server` and `deploy-server` arguments.
 - **-container *Java EE-container***
Indicates the Java EE container to use. Valid arguments include:
 - **client**
Indicates client container.
 - **ejb**
Indicates an Enterprise JavaBeans (EJB) container.
 - **none**
Indicates no container.
 - **web**
Indicates a web container.
- For client roles (see the `-role` option), the default argument is `none`. For server roles, the container must be `ejb` or `web`. The same container option must be used for both development and deployment.
- **-output *directory***
Sets the root directory for emitted files.

- `-inputMappingFile` mapping file

Specifies the file name of the Web Services for Java EE mapping file.

- `-introspect`

Uses existing Java beans with a new web service API.

In some scenarios, it is good to use existing Java classes instead of generating new classes. The `-introspect` option directs the **WSDL2Java** command to examine existing Java classes when generating classes. The existing classes are validated against the JAX-RPC specification. For example:

Suppose you have an existing Java bean

```
public class Bean {
    public Date x;
}
```

The WSDL file defines `x` as `xsd:dateTime`. Without the `-introspect` option, the **WSDL2Java** command generates a Java bean that is similar to the following example:

```
public class Bean {
    private Calendar x;
    public void setx(Calendar value) (x=value;)
    public Calendar getX() { return x;}
}
```

The **WSDL2Java** command uses the `-introspect` option to examine the original Java bean and to generate classes that are compatible with existing Java beans.

- `-classpath` *paths*

Defines an alternative class path to search for Java classes.

- `-noDataBinding`

Disables the binding of XML types to Java types. Instead, each XML type is mapped to a `javax.xml.soap.SOAPElement` interface defined by the SOAP with Attachments API for Java (SAAJ) specification.

The Java API for XML Web Services (JAX-WS) programming model supports SAAJ 1.2 and 1.3.

The JAX-RPC programming model supports SAAJ 1.2.

The Java programming models define Java mappings for a subset of XML types. Several XML types cannot be mapped to Java beans or primitives. In this situation, the **WSDL2Java** command maps the type to an SAAJ `SOAPElement`. A SAAJ `SOAPElement` is a generic representation of the element in the message. The methods on the `SOAPElement` can be used to examine the element and its children.

In some scenarios, it might be more appropriate to use the generic `SOAPElement` mapping exclusively. To learn more about the use of `SOAPElement`, see the information on SOAP with Attachments API for Java interface and custom data binders for JAX-RPC applications.

For a complete list of the supported standards and specifications, see the web services specifications and API documentation.

- `-help`

Displays a help message and exits.

- `-helpX`

Displays a help message for extended options. The options include:

- `-verbose`

Displays processing information, including the names of the generated files.

- `-NStoPkg` *namespace=package*

By default, package names are automatically derived from the namespace strings in the WSDL file. For example, if the namespace is of the form `http://x.y.com` or `urn:x.y.com`, the corresponding package is `com.y.x`.

You can provide your own mapping by using the `-NStoPkg` argument, which you can repeat as often as necessary, once for each unique namespace mapping. For example, if a namespace in the WSDL file is called `urn:AddressFetcher2`, and you want files generated from the objects in this namespace to reside in the `samples.addr` package, provide the `-NStoPkg "http://urn:AddressFetcher2/"=samples.addr` argument to the **WSDL2Java** command.

- `-timeout seconds`
Specifies how long the **WSDL2Java** command waits, in seconds, for the WSDL-URI to respond before giving up. The default is 45 seconds; -1 disables the timeout.
- `-genResolver`
Generates an absolute-import resolver class. The purpose of this class is to record the contents of the imported WSDL files that are used by the WSDL URI. This class is used by the run time and can also be used for future **WSDL2Java** command runs. This flexibility is desirable when the imported WSDL files are remote and possibly inaccessible. When an import resolver is used, the possibility that a remote WSDL file has different contents at run time that it did during development is eliminated. The generated class is named `_AbsoluteImportResolver.java`. Compile and package this class with the other Java classes that are generated by the **WSDL2Java** command.
- `-useResolver resolver-class`
Specifies an absolute-import resolver class to use during parsing. This class must be created during a previous run of the **WSDL2Java** command that uses the `-genResolver` option. The class must be available in the CLASSPATH variable.
- `-deployScope argument`
Indicates how to deploy the server implementation. Valid arguments include:
 - Application
Uses one instance of the implementation class for all requests.
 - Request
Creates a new instance of the implementation class for each request.
 - Session
Creates a new instance of the implementation class for each session.

Other arguments

- `-user id`
Specifies the login user name to access the WSDL URI.
- `-password password`
Specifies the login user password to access the WSDL URI.
- `-all`
Generates Java files for all types, even those that are not referenced.
- `-allowRelativeNamespace true or false`
Specifies whether to disable the relative namespace restrictions. If you specify `-allowRelativeNamespace=true`, the relative namespace restrictions are disabled.

Note: Only use this property if you have an established WSDL file or schema that relies on a relative namespaces and you are seeking to interoperate with a defined set of vendors that permit the use of relative namespaces.

- `-debug`
Prints debugging information.
- `-genJava argument`
Generates Java files. Valid arguments include:
 - IfNotExists, default
 - Overwrite
 - No
- `-javaSearch argument`
The `-javaSearch` option is used with the `-genJava` option. If the `-genJava IfNotExists`, use the `-javaSearch` option to determine how file existence is detected.
 - File (default): Looks for a file in the output directory
 - Classpath: Looks for a class in the CLASSPATH variable

- Both: Looks for a file in the output directory or in a class in the CLASSPATH variable
- `-genXML argument`
Generates the `.xml` and `.xmi` files. Valid arguments are:
 - `IfNotExists`, default
 - `Overwrite`
 - `No`
- `-genImplSer true or false`
Indicates that each generated Java bean implements the `java.io.Serializable`. The default is `false`.
- `-genEquals true or false`
Indicates that each generated Java bean have `equals` and `hashCode` methods. The default is `false`.
- `-noWrappedOperations`
Disables wrapped operations detection. Java beans for the request and response messages are generated.
- `-noWrappedArrays`
Disables wrapped array detection.
- `-fileNStoPkg file name`
Specifies the file of the namespace to package mappings. The default is `NStoPKG.properties`.
- `service wsdl service name`
Generates files for the installed WSDL service only.
- `-testCase`
Generates the template for a JUnit test case for testing web services. JUnit is a simple framework to write repeatable tests.

Developing JAX-RPC web services deployment descriptor templates for an enterprise bean implementation

You can develop deployment descriptor templates for an Enterprise JavaBeans (EJB) implementation that is enabled for Java API for XML-based RPC (JAX-RPC) web services.

Before you begin

You need to create a service endpoint interface and develop a Web Services Description Language (WSDL) file before you can develop the deployment descriptor templates because the service endpoint interface and the WSDL file are artifacts that are used to create the templates.

About this task

Completing this task creates deployment descriptor templates that describe how to map the service implementation to a Enterprise JavaBeans (EJB). This task is a required step in developing a web service from an enterprise bean.

To develop the deployment descriptor templates from a WSDL file, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use.

IBM i If the WSDL file is a local file, the URL looks like this example: `file:/path/file_name.wsdl`.

You can also specify local files using the absolute or relative file system path.

When the web service implementation contains an enterprise bean in an EJB module, the `webservices.xml`, `ibm-webservices-bnd.xmi` and `ibm-webservices-ext.xmi` deployment descriptors, and the Java API for XML-based remote procedure call (JAX-RPC) mapping file are generated in the `META-INF` subdirectory.

Procedure

Run the `WSDL2Java -verbose -role develop-server -container ejb -genJava no wsdlURL` command to generate the server deployment descriptor templates and mapping file into the META-INF subdirectory. If the `-verbose` option is specified, a list of all generated files displays when the command runs.

Results

You have deployment descriptor templates that are required to implement a web service.

Example

The following example uses the `AddressBookJ2WE.wsdl` WSDL file:

1. Generate the template files with the following command syntax:

```
WSDL2Java -verbose -role develop-server -container ejb -genJava no AddressBookJ2WE.wsdl
```

The deployment descriptor templates are generated into the META-INF subdirectory as follows:

```
Parsing XML file: AddressBookJ2WE.wsdl
Generating: META-INF\webservices.xml
Generating: META-INF\ibm-webservices-bnd.xmi
Generating: META-INF\ibm-webservices-ext.xmi
Generating: META-INF\AddressBookJ2WE_mapping.xml
```

What to do next

Continue to complete the steps that are necessary to develop a JAX-RPC web service from an enterprise bean. The next step is to complete the EJB implementation. When you complete the EJB implementation, you assemble an enterprise bean Java archive (JAR) file that contains the enterprise bean and supporting classes created from a WSDL file. To learn more, see the completing the EJB implementation for JAX-RPC applications information.

Completing the JavaBeans implementation for JAX-RPC applications

After you have developed the Java artifacts necessary to develop a Java API for XML-based RPC (JAX-RPC) web service, you must complete the JavaBeans implementation to assemble a Java archive (JAR) file or a web application archive (WAR) file based on your programming model. The resulting JAR file or WAR file contains the JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Develop web services deployment descriptor templates for a JavaBeans implementation using the `WSDL2java` command-line tool. You need to complete this step to create the deployment descriptor templates that are configured to map the service implementation to the JavaBeans implementation.

About this task

For JAX-RPC applications, complete the JavaBeans implementation by writing your business application.

Procedure

1. Edit the JavaBeans implementation template, `bindingImpl.java`. The `binding` is the name of the `<wsdl:binding>` element in the WSDL file. The JavaBeans implementation is generated by the `WSDL2java` command-line tool.
 - a. Complete the implementation of the methods in the template.
 - b. (Optional) Make changes if necessary.
 - c. (Optional) Change the class name if the binding name is not acceptable.

2. Compile all the Java classes.
3. Assemble a Web archive (WAR) file. Assemble all the Java classes into a WAR file using web module assembly tools. Include all of the classes generated from running the **WSDL2java** command tool for JAX-RPC web service applications when developing implementation templates and bindings from a WSDL file.

Results

You have now enabled the JavaBeans-based business application for JAX-RPC web services. You have a JAR file or a WAR file containing the JavaBeans implementation and supported classes created from the WSDL file.

What to do next

If you are developing a JAX-RPC web services application from JavaBeans, you need to configure the `webservices.xml` deployment descriptor and configure the `ibm-webservices-bnd.xmi` deployment descriptor so that the application server can process the incoming web services requests.

Completing the EJB implementation for JAX-RPC applications

After you have developed the Java artifacts necessary to develop a Java API for XML-based RPC (JAX-RPC) web service, you must complete the Enterprise JavaBeans (EJB) implementation to assemble a Java archive (JAR) file or a web application archive (WAR) file based on your programming model. The resulting JAR file or WAR file contains the Enterprise JavaBeans (EJB) implementation and the supported classes created from the tooling.

Before you begin

Develop EJB implementation templates and bindings from a WSDL file for JAX-RPC web services using the **wsdl2java** command-line tool. The deployment descriptor templates that are generated from a Web Services Description Language (WSDL) file are required to complete the EJB implementation in the web services development process.

About this task

For JAX-RPC applications, complete the enterprise beans implementation by writing your business application.

Procedure

1. Inspect the EJB remote interface template, `portType_RI.java`. If necessary, modify the template. The value `portType` is the name of the `<wsdl:portType>` element in the WSDL file.
2. Edit the `bindingImpl.java` EJB implementation template. Where `binding` is the name of the `<wsdl:binding>` element in the WSDL file.
3. Complete the implementation of the methods in the template.
4. (Optional) Make changes if necessary.
5. (Optional) Change the class name if the binding name is not acceptable.
6. Compile all the Java classes.
7. Assemble an EJB Java archive (JAR) file. Assemble all the Java classes into an enterprise bean JAR file using assembly tools. Include all of the classes generated from running the **WSDL2Java** command tool when developing implementation templates and bindings from a WSDL file.

Results

You have enabled an enterprise beans business application for JAX-RPC web services. You now have an enterprise bean JAR file containing an EJB and supporting classes created from web services artifacts.

What to do next

Now that you have gathered the required artifacts for developing a JAX-RPC web service with an enterprise bean, you need to, configure the `webservices.xml` deployment descriptor.

Configuring the `webservices.xml` deployment descriptor for JAX-RPC web services

You can configure the `webservices.xml` deployment descriptor with an assembly tool.

Before you begin

To configure the client deployment descriptor, read about the configuring the client deployment descriptor in the Rational Application Developer information.

Before you can configure the `ibm-webservices-bnd.xml` deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

About this task

For JAX-RPC web services, this task is one of the required steps in developing a web service. You need to configure the deployment descriptors so that the application server can process the incoming web services requests.

If you are developing a web service from JavaBeans, you can develop web services JavaBeans deployment descriptor templates from a Web Services Description Language (WSDL) file. Then, you complete the JavaBeans implementation. To learn more, read about developing JavaBeans deployment descriptor templates from a WSDL file and completing the JavaBeans implementation.

If you are developing a web service from an enterprise bean, you can develop web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file. Then, you complete the EJB implementation. To learn more, read about developing web services EJB deployment descriptor templates from a WSDL file and completing the EJB implementation.

When the JavaBeans implementation is complete, the web module web application archive (WAR) file is assembled. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. These archive files contain the `webservices.xml` deployment descriptor. The archive files must be assembled before you can configure the `webservices.xml` deployment descriptor.

The assembly tools provide a graphical interface for developing code artifacts, assembling the code artifacts into various archives (modules) and configuring compliant deployment descriptors for Java Platform, Enterprise Edition (Java EE).

Configure the `webservices.xml` deployment descriptor by following the steps provided in this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.

3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Results

You have a `webservices.xml` deployment descriptor that is configured.

What to do next

For JAX-RPC web services, you must configure the `ibm-webservices-bnd.xml` deployment descriptor. To learn more, see the configuring the `ibm-webservices-bnd.xml` deployment descriptor for JAX-RPC web services information.

Configuring the `webservices.xml` deployment descriptor for handler classes

You can use an assembly tool to configure the `webservices.xml` deployment descriptor for user-provided handler classes.

Before you begin

You can configure deployment descriptors with assembly tools provided with the application server.

A *handler class* is a class that is written to modify a SOAP message that represents a remote procedure call (RPC) request or response. Handlers can be associated with a web service or a web service client.

Similar to Java API for XML-based RPC (JAX-RPC) web services, you can use deployment descriptors to describe Java API for XML Web Services (JAX-WS) web services. For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

To complete this task, you need an enterprise archive (EAR) file for the applications that you want to configure. For some handler use, such as logging or tracing, only the server or client application require configuration. For other handler use, including sending information in the SOAP headers, the client and server applications must be configured with symmetrical handlers.

About this task

The modules in the EAR file contain the handler classes to configure. These classes implement the `javax.xml.rpc.handler.Handler` interface. For more information on writing handler classes, see chapter 6 of the Web Services for Java EE specification. See chapter 9 in the JAX-WS specification or chapter 12 in the JAX-RPC specification for additional information on the handler framework for your programming model. The application modules must contain the `webservices.xml` deployment descriptor. See the web services specifications and API information to review the JAX-RPC specification along with a complete list of the supported standards and specifications.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.

2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Configuring the `ibm-webservices-bnd.xml` deployment descriptor for JAX-RPC web services

Use assembly tools to configure the `ibm-webservices-bnd.xml` deployment descriptor. This file stores binding information that is associated with the endpoints defined with the `webservices.xml` deployment descriptor file.

Before you begin

Note: The `ibm-webservices-bnd.xml` deployment descriptor is for Java API for XML-based RPC (JAX-RPC) based web services application. It is not used for Java API for XML-Based Web Services (JAX-WS) enabled applications.

To configure the client deployment descriptor, read about the configuring the client deployment descriptor in the Rational Application Developer information.

Before you can configure the `ibm-webservices-bnd.xml` deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

About this task

This task is one of the steps in developing a web service. You need to configure the deployment descriptors so that WebSphere Application Server can process the incoming web services requests.

Depending on if you are developing a web service from JavaBeans or an enterprise bean:

- Develop web services JavaBeans deployment descriptor templates from a Web Services Description Language (WSDL) file.
- Develop web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file.

Then, complete the EJB implementation or complete the JavaBeans implementation. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. When the JavaBeans implementation is complete, the web module web application archive (WAR) file is assembled. These archive files contain the `webservices.xml` deployment descriptor. The archive files must be assembled before you can configure the `webservices.xml` deployment descriptor.

Configure the `webservices.xml` deployment descriptor by following the steps provided in this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.

3. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Results

The `ibm-webservices-bnd.xml` deployment descriptor is configured for the web service implementation module.

What to do next

If you are developing a web service from JavaBeans, assemble a WAR file that is enabled for web services from Java code. See the assembling a WAR file that is enabled for web services from Java code information.

If you are developing a web service from an enterprise bean, assemble a JAR file that is enabled for web services from an enterprise bean. To learn more about assembling the artifacts that are required to enable the EJB module for web services into the JAR file, see the assembling a JAR file that is enabled for web services from an enterprise bean information.

JAX-RPC web services enabled module - deployment descriptor settings (ibm-webservices-bnd.xml file)

The `ibm-webservices-bnd.xml` file is a deployment descriptor for a Java API for XML-based RPC (JAX-RPC) web services-enabled web module or an Enterprise JavaBeans (EJB) module. This file contains information for the web services run time that is required by WebSphere Application Server..

The following user-defined assembly properties are supported:

- **wsDescNameLink**
Attribute of the `wsdescBindings` element that specifies the link to the corresponding `<webservice-description-name>` element in the `webservices.xml` file.
- **pc-name-link**
Attribute of the `pcBindings` element that specifies the link to the `<port-component-name>` element in the `webservices.xml` file.
- **scope**
Attribute of the `pcBindings` element that specifies when new instances of implementation beans are created. Possible values are `request`, `session`, and `application`.

You can change scope value for a deployed web service using the administrative console. Click **Enterprise Applications** > *application* > **Web modules** or **EJB modules** > *module* > **Web Services Implementation Scope**.

Bindings file examples

The following examples demonstrate the spelling and position of the various attributes. You cannot cut and paste these examples because they do not contain the required ID attributes. If you add elements to a binding file template generated by the **WSDL2Java** command, you must confirm that each element has an ID attribute with a unique string value. Review the template xmi files generated by the **WSDL2Java** command for examples of ID strings. Read about the **WSDL2Java** command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

```
<com.ibm.etools.webservice.wsbind:WSBinding xmi:version="2.0" xmlns:xmi="http://www.omg.org/XMI" xmlns:com.ibm.etools.webservice.wsbind="http://www.ibm.com/websphere/appserver/schemas/5.0.2/wsbind.xmi">
```

```
<wsdescBindings wsDescNameLink="AddressBookService">
  <pcBindings pcNameLink="AddressBook" scope="Application"/>
</wsdescBindings>
</com.ibm.etools.webservice.wsbind:WSBinding>
```

Developing JAX-RPC web services with WSDL files (top-down)

Setting up a development environment for web services

The application server provides command-line tools to develop web services clients and implementations that are based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. You must set up your development environment before you start developing web services.

Before you begin

Before you can set up a web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information on installing the application server, read about installing your application server environment.

About this task

Set up a web services development environment by completing the following actions.

Procedure

Set up the environment.

IBM i Run the **setupCmdLine** script on the Qshell command line from the `./profile_root/bin` directory.

Results

You have set up an environment so that you can develop Web services.

What to do next

Implement web services applications. See the task overview for implementing web services applications information to learn about how to develop and implement a Java EE web service.

Developing Java artifacts for JAX-RPC applications from a WSDL file

You can develop Java artifacts from a Web Services Description Language (WSDL) file for JAX-RPC applications from a WSDL file by using the **WSDL2Java** command-line tool to create Java implementation templates and bindings.

Before you begin

To develop the JavaBeans implementation templates and bindings from a WSDL file, you must obtain the Uniform Resource Locator (URL) of the WSDL file.

IBM i If the WSDL file is a local file, the URL looks like this example: `file:/path/file_name.wsdl`.

You can also specify local files using the absolute or relative file system path.

Implementation templates are generated using the `-role develop-server` option of the **WSDL2Java** command. The **WSDL2Java** command also generates bindings and deployment descriptors.

About this task

Develop JavaBeans implementation templates and bindings from a WSDL file by issuing the proper command.

Note: It is a best practice to use absolute namespaces within your WSDL or schema. By default, the **WSDL2Java** tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. You can convert any relative namespaces to absolute namespaces. To learn more about the use of namespaces with the **WSDL2Java** tool, see the **WSDL2Java** command for JAX-RPC applications documentation.

Procedure

Run the `WSDL2Java -verbose -role develop-server -container web wsdURL` command. Since the `-verbose` option is specified, a list of all the generated files is displayed when the command runs.

Results

You have templates for the implementation and deployment descriptors required to implement a web service, as well as bindings files. These templates are partially filled with information from the WSDL file.

Example

The following example uses the `AddressBook` JavaBeans implementation and the `AddressBook.wsdl` WSDL file. After generating the template files from the `WSDL2Java -verbose -role develop-server -container web AddressBook.wsdl` command, the following files are generated:

```
Parsing XML file: file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file: AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookSoapBindingImpl.java..
WSWS3282I: Info: Generating WEB-INF\webservices.xml.
WSWS3282I: Info: Generating WEB-INF\ibm-webservices-bnd.xmi.
WSWS3282I: Info: Generating WEB-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating WEB-INF\ibm-webservices-ext.xmi.
```

The `AddressBookSOAPBindingImpl.java` file is the template for the implementation bean. It is named after the port in the WSDL file. Generally, this class is renamed to a more meaningful name.

What to do next

Complete the JavaBeans implementation for JAX-RPC applications.

Developing EJB implementation templates and bindings from a WSDL file for JAX-RPC web services

You can develop Enterprise JavaBeans (EJB) implementation deployment descriptor templates and bindings from a Web Services Description Language (WSDL) file for a JAX-RPC application.

Before you begin

To develop EJB implementation templates and bindings from a WSDL file for a Java API for XML-based RPC (JAX-RPC) web service, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use.

IBM i If the WSDL file is a local file, the URL looks like the following example: `file:/path/file_name.wsdl`.

You can also specify local files using the absolute or relative file system path.

About this task

This task is one a required step in developing a web service from an enterprise bean.

Implementation templates are generated using the `-role develop-server` option of the **WSDL2Java** command.

Templates are generated for an EJB implementation for the following components:

- enterprise bean
- EJB remote interface
- EJB Home

The **WSDL2Java** command also generates bindings and deployment descriptors.

Note: It is a best practice to use absolute namespaces within your WSDL or schema. By default, the **WSDL2Java** tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. You can convert any relative namespaces to absolute namespaces. To learn more about the use of namespaces with the **WSDL2Java** tool, see the **WSDL2Java** command for JAX-RPC applications documentation.

Procedure

Run the `WSDL2Java -verbose -role develop-server -container ejb wsdlURL` command. Because the verbose option is specified, a list of all the generated files is displayed when the command runs.

Results

You have templates for the implementation and deployment descriptors required to implement web services, as well as bindings files. These templates are partially completed with information from the WSDL file.

Example

The following example uses the enterprise bean `AddressBook` enterprise bean and the `AddressBook.wsdl` file. After generating the template files from the `WSDL2Java -verbose -role develop-server -container EJB AddressBook.wsdl` command, the following files are generated:

```
Parsing XML file: file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file: AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookSoapBindingImpl.java.
WSWS3282I: Info: Generating addr\AddressBook_RI.java.
WSWS3282I: Info: Generating addr\AddressBookHome.java.
WSWS3282I: Info: Generating META-INF\webservices.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservices-bnd.xmi.
WSWS3282I: Info: Generating META-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservices-ext.xmi.
```

What to do next

Complete the EJB implementation. When you complete the EJB implementation, an EJB Java archive (JAR) file that contains an EJB and supporting classes is created from a WSDL file.

Completing the JavaBeans implementation for JAX-RPC applications

After you have developed the Java artifacts necessary to develop a Java API for XML-based RPC (JAX-RPC) web service, you must complete the JavaBeans implementation to assemble a Java archive (JAR) file or a web application archive (WAR) file based on your programming model. The resulting JAR file or WAR file contains the JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Develop web services deployment descriptor templates for a JavaBeans implementation using the **WSDL2java** command-line tool. You need to complete this step to create the deployment descriptor templates that are configured to map the service implementation to the JavaBeans implementation.

About this task

For JAX-RPC applications, complete the JavaBeans implementation by writing your business application.

Procedure

1. Edit the JavaBeans implementation template, *bindingImpl.java*. The *binding* is the name of the `<wsdl:binding>` element in the WSDL file. The JavaBeans implementation is generated by the **WSDL2java** command-line tool.
 - a. Complete the implementation of the methods in the template.
 - b. (Optional) Make changes if necessary.
 - c. (Optional) Change the class name if the binding name is not acceptable.
2. Compile all the Java classes.
3. Assemble a Web archive (WAR) file. Assemble all the Java classes into a WAR file using web module assembly tools. Include all of the classes generated from running the **WSDL2java** command tool for JAX-RPC web service applications when developing implementation templates and bindings from a WSDL file.

Results

You have now enabled the JavaBeans-based business application for JAX-RPC web services. You have a JAR file or a WAR file containing the JavaBeans implementation and supported classes created from the WSDL file.

What to do next

If you are developing a JAX-RPC web services application from JavaBeans, you need to configure the `webservices.xml` deployment descriptor and configure the `ibm-webservices-bnd.xmi` deployment descriptor so that the application server can process the incoming web services requests.

Completing the EJB implementation for JAX-RPC applications

After you have developed the Java artifacts necessary to develop a Java API for XML-based RPC (JAX-RPC) web service, you must complete the Enterprise JavaBeans (EJB) implementation to assemble a Java archive (JAR) file or a web application archive (WAR) file based on your programming model. The resulting JAR file or WAR file contains the Enterprise JavaBeans (EJB) implementation and the supported classes created from the tooling.

Before you begin

Develop EJB implementation templates and bindings from a WSDL file for JAX-RPC web services using the `wsdl2java` command-line tool. The deployment descriptor templates that are generated from a Web Services Description Language (WSDL) file are required to complete the EJB implementation in the web services development process.

About this task

For JAX-RPC applications, complete the enterprise beans implementation by writing your business application.

Procedure

1. Inspect the EJB remote interface template, `portType_RI.java`. If necessary, modify the template. The value `portType` is the name of the `<wsdl:portType>` element in the WSDL file.
2. Edit the `bindingImpl.java` EJB implementation template. Where `binding` is the name of the `<wsdl:binding>` element in the WSDL file.
3. Complete the implementation of the methods in the template.
4. (Optional) Make changes if necessary.
5. (Optional) Change the class name if the binding name is not acceptable.
6. Compile all the Java classes.
7. Assemble an EJB Java archive (JAR) file. Assemble all the Java classes into an enterprise bean JAR file using assembly tools. Include all of the classes generated from running the `WSDL2Java` command tool when developing implementation templates and bindings from a WSDL file.

Results

You have enabled an enterprise beans business application for JAX-RPC web services. You now have an enterprise bean JAR file containing an EJB and supporting classes created from web services artifacts.

What to do next

Now that you have gathered the required artifacts for developing a JAX-RPC web service with an enterprise bean, you need to, configure the `webservices.xml` deployment descriptor.

Configuring the webservices.xml deployment descriptor for JAX-RPC web services

You can configure the `webservices.xml` deployment descriptor with an assembly tool.

Before you begin

To configure the client deployment descriptor, read about the configuring the client deployment descriptor in the Rational Application Developer information.

Before you can configure the `ibm-webservices-bnd.xml` deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

About this task

For JAX-RPC web services, this task is one of the required steps in developing a web service. You need to configure the deployment descriptors so that the application server can process the incoming web services requests.

If you are developing a web service from JavaBeans, you can develop web services JavaBeans deployment descriptor templates from a Web Services Description Language (WSDL) file. Then, you complete the JavaBeans implementation. To learn more, read about developing JavaBeans deployment descriptor templates from a WSDL file and completing the JavaBeans implementation.

If you are developing a web service from an enterprise bean, you can develop web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file. Then, you complete the EJB implementation. To learn more, read about developing web services EJB deployment descriptor templates from a WSDL file and completing the EJB implementation.

When the JavaBeans implementation is complete, the web module web application archive (WAR) file is assembled. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. These archive files contain the `webservices.xml` deployment descriptor. The archive files must be assembled before you can configure the `webservices.xml` deployment descriptor.

The assembly tools provide a graphical interface for developing code artifacts, assembling the code artifacts into various archives (modules) and configuring compliant deployment descriptors for Java Platform, Enterprise Edition (Java EE).

Configure the `webservices.xml` deployment descriptor by following the steps provided in this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Results

You have a `webservices.xml` deployment descriptor that is configured.

What to do next

For JAX-RPC web services, you must configure the `ibm-webservices-bnd.xmi` deployment descriptor. To learn more, see the configuring the `ibm-webservices-bnd.xmi` deployment descriptor for JAX-RPC web services information.

Configuring the `webservices.xml` deployment descriptor for handler classes

You can use an assembly tool to configure the `webservices.xml` deployment descriptor for user-provided handler classes.

Before you begin

You can configure deployment descriptors with assembly tools provided with the application server.

A *handler class* is a class that is written to modify a SOAP message that represents a remote procedure call (RPC) request or response. Handlers can be associated with a web service or a web service client.

Similar to Java API for XML-based RPC (JAX-RPC) web services, you can use deployment descriptors to describe Java API for XML Web Services (JAX-WS) web services. For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

To complete this task, you need an enterprise archive (EAR) file for the applications that you want to configure. For some handler use, such as logging or tracing, only the server or client application require configuration. For other handler use, including sending information in the SOAP headers, the client and server applications must be configured with symmetrical handlers.

About this task

The modules in the EAR file contain the handler classes to configure. These classes implement the `javax.xml.rpc.handler.Handler` interface. For more information on writing handler classes, see chapter 6 of the Web Services for Java EE specification. See chapter 9 in the JAX-WS specification or chapter 12 in the JAX-RPC specification for additional information on the handler framework for your programming model. The application modules must contain the `webservices.xml` deployment descriptor. See the web services specifications and API information to review the JAX-RPC specification along with a complete list of the supported standards and specifications.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Configuring the `ibm-webservices-bnd.xml` deployment descriptor for JAX-RPC web services

Use assembly tools to configure the `ibm-webservices-bnd.xml` deployment descriptor. This file stores binding information that is associated with the endpoints defined with the `webservices.xml` deployment descriptor file.

Before you begin

Note: The `ibm-webservices-bnd.xml` deployment descriptor is for Java API for XML-based RPC (JAX-RPC) based web services application. It is not used for Java API for XML-Based Web Services (JAX-WS) enabled applications.

To configure the client deployment descriptor, read about the configuring the client deployment descriptor in the Rational Application Developer information.

Before you can configure the `ibm-webservices-bnd.xml` deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

About this task

This task is one of the steps in developing a web service. You need to configure the deployment descriptors so that WebSphere Application Server can process the incoming web services requests.

Depending on if you are developing a web service from JavaBeans or an enterprise bean:

- Develop web services JavaBeans deployment descriptor templates from a Web Services Description Language (WSDL) file.
- Develop web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file.

Then, complete the EJB implementation or complete the JavaBeans implementation. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. When the JavaBeans implementation is complete, the web module web application archive (WAR) file is assembled. These archive files contain the `webservices.xml` deployment descriptor. The archive files must be assembled before you can configure the `webservices.xml` deployment descriptor.

Configure the `webservices.xml` deployment descriptor by following the steps provided in this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Results

The `ibm-webservices-bnd.xmi` deployment descriptor is configured for the web service implementation module.

What to do next

If you are developing a web service from JavaBeans, assemble a WAR file that is enabled for web services from Java code. See the assembling a WAR file that is enabled for web services from Java code information.

If you are developing a web service from an enterprise bean, assemble a JAR file that is enabled for web services from an enterprise bean. To learn more about assembling the artifacts that are required to enable the EJB module for web services into the JAR file, see the assembling a JAR file that is enabled for web services from an enterprise bean information.

JAX-RPC web services enabled module - deployment descriptor settings (ibm-webservices-bnd.xmi file)

The `ibm-webservices-bnd.xmi` file is a deployment descriptor for a Java API for XML-based RPC (JAX-RPC) web services-enabled web module or an Enterprise JavaBeans (EJB) module. This file contains information for the web services run time that is required by WebSphere Application Server..

The following user-defined assembly properties are supported:

- **wsDescNameLink**
Attribute of the wsdescBindings element that specifies the link to the corresponding <webservice-description-name> element in the webservices.xml file.
- **pc-name-link**
Attribute of the pcBindings element that specifies the link to the <port-component-name> element in the webservices.xml file.
- **scope**
Attribute of the pcBindings element that specifies when new instances of implementation beans are created. Possible values are request, session, and application.

You can change scope value for a deployed web service using the administrative console. Click **Enterprise Applications** > *application* > **Web modules** or **EJB modules** > *module* > **Web Services Implementation Scope**.

Bindings file examples

The following examples demonstrate the spelling and position of the various attributes. You cannot cut and paste these examples because they do not contain the required ID attributes. If you add elements to a binding file template generated by the **WSDL2Java** command, you must confirm that each element has an ID attribute with a unique string value. Review the template xmi files generated by the **WSDL2Java** command for examples of ID strings. Read about the **WSDL2Java** command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

```
<com.ibm.etools.webservice.wsbind:WSBinding xmi:version="2.0" xmlns:xmi="http://www.omg.org/XMI" xmlns:com.ibm.etools.webservice.wsbind="http://www.ibm.com/websphere/appserver/schemas/5.0.2/wsbind.xmi">
  <wsdescBindings wsDescNameLink="AddressBookService">
    <pcBindings pcNameLink="AddressBook" scope="Application"/>
  </wsdescBindings>
</com.ibm.etools.webservice.wsbind:WSBinding>
```

Developing JAX-RPC web services clients

Developing client bindings from a WSDL file for a JAX-RPC Web services client

You can develop client bindings from a Web Services Description (WSDL) file for a JAX-RPC web services client.

Before you begin

To develop the client bindings from a WSDL file for JAX-RPC web service applications, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use. You need bindings and deployment descriptors in order for a client to use a web service.

 If the WSDL file is a local file, the URL looks like the following example: `file:/path/file_name.wsdl`.

You can also specify local files using the absolute or relative file system path.

Client bindings are generated using the `-role develop-client` option in combination with the `-container` option of the **WSDL2Java** command. The `-container` option takes the following parameters:

- **-container client**
Generates bindings and deployment descriptors for a client residing in the application client container.
- **-container ejb**

Generates bindings and deployment descriptors for a client that is an enterprise bean in the Enterprise JavaBeans (EJB) module.

- **-container web**

Generates bindings and deployment descriptors for a client residing in the web container.

About this task

Develop client bindings from a WSDL file by running the appropriate command.

Note: It is a best practice to use absolute namespaces within your WSDL or schema. By default, the **WSDL2Java** tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. You can convert any relative namespaces to absolute namespaces. To learn more about the use of namespaces with the **WSDL2Java** tool, see the **WSDL2Java** command for JAX-RPC applications documentation.

Procedure

Run the `WSDL2Java -verbose -role develop-client -container type wsdlURL` command, where *type* is **ejb** for an enterprise EJB client, **web** for a JavaBeans client, or **client** for an application client.

You can use the following combinations in the command-line:

- `-container web`
- `-container ejb`
- `-container client`

Because the verbose option is specified, a list of all generated files is displayed when the command runs.

Results

You have the bindings and deployment descriptors needed by a client to use a web service.

Example

The following example uses the AddressBook enterprise bean the AddressBook.wsdl WSDL file. After generating the bindings from the `WSDL2Java -verbose -role develop-client -container client AddressBook.wsdl` command, the following files are generated:

```
Parsing XML file: file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file: AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookService.java.
WSWS3282I: Info: Generating META-INF\ibm-webservicesclient-bnd.xmi.
WSWS3282I: Info: Generating META-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservicesclient-ext.xmi.
```

What to do next

Complete the client implementation by writing your client application and then assembling the client artifacts.

Changing SOAP message encoding to support WSI-Basic Profile

Support for Universal Transformation Format (UTF)-16 encoding is required by the WS-I Basic Profile 1.0. WebSphere Application Server conforms to the WS-I Basic Profile 1.1. UTF-16 is a kind of unicode encoding scheme using 16-bit values to store Universal Character Set (UCS) characters. UTF-8 is the most common encoding that is used on the Internet and UTF-16 encoding is typically used for Java and Windows product applications. You can change the encoding in a SOAP message from UTF-8 to UTF-16.

Before you begin

To learn more about the requirements of the Web Services-Interoperability Basic Profile (WS-I), including UTF-16, see Web Services-Interoperability Basic Profile information.

About this task

Support for UTF-16 encoding is required by WS-I Basic Profile. The application server only supports UTF-8 and UTF-16 encoding of SOAP messages.

You can change the character encoding in one of two ways:

Procedure

- Use a property on the Stub for users to set.

This choice applies to the client only.

For a client, the encoding is specified in the SOAP request. The SOAP engine serializes the request and sends it to the web service engine. The web service engine receives the request and deserializes the message to Java objects, which are returned to you in a response.

When the web service engine on the server receives the serialized request, a raw message in the form of an input stream, is passed to the parser, which understands Byte Order Mark (BOM). BOM is mandatory for UTF-16 encoding and it can be used in UTF-8. The message is deserialized to a Java objects and a service invocation is made. For two-way invocation, the engine needs to serialize the message using a specific encoding and send it back to the caller. The following example shows you how to use a property on the Stub to change the character set:

```
javax.xml.rpc.Stub stub=service.getPort("MyPortType");
((javax.xml.rpc.Stub)stub).setProperty(com.ibm.wsspi.webservices.Constants.MESSAGE_CHARACTER_SET_ENCODING, "UTF-16");
stub.invokeMethod();
```

In this code example, `com.ibm.wsspi.webservices.Constants.MESSAGE_CHARACTER_SET_ENCODING = "com.ibm.wsspi.webservices.xmlcharset"`;

- Use a handler to change the character set through SOAP with Attachments API for Java (SAAJ).

If you are using a handler, the SOAP message is transformed to a SAAJ format from other possible forms, such as an input stream. In such cases as a `handleRequest` method on the client side and a `handleResponse` method on the server side, the web services engine transforms from a SAAJ format back to the stream with appropriate character encoding. This transformation or change is called a *roundtrip transformation*. The following is an example of how you can use a handler to specify the character encoding through SAAJ:

```
handleResponse(MessageContext mc) {
    SOAPMessageContext smc = (SOAPMessageContext) context;
    javax.xml.soap.SOAPMessage msg = smc.getMessage();
    msg.setProperty (javax.xml.soap.SOAPMessage.CHARACTER_SET_ENCODING, "UTF-16");
}
}
```

Results

You have modified the character encoding from UTF-8 to UTF-16 in the web service SOAP message.

Configuring the JAX-RPC web services client deployment descriptor with an assembly tool

You can configure JAX-RPC web services client deployment descriptor with an assembly tool.

Before you begin

You can configure deployment descriptors with assembly tools provided with WebSphere Application Server.

Also, you need an enterprise JavaBeans (EJB) Java archive (JAR) file, web application archive (WAR) file or an application client file that you can import into the assembly tool.

Assemble the client JAR file into an EAR file or assemble the client WAR file into an EAR file. To learn more, see the information on assembling a web services-enabled client JAR file into an EAR file or assembling a web services-enabled client WAR file into an EAR file.

About this task

Complete this task if you are developing a managed client that runs in the Java EE client container. This task is done after you assemble the EJB or web module.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) or Java Archive (JAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to assembly tools. To migrate files, import your WAR or JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Results

You have a client deployment descriptor that is configured.

What to do next

Test the web services client. See the testing web services-enabled clients information to learn more about how to test an unmanaged client Java archive (JAR) file and an unmanaged client application.

Configuring the JAX-RPC client deployment descriptor for handler classes

You can configure the JAX-RPC client deployment descriptor for user-provided handler classes.

Before you begin

You need an enterprise archive (EAR) file for the applications that you want to configure. For some handler use, such as logging or tracing, only the server or client application needs to be configured. For other handler use, including sending information in SOAP headers, the client and server applications must be configured with symmetrical handlers.

The modules in the EAR file should contain the handler classes to configure. These classes implement the `javax.xml.rpc.handler.Handler` interface. For more information on writing handler classes, see chapter 6 of the Web Services for Java Platform, Enterprise Edition (Java EE) specification and chapter 12 of the Java API for XML-based remote procedure call (JAX-RPC) specification. The application modules must contain the `webservices.xml` (for server) and the client deployment descriptors.

For a complete list of the supported standards and specifications, see the web services specifications and API documentation.

About this task

Configure a handler in the client deployment descriptor by following the steps provided:

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) or Java archive (JAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. Read about importing WAR or JAR files using an assembly tool in the Rational Application Developer information.
4. Configure the client deployment descriptor. Read about creating web services handlers in the Rational Application Developer information.

Results

You have a client deployment descriptor that is configured.

What to do next

Test the web services client. See the testing web services-enabled clients information to learn more about how to test an unmanaged client Java archive (JAR) file and an unmanaged client application.

Handler class properties with JAX-RPC

This article describes handler class properties using Java API for XML-based RPC (JAX-RPC).

You can configure the following handler class properties with assembly tools provided with WebSphere Application Server. See *Configuring the `webservices.xml` deployment descriptor for Handler classes* or *Configuring the client deployment descriptors for Handler classes* for instructions on how to configure the properties.

You can configure the following handler class properties with assembly tools provided with WebSphere Application Server. For instructions on how to configure the handler class properties, read about *configuring the `webservices.xml` deployment descriptor for handler classes* or *configuring the client deployment descriptors for handler classes*.

Description:

Standard Java Platform, Enterprise Edition (Java EE) technology descriptor field.

Display name:

Standard Java EE technology descriptor field.

Small icon:

Standard Java EE technology descriptor field.

Large icon:

Standard Java EE technology descriptor field.

Handler name:

The name of the handler. This name must be unique within the module.

Handler class:

The fully qualified name of the handler class. Initially, it is set by an assembly tool.

Initial parameters:

Property names and values available to the handler.

SOAP headers:

Qualified names (Qnames) of the SOAP headers that are processed by this handler.

See section 12.2.2 of the Java API for XML-based remote procedure call (JAX-RPC) specification, available through the web services specifications and APIs information, for more information about setting this property.

SOAP roles:

URIs containing the SOAP actor names for which the handler acts in the role.

See section 12.2.2 of the Java API for XML-based remote procedure call (JAX-RPC) specification, available through the web services specifications and APIs information, for more information about setting this property.

Example: Configuring handler classes for web services deployment descriptors

This scenario explains how to add a client and server handler class to a sample application, `WebServicesSamples.ear`. The handler classes display messages when given a request or response to handle.

The code for the client handler class is illustrated in the following example:

```
package samples;

public class ClientHandler implements javax.xml.rpc.handler.Handler {
    public ClientHandler() { }

    public boolean handleRequest(javax.xml.rpc.handler.MessageContext context) {
        System.out.println("ClientHandler: In handleRequest");
        return true; }

    public boolean handleResponse(javax.xml.rpc.handler.MessageContext context) {
        System.out.println("ClientHandler: In handleResponse");
        return true; }

    public boolean handleFault(javax.xml.rpc.handler.MessageContext context) {
        System.out.println("ClientHandler: In handleFault");
        return true; }

    public void init(javax.xml.rpc.handler.HandlerInfo config) {}

    public void destroy() {}
}
```

```
public javax.xml.namespace.QName[] getHeaders() {
    return null; }
}
```

The code for the server handler class is illustrated in the following example:

```
package sample;
public class ServerHandler implements javax.xml.rpc.handler.Handler {
    public ServerHandler() { }

    public boolean handleRequest(javax.xml.rpc.handler.MessageContext context) {
        System.out.println("ServerHandler: In handleRequest");
        return true; }

    public boolean handleResponse(javax.xml.rpc.handler.MessageContext context) {
        System.out.println("ServerHandler: In handleResponse");
        return true; }

    public boolean handleFault(javax.xml.rpc.handler.MessageContext context) {
        System.out.println("ServerHandler: In handleFault");
        return true; }

    public void init(javax.xml.rpc.handler.HandlerInfo config) {}

    public void destroy() {}

    public javax.xml.namespace.QName[] getHeaders() {
        return null; }
}
```

1. Compile these classes using:
2. Open an assembly tool and import the two sample enterprise archive (EAR) files:
 -
 -
3. Import the compiled handler classes into the projects for the sample modules:
 - Import sample.ClientHandler into the **appClientModule** directory of the **AddressBookClient** project.
 - Import sample.ServerHandler into the **ejbModule** directory of the **AddressBookW2JE** project.
4. Configure the client deployment descriptor for handler classes.
This topic explains how to configure the client deployment descriptor for user-provided handler classes.
5. Configure the webservices.xml deployment descriptor for handler classes.
This topic explains how to configure the webservices.xml deployment descriptor for user-provided handler classes.
6. Save your changes and export the EAR files.
7. Uninstall the WebServicesSamples.ear application from your server if it is already installed.
8. Install the new WebServicesSamples.ear application.
9. Start the server.
10. Run the client:

```
launchClient ApplicationClients.ear -CCjar=AddressBookClient.jar
```

When the client runs, the console output looks like the following example. The messages from the handlers are shown in bold.

```
IBM WebSphere Application Server
J2EE Application Client Tool
Copyright IBM Corp., 1997-2003
WSDL0012I: Processing command line arguments.
WSDL0013I: Initializing the J2EE Application Client
Environment.

com.ibm.websphere.samples.webservices.addr.AddressBookClient
>> Querying address for 'Purdue Boilermaker' using port
AddressBookW2JE
```

```

ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
    1 University Drive
    West Lafayette, IN 47907
    Phone: (765) 555-4900
>> Querying address for 'Purdue Boilermaker' using port
AddressBookJ2WE
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
    2 University Drive
    West Lafayette, IN 47907
    Phone: (765) 555-4900
>> Querying address for 'Purdue Boilermaker' using port
AddressBookJ2WB
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
    3 University Drive
    West Lafayette, IN 47907
    Phone: (765) 555-4900
>> Querying address for 'Purdue Boilermaker' using port AddressBookW2JB
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
    4 University Drive
    West Lafayette, IN 47907
    Phone: (765) 555-4900

```

For the client, the handler class is configured for each service reference, not for each port. The AddressBook sample has four ports, but only one service reference, therefore the ClientHandler handles requests and responses on all ports.

When the server log file is examined, it contains the following data:

```

[9/24/03 16:39:22:661 CDT] 4deec1c6 WebGroup      I SRVE0180I:
[HTTP router for AddressBookW2JE.jar] [/AddressBookW2JE] [Servlet.LOG]:
AddressBook: init
[9/24/03 16:39:23:161 CDT] 4deec1c6 SystemOut    0 ServerHandler: In handleRequest
[9/24/03 16:39:23:211 CDT] 4deec1c6 SystemOut    0 ServerHandler: In handleResponse

```

Results

The deployment descriptors for handler classes are configured. Deployment descriptors are required so that so that WebSphere Application Server can process the incoming web services requests.

What to do next

Deploy the EAR file that has been configured and enabled for web services. Then you can test the application to make sure it runs within the WebSphere Application Server environment.

Configuring the JAX-RPC web services client bindings in the ibm-webservicesclient-bnd.xmi deployment descriptor

You can configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor file with assembly tools.

Before you begin

You can configure deployment descriptors with assembly tools provided with the application server.

You must configure the assembly tool before you can use it. Read about configuring the assembly tool in the Rational Application Developer documentation.

About this task

Now that you have assembled the client module, complete this step to configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor. Deployment descriptors are required so that so that WebSphere Application Server can process the incoming web services requests.

Configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor file with the following steps provided:

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. Switch to the Java EE Perspective.
 - a. Click **Window > Open Perspective > Other > Java EE**.
3. Open the Project Explorer.
 - a. Click **Window > Show View > Other > Project Explorer**.
4. Locate the deployment descriptor file for the module. Hint: Deployment Descriptor: `<module>`
5. Double-click the deployment descriptor file to open the Deployment Descriptor editor.
 - a. Select the **WS Binding** tab at the bottom of the editor window to open the Web Services Client Bindings editor.
6. Verify the `serviceRefLink` element settings.
 - a. Open the **Web Services Client Bindings** editor.
 - b. Click the **Services References** tab.
 - c. Click **Add**.
 - d. Select the service references defined in the client deployment descriptor file from the list.
7. Verify the `deployedWSDLFile` element settings.
 - a. Open the **Web Services Client Bindings** editor.
 - b. Select the service reference.
 - c. Expand the **Service Reference Details** section.
 - d. Click **Browse** that is located to the right of the Deployed WSDL file field.
 - e. Select the new Web Services Description Language (WSDL) file.
 - f. Click **OK**.

You can also change the `deployedWSDLFile` element of a deployed web service using the administrative console. Click **Enterprise Applications > *application* > Web module or EJB module > *module* > Web services client bindings**.

8. Verify the `defaultMappings` element settings.
 - a. Open the **Web services client bindings** editor.
 - b. Click **Default mappings**.
 - c. Click **Add**.
 - d. Edit the entries in the newly added row to establish a mapping between a `portType` and a `port` in the WSDL file. Only one entry is supported for each `portType`.
 - e. Click **OK**.

You can also change the `defaultMappings` element of a deployed web service using the administrative console. Click **Enterprise Applications > *application* > Web module or EJB module > *module* > Web services client bindings**.

9. Access the web services client Port bindings editor through the **Port qualified name binding details** section at the bottom of the editor pane.
10. Verify the `syncTimeout` element settings.
 - a. Create a Port qualified name bindings for the port.

- b. Open the **Web services client bindings** editor.
 - c. Confirm that a service reference is selected in either the **Component-scoped references** or the **Service references** section.
 - d. Expand the **Port qualified name binding** section.
 - e. Click **Add**. The **Add port qualified name binding** dialog opens.
 - f. Type the *namespace* of the WSDL file port you want to configure, in the **Port namespace link** field.
 - g. Type the *local_name* of the WSDL file port you want to configure in the **Port local name link** field. The name displayed in the **Port qualified name binding** list is the local name of the WSDL file port.
 - h. Click **OK**.
 - a. Configure the `syncTimeout` property by locating the Synchronization timeout field and enter the desired value. The default is 300 seconds.
11. Verify the `basicAuth` element settings.
 - a. Locate the **HTTP basic authentication** field in the **Port qualified name binding details** section.
 - b. Type the desired value in the User ID and Password fields.
 - c. Click **OK**.
 12. Verify the `sslConfig` element settings.
 - a. Locate the **SSL configuration** field in the **Port qualified name binding details** section.
 - b. Type the desired value in the **Name** field.
 - c. Click **OK**.
 13. After editing the properties, type `ctrl-s` on your keyboard to save the changes.

Results

You have configured the `ibm-webservicesclient-bnd.xmi` deployment descriptor. If you have configured all of the client deployment descriptors, test the web services client. If you have not configured all of the client deployment descriptors, complete the configurations and then test the web services client.

ibm-webservicesclient-bnd.xmi assembly properties for JAX applications

The `ibm-webservicesclient-bnd.xmi` deployment descriptor file contains information for the web services run time that is WebSphere product-specific. This deployment descriptor file is used with Java API for XML-based web services.

You can configure deployment descriptors with assembly tools provided with WebSphere Application Server. Read about configuring the JAX-RPC web services client bindings in the `ibm-webservicesclient-bnd.xmi` deployment descriptor to learn more about configuring this deployment descriptor.

Assembly properties

The following list is a collection of supported properties and attributes that you can define for your applications.

Note: The `overriddenEndpointURI` property is the only property that is applicable for Java API for XML-Based Web Services (JAX-WS) Web services.

componentNameLink

An attribute of the `componentScopedRefs` element. When a web service is implemented by an Enterprise JavaBeans (EJB) implementation, each `<componentScopedRefs>` element contains assembly properties for an individual enterprise bean. The `componentNameLink` attribute of the `<componentScopedRefs>` element identifies the enterprise bean that the assembly properties apply to by specifying the `<ejb-name>`. This property is used only when the web service client is an enterprise bean.

serviceRefLink

An attribute of the serviceRefs element. Specifies the link to the <service-ref-name> in the <service-ref> element in the client deployment descriptor. The client deployment descriptor is either ejb-jar.xml, web.xml or application-client.xml.

deployedWSDLFile

An attribute of the serviceRefs element is optional. Permits an alternate Web Services Description Language (WSDL) file to use other than that specified in the <wsdl-file> element of the <service-ref> element in the client deployment descriptor. If an attribute is specified, the alternate WSDL file must be packaged in the same module and must be compatible with the development WSDL file. The deployedWSDLFile property supplies a new WSDL file containing a different endpoint web address than the original WSDL file.

defaultMappings

An element that identifies which port to use for a given portType when one is not selected by the client. This element has the following attributes: portTypeNamespace, portTypeLocalName, portNamespace, portLocalName. These attributes identify which wsdl:port is used for a wsdl:portType.

syncTimeout

An attribute of the portQnameBindings element. Specifies how long, in seconds, to wait for a response from a synchronous call. The default is 300 seconds.

basicAuth

An element of the portQnameBindings element. Authenticates a service client to the service endpoint, independent of the underlying transport that includes, HTTP, HTTPS, and Java Message Service (JMS). Set the user ID and password attributes as needed.

sslConfig

An element of the portQnameBindings element. Specifies the Secure Sockets Layer (SSL) configuration of an HTTPS outbound request. The name attribute is the name of an SSL configuration entry or alias that is defined in the SSL configuration repertoire. This attribute is used only when the client is running in the WebSphere Application Server.

overriddenEndpointURI

A property that specifies the final URL to which requests will be sent. When the client is run to invoke the web service, the request is sent to this property's URL, which takes precedence over the address given in the WSDL file and the client code. This property is the only property in the ibm-webservicesclient-bnd.xmi file which is applicable to JAX-WS services.

A bindings file example

The following example demonstrates the spelling and position of the various attributes. You cannot cut and paste these examples because they do not contain the required ID attributes. If you add elements to a binding file template generated by the **WSDL2Java** command, you must confirm that each element has an ID attribute whose value is a unique string. Review the template xmi files generated by the **WSDL2Java** command for examples of ID strings. Read about the **WSDL2Java** command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

```
<com.ibm.etools.webservice.wscbnd:ClientBinding xmi:version="2.0"
xmlns:xmi="http://www.omg.org/XMI" xmlns:com.ibm.etools.webservice.wscbnd=
"http://www.ibm.com/websphere/appserver/schemas/5.0.2/wscbnd.xmi">

  <componentScopedRefs componentNameLink="myComponent ref"/>

  <serviceRefs serviceRefLink="myService ref" deployedWSDLFile="META-INF/wsdl/alternate.wsdl">
    <defaultMappings portTypeLocalName="AddressBook" portTypeNamespace="http://www.com.ibm"
portLocalName="AddressBookPort" portNamespace="http://www.com.ibm"/>
    <portQnameBindings portQnameNamespaceLink="http://www.com.ibm"
portQnameLocalNameLink="AddressBookPort" syncTimeout="99">
      <basicAuth userid="myId" password="myPassword"/>
    </portQnameBindings>
  </serviceRefs>
</com.ibm.etools.webservice.wscbnd:ClientBinding>
```

```
<sslConfig name="mynode/DefaultSSLSettings"/>
</portQnameBindings>
</serviceRefs>
</com.ibm.etools.webservice.wscbnd:ClientBinding>
```

Implementing extensions to JAX-RPC web services clients

WebSphere Application Server provides extensions to web services clients using the Java API for XML-based RPC (JAX-RPC) programming model.

About this task

You can customize web services by using the following extensions to the JAX-RPC client programming model.

Procedure

- Set the **REQUEST_SOAP_HEADERS** and **RESPONSE_SOAP_HEADERS** properties in a JAX-RPC client Stub to enable a web services client to send or retrieve implicit SOAP headers.

An implicit SOAP header is a SOAP header that is not explicitly defined in the WSDL file. An implicit SOAP header file fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the WSDL file, but the message definition is not referenced by a portType within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

To learn how to modify your client code to send or retrieve transport headers, see the information on sending implicit SOAP headers with JAX-RPC or receiving implicit SOAP headers with JAX-RPC.

- Set the **REQUEST_TRANSPORT_PROPERTIES** and **RESPONSE_TRANSPORT_PROPERTIES** properties to enable a web services client to send or retrieve transport headers.

Set the properties on the Stub or Call object.

By modifying your client code to send or retrieve transport headers, you can send or receive specific information within the transport headers of outgoing requests or incoming responses from the server. For requests or responses that use the HTTP transport, the information is sent or retrieved in an HTTP header. Similarly, for a request or response that uses the Java Message Service (JMS) transport, the information is sent or retrieved in a JMS message property.

To learn how to modify your client code to send or retrieve transport headers, see the information on sending transport headers with JAX-RPC or retrieving transport headers with JAX-RPC.

To learn how to enable a Web services client to send or retrieve transport headers, see the transport header properties best practices information.

- Implement support for `javax.xml.rpc.ServiceFactory.loadService()` methods.

The `loadService` methods create an instance of the generated service implementation class in an implementation-specific manner. The `loadService` methods are new for JAX-RPC 1.1 and include three signatures:

- **public javax.xml.rpc.Service loadService (Class serviceInterface)**

As documented in the JAX-RPC specification, this method returns the generated service implementation for the service interface. See the web services specifications and API documentation to review the JAX-RPC specification.

- **public javax.xml.rpc.Service loadService (URL wsdlDocumentLocation, Class serviceInterface, Properties properties)**

This method behaves like the `loadService (Class serviceInterface)` because the following parameters are ignored:

- `wsdlDocumentLocation`
- `properties`

- **public.javax.xml.rpc.Service loadService (URL wsdlDocumentLocation, QName serviceName, Properties properties)**

This method returns the generated service implementation for the specified service by using optional namespace-to-package mapping information.

- wsdlDocumentLocation - ignored
- serviceName - QName (namespace, localpart) of the service
- properties - If this parameter is non-null, it contains namespace-to-package mapping entries. Each Property entry key is a String corresponding to the namespace. Each Property entry value is a String corresponding to the Java package name.

If the properties argument contains an entry with a key (namespace) that matches the namespace portion of the QName serviceName argument, the entry value (javaPackage) is used as the package name when trying to locate the service implementation.

For more information on these methods, see the JAX-RPC specification.

- Implement the CustomBinder interface to provide concrete custom data binders for a specific XML schema type (**JAX-RPC applications only**).

Custom data binders are used to map XML schema types with Java objects. Custom data binders provide bindings for XML schema types that are not supported by the current Java API for XML-based Remote Call Procedure (JAX-RPC) specification. WebSphere Application Server provides an extension to the Web Services for Java Platform, Enterprise Edition (Java EE) programming model called the CustomBinder interface that implements these custom bindings for a specific XML schema type. The CustomBinder interface has three properties, in addition to deserialize and serialize methods:

- QName for the XML schema type
- QName scope
- Java type

The custom data binder defines serialize and deserialize methods to convert between a Java object and a SOAPElement interface. A custom data binder is added to the runtime system and interacts with the web services runtime using a SOAPElement. They are added to the runtime by using custom binding providers. Read about the custom data binders and the custom binding provider to learn more. See the CustomBinder interface documentation to learn more about how you can implement this interface to provide concrete custom data binders for a specific XML schema type.

Custom data binders for JAX-RPC applications

A *custom data binder* is used to map XML schema types with Java objects. Custom data binders provide bindings for XML schema types that are not supported by the current Java API for XML-based Remote Call Procedure (JAX-RPC) specification.

The custom data binder defines serialize and deserialize methods to convert between a Java object and a SOAPElement interface. A custom data binder is added to the runtime system and interacts with the web services run time using a SOAPElement. Unlike conventional deserializers, custom data binders do not rely on the low-level parsing events from the run time to build the Java object, such as Simple API for XML (SAX). Instead, the run time builds the custom data binder by rendering the incoming SOAP message into a SOAPElement. The SOAPElement that contains the message is passed to the customer data binder. For example, if the incoming message contains a Service Data Object (SDO) datagraph, the runtime system processes as follows:

1. The runtime system recognizes the `<sdo:Datagraph>` code.
2. The run time queries the type mapping system to locate the custom data binder for the datagraph data, for example `SDOCustomBinder`.
3. A SOAPElement is created that represents the incoming SDO datagraph.
4. The run time passes the SOAPElement to the `SDOCustomBinder`.

Within the deserialized method, the `SDOCustomBinder` extracts the content from the SOAPElement and builds a concrete `DataGraph` object with a `commonj.sdo.DataGraph` type.

When a Java object is serialized, a similar process occurs. The run time locates a custom data binder and converts the Java object to a SOAPElement. The runtime serializes the SOAPElement to the raw message that is transported in the output stream.

The following is an example of an XML schema that is defined by the SDO specification:

```

<xsd:schema
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:sdo="commonj.sdo"
  targetNamespace="commonj.sdo">

  <xsd:element name="datagraph" type="sdo:DataGraphType"/>

  <xsd:complexType name="DataGraphType">
    <xsd:complexContent>
      <xsd:extension base="sdo:BaseDataGraphType">
        <xsd:sequence>
          <xsd:any minOccurs="0" maxOccurs="1"
            namespace="##other" processContents="lax"/>
        </xsd:sequence>
      </xsd:extension>
    </xsd:complexContent>
  </xsd:complexType>

  <xsd:complexType name="BaseDataGraphType" abstract="true">
    <xsd:sequence>
      <xsd:element name="models" type="sdo:ModelsType" minOccurs="0"/>
      <xsd:element name="xsd" type="sdo:XSDType" minOccurs="0"/>
      <xsd:element name="changeSummary"
        type="sdo:ChangeSummaryType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>

  <xsd:complexType name="ModelsType">
    <xsd:sequence>
      <xsd:any minOccurs="0" maxOccurs="unbounded"
        namespace="##other" processContents="lax"/>
    </xsd:sequence>
  </xsd:complexType>

  <xsd:complexType name="XSDType">
    <xsd:sequence>
      <xsd:any minOccurs="0" maxOccurs="unbounded"
        namespace="http://www.w3.org/2001/XMLSchema" processContents="lax"/>
    </xsd:sequence>
  </xsd:complexType>

```

```

<xsd:complexType name="ChangeSummaryType">
<xsd:sequence>
  <xsd:any minOccurs="0" maxOccurs="unbounded"
    namespace="##any" processContents="lax"/>
</xsd:sequence>
<xsd:attribute name="create" type="xsd:string"/>
<xsd:attribute name="delete" type="xsd:string"/>
</xsd:complexType>
</xsd:schema>

```

WebSphere Application Server defines the CustomBinder interface that implements concrete custom bindings for a specific XML schema type.

The custom binding provider is used to import the custom bindings into the run time. To learn how to plug your custom data binders into the **WSDL2Java** command-line tool for development, read about custom binding providers. You can also read about usage patterns for deploying custom data binders to learn more about how to deploy the provider package to your runtime, as well as the roles involved in the custom binding process.

Custom binding providers for JAX-RPC applications

A *custom binding provider* is the packaging of custom data binder classes with a declarative metadata file. The main purpose of a custom binding provider is to aggregate related custom data binders to support particular user scenarios. The custom binding provider is used to plug the custom data binders into the emitter tools and the run time system so that the emitter tools can generate the appropriate artifacts and the run time system can augment its existing type mapping system to reflect the applied custom data binders and invoke them.

A custom binding provider works with a specific XML schema type, while applications involve a few related XML schema types. You need a mechanism to aggregate and declare various custom data binders to provide a complete binding solution. The concept of the custom binding provider defines a declarative model that can be used to plug in a set of custom data binders to either emitter tools or the run time system.

See the custom data binders information and the information on the CustomBinder interface to learn more about custom data binders and the CustomBinder API included in WebSphere Application Server to define the custom data binders. After you have defined the custom data binders, you are ready to deploy the custom binder package. To learn how to deploy this package, see the information on usage patterns for deploying custom data binders for JAX-RPC applications.

The declarative metadata file, CustomBindingProvider.xml, is an XML file that is packaged with the custom provider classes in a single Java archive (JAR) file and located in the /META-INF/services/directory. Once a provider JAR file is packaged, the binary information and the metadata file located in the JAR file can be used by the **WSDL2Java** command-line tool and the run time system.

The following example is the XML schema for the CustomBindingProvider.xml file. The top-level type is the providerType that contains a list of mapping elements. Each mapping element defines the associated custom data binder and properties, including xmlQName, javaName and qnameScope. You can read more about these properties in the information for CustomBinder interface for JAX-RPC applications. The providerType also has an attribute called scope that has a value of *server*, *application* or *module*. The scope attribute is used by the server deployment to resolve the conflict and to realize a custom binding hierarchy.

```

<?xml version="1.0" encoding="UTF-8"?>
<xsd:schema
  targetNamespace=
    "http://www.ibm.com/webservices/customdatabinding/2004/06"
  xmlns:customdatabinding=
    "http://www.ibm.com/webservices/customdatabinding/2004/06"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  elementFormDefault="qualified" attributeFormDefault="qualified">

```

```

<xsd:element name="provider" type="customdatabinding:providerType"/>

<xsd:complexType name="providerType">
  <xsd:sequence>
    <xsd:element name="description" type="xsd:string" minOccurs="0"/>
    <xsd:element name="mapping" minOccurs="0" maxOccurs="unbounded">
      <xsd:complexType>
        <xsd:sequence>
          <xsd:element name="description" type="xsd:string" minOccurs="0"/>
          <xsd:element name="xmlQName" type="xsd:QName"/>
          <xsd:element name="javaName" type="xsd:string"/>
          <xsd:element name="qnameScope"
            type="customdatabinding:qnameScopeType"/>
          <xsd:element name="binder" type="xsd:string"/>
        </xsd:sequence>
      </xsd:complexType>
    </xsd:element>
    <xsd:attribute name="scope"
      type="customdatabinding:ProviderScopeType" default="module"/>
  </xsd:sequence>
</xsd:complexType>

<xsd:simpleType name="qnameScopeType">
  <xsd:restriction base="xsd:string">
    <xsd:enumeration value="simpleType"/>
    <xsd:enumeration value="complexType"/>
    <xsd:enumeration value="element"/>
  </xsd:restriction>
</xsd:simpleType>

<xsd:simpleType name="ProviderScopeType">
  <xsd:restriction base="xsd:string">
    <xsd:enumeration value="server"/>
    <xsd:enumeration value="application"/>
    <xsd:enumeration value="module"/>
  </xsd:restriction>
</xsd:simpleType>
</xsd:schema>

```

The following is an example of the CustomBindingProvider.xml file for the SDO DataGraph schema that was introduced in CustomBinder interface. The example displays the mapping between a schema type, DataGraphType, and a Java type, commonj.sdo.DataGraph. The binder that represents this mapping is called test.sdo.SDODataGraphBinder.

```

<cdb:provider
  xmlns:cdb="http://www.ibm.com/webservices/customdatabinding/2004/06"
  xmlns:sdo="commonj.sdo">
  <cdb:mapping>
    <cdb:xmlQName>sdo:DataGraphType</cdb:xmlQName>
    <cdb:javaName>commonj.sdo.DataGraph</cdb:javaName>
    <cdb:qnameScope>complexType</cdb:qnameScope>
    <cdb:binder>test.sdo.SDODataGraphBinder</cdb:binder>
  </cdb:mapping>
</cdb:provider>

```

You need to import your custom data binders into the **WSDL2Java** command-line tool for development purposes. The custom data binders affect how the development artifacts, including the Service Endpoint Interface and the JSR 109 mapping data, are generated from the Web Services Description Language (WSDL) file. The **WSDL2Java** command-line tool ships with WebSphere Application Server and uses the custom binder Java archive file, or custom binder package, to generate these the development artifacts.

The following example is a WSDL file that references the SDO DataGraph schema that is introduced in the CustomBinder interface topic.

```

<?xml version="1.0" encoding="UTF-8"?>
<wsdl:definitions targetNamespace="http://sdo.test"
  xmlns:impl="http://sdo.test"
  xmlns:intf="http://sdo.test"
  xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
  xmlns:wsdlsoap="http://schemas.xmlsoap.org/wsdl/soap/"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:sdo="commonj.sdo">

```

```

<wsdl:types>
  <schema elementFormDefault="qualified" targetNamespace="http://sdo.test"
    xmlns="http://www.w3.org/2001/XMLSchema" xmlns:sdo="commonj.sdo">
    <import namespace="commonj.sdo" schemaLocation="sdo.xsd"/>
  </schema>
</wsdl:types>

<wsdl:message name="echoResponse">
  <wsdl:part element="sdo:datagraph" name="return"/>
</wsdl:message>

<wsdl:message name="echoRequest">
  <wsdl:part element="sdo:datagraph" name="parameter"/>
</wsdl:message>

<wsdl:portType name="EchoService">
  <wsdl:operation name="echo">
    <wsdl:input message="impl:echoRequest" name="echoRequest"/>
    <wsdl:output message="impl:echoResponse" name="echoResponse"/>
  </wsdl:operation>
</wsdl:portType>

<wsdl:binding name="EchoServiceSoapBinding" type="impl:EchoService">
  <wsdl:soap:binding style="document"
    transport="http://schemas.xmlsoap.org/soap/http"/>
  <wsdl:operation name="echo">
    <wsdl:soap:operation soapAction=""/>
    <wsdl:input name="echoRequest">
      <wsdl:soap:body use="literal"/>
    </wsdl:input>

    <wsdl:output name="echoResponse">
      <wsdl:soap:body use="literal"/>
    </wsdl:output>
  </wsdl:operation>
</wsdl:binding>

<wsdl:service name="EchoServiceService">
  <wsdl:port binding="impl:EchoServiceSoapBinding" name="EchoService">
    <wsdl:soap:address location="http://<uri>"/>
  </wsdl:port>
</wsdl:service>

</wsdl:definitions>

```

If you run the **WSDL2Java** command without the custom data binding package, the following Service Endpoint Interface is generated with a parameter type, as dictated by the JAX-RPC specification:

```

public interface EchoService extends java.rmi.Remote {
  public javax.xml.soap.SOAPElement
  echo(javax.xml.soap.SOAPElement parameter)
  throws java.rmi.RemoteException;
}

```

When you run the **WSDL2Java** command with the custom data binding package, the custom data binders are used to generate the parameter types. To apply the custom data binders, use the `-classpath` option on the **WSDL2Java** tool. The tool searches its classpath to locate all the files with the same file path of `/META-INF/services/CustomBindingProvider.xml`. The following is an example how you can use the command to generate a Service Endpoint Interface with the parameter type of `commonj.sdo.DataGraph`:

```
WSDL2Java -role develop-server -container web classpath sdobinder.jar echo.wsdl
```

The Service Endpoint Interface that is generated looks like the following:

```

public interface EchoService extends java.rmi.Remote {
  public commonj.sdo.DataGraph
  echo(commonj.sdo.DataGraph parameter)
  throws java.rmi.RemoteException;
}

```

The custom binder packaged JAR file has to be made available at runtime to make sure the web service client is invoked, regardless if it is a stub-based client or a Dynamic Invocation Interface (DII) client. The same applies to the service.

CustomBinder interface for JAX-RPC applications

WebSphere Application Server defines a CustomBinder interface that you can implement for Java API for XML-based Remote Call Procedure (JAX-RPC) applications to provide concrete custom data binders for a specific XML schema type.

The CustomBinder interface has three properties, in addition to deserialize and serialize methods. These properties are QName for the XML schema type, the QName scope, and the Java type that the schema type maps to. The properties are accessible through the corresponding getter methods.

getQName

The getQName method returns the QName of the target XML schema type. Custom data binders only work with the root level schema type.

For anonymous types, the getQName method returns the QName of the containing element.

For named types, the getQName method returns the QName of the complexType or the simpleType.

getQNameScope

The getQNameScope method returns the binder qnameScope property that indicates whether the schema type is a named type or an anonymous type. The qnameScope property value can be *complexType* for an <xsd:complexType>, *simpleType* for an <xsd:simpleType> or *element* for an <xsd:element> that is defined with an anonymous type.

In the following schema, data1 is an element that is defined with an anonymous type. The element, data2, is defined using the named type, data2Type.

```
<xsd:element name="data1">
  <xsd:complexType>
    ...
  </xsd:complexType>
</xsd:element>

<xsd:element name="data2" type="data2Type"/>
<xsd:complexType name="data2Type">
  ...
</xsd:complexType>
```

The anonymous type, data1, has a qNameScope of element and a qName of data1. The type, data2Type, has a qNameScope of complexType and a qName of data2Type.

The element, data2, is not represented in the custom data binder. The custom data binder only processes types and not elements.

getJavaName

The getJavaName method returns the fully-qualified class name for the Java type that is mapped to the named or anonymous type. The class can be an interface or a concrete class. The object returned from the deserialize method has a type that is compatible with the Java type that is returned by the getJavaName method.

serialize

The serialize method returns the SOAPElement that the custom data binder builds from the Java object. The Java object is passed from the run time system and is expected to match what is returned from the getJavaName method. The SOAPElement parameter does not have child elements, but it does have a valid QName. This parameter is a reference for the binder to create the final SOAPElement.

In most cases, the binder implementation appends the child elements to the root SOAPElement. The run time system guarantees that the SOAPElement QName is correct. Therefore, the custom data binder for named types keeps the QName of the root element because the binder does not know the enclosing element. The binder implementation for an anonymous type should always include the QName in the returned SOAPElement that matches the defined schema type. WebSphere Application Server does not have concrete methods in the CustomBindingContext parameter.

deserialize

The deserialize method returns a Java object that the custom data binder builds from the passed root SOAPElement. The object type of the returned Java object must match what is returned from the getJavaName method. Unlike the parameter serialize method, the passed SOAPElement contains the original XML data with the necessary namespace declarations.

The following is an example of an implementation of the SDO DataGraph binder, where the convertToSDO and convertToSAAJ utility methods convert between SOAPElement and an SDO object.

```
package test.sdo.binder;

import javax.xml.namespace.QName;
import javax.xml.soap.SOAPElement;

import com.ibm.wsspi.webservices.binding.CustomBinder;
import com.ibm.wsspi.webservices.binding.CustomBindingContext;

public class DataGraphBinder implements CustomBinder {
    public QName getQName() {
        return new QName("commonj.sdo", "DataGraphyType");
    }
    public String getJavaName() {
        return CustomBinder.QNAME_SCOPE_COMPLEXTYPE;
    }
    public String getJavaName() {
        return commonj.sdo.DataGraph.class.getName();
    }
    public javax.xml.soap.SOAPElement serialize(
        Object bean,
        SOAPElement rootNode,
        CustomBindingContext context)
        throws javax.xml.soap.SOAPException {
        // convertToSAAJ is a utility method to convert
        // the SDO DataGraph to the SOAPElement
        return convertToSAAJ(bean, rootNode);
    }

    public Object deserialize(
        SOAPElement source,
        CustomBindingContext context)
        throws javax.xml.soap.SOAPException {
        // convertToSDO is a utility method to convert
        // the SOAPElement to the SDO DataGraph
        return convertToSDO(source);
    }
}
```

To learn more about custom data binders, see the custom data binders for JAX-RPC applications information. To learn how to plug your custom data binders into the **WSDL2Java** command-line tool for development, see the custom binding providers for JAX-RPC applications information.

Usage patterns for deploying custom data binders for JAX-RPC applications

Custom data binders are used to map XML schema types with Java objects. Custom data binders provide bindings for XML schema types that are not supported by the current Java API for XML-based Remote Call Procedure (JAX-RPC) specification. WebSphere Application Server provides an extension to the Web Services for Java Platform, Enterprise Edition (Java EE) programming model called the CustomBinder interface that implements these custom bindings for a specific XML schema type. The custom binding provider is the package for the custom data binders that is imported into the runtime.

To learn more about the CustomBinder API, see the CustomBinder interface for JAX-RPC applications information. For general information about custom binders, see the custom data binders for JAX-RPC applications information. See the custom binding providers for JAX-RPC applications information to review how custom binding providers are packaged for development.

This usage pattern reviews how to deploy the provider package to your runtime, as well as the roles involved in the custom binding process.

Roles involved in custom data binding

Four roles are involved with custom data binding. These roles that are defined by the Web Services for Java Platform, Enterprise Edition (Java EE) specification are as follows:

- **Custom binding provider** is responsible for implementing the required custom data binders, declaring these binders in a `CustomBindingProvider.xml` file and packaging the binding classes into a Java archive (JAR) file.
- **Application developer** is responsible for applying the custom binding provider JAR file and generating the development artifacts.
- **Application assembler** needs to understand the application requirements in terms of the custom data binding and decides how to package the custom provider JAR file as a part of the application.
- **Application deployer** configures the shared libraries to make custom data binding support available to the applications. This needs to be done if the custom provider JAR file is not packaged with the application. If the application is not deployed, the deployer has to run the web services deployment tools after the application is installed.

Common usage patterns

The custom binder provider package can be deployed in various ways to provide flexibility beyond the standard JAX-RPC mapping standards. Three primary deployment usage patterns are as follows:

- **Deploy the custom data binders at the server level**

This pattern ensures that all the applications that are running on the server are affected by the custom data binders and is useful if fundamental XML types are introduced but are not supported by the standard JAX-RPC mapping rules.

This type of situation occurs frequently for new web services specifications that define new schema types. For example, the WS-Addressing specification defines an `EndpointReferenceType` schema type that is not supported by the JAX-RPC mapping rules. Because this pattern requires augmenting the server classpath, it has a significant impact on the server runtime and affects the installed applications. This pattern is most suitable for WebSphere Application Server internal components.

- **Deploy the custom binders for one or more application**

Use this pattern if you only want specified applications to be affected by the custom data binders and if relevant XML schema types apply to a set of applications. You can share the custom data binders within a set of applications while achieving isolation between different sets of applications.

- **Deploy the custom binders for a specific web module within an application**

Using this pattern ensures that a specific Web module is affected by the deployed custom data binders. This pattern is useful when fine granularity for custom binding is required. You cannot use this pattern with EJB modules because the module and its referenced library belong to the entire application.

Usage patterns

This section reviews deploying custom data binders using one of the three patterns:

- **Server level deployment**

If you deploy the custom data binders at the server level, you need to set the scope attribute of the declared binding provider as `server`. Setting the value to `server` guarantees a higher priority for declared binders if there are conflicts between the server and applications. The custom binding provider JAR file

needs to be in the appropriate place to be picked up by the server runtime. Configure the server path and make the custom binding provider JAR file a part of the server classpath. To learn about values used in configuring the server classpath, see the Java virtual machine settings information.

- **Deploying custom data binders for one or more applications**

To deploy custom data binders for one or more applications, set the scope attribute of the declared custom binding provider as *application*. Setting the value to application guarantees higher priority binders in case of conflicts between the application and the module. If the custom data binders are used by more than one application, configure a shared library for the applications to reference. To learn about values used in configuring the shared libraries path, see the managing shared libraries information.

- **Deploy the custom data binders for a specific web module within an application**

To deploy custom data binders for a specific web module within an application, set the scope attribute of the declared custom binding provider to the value *module*. The only way to apply the custom data binder for this pattern is to pre-package the custom binding provider JAR file with the web module, for example, place the JAR file in the `/WEB-INF/lib` directory.

Sending implicit SOAP headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to send values in implicit SOAP headers. By modifying your client code to send implicit SOAP headers, you can send specific information within an outgoing web service request.

Before you begin

To complete this task, you need a web services client that you can enable to send implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a portType element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

You cannot manipulate protected SOAP headers. A SOAP header that is declared protected by its owning component, for example, Web Services Security, is not accessible to client applications. An exception occurs if you try to manipulate protected SOAP headers.

About this task

The client application sets properties on the Stub or Call object to send and receive implicit SOAP headers.

Procedure

1. Create a `java.util.HashMap` object.
2. Add an entry to the `HashMap` object for each implicit SOAP header that the client wants to send. The `HashMap` entry key is the `QName` of the SOAP header. The `HashMap` entry value is either an `SAAJ SOAPElement` object or a `String` that contains the XML text of the entire SOAP header element.
3. Set the `HashMap` object as a property on the Stub or Call object. The property name is `com.ibm.websphere.webservices.Constants.REQUEST_SOAP_HEADERS`. The value of the property is the `HashMap`.
4. Issue the remote method calls using the Stub or Call object. The headers within the `HashMap` object are sent in the outgoing message.

A `JAXRPCException` error can occur if any of the following are true:

- The HashMap object contains a key that is not a QName object or if the HashMap object contains a value that is not a String or a SOAPElement object.
- The HashMap object contains a key that represents a SOAP header that is declared protected by the owning component.

Results

You have a JAX-RPC web services client that is configured to send implicit SOAP headers.

Example

The following programming example illustrates how to send two request SOAP headers and receive one response SOAP header within a web services request and response:

```

1 //Create the request and response hashmaps.
2 HashMap requestHeaders=new HashMap();
3 HashMap responseHeaders=new HashMap();
4
5 //Add "AtmUuid1" and "AtmUuid2" to the request hashmap.
6 requestHeaders.put(new QName("com.rotbank.security", "AtmUuid1"),
7 "<AtmUuid1 xmlns=\><uuid>ROTB-0A01254385FCA09</uuid></AtmUuid1>");
8 requestHeaders.put(new QName("com.rotbank.security", "AtmUuid2"),
9 ((IBMSOAPFactory)SOAPFactory.newInstance()).createElementFromXMLString(
10 "x:AtmUuid2 xmlns:x=\"com.rotbank.security\"><x:uuid>ROTB-0A01254385FCA09
   </x:uuid><x:AtmUuid2>");
11
12 //Add "ServerUuid" to the response hashmap.
13 //If "responseHeaders" is empty, all the SOAP headers are
14 //extracted from the response message.
15 responseHeaders.put(new QName("com.rotbank.security","ServerUuid"), null);
16
17 //Set the properties on the Stub object.
18 stub.setProperty(Constants.REQUEST_SOAP_HEADERS,requestHeaders);
19 stub.setProperty(Constants.RESPONSE_SOAP_HEADERS,responseHeaders);
20
21 //Call the operation on the Stub.
22 stub.foo(parm2, parm2);
23
24 //Retrieve "ServerUuid" from the response hashmap.
25 SOAPElement serverUuid =
26 (SOAPElement) responseHeaders.get(new QName("com.rotbank.security","ServerUuid"));
27
28 //Note: "serverUuid" now equals a SOAPElement object that represents the
29 //following code:
30/<y:ServerUuid xmlns:y=\"com.rotbank.security\"><y:uuid>ROTB-0A03519322FSA01
   </y:uuid></y:ServerUuid.>");

```

On lines 2-3, new HashMaps are created that are used for the request and response SOAP headers.

On lines 6-10, the AtmUuid1 and AtmUuid2 headers elements are added to the request HashMap.

On line 15, the ServerUuid header element name, along with a null value, is added to the response HashMap.

On line 18, the request HashMap is set as a property on the Stub object. This causes the AtmUuid1 and AtmUuid2 headers to be added to each request message that is associated with an operation that is invoked on the Stub object.

On line 19, the response HashMap is set as a property on the Stub object. This causes the ServerUuid header to be extracted from each response message that is associated with an operation that is invoked on the Stub object.

On line 22, the web service operation is invoked on the Stub object.

On lines 25-26, the ServerUuid header is retrieved from the response HashMap. The header was extracted from the response message and inserted into the HashMap by the web services engine.

Receiving implicit SOAP headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to receive values from implicit SOAP headers. By modifying your client code to receive implicit SOAP headers, you can receive specific information within an incoming web service response.

Before you begin

To complete this task, you need a web services client that you can enable to receive implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a portType element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

You cannot manipulate protected SOAP headers. A SOAP header that is declared protected by its owning component, for example, Web Services Security, is not accessible to client applications. An exception occurs if you try to manipulate protected SOAP headers.

About this task

The client application sets properties on the Stub or Call object to send and receive implicit SOAP headers.

Procedure

1. Create a `java.util.HashMap` object
2. Add an entry to the HashMap object for each implicit SOAP header that the client wants to receive. The HashMap entry key is the QName of the SOAP header. The HashMap entry value is `null`.
3. Set the HashMap entry on the Stub or Call object. The property name is `com.ibm.websphere.webservices.Constants.RESPONSE_SOAP_HEADERS`. The value of the property is the HashMap.
4. Issue remote method calls against the Stub or Call object. The web services engine extracts the specified response headers from the web services response message and inserts them into the HashMap. After the remote method returns, the response headers are accessible from the HashMap object.

A `JAXRPCException` error can occur if any of the following are true:

- The HashMap contains a key that is not a QName.
- The HashMap contains a key that represents a SOAP header that is declared protected by the owning component.

Results

You have a JAX-RPC web services client that can receive values from implicit SOAP headers.

Sending transport headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to send application-defined information along with your Web services requests by using transport headers.

Before you begin

You need a JAX-RPC web services client that you can enable to send transport headers.

Sending transport headers is supported only by web services clients, and only supported for the HTTP and JMS transports. The web services client must call the JAX-RPC APIs directly and not through any intermediary layers, such as a gateway function. Sending and retrieving transport headers on the web services server is done through non-web services APIs.

About this task

When using the JAX-RPC programming model, the client must set a property on the Stub or Call object to send values in transport headers. After you set the property, the values are set in all the requests for subsequent remote method invocations against that Stub or Call object until the associated property is set to null or the Stub or Call object is discarded.

To send values in the transport headers on outbound requests, modify the client code as follows:

Procedure

1. Create a `java.util.HashMap` object that contains the transport header identifiers.
2. Add an entry to the `HashMap` object for each transport header that you want the client to send.
 - a. Set the `HashMap` entry key to a string that exactly matches the transport header identifier. You can define the header identifier with a reserved header name, such as `Cookie` in the case of HTTP, or the header identifier can be user defined, such as `MyTransportHeader`. Certain header identifiers are processed in a unique manner, but no other checks are made as to the header identifier value. To learn more about the HTTP header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as `HTTP_HEADER_SET_COOKIE` in the `com.ibm.websphere.webservices.Constants` class.
 - b. Set the `HashMap` entry value to a string that contains the value of the transport header.
3. Set the `HashMap` entry on the Stub or Call object using the `com.ibm.websphere.webservices.Constants.REQUEST_TRANSPORT_PROPERTIES` property. When the `REQUEST_TRANSPORT_PROPERTIES` property value is set, that `HashMap` is used on subsequent invocations to set the header values in the outgoing requests. If the `REQUEST_TRANSPORT_PROPERTIES` property value is set to null, no `HashMap` is used on subsequent invocations to set header values in outgoing requests. To learn more about these properties, see the transport header properties documentation.
4. Issue remote method calls against the Stub or Call object. The headers and the associated values from the `HashMap` are added to the outgoing request for each method invocation. If the invocation uses HTTP, then the transport headers are sent as HTTP headers within the HTTP request. If the invocation uses JMS, then the transport headers are sent as JMS message properties.

If the property is not set correctly, you might experience API usage errors that result in a `JAXRPCException` error. The following requirements must be met, or the process fails:

 - The property value that is set on the Stub or Call object must be a `HashMap` object or null.
 - The `HashMap` must not be empty.
 - Each key in the `HashMap` must be a `String` object.
 - Each value in the `HashMap` must be a `String` object.

Results

You have a JAX-RPC web services client that is configured to send transport headers.

Retrieving transport headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to retrieve values from transport headers. For a request that uses HTTP, the transport headers are retrieved from HTTP headers found in the HTTP response message. For a request that uses Java Message Service (JMS), the transport headers are retrieved from the JMS message properties found on the JMS response message.

Before you begin

You need a web services client that you can enable to retrieve transport headers.

Retrieving transport headers is supported only by web services clients, and only supported for the HTTP and JMS transports. The web services client must call the JAX-RPC APIs directly and not through any intermediary layers, such as a gateway function. Sending and retrieving transport headers on the web services server is done through non-web services APIs.

About this task

When using the JAX-RPC programming model, the client must set a property on the Stub or Call object in order to retrieve values from the transport headers. After you set the property, values are read from responses for the subsequent method invocations against that Stub or Call instance until the associated property is set to null or the Stub or Call object is discarded.

To retrieve values from the transport headers on inbound responses, modify the client code.

Procedure

1. Create a `java.util.HashMap` object that contains the names of the transport headers to be retrieved from incoming response messages.
2. Add an entry to the `HashMap` for each header that you want to retrieve a value from every incoming response message.
 - a. Set the `HashMap` entry key to a string that exactly matches the transport header identifier. You can define the header identifier with a reserved header name, such as `Cookie` in the case of HTTP, or the header identifier can be user-defined, such as `MyTransportHeader`. Certain header identifiers are processed in a unique manner, but no other checks are made to confirm the header identifier value. To learn more about the HTTP header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as `HTTP_HEADER_SET_COOKIE` in the `com.ibm.websphere.webservices.Constants` class. The `HashMap` entry value is ignored and does not need to be set. An empty `HashMap`, for example, one that is non-null, but does not contain any keys, causes all the transport headers in the response to be retrieved.
3. Set the `HashMap` entry on the Stub or Call object using the `com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES` property. When the `HashMap` is set, the `RESPONSE_TRANSPORT_PROPERTIES` property is used in subsequent invocations to retrieve the headers from the responses. If you set the property to null, no headers are retrieved from the response. To learn more about these properties, see the transport header properties documentation.
4. Issue remote method calls against the Stub or Call object. The values from the specified transport headers are retrieved from the response message and placed in the `HashMap`.

If the property is not set correctly, you might experience API usage errors that result in a `JAXRPCException` error. The following requirements must be met, or the process fails:

- The property value that is set on the Stub or Call object must be either null or an instance of a `HashMap`.
- All the `HashMap` keys must be a string data type, and the keys must not be null.

Results

You have a JAX-RPC web service that can receive transport headers from incoming response messages.

Assembling web services applications

Assembling web services applications

You can assemble Java-based web services applications using assembly tools.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with the application server.

About this task

After you develop your web service application, you are now ready to assemble the application. Assembling a web service application consists of creating the Java Platform, Enterprise Edition (Java EE) modules that you can deploy onto application servers. The modules are created from code artifacts such as web application archives (WAR) files for JavaBeans applications or enterprise beans Java archive (JAR) files for enterprise beans applications. This packaging and configuring of code artifacts into enterprise application modules (EAR files) or standalone web modules is necessary for deploying the modules onto an application server.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. Assemble your web services enabled bean into the appropriate module.
 - For JavaBeans enabled as web services:
 - a. “Assembling a WAR file that is enabled for web services from Java code” on page 1086.
 - b. “Assembling a web services-enabled WAR file from a WSDL file” on page 1087.
 - For enterprise beans enabled as web services:
 - a. “Assembling a JAR file that is enabled for web services from an enterprise bean” on page 1084.
 - b. “Assembling a web services-enabled enterprise bean JAR file from a WSDL file” on page 1085.

Note: This product supports packaging enterprise beans in WAR files. If you include a web services-enabled enterprise bean JAR file into a WAR file, you must merge any information in the webservices.xml deployment descriptor files that are in the JAR files into the webservices.xml deployment descriptor in the WEB-INF directory of the WAR file. To learn more, see the EJB content in WAR modules information.

Note: When developing faults for a JAX-WS application, it is a best practice to always include the fault bean that is generated by the JAX-WS tooling in the packaging of your JAX-WS application. However if your application does not use the fault bean classes that are generated by the JAX-WS tooling (that is, you use a bottom-up development approach starting from Java and you choose not to package the fault bean classes), the application server runtime environment dynamically generates the fault beans. Even so, it is a best practice to always package the fault bean.

3. Assemble the web services enabled module into an enterprise archive (EAR) file.
 - “Assembling a web services-enabled WAR into an EAR file” on page 1089.
 - “Assembling an enterprise bean JAR file into an EAR file” on page 1088.

4. Enable the EAR file for EJB modules that contain web services. When the EAR file contains Enterprise JavaBeans (EJB) modules that contain web services, you must run the **endptEnabler** command-line tool or an assembly tool before deployment to produce a web services endpoint WAR file. This tool is also used to specify whether the web services are exposed using SOAP over Java Message Service (JMS) or SOAP over HTTP.
5. Assemble a web services-enabled WAR file into an EAR file.

Results

You have a web services-enabled EAR file that you can deploy onto the application server.

What to do next

Now you need to deploy the web services-enabled EAR file onto your application server. To learn more, read about deploying web services applications onto application servers

Assembling a JAR file that is enabled for web services from an enterprise bean

You can assemble a web service-enabled enterprise bean Java archive (JAR) file with an assembly tool using artifacts generated from tooling.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

You need the following artifacts that are generated from the **WSDL2Java** command-line tool to complete this task:

- An assembled enterprise bean JAR file that is not enabled for web services
- A compiled Java class for the service endpoint interface
- A Web Services Description Language (WSDL) file
- The complete `webservices.xml`, `ibm-webservices-bnd.xmi`, and `ibm-webservices-ext.xmi` deployment descriptor, and Java API for XML-based remote procedure call (JAX-RPC) mapping file.

About this task

Assemble a web services-enabled enterprise bean JAR file from Java code by following the actions in the steps for this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.

Results

You have the artifacts required to web service-enable an Enterprise JavaBeans (EJB) module for web services. The artifacts are added to the JAR file. Now you need to configure the deployment descriptors so that you can deploy the web service into the application server run time environment.

Example

The AddressBook.jar JAR file contains the following files after assembly. The files added in this task are in bold. These files include the WSDL file, the deployment descriptors, and the JAX-RPC mapping file.

```
META-INF/MANIFEST.MF
META-INF/ejb-jar.xml
addr/Address.class
addr/AddressBook_RI.class
addr/AddressBookBean.class
addr/AddressBookHome.class
addr/Phone.class
addr/StateType.class
addr/AddressBook.class
META-INF/wsdl/AddressBook.wsdl
META-INF/ibm-webservices-bnd.xmi
META-INF/ibm-webservices-ext.xmi
META-INF/webservices.xml
META-INF/AddressBook_mapping.xml
```

What to do next

Assemble the EAR file so that you can deploy the EAR file into WebSphere Application Server.

Assembling a web services-enabled enterprise bean JAR file from a WSDL file

You can assemble a web services-enabled enterprise bean Java archive (JAR) file from a Web Services Description Language (WSDL) file with an assembly tool.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

You need the following artifacts to complete this task:

- An assembled enterprise bean JAR file that contains the Enterprise JavaBeans (EJB) implementation and all classes that generate from the **WSDL2Java** command-line tool when the role argument is develop-server and the container argument is EJB.
- A WSDL file
- The complete webservices.xml, ibm-webservices-bnd.xmi and ibm-webservices-ext.xmi deployment descriptors, and the Java API for XML-based remote procedure call (JAX-RPC) mapping file.

About this task

Assemble a web services-enabled enterprise bean JAR file from a WSDL file by following the actions in the steps for this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.

Results

You have the artifacts required to web service-enable an EJB module for web services. The artifacts are added to the JAR file. Now you need to configure the deployment descriptors so that you can deploy the web service into the application server runtime environment.

Example

The `AddressBook.jar` JAR file contains the following files after assembly. The files added in this task are in bold. These files include the WSDL file, the deployment descriptors, and the JAX-RPC mapping file.

```
META-INF/MANIFEST.MF
META-INF/ejb-jar.xml
addr/Address.class
addr/AddressBook_RI.class
addr/AddressBookSoapBindingImpl.class
addr/AddressBookHome.class
addr/Phone.class
addr/StateType.class
addr/AddressBook.class
META-INF/wsdl/AddressBook.wsdl
META-INF/ibm-webservices-bnd.xmi
META-INF/ibm-webservices-ext.xmi
META-INF/webservices.xml
META-INF/AddressBook_mapping.xml
```

What to do next

For JAX-RPC web services, configure the `webservices.xml` deployment descriptor. You need to configure the deployment descriptors for the web service so that WebSphere Application Server can process the incoming web services requests.

Assembling a WAR file that is enabled for web services from Java code

You can assemble a web application archive (WAR) file that is enabled for web services from Java code with an assembly tool.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

For Java API for XML-Based Web Services (JAX-WS) web service applications, you need the portable artifacts that are generated by the `wsgen` command-line tool when starting from a service endpoint implementation to complete this task. The `wsgen` tool processes a compiled service endpoint implementation class as input and generates the following portable artifacts:

- any additional Java Architecture for XML Binding (JAXB) classes that are required to marshal and unmarshal the message contents. The additional classes include classes that are represented by the `@RequestWrapper` annotation and the `@ResponseWrapper` annotation for a wrapped method.
- a WSDL file if the optional `-wsdl` argument is specified. The `wsgen` command does not automatically generate the WSDL file. The WSDL file is automatically generated when you deploy the service endpoint.

For Java API for XML-based RPC (JAX-RPC) web service applications, you need the following artifacts that are generated by the `WSDL2Java` command-line tool to complete this task:

- An assembled WAR file that contains the `web.xml` file, but is not enabled for web services.
- The Java class for the service endpoint interface
- A Web Services Description Language (WSDL) file
- The complete `webservices.xml`, `ibm-webservices-bnd.xmi`, and `ibm-webservices-ext.xmi` deployment descriptors, and the Java API for XML-based remote procedure call (JAX-RPC) mapping file classes that are generated by the `WSDL2Java` command.

About this task

Assemble a web services-enabled WAR file from Java code by following the actions in the steps for this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Import the JavaBeans implementation and the artifacts generated by the command-line tooling into the assembly tool.
4. Migrate WAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.

Results

The artifacts required to enable the web module for web services are added to the WAR file.

What to do next

Now you can assemble the WAR file that is enabled for Web services into an EAR file. To learn more, read about assembling a web services-enabled WAR into an EAR file.

Assembling a web services-enabled WAR file from a WSDL file

You can assemble a web application archive (WAR) file from a Web Services Description Language (WSDL) file that is enabled for web services.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

For Java API for XML-Based Web Services (JAX-WS) web service applications, you need the portable artifacts that are generated by the **wsimport** command-line tool when starting from a WSDL file to complete this task. The **wsimport** tool processes a WSDL file as input and generates the following portable artifacts:

- Service Endpoint Interface (SEI)
- Service class
- Exception classes that are mapped from the `wsdl:faul`t class (if any)
- Java Architecture for XML Binding (JAXB) generated type values which are Java classes mapped from XML schema types

You can package the generated artifacts in a web application archive (WAR) file with the WSDL file and schema documents along with the endpoint implementation that you plan to deploy.

For Java API for XML-based RPC (JAX-RPC) web service applications, you need the following artifacts that are generated by the **WSDL2Java** command-line tool to complete this task:

- An assembled WAR file that contains the Enterprise JavaBeans (EJB) implementation, all the classes that generate from the **WSDL2Java** command-line tool and the `web.xml` deployment descriptor file.
- A WSDL file

- The complete `webservices.xml`, `ibm-webservices-bnd.xmi`, and `ibm-webservices-ext.xmi` deployment descriptors, and the Java API for XML-based remote procedure call (JAX-RPC) mapping file.

About this task

Assemble a web services-enabled WAR file from a WSDL file by following the actions in the steps for this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Import the JavaBeans implementation and the artifacts generated by the command-line tooling into the assembly tool.
4. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.

Results

The artifacts required to enable the web module for web services is added to the WAR file.

What to do next

Now you can assemble the WAR file that is enabled for Web services into an EAR file. To learn more, read about assembling a web services-enabled WAR into an EAR file.

Assembling an enterprise bean JAR file into an EAR file

You can assemble an enterprise bean Java archive (JAR) file into an enterprise archive (EAR) file with an assembly tool. Assembling the JAR file, and now the EAR file, are required tasks to enable Java code for web services.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

Before assembling a web services-enabled EAR file you must assemble an enterprise bean JAR file that you want to enable for Web services. To learn more about the artifacts that are needed for the assembly of the enterprise bean JAR file, see the information on assembling an enterprise bean JAR file from Java code that is enabled for web services.

Restriction: Do not include a pound sign (#) in the name of files that are packaged within an application archive. Due to internal processing, the application server fails to correctly deploy the application when a pound sign is included in a file name within the application archive. When this failure occurs, an exception might occur when the application is being processed. Also, parts of the application might be missing after the application is deployed. To address this issue, rename any file names within the application archive so that they do not contain a pound sign.

About this task

To assemble a web services-enabled EAR file:

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Assemble the web services-enabled JAR file into an EAR file. The EAR file can contain an enterprise bean or application client JAR files, WAR files, web applications, and metadata describing the applications or application.xml files.

Results

A web services-enabled EAR file.

Example

In the following example, there is an application.xml deployment descriptor packaged with a web services-enabled JAR file called AddressBook.jar that is packaged into an EAR file called AddressBook.ear. The EAR file contains:

```
META-INF/MANIFEST.MF
META-INF/application.xml
AddressBook.jar
```

An example of the application.xml deployment descriptor is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE application PUBLIC "-//Sun Microsystems, Inc.//DTD J2EE Application 1.3//EN"
"http://java.sun.com/dtd/application_1_3.dtd">
<application id="Application_ID">
  <display-name>AddressBookJ2WEE</display-name>
  <description>AddressBook EJB Example from Java</description>
  <module id="EjbModule_1">
    <ejb>AddressBook.jar</ejb>
  </module>
</application>
```

What to do next

You can enable an EAR file for EJB modules that contain web services. Then, deploy the EAR file into WebSphere Application Server.

Assembling a web services-enabled WAR into an EAR file

You can assemble a web services-enabled web application archive (WAR) file into an enterprise archive (EAR) file with an assembly tool.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

Restriction: Do not include a pound sign (#) in the name of files that are packaged within an application archive. Due to internal processing, the application server fails to correctly deploy the application when a pound sign is included in a file name within the application archive. When this failure occurs, an exception might occur when the application is being processed. Also,

parts of the application might be missing after the application is deployed. To address this issue, rename any file names within the application archive so that they do not contain a pound sign.

About this task

Assemble a web services-enabled WAR file into an EAR file using the steps provided in this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. Assemble the web services-enabled WAR file into an EAR file. Assemble the EAR file that contains the JAR or WAR files. The EAR file can contain an enterprise bean or application client JAR files; web applications or WAR files; and metadata describing the applications or application.xml files. To learn more about how to assemble the WAR file, see the assembling applications documentation.

Results

A web services-enabled EAR file.

Example

In the following example, there is an application.xml deployment descriptor packaged with a web services-enabled JAR file called AddressBook.jar that is packaged into an EAR file called AddressBook.ear. The EAR file contains:

```
META-INF/MANIFEST.MF
META-INF/application.xml
AddressBook.war
```

An example of the application.xml deployment descriptor is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE application PUBLIC "-//Sun Microsystems, Inc.//DTD J2EE Application 1.3//EN"
"http://java.sun.com/dtd/application_1_3.dtd">
<application id="Application_ID">
  <display-name>AddressBook</display-name>
  <description>AddressBook Example from Java bean</description>
  <module id="WebModule_1">
    <web>
      <web-uri>AddressBook.war</web-uri>
      <context-root>/AddressBook</context-root>
    </web>
  </module>
</application>
```

What to do next

Deploy your web services.

Enabling an EAR file for EJB modules that contain web services

When your enterprise archive (EAR) file contains enterprise JavaBeans (EJB) modules that contain Web services, you must run the **endptEnabler** command-line tool or an assembly tool before deployment to produce a web services endpoint web application archive (WAR) file.

Before you begin

Assemble an enterprise Java archive (JAR) file that is enabled for web services from an enterprise bean. The enterprise JAR file is an artifact that is required to build the EAR file.

About this task

You can add router modules to your application that is enabled for web services with either the **endptEnabler** command-line tool or with assembly tools provided with WebSphere Application Server. The tool that you choose to use for this task depends on your preference to work with a command-line tool or a graphical user interface. See the assembly tools documentation to learn how to use assembly tool to accomplish this task.

These tools add one or more router modules to the EAR file for each web service-enabled enterprise JavaBeans (EJB) module contained in the EAR file. A router module provides an endpoint for the web service in a particular EJB module.

You should not modify the contents of the EJB module or the web module that was generated using the **endptEnabler** command-line tool. If you do, an error occurs during run time. The following is an example of the error that displays:

```
"Error]- WSW3142E: Error: Could not find web services engine.]: javax.servlet.ServletException: WSW3142E:  
Error: Could not find web services engine."
```

Each router module supports a specific transport such as HTTP or Java Message Service (JMS). If no enterprise bean JAR modules are located in the EAR file, it is not necessary to use these tools.

Procedure

Enable an EAR file with the **endptEnabler** command-line tool. In its interactive mode, the **endptEnabler** command guides you through the required steps to enable one or more services within an application.

What to do next

Deploy the EAR file into WebSphere Application Server. An assembled EAR file that is enabled for web services is required for deployment.

Enabling an EAR file for web services with the endptEnabler command:

Use the **endptEnabler** command-line tool to enable an enterprise archive (EAR) file for Enterprise JavaBeans (EJB) modules that contain web services and to specify whether the web services are exposed using SOAP over Java Message Service (JMS) or SOAP over HTTP.

Before you begin

Before doing this task, you need to assemble a web services-enabled enterprise Java archive (JAR) into an EAR file.

About this task

The **endptEnabler** command-line tool adds one or more router modules to the EAR file for each Java API for XML Web Services (JAX-WS) or Java API for XML-based RPC (JAX-RPC) based Web service-enabled enterprise bean Java archive (JAR) module within the EAR file. A router module provides an endpoint for the web services in a particular enterprise bean JAR module.

Each router module supports a specific transport such as HTTP or JMS. An HTTP router module is a web application archive (WAR) module that provides an HTTP endpoint for each of the web services contained within a particular enterprise bean JAR module. Likewise, a JMS router module is an enterprise bean JAR module that contains a Message Driven Bean (MDB) that serves as the message listener for requests intended for the web service endpoints.

If no enterprise bean JAR modules exist in the EAR file, it is not necessary to use this tool.

Procedure

1. Invoke the **endptEnabler** command.

IBM i Invoke the **endptEnabler** script on the Qshell command line from the *app_server_root/bin* directory.

2. Enter the name of the EAR file, when prompted.
3. Enter various input values as requested by the **endptEnabler** command. You are prompted for various input values for each enterprise bean JAR module that is enabled for web services in the EAR file. Typically, you accept the defaults for each prompt. To learn about the properties of this command, see the **endptEnabler** command documentation.
 - a. Specify an HTTP router module to transport your EJB-based web service. Use the `-transport http` option to indicate the web service is available using HTTP. One router module is created for each enterprise bean JAR file that contains either JAX-WS or JAX-RPC web services.
 - b. Specify an JMS router module to transport your EJB-based web service. Use the `-transport jms` option to indicate the web service is available using JMS. One router module is created for each enterprise bean JAR file that contains either JAX-WS or JAX-RPC web services.

Results

An HTTP or JMS router module is added to the EAR file for each enterprise bean JAR module within the EAR file that contains web services endpoints. For HTTP, a context-root is configured for the application so that the web service can be invoked through a Web address. The web address used to invoke the web service is:

```
http://host[:port]/<context-root>/services/<port-component-name>
```

Ensure that you install the HTTP or Java Message Service (JMS) router module that you generated with the **endptEnabler** command onto the same target as your web services enterprise bean JAR files. These HTTP or JMS router modules are included in your web services application and they need to use the runtime libraries of the application server.

What to do next

Deploy the EAR file onto your application server. An assembled EAR file that is enabled for web services is required for deployment.

If you are using JMS as a transport for your web service requests, define the various JMS objects such as queues, topics, or connection factories, that will be used by your application prior to installing the application.

endptEnabler command:

The **endptEnabler** command is used to enable a set of web services within an enterprise archive (EAR) file. The **endptEnabler** command must run on EAR files containing Enterprise JavaBeans (EJB) modules that are enabled for web services.

Each router module provides a web service endpoint for a particular transport. For example, you can add a HTTP router module so that the web service can receive requests over the HTTP transport. Or, you can add a Java Message Service (JMS) router module so that the web service can receive requests from a JMS queue or topic.

In its interactive mode, the **endptEnabler** command guides you through the required steps to enable one or more services within an application. The **endptEnabler** command makes a backup copy of your original EAR file in the event that you need to remove or add services at a later time. If your EAR file contains an enterprise bean Java archive (JAR) file that is enabled for web services, you must run the **endptEnabler** command before the EAR file is deployed. Otherwise, you do not need to run the command.

endptEnabler usage syntax

Invoke the **endptEnabler** command from the WebSphere Application Server bin directory. The command syntax is presented in the following example:

```
endptEnabler
  [-verbose|-v]
  [-quiet|-q]
  [-help|-h|-?]
  [-properties|-p properties-filename]
  [-transport|-t default-transport]
  [-enableHttpRouterSecurity]
  [-enableClientCertSecurity]
  [ear-filename]
  [-classpath|-cp]
```

All parameters are optional and described in the following list:

-verbose, -v

This parameter details and displays progress messages as the endptEnabler tool processes the EAR file. This command-line option is mapped to the verbose global property.

-quiet, -q

This parameter makes sure that there are no displays of per-module progress messages as the endptEnabler tool processes the EAR file. This command-line option is mapped to the quiet global property.

-help, -h, -?

This parameter displays a brief help message that explains the various options.

-properties, -p <properties-filename>

This parameter reads properties from the *properties-filename* properties and controls the behavior of the endptEnabler tool.

-transport, -t <default-transport>

This parameter specifies the default list of transports for which router modules are created for each enterprise bean JAR file contained in the EAR file. This command-line option is mapped to the *defaultTransports* global property. The following are examples of this parameter:

```
-transport http (the default)
-transport jms
-t http,jms
```

-enableHttpRouterSecurity

This parameter enables you to add a security policy for all authenticated users to protect the HTTP router module if all the EJB modules are secured in the enterprise bean JAR file. This command-line option is mapped to the *http.enableRouterSecurity* global property.

-enableClientCertSecurity

This parameter enables you to add the following login-config stanza to the *web.xml* file for certificate authentication, instead of basic-auth or form-login. This command-line option is mapped to the *http.enableClientCertSecurity* global property.

```
<login-config>
  <auth-method>CLIENT-CERT</auth-method>
</login-config>
```

Note: Use the *-enableClientCertSecurity* parameter with the *-enableHttpRouterSecurity* parameter.

<ear-filename>

This parameter specifies the name of the EAR file to be processed.

If the **ear-filename** parameter is not entered on the command line, the interactive mode is used. In the interactive mode, you are prompted for the EAR file name, the router module names and other important values as the processing occurs. The following dialog is an example of the endptEnabler interactive mode.

In this dialog, the user input is in fixed width font and the `endptEnabler` output is in bold.

```

endptEnabler<enter>
WSWS2004I: IBM WebSphere Application Server Release 5
WSWS2005I: Web Services Enterprise Archive Endpoint Enabler Tool.
WSWS2007I: (C) COPYRIGHT International Business Machines Corp. 1997, 2003
WSWS2006I: Please enter the name of your EAR file: AddressBook.ear<enter>

WSWS2003I: Backing up EAR file to: AddressBook.ear~

WSWS2016I: Loading EAR file: AddressBook.ear
WSWS2017I: Found EJB Module: AddressBookEJB.jar

WSWS2029I: Enter http router name for EJB Module AddressBookEJB
[AddressBookEJB_HTTPRouter.war]:<enter>
WSWS2030I: Enter http context root for EJB Module AddressBookEJB
[/AddressBookEJB]:<enter>
WSWS2024I: Adding http router for EJB Module AddressBookEJB.jar.
WSWS2036I: Saving EAR file AddressBook.ear...
WSWS2037I: Finished saving the EAR file.
WSWS2018I: Finished processing EAR file AddressBook.ear.

```

If the `ear-filename` parameter is entered on the command-line, the non-interactive mode is used. In the non-interactive mode, the router module names and other important values are determined from the user-specified properties or default values.

-classpath, -cp

This parameter enables you to specify separate JAR files in the class path for the `endptEnabler` command. Use this parameter if the EJB file references Java types in separate JAR files that do not exist within the EAR file. You can specify multiple values for this parameter. For example:

```
endptEnabler -classpath C:\MyWork\Utility.jar;D:\SharedFiles\Hello.zip;HelloWorld.jar
```

When you do not specify this parameter, you might encounter an error that is similar to the following message:

```
WSWS2021I: Skipping the enterprise bean module module_name
because it contains no web services.
```

endptEnabler properties

With the `endptEnabler` command you can control its runtime behavior by specifying a set of properties with the `-properties` command-line option. These properties are organized in one of two ways: global and per-module. Global properties affect the overall behavior of the tool as it processes multiple enterprise bean JAR modules within the EAR file. Per-module properties affect the processing of a particular enterprise bean JAR module.

Table 109. Global properties for the `endptEnabler` command. Use these global properties of the `endptEnabler` command when enabling a set of web services within an enterprise archive (EAR) file.

Property name	Description	Default value
verbose	Displays detailed progress messages.	False
quiet	Displays only brief progress messages.	False
http.enableRouterSecurity	Enables you to add a security policy for all authenticated users to protect the HTTP router module if all the EJB modules are secured in the enterprise bean JAR file.	False
http.enableClientCertSecurity	Enables you to add the following login-config stanza to the web.xml file for certificate authentication, instead of basic-auth or form-login: <pre><login-config> <auth-method>CLIENT-CERT</auth-method> </login-config></pre>	False
http.routerModuleNameSuffix	Specifies the suffix used to construct default HTTP router module names. The <code>.war</code> extension is added by the <code>endptEnabler</code> command.	<code>_HTTPRouter</code>
jms.routerModuleNameSuffix	Specifies the suffix used to construct default JMS router module names. The <code>.jar</code> extension is added by the <code>endptEnabler</code> command.	<code>_JMSRouter</code>
jms.defaultDestinationType	Specifies the default destination type to use for all JMS router modules that are added to the EAR file. This type is either <code>queue</code> or <code>topic</code> .	<code>queue</code>

Table 109. Global properties for the **endptEnabler** command (continued). Use these global properties of the **endptEnabler** command when enabling a set of web services within an enterprise archive (EAR) file.

Property name	Description	Default value
defaultTransports	Specifies the default list of transports for which router modules are created. The list can contain the values <code>http</code> and <code>jms</code> . Multiple values are separated by a comma. Examples are: <code>http, jms</code> and <code>http,jms</code> .	http

The following table describes the per-module properties supported by the **endptEnabler** command. The *ejbJarName* variable refers to the name of an enterprise bean JAR module within the EAR file, without the `.jar` extension.

Table 110. Per-module properties for the **endptEnabler** command. Use these properties of the **endptEnabler** command that affect the processing of a particular enterprise bean JAR module.

Property name	Description	Default value
<ejbJarName>.transports	Lists the transports for which router modules are created for a particular enterprise bean JAR file. The list can contain the values <code>http</code> and <code>jms</code> . Multiple values are separated by a comma. Examples are: <code>http, jms</code> and <code>http,jms</code> .	http
<ejbJarName>.http.skip	Specifies the flag which bypasses the addition of an HTTP router module, even if it otherwise is added based on other properties. Valid values are <code>true</code> and <code>false</code> .	false
<ejbJarName>.http.routerModuleName	Specifies the name of the HTTP router module for a particular enterprise bean JAR file.	<i>ejbJarName_HTTPRouter</i>
<ejbJarName>.http.contextRoot	Specifies the context root associated with the HTTP router module for a particular enterprise bean JAR file.	<i>/ejbJarName</i>
<ejbJarName>.jms.skip	Specifies the flag that bypasses the addition of an JMS router module even if it otherwise is added based on other properties. Valid values are <code>true</code> and <code>false</code> .	false
<ejbJarName>.jms.routerModuleName	Specifies the name of the JMS router module for a particular enterprise bean JAR file.	<i>ejbJarName_JMSRouter</i>
<ejbJarName>.jms.activationSpecJndiName	Specifies the Java Naming and Directory Interface (JNDI) name of the activation specification that is configured for the Message Driven Bean (MDB) within the JMS router module.	null
<ejbJarName>.jms.listenerInputPortName	Specifies the name of the listener port to configure for the MDB within the JMS router module. The listener port is configured only if an <code>activationSpecJndiName</code> property is not specified.	null
<ejbJarName>.jms.destinationType	Specifies the JMS destination type associated with the MDB within the JMS router. Valid values are <code>queue</code> and <code>topic</code> .	queue
<ejbJarName>.<port_local_name>.http.urlPattern=<url_pattern_name>	Specifies the URL pattern for ports. If you have EJB module with the indicated name that has a port with the indicated local name, you can specify the HTTP URL pattern with this property. This property only applies to HTTP router modules. It has no affect on JMS router modules.	null

Properties example

Suppose an EAR file contains an enterprise bean JAR file named, `StockQuoteEJB.jar` that contains web services. The following set of properties can be used to control the **endptEnabler** command runtime behavior as it processes the EAR file:

```
StockQuoteEJB.transports=http,jms
```

```
StockQuoteEJB.http.routerModuleName=StockQuoteEJB_HTTP
```

```
StockQuoteEJB.http.contextRoot=/StockQuote
```

```
StockQuoteEJB.jms.routerModuleName=StockQuoteEJB_JMS
```

```
StockQuoteEJB.jms.destinationType=queue
```

endptEnabler examples

The following commands are examples of how the **endptEnabler** command can be used:

```
endptEnabler MyApp.ear
endptEnabler -t jms,http MyApp.ear
endptEnabler -v -properties MyApp.props MyApp.ear
endptEnabler -q -t jms MyApp.ear
endptEnabler -v -t http,jms
```

Assembling web services-enabled clients

Assembling a web services-enabled client JAR file into an EAR file

Now that you have generated your application artifacts, you need to assemble these artifacts to create an enterprise archive (EAR) file that is used in the web services application.

Before you begin

For Java API for XML-Based Web Services (JAX-WS) web service applications, you need the portable artifacts that are generated by the **wsimport** command-line tool when starting from a WSDL file to complete this task. The **wsimport** tool processes a WSDL file as input and generates the following portable artifacts:

- Service Endpoint Interface (SEI)
- Service class
- Exception classes that are mapped from the `wsdl:fault` class (if any)
- Java Architecture for XML Binding (JAXB) generated type values which are Java classes mapped from XML schema types
- An assembled client module that contains the implementation, all of the classes generated by the **wsimport** command-line tool and the `ejb-jar.xml` deployment descriptor or the `application-client.xml` deployment descriptor. This module can be:
 - An application client module that contains the `META-INF/application-client.xml` file.
 - An Enterprise JavaBeans (EJB) module that contains the `META-INF/ejb-jar.xml` file.

For Java API for XML-based RPC (JAX-RPC) web service applications, you need the following artifacts that are generated from the **WSDL2Java** command-line tool to complete this task:

- An assembled client module that contains the implementation, all of the classes generated by the **WSDL2Java** command-line tool and the `ejb-jar.xml` deployment descriptor or the `application-client.xml` deployment descriptor. This module can be:
 - An application client module that contains the `META-INF/application-client.xml` file.
 - An Enterprise JavaBeans (EJB) module that contains the `META-INF/ejb-jar.xml` file.
- The WSDL file that you used to develop the client.
- The templates for the `ibm-webservicesclient-ext.xmi` and `ibm-webservicesclient-bnd.xmi` deployment descriptor, if used.
- A generated Java API for XML-based remote procedure call (JAX-RPC) mapping deployment descriptor.

Restriction: Do not include a pound sign (#) in the name of files that are packaged within an application archive. Due to internal processing, the application server fails to correctly deploy the application when a pound sign is included in a file name within the application archive. When this failure occurs, an exception might occur when the application is being processed. Also, parts of the application might be missing after the application is deployed. To address this issue, rename any file names within the application archive so that they do not contain a pound sign.

About this task

You can use assembly tools included with WebSphere Application Server to assemble web services-enabled client applications.

Assemble the client code and artifacts that enable the application client to access a web service with steps provided:

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Import the client implementation and the artifacts generated by the command-line tooling into the assembly tool.
4. Migrate JAR files created with the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.
5. Assemble the JAR file into an enterprise archive (EAR) file using typical assembly techniques if the client runs in a container.

Results

You have assembled the artifacts required to enable the client application for web services into an EAR file.

Example

This example of the assembly process uses the `AddressBookClient.jar` JAR file the `AddressBookClient.ear` EAR file:

```
META-INF/MANIFEST.MF
META-INF/application-client.xml
META-INF/wsdl/AddressBook.wsdl
META-INF/AddressBook_mapping.xml

com/ibm/websphere/samples/webservices/addr/Address.class
com/ibm/websphere/samples/webservices/addr/AddressBook.class
com/ibm/websphere/samples/webservices/addr/AddressBookClient.class
com/ibm/websphere/samples/webservices/addr/AddressBookService.class
...other generated classes...
```

After assembling the `AddressBookClient.jar` file into the `AddressBookClient.ear` file, the `AddressBookClient.ear` file contains the following files:

```
META-INF/MANIFEST.MF
AddressBookClient.jar
META-INF/application.xml
```

What to do next

For Java API for XML-Based Web Services (JAX-WS) applications, you are ready to deploy the web services client application.

For Java API for XML-based RPC (JAX-RPC) applications, you need to configure the client deployment descriptor bindings with an assembly tool so that the client can communicate with a web service that is deployed on a server.

Assembling a web services-enabled client WAR file into an EAR file

Now that you have generated your application artifacts, you need to assemble these artifacts to create an enterprise archive (EAR) file that is used in the web services application.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

Restriction: Do not include a pound sign (#) in the name of files that are packaged within an application archive. Due to internal processing, the application server fails to correctly deploy the application when a pound sign is included in a file name within the application archive. When this failure occurs, an exception might occur when the application is being processed. Also, parts of the application might be missing after the application is deployed. To address this issue, rename any file names within the application archive so that they do not contain a pound sign.

About this task

Assemble the client code and artifacts that enable the application client to access a web service with steps provided:

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Migrate WAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to an assembly tool. Read about importing web application archive (WAR) files using an assembly tool in the Rational Application Developer documentation.

Results

You have assembled the artifacts required to enable the client application for web services into an EAR file.

Example

This example of the assembly process uses the `AddressBookWeb.war` WAR file and the `AddressBook.ear` EAR file:

```
WEB-INF/MANIFEST.MF
WEB-INF/web.xml
WEB-INF/wsdl/AddressBook.wsdl
WEB-INF/AddressBook_mapping.xml
WEB-INF/ibm-webservicesclient-ext.xmi (optional)
WEB-INF/ibm-webservicesclient-bnd.xmi
com/ibm/websphere/samples/webservices/addr/Address.class
com/ibm/websphere/samples/webservices/addr/AddressBook.class
com/ibm/websphere/samples/webservices/addr/AddressBookClient.class
com/ibm/websphere/samples/webservices/addr/AddressBookService.class
...other generated classes...
```

After assembling the `AddressBookWeb.war` file into the `AddressBook.ear` file, the `AddressBook.ear` file contains the following files:

META-INF/MANIFEST.MF
AddressBookWeb.war
META-INF/application.xml

What to do next

For Java API for XML-Based Web Services (JAX-WS) applications, you are ready to deploy the web services client application.

For Java API for XML-based RPC (JAX-RPC) applications, you need to configure the client deployment descriptor bindings with an assembly tool so that the client can communicate with a web service that is deployed on a server.

Chapter 28. Developing web services - Addressing (WS-Addressing)

The Web Services Addressing (WS-Addressing) support in this product provides the environment for web services that use the World Wide Web Consortium (W3C) WS-Addressing specifications. This family of specifications provide transport-neutral mechanisms to address web services and to facilitate end-to-end addressing.

Using the Web Services Addressing APIs: Creating an application that uses endpoint references

This product provides application programming interfaces for applications that have to create endpoint references and use those endpoint references to target web service endpoints.

Before you begin

The steps described in this task apply to servers and clients that run on WebSphere Application Server.

About this task

Complete this task if you are a web service developer who needs to create endpoint references within an application, and then use these references to target web service resource instances. For example, a WSRF application developer.

Procedure

1. Create a web service that is referenced by an endpoint reference, and a client that accesses the web service. For JAX-WS applications, use the instructions in “Creating a JAX-WS web service application that uses Web Services Addressing.” For JAX-RPC applications, use the instructions in “Creating a JAX-RPC web service application that uses Web Services Addressing” on page 1106
2. Optional: You can extend the application that you created in the previous step so that it conforms to the Web Services Resource Framework (WSRF) specifications, by following the instructions in Creating stateful web services by using the Web Services Resource Framework.

Creating a JAX-WS web service application that uses Web Services Addressing

Web Services Addressing (WS-Addressing) aids interoperability between web services by defining a standard way to address web services and provide addressing information in messages. This task describes the steps that are required to create a JAX-WS web service that is accessed using a WS-Addressing endpoint reference. The task also describes the extra steps that are required to use stateful resources as part of the web service.

Before you begin

The steps that are described in this task apply to servers and clients that run on WebSphere Application Server.

About this task

Complete this task if you are creating a JAX-WS web service that uses the WS-Addressing specification. This task uses the JAX-WS WS-Addressing APIs to create the required endpoint reference. Alternatively, you can create endpoint references by using the IBM proprietary WS-Addressing API, and convert them into JAX-WS API objects for use with the rest of the application.

Procedure

1. Provide a web service interface that returns an endpoint reference to the target service.
The interface must return an endpoint reference, which it can do by using a factory operation or a separate factory service. The target service can front a resource instance, for example a shopping cart.
2. Implement the web service created in the previous step. For the WS-Addressing portion of the implementation, complete the following steps:
 - a. Optional: Include annotations to specify WS-Addressing behavior. See “Web Services Addressing annotations” on page 1153 for more details.
 - b. Optional: If your interface involves a web service that fronts a resource instance, create or look up the resource instance.
 - c. Optional: If you are using a resource instance, obtain the identifier of the resource. The resource identifier is application dependent and might be generated during the creation of the resource instance.
Attention: Do not put sensitive information in the resource identifier, because the identifier is propagated in the SOAP message.
 - d. Create an endpoint reference that references the web service by following the instructions in “Creating endpoint references by using the JAX-WS Web Services Addressing API” on page 1104. If you are using a resource instance, pass in the resource identifier as a parameter.
 - e. Return the endpoint reference.
3. If your web service uses resource instances, extend the implementation to match incoming messages to the appropriate resource instances. Because you associated the resource identifier with the endpoint reference that you created earlier, any incoming messages targeted at that endpoint reference contain the resource identifier information as a reference parameter in the SOAP header of the message. Because the resource identifier is passed in the SOAP header, you do not have to expose it on the web service interface. When WebSphere Application Server receives the message, it puts this information into the message context on the thread. Extend the implementation to undertake the following actions:
 - a. Obtain the resource instance identifier from the message context.
 - If you are using the 2005/08 WS-Addressing namespace, use the REFERENCE_PARAMETERS property of the MessageContext class.
 - If you are using the 2004/08 WS-Addressing namespace, you must use the IBM WS-Addressing API, specifically the EndpointReferenceManager.getReferenceParameterFromMessageContext(QName resource_id) method.

Use the following method for the 2005/08 namespace:

```
...  
List resourceIDList = (List)getContext().getMessageContext().get(MessageContext.REFERENCE_PARAMETERS);  
...
```

Use the following method for the 2004/08 namespace:

```
...  
String resource_identifier =  
    EndpointReferenceManager.getReferenceParameterFromMessageContext(PRINTER_ID_PARAM_QNAME);  
...
```

 - b. Forward the message to the appropriate resource instance.
4. Optional: Configure a proxy client to communicate with the service.
 - a. Use the wsimport or xjc tool to generate the artifacts required by the client.

Note: If you want to use the 2004/08 WS-Addressing specification, specify the provided binding file, *app_server_root/util/SubmissionEndpointReference.xjb*, as the -b parameter of the tool. This parameter tells the tool to generate endpoint reference objects by using the SubmissionEndpointReference class that is part of the IBM implementation of the standard JAX-WS API. If you do not specify this bindings file, the resulting endpoint reference objects will not work with the standard JAX-WS API.

- b. In the client code, create an instance of the service class.
- c. Obtain a proxy object from the service class. There are several ways to use the JAX-WS API to obtain proxy objects. For example, there are several `getPort` methods on the `Service` class and one on the `EndpointReference` class. For more information, refer to the API documentation.
- d. Optional: Use the `Addressing` or `SubmissionAddressing` feature to enable WS-Addressing support. For example, create a proxy by using a `getPort` method that accepts web service features as a parameter. If you prefer, you can enable WS-Addressing support by using another method, such as `policy sets`. For more information see “Enabling Web Services Addressing support for JAX-WS applications” on page 1117.
- e. Use the proxy object to invoke the service method that returns the endpoint reference.

The following sample code shows a client invoking a web service to add two numbers together. The web service issues a ticket (the resource identifier) to the client, and requires the client to use this ticket when invoking the web service.

The client creates two proxies. The first proxy obtains the ticket as an endpoint reference from the service. The second proxy uses the `AddressingFeature` class to enable WS-Addressing for the 2005/08 specification, and invokes the service to add the two numbers together.

```
...
CalculatorService service = new CalculatorService();
// Create the first proxy
Calculator port1 = service.getCalculatorServicePort();
// Obtain the ticket as an endpoint reference from the service
W3CEndpointReference epr = port1.getTicket();

// Create the second proxy, using an addressing feature to enable WS-Addressing
Calculator port2 = epr.getPort(Calculator.class, new AddressingFeature());
// Invoke the service to add the numbers
int answer = port2.add(value0, value1);
System.out.println("The answer is: " + answer);
...
```

Note: If the metadata of the endpoint reference conflicts with the information already associated with the outbound message, for example if the proxy object is configured to represent a different interface, a `javax.xml.ws.WebServiceException` exception is thrown on attempts to invoke the endpoint.

If you want to set message-addressing properties, such as a reply to endpoint, you must use the IBM proprietary WS-Addressing SPI and the `BindingProvider` class, as described in “Specifying and acquiring message-addressing properties by using the IBM proprietary Web Services Addressing SPIs” on page 1114.

5. Optional: Configure a `Dispatch` client to communicate with the service. You can configure a client in different ways; the following steps describe one example.
 - a. Create an instance of the service.
 - b. Add a port to the service object.
 - c. Create an instance of the `Dispatch` class, passing in the endpoint reference.
 - d. Create a `Dispatch<T>` object. Use the `Service.createDispatch` method with the following parameters:
 - The endpoint reference returned by the service, which represents the resource to forward messages to.
 - An array of web service features. Include one or more WS-Addressing features to enable WS-Addressing. See “Enabling Web Services Addressing support for JAX-WS applications” on page 1117 for more details.

There are several variations of the `Service.createDispatch` method; see the API documentation for more details.

- e. Compose the client request message.
- f. Invoke the service endpoint with the `Dispatch` client.

The following code shows an example fragment of a `Dispatch` client that enables 2004/08 WS-Addressing.

```

...
CalculatorService service = new CalculatorService();
Dispatch(<SOAPMessage> dispatch = service.createDispatch(
    endpointReference,
    SOAPMessage.class,
    Service.Mode.MESSAGE,
    new SubmissionAddressingFeature(true));
...

```

Results

The web service and client are configured to use endpoint references through the WS-Addressing support. For a detailed example that includes code, see “Example: Creating a web service that uses the JAX-WS Web Services Addressing API to access a generic web service resource instance” on page 1112.

What to do next

- Refer to “Web Services Addressing security” on page 1155 for information about security with WS-Addressing.
- Deploy the application. If you used WS-Addressing annotations or features in the code, you do not have to take any additional steps to enable WS-Addressing support. For more information and for other scenarios that might require additional steps, for example enabling WS-Addressing support by using policy sets, see “Enabling Web Services Addressing support for JAX-WS applications” on page 1117.

Creating endpoint references by using the JAX-WS Web Services Addressing API

Endpoint references are a primary concept of the Web Services Addressing (WS-Addressing) interoperability protocol, and provide a standard mechanism to encapsulate information about specific web service endpoints. This product provides interfaces for you to create endpoint references by using the standard JAX-WS API.

About this task

This task is a subtask of “Creating a JAX-WS web service application that uses Web Services Addressing” on page 1101.

Complete this task if you are writing an application that uses the standard JAX-WS WS-Addressing API. Such applications require endpoint references to target web service endpoints. The standard JAX-WS API is designed to create only simple endpoint references, and therefore has the following restrictions:

- You cannot create highly available or workload managed endpoint references.
- You cannot create endpoint references that represent stateful session beans.
- You cannot use classes that are created by using the JAX-WS API with the IBM proprietary WS-Addressing SPI.

You can overcome these restrictions by using the IBM proprietary WS-Addressing API to create the endpoint references and then converting them into standard JAX-WS endpoint references that can be used by the rest of the application.

Procedure

- If an endpoint needs to create an endpoint reference that represents itself, use the `getEndpointReference` method of the web service context object, passing in an `Element` object representing the reference parameters to be associated with the endpoint reference (or a null object if you do not want to specify any reference parameters).

By default, this method creates a `W3CEndpointReference` object. If you want to create a `SubmissionEndpointReference` object, representing an endpoint that conforms to the 2004/08 WS-Addressing specification, pass the endpoint reference type as a parameter. For example, the following code fragment uses the `getEndpointReference` method to return a `W3CEndpointReference` object that has a ticket ID associated with it:

```

...
@WebService(name="Calculator",
            targetNamespace="http://calculator.org")

public class Calculator {
    @Resource
    WebServiceContext wsc;

    ...
    // Create the ticket id
    element = document.createElementNS(
        "http://calculator.jaxws.axis2.apache.org", "TicketId");
    element.appendChild( document.createTextNode("123456789") );
    ...

    public W3CEndpointReference getEPR() {
        // Get the endpoint reference and associate the ticket id
        // with it as a reference parameter
        W3CEndpointReference epr = (W3CEndpointReference)wsc.getEndpointReference(element);

        return epr;
    }
}
...

```

The following line of code shows how to create a 2004/08 endpoint reference for the preceding sample:

```

SubmissionEndpointReference epr = (SubmissionEndpointReference)
    wsc.getEndpointReference(SubmissionEndpointReference.class, element);

```

- If an endpoint needs to create an endpoint reference that represents a different endpoint, use either the `W3CEndpointReferenceBuilder` class or the `SubmissionEndpointReferenceBuilder` class, depending on the namespace that you want to use.

1. Create an instance of the appropriate builder class. Use the `W3CEndpointReferenceBuilder` class if you want to create an endpoint reference that complies with the 2005/08 WS-Addressing specification. Use the `SubmissionEndpointReferenceBuilder` class if you want to create an endpoint reference that complies with the 2004/08 WS-Addressing specification.
2. Set the following property or properties of the builder instance according to the location of the endpoint.
 - If the endpoint is in another module in this application, set the `serviceName` and `endpointName` properties to appropriate values. You must set the `serviceName` property before you set the `endpointName` property, otherwise the application throws an error. The endpoint reference that is returned contains a suitable address for the endpoint, as determined by the implementation.

Note: This behavior differs from the IBM WS-Addressing API, in that creating an endpoint reference using the `com.ibm.websphere.wsaddressing.EndpointReferenceManager.createEndpointReference(QName serviceName, String endpointName)` method is not restricted to endpoints in the same application.

- If the endpoint is in another Java EE application, set the `address` property to point to the endpoint.
3. Optional: Set other properties of the builder instance as required. For example, if the web service is used to access a resource instance, use the `referenceParameter` property to associate the identifier of the resource with the endpoint reference. For more information on the properties that you can set, see the API documentation.
 4. Invoke the `build` method on the builder instance to obtain the endpoint reference.

For example, the following code fragment uses the `W3CEndpointReferenceBuilder` class to obtain an endpoint reference that complies with the 2005/08 specification, and points to an endpoint that is in another application:

```

...
@WebService(name="Calculator", targetNamespace="http://calculator.org")
public class Calculator {

    public W3CEndpointReference getEPR() {
        ...
        // Create the builder object
        W3CEndpointReferenceBuilder builder = new
            W3CEndpointReferenceBuilder();
    }
}
...

```

```

    // Modify builder properties
    builder.address(otherServiceURI);

    // Create the endpoint reference from the builder object
    W3CEndpointReference epr = builder.build();
    return epr;
}
...

```

The following code fragment uses the `SubmissionEndpointReferenceBuilder` class to obtain an endpoint reference that complies with the 2004/08 specification, and points to an endpoint that is in another module in this application:

```

...
@WebService(name="Calculator", targetNamespace="http://calculator.org")
public class Calculator {

    public W3CEndpointReference getEPR() {
        ...
        // Create the builder object
        SubmissionEndpointReferenceBuilder builder = new
            SubmissionEndpointReferenceBuilder();

        // Modify builder properties
        builder.serviceName(calculatorService);
        builder.endpointName(calculatorPort);

        // Create the endpoint reference from the builder object
        SubmissionEndpointReference epr = builder.build();
        return epr;
    }
    ...
}

```

Results

You created an endpoint reference for use by your application.

What to do next

1. If required, convert the endpoint reference to an instance of the `com.ibm.websphere.wsaddressing.EndpointReference` class, by using the `createIBMEndpointReference` method. For example, on a client you might want to set the `FaultTo` message addressing property for outbound messages. You cannot set this property by using the JAX-WS API, so you must convert the endpoint reference representing the `FaultTo` endpoint to an instance of the `com.ibm.websphere.wsaddressing.EndpointReference` class, before setting it as a property on the `BindingProvider` object.
2. Continue with “Creating a JAX-WS web service application that uses Web Services Addressing” on page 1101.

Creating a JAX-RPC web service application that uses Web Services Addressing

Web Services Addressing (WS-Addressing) aids interoperability between web services by defining a standard way to address web services and provide addressing information in messages. This task describes the steps that are required to create a JAX-RPC web service that is accessed by using a WS-Addressing endpoint reference. The task also describes the extra steps that are required to use stateful resources as part of the web service.

Before you begin

The steps that are described in this task apply to servers and clients that run on WebSphere Application Server.

About this task

Complete this task if you are creating a web service that uses the WS-Addressing specification.

Procedure

1. Provide a web service interface, by creating or generating a Web Services Description Language (WSDL) document for the web service, that returns an endpoint reference to the target service. The interface must return an endpoint reference, which it can do by using a factory operation or a separate factory service. The target service can front a resource instance, for example a shopping cart.
2. Implement the web service created in the previous step. For the WS-Addressing portion of the implementation, complete the following steps:
 - a. Create an endpoint reference that references the web service, by following the instructions in “Creating endpoint references by using the IBM proprietary Web Services Addressing API” on page 1110.
 - b. Optional: If your interface involves a web service that fronts a resource instance, create or look up the resource instance.
 - c. Optional: If you are using a resource instance, obtain the identifier of the resource and associate it with the endpoint reference as a reference parameter, by using the `EndpointReference.setReferenceParameter(QName resource_id_name, String value)` method. The resource identifier is application-dependent and might be generated during the creation of the resource instance.

Attention: Do not put sensitive information in the resource identifier, because the identifier is propagated in the SOAP message.
The endpoint reference now targets the resource.
 - d. Return the endpoint reference.
3. If your web service uses resource instances, extend the implementation to match incoming messages to the appropriate resource instances. Because you associated the resource identifier with the endpoint reference that you created earlier, any incoming messages targeted at that endpoint reference contain the resource identifier information as a reference parameter in the SOAP header of the message. Because the resource identifier is passed in the SOAP header, you do not have to expose it on the web service interface. When WebSphere Application Server receives the message, it puts this information into the message context on the thread. Extend the implementation to undertake the following actions:
 - a. Obtain the resource instance identifier from the message context, by using the `EndpointReferenceManager.getReferenceParameterFromMessageContext(QName resource_id_name)` method.
 - b. Forward the message to the appropriate resource instance.
4. To configure a client to communicate with the service, use the endpoint reference that is produced by the service in the first step to send messages to the endpoint.
 - a. Obtain a Stub object (by looking up the service in the Java Naming and Directory Interface (JNDI)), or create an empty Call object.
 - b. Associate the endpoint reference with the proxy object. Use the `setProperty(String property_name, Object value)` method of the Stub or Call object. Use the WS-Addressing constant `WSADDRESSING_DESTINATION_EPR` as the property name, and the endpoint reference as the value.

This procedure automatically configures the Stub or Call object, to represent the web service (or resource instance if your interface uses a web service that fronts a resource instance) of the endpoint reference. For Call objects, this process includes the configuration of the interface and endpoint metadata (portType and port elements) that are associated with the endpoint reference.

Note: If the metadata of the endpoint reference conflicts with the information already associated with the outbound message, for example if the Stub object is configured to represent a different interface, a `javax.xml.rpc.JAXRPCException` exception is thrown on attempts to invoke the endpoint.

Invocations on the Stub or Call object are now targeted at the web service or resource instance that is defined by the endpoint reference. When an invocation occurs, the product adds appropriate message

addressing properties, such as a reference parameter contained within the endpoint reference that identifies a target resource, to the message header.

Results

The web service and client are configured to use endpoint references through the WS-Addressing support.

Providing a web service interface that returns an endpoint reference to the target service

The following examples correspond to steps 1 to 4 in the procedure. The examples show how an IT organization might use web services to manage a network of printers. The organization might represent each printer as a resource that is addressed through an endpoint reference. The following examples show how to code such a service by using the IBM proprietary Web Services Addressing (WS-Addressing) application programming interfaces (APIs) that are provided by WebSphere Application Server, and JAX-WS.

The IT organization implements a PrinterFactory service that offers a CreatePrinter portType element. This portType element accepts a CreatePrinterRequest message to create a resource that represents a logical printer, and responds with an endpoint reference that is a reference to the resource.

The WSDL definition for such a PrinterFactory service might include the following code:

```
<wsdl:definitions targetNamespace="http://example.org/printer" ...
    xmlns:pr=" http://example.org/printer">
  <wsdl:types>
    ...
    <xsd:schema...>
      <xsd:element name="CreatePrinterRequest"/>
      <xsd:element name="CreatePrinterResponse"
        type="wsa:EndpointReferenceType"/>
    </xsd:schema>
  </wsdl:types>
  <wsdl:message name="CreatePrinterRequest">
    <wsdl:part name="CreatePrinterRequest"
      element="pr:CreatePrinterRequest" />
  </wsdl:message>
  <wsdl:message name="CreatePrinterResponse">
    <wsdl:part name="CreatePrinterResponse"
      element="pr:CreatePrinterResponse" />
  </wsdl:message>
  <wsdl:portType name="CreatePrinter">
    <wsdl:operation name="createPrinter">
      <wsdl:input name="CreatePrinterRequest"
        message="pr:CreatePrinterRequest" />
      <wsdl:output name="CreatePrinterResponse"
        message="pr:CreatePrinterResponse" />
    </wsdl:operation>
  </wsdl:portType>
</wsdl:definitions>
```

The CreatePrinter operation in the previous example returns a wsa:EndpointReference object that represents the newly created Printer resource. The client can use this endpoint reference to send messages to the service instance that represents the printer.

The createPrinter method shown in the following example creates an endpoint reference to the Printer service. The operation then obtains the identifier for the individual printer resource instance, and associates it with the endpoint reference. Finally, the createPrinter method converts the EndpointReference object, which now represents the new printer, into a W3CEndpointReference object, and returns the converted endpoint reference.

```
import com.ibm.websphere.wsaddressing.EndpointReferenceManager;
import com.ibm.websphere.wsaddressing.EndpointReference;
import com.ibm.websphere.wsaddressing.jaxws.EndpointReferenceConverter;
import com.ibm.websphere.wsaddressing.jaxws.W3CEndpointReference;

import javax.xml.namespace.QName;

public class MyClass {

    // Create the printer
    ...
}
```

```

// Define the printer resource ID as a static constant as it is required in later steps
public static final QName PRINTER_ID_PARAM_QNAME = new QName("example.printersample",
    "IBM_WSRF_PRINTERID", "ws-rf-pr" );
public static final QName PRINTER_SERVICE_QNAME = new QName("example.printer.com", "printer", "...");
public static final String PRINTER_ENDPOINT_NAME = new String("PrinterService");

public W3CEndpointReference createPrinter(java.lang.Object createPrinterRequest)
throws Exception {
    // Create an EndpointReference that targets the appropriate WebService URI and port name.
    EndpointReference epr = EndpointReferenceManager.createEndpointReference(PRINTER_SERVICE_QNAME,
        PRINTER_ENDPOINT_NAME);

    // Create or lookup the stateful resource and derive a resource
    // identifier string.
    String resource_identifier = "...";

    // Associate this resource identifier with the EndpointReference as
    // a reference parameter.
    // The choice of name is arbitrary, but should be unique
    // to the service.
    epr.setReferenceParameter(PRINTER_ID_PARAM_QNAME,resource_identifier);
    // The endpoint reference now targets the resource rather than the service.
    ...

    return EndpointReferenceConverter.createW3CEndpointReference(epr);
}
}

```

Because of the web service implementation described previously, the printer resource instance now has a unique identifier embedded in its endpoint reference. This identifier becomes a reference parameter in the SOAP header of subsequent messages that are targeted at the web service, and can be used by the web service to match incoming messages to the appropriate printer.

When a web service receives a message containing WS-Addressing message-addressing properties, the WebSphere Application Server processes these properties before the message is dispatched to the application endpoint, and sets them into the message context on the thread. The Printer web service application accesses the reference parameters that are associated with the target endpoint from the WebServiceContext object, as illustrated in the following example:

```

import com.ibm.websphere.wsaddressing.EndpointReferenceManager;
...
// Initialize the reference parameter name
QName name = new QName(..);
// Extract the String value.
String resource_identifier =
    EndpointReferenceManager.getReferenceParameterFromMessageContext(PRINTER_ID_PARAM_QNAME);

```

The web service implementation can forward messages based on the printer identity acquired from the `getReferenceParameterFromMessageContext` method to the appropriate printer instances.

The client creates a JAX-WS proxy for the printer, and converts the proxy into a `BindingProvider` object. The client then associates the `EndpointReference` object obtained previously with the request context of the `BindingProvider` object, as illustrated in the following example.

```

import javax.xml.ws.BindingProvider;
...

javax.xml.ws.Service service= ...;
Printer myPrinterProxy = service.getPort(portName, Printer.class);

javax.xml.ws.BindingProvider bp = (javax.xml.ws.BindingProvider)myPrinterProxy;

// Retrieve the request context for the BindingProvider object
Map myMap = myBindingProvider.getRequestContext();

// Associate the endpoint reference that represents the new printer to the request context
// so that the BindingProvider object now represents a specific printer instance.
myMap.put(WSADDRESSING_DESTINATION_EPR, destinationEpr);

...

```

The `BindingProvider` object now represents the new printer resource instance, and can be used by the client to send messages to the printer through the Printer web service. When the client invokes the

BindingProvider object, WebSphere Application Server adds appropriate message-addressing properties to the message header, which in this case is a reference parameter contained within the endpoint reference that identifies the target printer resource.

Alternatively, the client can use a JAX-RPC Stub or Call object, which the client configures to represent the new printer. The use of the Call object is illustrated in the following example.

```
import javax.xml.rpc.Call;
...
:
// Associate the endpoint reference that represents the new printer with the call.
call.setProperty(
    "com.ibm.websphere.wsaddressing.WSConstants.
        WSADDRESSING_DESTINATION_EPR ", epr);
```

From the perspective of the client, the endpoint reference is opaque. The client cannot interpret the contents of any endpoint reference parameters and should not try to use them in any way. Clients cannot directly create instances of endpoint references because the reference parameters are private to the service provider; clients must obtain endpoint references from the service provider, for example through a provider factory service, and then use them to direct web service operations to the endpoint that is represented by the endpoint reference, as shown.

What to do next

- Refer to “Web Services Addressing security” on page 1155 for information about security with WS-Addressing.
- Deploy the application. For this scenario, you do not have to take any additional steps to enable the WS-Addressing support in WebSphere Application Server because you specified a WS-Addressing property on the client. For more information, and for other scenarios that might require additional steps, see “Enabling Web Services Addressing support for JAX-RPC applications” on page 1159.

Creating endpoint references by using the IBM proprietary Web Services Addressing API

Endpoint references are a primary concept of the Web Services Addressing (WS-Addressing) interoperability protocol, and provide a standard mechanism to encapsulate information about specific Web service endpoints. This product provides interfaces for you to create endpoint references by using the IBM proprietary implementation of the WS-Addressing standard.

About this task

This task is a subtask of “Creating a JAX-RPC web service application that uses Web Services Addressing” on page 1106.

Complete this task if you are writing an application that uses the IBM proprietary WS-Addressing API. Such applications require endpoint references to target web service endpoints. When you are writing the application, you might not know the address of the endpoint, because the address can change when the application is deployed. By using the IBM proprietary API, you can either specify the endpoint address, or allow the product to generate it for you at run time.

If you want to use endpoint reference objects from the standard JAX-WS API instead of the IBM proprietary equivalents, but want the extra functions provided by the IBM proprietary API, create the endpoint references by using the methods described in this task and then convert them by using the supplied converter classes. For example, you might want to undertake such a conversion if you have a JAX-WS service application and you are creating endpoint references that represent stateful session beans, or that have an affinity to a particular server, or are workload managed. You cannot create such endpoint references by using the JAX-WS API.

Procedure

- To create an endpoint reference with an address that you specify directly, use the WS-Addressing `EndpointReferenceManager.createEndpointReference(URI address)` method of the system programming interface (SPI) provided. This method is useful in test scenarios, where the address of the service does not change.
- To create an endpoint reference with an address that is automatically generated by the product, complete the following steps:
 1. If you created the web service deployment descriptor file, `webservices.xml`, manually, ensure that the `webservice-description-name` in the file is the same as the local part of the Web Services Description Language (WSDL) service name. If you generated the `webservices.xml` file by using the tools provided, the names match by default. This match is required for the generation of the correct URI for the endpoint reference.
 2. Create the endpoint reference by using the method that is appropriate for the object that the reference will represent.
 - If you are creating an endpoint reference to represent a stateful session bean that maintains in-memory state, create the endpoint reference using the `EndpointReferenceManager.createEndpointReference(QName serviceName, String endpointName, Remote statefulSessionBean)` method of the application programming interface (API) provided. This method ensures that requests are targeted at the specific server that hosts the stateful session bean instance, and are not workload-managed.
 - If you are creating an endpoint reference to represent any other object, create the endpoint reference by using the `EndpointReferenceManager.createEndpointReference(QName serviceName, String endpointName)` method of the API. The combination of service name and endpoint name must be unique in the server. If there is more than one web service application with the same service name and endpoint name, the application server cannot generate a unique URI object for the endpoint. If you cannot ensure that the combination of service name and endpoint name is unique, use an SPI method to create the endpoint reference.

When the application invokes either of the previous two methods, the product generates the address URI for the endpoint reference, and puts the service name and endpoint name into the metadata of the newly created endpoint reference.

Note: If you configured a virtual host for the server on which the endpoint is created, the URI of the endpoint reference refers to the virtual host of the HTTP server configuration. You can use the administrative console to override this setting and provide your own HTTP endpoint URL information. The methods described previously will use the overridden value to generate the address URI for the endpoint reference.

Results

You created an endpoint reference for use by your application.

What to do next

1. If you want to convert the endpoint references from IBM proprietary WS-Addressing objects to standard JAX-WS WS-Addressing objects, use one of the following methods of the `com.ibm.websphere.wsaddressing.jaxws21.EndpointReferenceConverter` class, depending on the namespace of the endpoint reference:
 - `createW3CEndpointReference(EndpointReference epr)`: use this method if the `EndpointReference` object uses the 2005/08 specification. This method creates a `W3CEndpointReference` object.
 - `createSubmissionEndpointReference(EndpointReference epr)`: use this method if the `EndpointReference` object uses the 2004/08 specification. This method creates a `SubmissionEndpointReference` object.

2. Continue with “Creating a JAX-RPC web service application that uses Web Services Addressing” on page 1106, or if you converted the endpoint reference to the standard JAX-WS API, continue with “Creating a JAX-WS web service application that uses Web Services Addressing” on page 1101.

Example: Creating a web service that uses the JAX-WS Web Services Addressing API to access a generic web service resource instance

Consider an IT organization that has a network of printers that it wants to manage using web services. The organization might represent each printer as a resource that is addressed through an endpoint reference. This example shows how to code such a service by using the JAX-WS Web Services Addressing (WS-Addressing) application programming interfaces (APIs) that are provided by WebSphere Application Server.

Providing a web service interface that returns an endpoint reference to the target service

The IT organization implements a PrinterFactory service that offers a CreatePrinter portType element. This portType element accepts a CreatePrinterRequest message to create a resource that represents a logical printer, and responds with an endpoint reference that is a reference to the resource.

The WSDL definition for such a PrinterFactory service might include the following code:

```
<wsdl:definitions targetNamespace="http://example.org/printer" ...
    xmlns:pr=" http://example.org/printer">
  <wsdl:types>
    ...
    <xsd:schema...>
      <xsd:element name="CreatePrinterRequest"/>
      <xsd:element name="CreatePrinterResponse"
        type="wsa:EndpointReferenceType"/>
    </xsd:schema>
  </wsdl:types>
  <wsdl:message name="CreatePrinterRequest">
    <wsdl:part name="CreatePrinterRequest"
      element="pr:CreatePrinterRequest" />
  </wsdl:message>
  <wsdl:message name="CreatePrinterResponse">
    <wsdl:part name="CreatePrinterResponse"
      element="pr:CreatePrinterResponse" />
  </wsdl:message>
  <wsdl:portType name="CreatePrinter">
    <wsdl:operation name="createPrinter">
      <wsdl:input name="CreatePrinterRequest"
        message="pr:CreatePrinterRequest" />
      <wsdl:output name="CreatePrinterResponse"
        message="pr:CreatePrinterResponse" />
    </wsdl:operation>
  </wsdl:portType>
</wsdl:definitions>
```

The CreatePrinter operation in the previous example returns a wsa:EndpointReference object that represents the newly created Printer resource. The client can use this endpoint reference to send messages to the service instance that represents the printer.

Implementing the web service interface

The createPrinter method shown in the following example obtains the identifier for the individual printer resource instance. The operation then creates an endpoint reference to the Printer service, and associates the printer ID with the endpoint reference. Finally, the createPrinter method returns the endpoint reference.

```
import javax.xml.ws.addressing.W3CEndpointReference;
import javax.xml.ws.addressing.W3CEndpointReferenceBuilder;

import javax.xml.namespace.QName;

import org.w3c.dom.Document;
import org.w3c.dom.Element;

public class MyClass {

    // Create the printer
    ...
}
```

```

//Define the printer resource ID as a static constant as it is required in later steps
public static final QName PRINTER_SERVICE_QNAME = new QName("example.printer.com", "printer", "...");
public static final QName PRINTER_ENDPOINT_NAME = new QName("example.printer.com", "PrinterService", "...");

public W3CEndpointReference createPrinter(java.lang.Object createPrinterRequest)
{
    Document document = ...;

    // Create or lookup the stateful resource and derive a resource
    // identifier string.
    String resource_identifier = "...";

    // Associate this resource identifier with the EndpointReference as
    // a reference parameter.
    // The choice of name is arbitrary, but should be unique
    // to the service.
    Element element = document.createElementNS("example.printersample",
        "IBM_WSRF_PRINTERID");
    element.appendChild( document.createTextNode(resource_identifier) );
    ...

    // Create an EndpointReference that targets the appropriate WebService URI and port name.
    // Alternatively, the getEndpointReference() method of the MessageContext can be used.
    W3CEndpointReferenceBuilder builder = new W3CEndpointReferenceBuilder();
    builder.serviceName(PRINTER_SERVICE_QNAME);
    builder.endpointName(PRINTER_ENDPOINT_NAME);
    builder.referenceParameter(element);

    // The endpoint reference now targets the resource rather than the service.
    return builder.build();
}
}

```

Extending the target service to match incoming messages to web service resource instances

Because of the web service implementation described previously, the printer resource instance now has a unique identifier embedded in its endpoint reference. This identifier becomes a reference parameter in the SOAP header of subsequent messages that are targeted at the web service, and can be used by the web service to match incoming messages to the appropriate printer.

When a web service receives a message containing WS-Addressing message addressing properties, the WebSphere Application Server processes these properties before the message is dispatched to the application endpoint, and sets them into the message context on the thread. The Printer web service application accesses the reference parameters that are associated with the target endpoint from the `WebServiceContext` object, as illustrated in the following example:

```

@Resource
private WebServiceContext context;
...
List list = (List) context.getMessageContext().get(MessageContext.REFERENCE_PARAMETERS);

```

If your application uses the 2004/08 version of the WS-Addressing specification, use the IBM proprietary API to retrieve the message parameters, as illustrated in the following example.

```

import com.ibm.websphere.wsaddressing.EndpointReferenceManager;
...
// Initialize the reference parameter name
QName name = new QName(..);
// Extract the String value.
String resource_identifier =
    EndpointReferenceManager.getReferenceParameterFromMessageContext(PRINTER_ID_PARAM_QNAME);

```

The web service implementation can forward messages based on the printer ID to the appropriate printer instances.

Using endpoint references to send messages to an endpoint

The client uses the endpoint reference returned from the service to create a JAX-WS proxy for the printer, as illustrated in the following example.

```

javax.xml.ws.Service jaxwsServiceObject= ...;
W3CEndpointReference epr = ...;
...
Printer myPrinterProxy = jaxwsServiceObject.getPort(epr, Printer.class, new AddressingFeature());

```

The proxy object now represents the new printer resource instance, and can be used by the client to send messages to the printer through the Printer Web service. When the client invokes the service, WebSphere Application Server adds appropriate message addressing properties to the message header, which in this case is a reference parameter contained within the endpoint reference that identifies the target printer resource.

From the perspective of the client, the endpoint reference is opaque. The client cannot interpret the contents of any endpoint reference parameters and should not try to use them in any way. Clients cannot directly create instances of endpoint references because the reference parameters are private to the service provider; clients must obtain endpoint references from the service provider, for example through a provider factory service, and then use them to direct web service operations to the endpoint that is represented by the endpoint reference, as shown.

Using the IBM proprietary Web Services Addressing SPIs: Performing more advanced Web Services Addressing tasks

This product provides proprietary system programming interfaces for more advanced Web Services Addressing (WS-Addressing) tasks, which involve the WS-Addressing message-addressing properties that are passed in the SOAP header of a web service message. You can also use the SPIs to choose a WS-Addressing specification level other than the default used by the product.

Before you begin

You cannot use the standard JAX-WS API classes with these proprietary SPIs. However, you can convert endpoint references created using the standard JAX-WS API classes to instances of the `com.ibm.websphere.wsaddressing.EndpointReference` class, by using the `com.ibm.websphere.wsaddressing.jaxws21.EndpointReferenceConverter` class. You can then use these converted endpoint references with the SPIs.

The steps described in this task apply to servers and clients that run on WebSphere Application Server.

About this task

Complete this task to specify or acquire WS-Addressing message-addressing properties, or if you have an application that needs to interoperate with a client or endpoint that is not using the default WS-Addressing specification supported by this product.

Procedure

- To manipulate message-addressing properties, follow the instructions in “Specifying and acquiring message-addressing properties by using the IBM proprietary Web Services Addressing SPIs”
- To interoperate with the pre-W3C specification of WS-Addressing, with the namespace <http://schemas.xmlsoap.org/ws/2004/08/addressing>, refer to “Interoperating with Web Services Addressing endpoints that do not support the default specification supported by WebSphere Application Server” on page 1116.

Specifying and acquiring message-addressing properties by using the IBM proprietary Web Services Addressing SPIs

Using the proprietary Web Services Addressing (WS-Addressing) system programming interfaces (SPIs), you can add WS-Addressing message addressing properties (MAPs) to the SOAP headers of an outbound client message, through properties on the JAX-WS BindingProvider request context, or the JAX-RPC Stub or Call object. When the target endpoint receives the message, the SPI enables the endpoint to acquire the MAPs through properties on the message context.

About this task

There are no equivalent SPIs in the JAX-WS standard. If you want to set message-addressing properties in a client that uses JAX-WS endpoint references, you must convert the endpoint references to the IBM proprietary classes, before using them with these SPIs.

Complete this task if you are a web service developer that uses the WS-Addressing support, or a system programmer that uses the IBM proprietary WS-Addressing SPIs to specify message addressing properties, such as fault or reply endpoint references, on web services messages.

The properties that you can set or retrieve are described, with the Java type of property instances, in IBM proprietary Web Services Addressing SPIs. Most properties are of type `com.ibm.websphere.wsaddressing.EndpointReference`, for example destination, reply, or fault endpoint references. The relationship property is a `java.util.Set` object that contains instances of the `com.ibm.wsspi.wsaddressing.Relationship` class. Use relationships when you want to specify an association between messages; for example, in a response message you might want to specify the ID of the message to which you are replying. The action property is an `AttributedURI` object that identifies a specific method or operation within the target endpoint.

Attention: The destination endpoint reference and action properties are required for the message to be WS-Addressing compliant.

Procedure

1. On the client, obtain the endpoint reference from the service and associate it with your `BindingProvider` object request context, or your `Stub` or `Call` object, as described in “Creating a JAX-RPC web service application that uses Web Services Addressing” on page 1106.
2. Create instances of the required properties. For example, if you want to specify an endpoint reference for the target service to send replies to, create an instance of the `com.ibm.websphere.wsaddressing.EndpointReference` class, to use as the `WSADDRESSING_REPLYTO_EPR` property.
3. Set the required properties by associating them with the `BindingProvider` object request context, or the `Stub` or `Call` object. If you are using a `Stub` or `Call` object, use the `setProperty(String property_name, Object value)` method. Note that unlike the endpoint reference required for the first step, these endpoint references do not have to be converted to another type, because they are passed in the header of the SOAP message rather than the body. The following example sets a destination endpoint reference and a reply endpoint reference on a `BindingProvider` object request context:

```
import javax.xml.ws.BindingProvider;
...
javax.xml.ws.Service jaxwsServiceObject=...;
Printer myPrinterProxy = jaxwsServiceObject.getPort(portName, Printer.class);

javax.xml.ws.BindingProvider myBindingProvider = (javax.xml.ws.BindingProvider)myPrinterProxy;

// Retrieve the request context for the BindingProvider object
Map myMap = myBindingProvider.getRequestContext();

// Associate the endpoint reference for the web service. This property is required for the message
// to be WS-Addressing compliant.
myMap.put(WSADDRESSING_DESTINATION_EPR, destinationEpr);

// Associate the endpoint reference that represents the reply to the request context
myMap.put(WSADDRESSING_REPLYTO_EPR, replyToEpr);
```

When an invocation occurs on the `BindingProvider`, `Stub`, or `Call` object, the product adds the appropriate MAPs to the message header.

4. On the server, retrieve the MAPs from the inbound message through the `javax.xml.ws.WebServiceContext` or `javax.xml.rpc.handler.MessageContext` object that is currently on the thread. When WebSphere Application Server receives the message, it puts the MAP information into the message context on the thread, making it available to the service. You can retrieve the message context by, for example, using the session context of the endpoint enterprise bean. For more

information about message contexts, refer to the JSR-109 standard. The following example retrieves the reply endpoint reference by using the web service context:

```
import javax.xml.ws.handler.MessageContext;
import javax.xml.ws.WebServiceContext;
...

// Obtain the message context from the WebService context
private WebServiceContext wsContext;
MessageContext context = wsContext.getMessageContext();

// Retrieve the reply endpoint reference
replyToEpr = context.getProperty(WSADDRESSING_INBOUND_REPLYTO_EPR);
```

Interoperating with Web Services Addressing endpoints that do not support the default specification supported by WebSphere Application Server

A target web service endpoint might not support the same Web Services Addressing (WS-Addressing) namespace as this product. In most cases, you do not have to undertake any extra actions to interoperate with such endpoints, however some scenarios require additional steps in the implementation of your web service.

About this task

WebSphere Application Server supports the default WS-Addressing 2005/08 namespace <http://www.w3.org/2005/08/addressing>. Complete this task to interoperate with endpoints that support other namespaces. This task specifically describes interoperation with endpoints that are hosted on a node that supports only the 2004/08 namespace: <http://schemas.xmlsoap.org/ws/2004/08/addressing>.

If you are using the standard JAX-WS API, ensure that you use the appropriate feature, annotation or endpoint reference class for the 2004/08 namespace.

If you are sending to or receiving messages from an endpoint that supports only the 2004/08 namespace, you do not have to undertake any additional steps for interoperability. This product recognizes and understands incoming WS-Addressing messages that conform to the 2004/08 specification, and outbound messages automatically adhere to the namespace of their destination endpoint reference. If you are sending a request, all WS-Addressing elements, such as reply endpoint or fault endpoint elements, must use the same namespace as the message. Any discrepancy results in a JAX-WS or JAX-RPC configuration error.

If you are interacting in a different way with an endpoint that supports only the 2004/08 namespace, such as exporting endpoint references in the message header or body, and you are not using the JAX-WS standard API, you must undertake additional steps as detailed below.

Procedure

- If you are generating a web service for use by a client that supports only the 2004/08 specification, update the WS-Addressing namespace in the Web Services Description Language (WSDL) document for your web service, by changing <http://www.w3.org/2006/05/addressing/wsd1> to <http://schemas.xmlsoap.org/ws/2004/08/addressing>.

Note: Only the WS-Addressing WSDL Action extensibility element is recognized by pre-W3C WS-Addressing clients.

- If you are creating endpoint references at run time for export to an endpoint that supports the 2004/08 namespace only, perform the following steps:
 1. Create the endpoint reference to export.
 2. Associate the appropriate namespace with the endpoint reference, by using the `setNamespace` method. The following example illustrates the association of the 2004/08 namespace with an endpoint reference:

```

import com.ibm.wsspi.wsaddressing.EndpointReference;
import com.ibm.wsspi.wsaddressing.NamespaceNotSupportedException;
import com.ibm.wsspi.wsaddressing.WSConstants;

:
EndpointReference epr = ...

try
{
    epr.setNamespace(WSConstants.WSADDRESSING_NAMESPACE_2004_08);
} catch (NamespaceNotSupportedException e)
{
    // Error handling code here
}

```

When you pass the endpoint reference to the target endpoint, in either the SOAP body or the SOAP header of a message, the endpoint reference is appropriately serialized into SOAP elements according to its namespace.

- To establish the namespace of an inbound request, use the IBM proprietary WS-Addressing system programming interface (SPI) to retrieve the `WSADDRESSING_INBOUND_NAMESPACE` property from the inbound message context. This property specifies the Core WS-Addressing specification namespace of the incoming message.

Note: This procedure uses the IBM proprietary WS-Addressing API. There is no equivalent procedure in the JAX-WS API.

You can retrieve the message context by, for example, using the session context of the endpoint enterprise bean. For more information about message contexts, refer to the JSR-109 specification. The following code example shows how you can establish the namespace of an incoming message on the receiving endpoint:

```

import com.ibm.wsspi.wsaddressing.WSConstants;
import javax.xml.rpc.handler.MessageContext;

:
// If the endpoint is implemented as an enterprise bean, you can use its session context
// to obtain the message context
private SessionContext sessionContext;
MessageContext context = sessionContext.getMessageContext();

try
{
    String namespace = (String)msgContext.getProperty(WSConstants.WSADDRESSING_INBOUND_NAMESPACE);
} catch (IllegalArgumentException e)
{
    // Error handling code here
}

```

Enabling Web Services Addressing support for JAX-WS applications

The Web Services Addressing (WS-Addressing) support provides mechanisms to address web services and provide addressing information in messages. For JAX-WS applications, you can enable WS-Addressing support in several different ways, such as configuring policy sets or using annotations in code.

About this task

Perform this task to enable the WS-Addressing support, either as a service provider or as a client of a service provided by another party.

For service providers, WS-Addressing support is enabled by default, so you do not have to undertake any actions to enable support. However, you can use the enabling mechanisms to modify other WS-Addressing behavior for the service, such as whether WS-Addressing information is required, and what is included in the generated WSDL document.

- Modify the behavior of the WS-Addressing support after the application is deployed by attaching a policy set to the application. Within the policy set, you can configure the WS-Addressing policy type to specify whether WS-Addressing information is required in incoming messages, and whether to use synchronous or asynchronous messaging. You can communicate the WS-Addressing policy configuration to other

servers and clients that support WS-Policy, by enabling policy sharing on the server, and by applying the provider policy on the client. This method overrides other methods.

- Use deployment descriptor elements within a `port-component` element.
- Modify the behavior of the WS-Addressing support during development of the service by using the `Addressing` or `SubmissionAddressing` annotations in the service code. Within each annotation you can specify whether WS-Addressing is enabled on the server, whether the server requires WS-Addressing information in incoming messages and the message exchange pattern the server will use. The presence of the `Addressing` annotation in the code adds a `UsingAddressing` element and a WS-Policy assertion to any WSDL document that is generated for the service.
- Modify the behavior of the WS-Addressing support during development of the service by either adding `UsingAddressing` elements or WS-Policy assertions into the WSDL document. If you do provide your own WSDL document, instead of relying on the JAX-WS runtime environment to generate one, and your WSDL document is being consumed by non JAX-WS 2.2 clients, you may wish to include the `UsingAddressing` element as such clients will not process WS-Policy assertions.

For service clients, WS-Addressing support is disabled by default. Use one of the following methods to enable WS-Addressing support. The following list is in descending order of precedence, because you can apply multiple methods. For example the deployment descriptor method overrides the use of annotations or features, but is itself overridden by the use of policy sets.

- Attach a policy set to the client artifact and perform one of the following actions:
 - Specify in the policy that WS-Addressing is mandatory.
 - Apply both client and provider policies. In this situation, WS-Addressing support is enabled on the client only if policy sharing is enabled on the service provider and the policy configuration for the provider specifies that WS-Addressing is mandatory.

This method overrides other methods.

- Set the `com.ibm.websphere.webservices.use.async.mep` property on the client request context.
- Use the IBM proprietary WS-Addressing SPI to add message-addressing properties to the message request context.
- Use deployment descriptor elements within a `port-component-ref` element.
- Use the `Addressing` annotation in combination with the `WebServiceRef` annotation in the client code (when you are using an injected Web services proxy reference).
- Use addressing features in the client code. Properties set by using this method override those set in the WSDL document for the service.
- Use WS-Policy assertions in the WSDL document to specify WS-Addressing support. If you add `Addressing` annotations to your client application code, the generated WSDL document will contain WS-Policy assertions.
- Specify the `UsingAddressing` element in the WSDL document for the service. If the service uses the `Addressing` annotation and you generate the WSDL document from the code, the `UsingAddressing` element already exists.

The following tables summarize the behavior of the WS-Addressing support. Use this table to determine whether a request message is accepted for client settings that do not involve policy configuration.

This is a complex table containing spanned column headings. There is a header column on the left entitled "Client settings" which specifies whether WS-Addressing support is enabled on the client and also which messaging style is configured. The second main column shows the policy settings on the provider, with two sub-columns for whether WS-Addressing is optional or mandatory. Both of these sub-columns are further sub-divided into three sub-columns for messaging style (synchronous, asynchronous, or both). The third main column shows the WSDL settings on the provider, with two sub-columns for whether WS-Addressing is optional or mandatory.

Table 111. How client and provider settings interact to determine whether a request message is accepted. The preceding paragraph describes this table.

Client settings	Provider policy settings						Provider WSDL settings (UsingAddressing required attribute)	
	WS-Addressing is optional			WS-Addressing is mandatory ¹			false (WS-Addressing is optional)	true (WS-Addressing is mandatory ¹)
	Synchronous and asynchronous	Synchronous only	Asynchronous only	Synchronous and asynchronous	Synchronous only	Asynchronous only		
WS-Addressing support enabled and messaging style synchronous	Message accepted	Message accepted	Fault	Message accepted	Message accepted	Fault	Message accepted	Message accepted
WS-Addressing support enabled and messaging style asynchronous	Message accepted	Fault	Message accepted	Message accepted	Fault	Message accepted	Message accepted	Message accepted
WS-Addressing support not enabled and messaging style synchronous	Message accepted	Message accepted	Message accepted ²	Fault	Fault	Fault	Message accepted	Fault
WS-Addressing support not enabled and messaging style asynchronous ³	Fault	Fault	Fault	Fault	Fault	Fault	Fault	Fault

Notes:

1. If WS-Addressing is mandatory, all requests without WS-Addressing headers are rejected.
2. The messaging style is only enforced if WS-Addressing headers are present in the request.
3. Asynchronous messaging is not possible without WS-Addressing headers.

Use the following table to determine whether a request message is accepted when the client and provider both have a WS-Addressing policy configuration; the client has provider and client policies applied; and policy sharing is enabled on the server.

This is a complex table containing spanned column headings. There is a header column on the left entitled "Client settings" which specifies whether WS-Addressing support is optional or mandatory on the client and also which messaging style is configured. The second main column shows the policy settings on the provider, with two sub-columns for whether WS-Addressing is optional or mandatory. Both of these sub-columns are further sub-divided into three sub-columns for messaging style (synchronous and asynchronous, synchronous only, or asynchronous only).

Table 112. How client and provider policy settings interact to determine whether a request message is accepted. The preceding paragraph describes this table.

Client policy settings	Provider policy settings					
	WS-Addressing is optional			WS-Addressing is mandatory		
	Synchronous and asynchronous	Synchronous only	Asynchronous only	Synchronous and asynchronous	Synchronous only	Asynchronous only
WS-Addressing optional and messaging style synchronous and asynchronous	Message accepted	Message accepted	Message accepted	Message accepted	Message accepted	Message accepted
WS-Addressing optional and messaging style synchronous only	Message accepted	Message accepted	Message accepted ¹	Message accepted	Message accepted	Fault
WS-Addressing optional and messaging style asynchronous only ²	Fault	Fault	Fault	Message accepted	Fault	Message accepted
WS-Addressing mandatory and messaging style synchronous and asynchronous	Message accepted	Message accepted	Message accepted	Message accepted	Message accepted	Message accepted
WS-Addressing mandatory and messaging style synchronous only	Message accepted	Message accepted	Fault	Message accepted	Message accepted	Fault
WS-Addressing mandatory and messaging style asynchronous only	Message accepted	Fault	Message accepted	Message accepted	Fault	Message accepted

Notes:

1. The messaging style is only enforced if WS-Addressing headers are present in the request.
2. Asynchronous messaging is not possible without WS-Addressing headers.

If the provider and client policies are not shared, the client does not send WS-Addressing headers (unless you enable WS-Addressing on the client by another method). In this situation, if the provider policy specifies that WS-Addressing is mandatory, the server generates a fault regardless of the messaging style.

Procedure

- To modify the behavior of the WS-Addressing support by creating or modifying policy sets on either the service provider or client, see the topic: “Enabling Web Services Addressing support for JAX-WS applications using policy sets” on page 1121.
- Set the `com.ibm.websphere.webservices.use.async.mep` property on the client request context when using WebSphere Application Server clients to enable WS-Addressing support. See the topic: “Invoking JAX-WS web services asynchronously” on page 1010 for more information.
- To modify the behavior of the WS-Addressing support by using the deployment descriptor of the service or client application, see the topic: “Enabling Web Services Addressing support for JAX-WS applications using deployment descriptors” on page 1148.
- To modify the behavior of the WS-Addressing support programmatically by using addressing annotations in the service application, or on the client with an injected web service proxy reference, see the topic: “Enabling Web Services Addressing support for JAX-WS applications using addressing annotations” on page 1149.
- To enable WS-Addressing support programmatically on the client by creating an instance of an addressing feature class, see the topic: “Enabling Web Services Addressing support for JAX-WS applications using addressing features” on page 1151.

- To modify the behavior of the WS-Addressing support during the development of a client or service application by adding WS-Policy assertions into the WSDL file, see the topic: “Enabling Web Services Addressing support for JAX-WS applications using WS-Policy” on page 1152.

Results

WS-Addressing properties are now included in the SOAP message header, and are processed by the server on receipt of the message.

Enabling Web Services Addressing support for JAX-WS applications using policy sets

For JAX-WS applications, you can enable WS-Addressing support after you deploy an application to the server, by creating or modifying policy sets, and attaching those policy sets to either a service or client application.

About this task

You can also configure the WS-Addressing support using other methods, for example in the code of the application, however this method overrides all other methods. Note that WS-Addressing support is enabled by default for service providers.

Procedure

1. Ensure that you have a policy set that contains the WS-Addressing policy type. If you have to create a new policy set, or add the WS-Addressing policy to an existing policy set, refer to Managing policy sets using the administrative console for instructions.
2. Configure the WS-Addressing policy type according to the instructions in “Configuring the WS-Addressing policy” on page 1129. Use the two settings to specify whether WS-Addressing is mandatory, and whether to use a synchronous or asynchronous message exchange pattern. The default settings are that WS-Addressing is not mandatory, and that both synchronous and asynchronous messaging patterns are used.
3. Attach the policy set to a web service provider or client artifact, according to the instructions in “Attaching a policy set to a service artifact” on page 1131.
4. Optional: If you want to communicate the WS-Addressing policy settings to other servers and clients, configure policy sharing as described in “Configuring a service provider to share its policy configuration” on page 1132 or “Configuring the client policy to use a service provider policy” on page 1140. If policy sharing is enabled and the server and client cannot agree a policy, normal WS-Policy behavior applies (a policy error is produced).

Results

WS-Addressing properties are now included in the SOAP message header, and are processed by the server on receipt of the message.

Creating policy sets using the administrative console

You can use the administrative console to either create a policy set by specifying all the necessary information or by copying an existing policy set that you rename. You can use policy sets, or assertions that define services, to simplify your web services configuration because policy sets group security and other web services settings into reusable units.

Before you begin

To create a new policy set, you can either specify the information to create a new policy set or you can copy and rename an existing policy set. Using either method, you need basic information about the policy set that you want to create, such as the name, description, policies to include, policy details, attachments,

and binding configurations. If you are creating a policy set by copying an existing policy set, then you should also view the existing policy sets to choose one with properties that are most similar to the one you plan to create.

About this task

Whether you choose to create a new policy set or copy and rename an existing one, start from the Applications policy sets collection in the administrative console.

Procedure

1. From the administrative console, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**.
2. If the policy set you are creating is:
 - a new policy set, then click **New**.
 - an existing policy set to be copied and renamed, click the **Select** box beside the name of the policy set to be copied in the **Name** column and click **Copy**.

Using either method, this action opens the Policy set settings view to specify the required information about the policy set being created or copied.

3. Enter the name of the policy set that you want to create or copy in the **Name** field.
4. Enter a brief description of the policy set in the **Description** field. This is the description that displays in the Application policy sets or the System policy set collection, so it must be meaningful to you and other potential users of this policy set.

Note: If you created a new policy set, it does not contain policies to edit until you add them to the policy set. The policy set is initially empty.

Results

You have provided the basic information to create a policy set.

Example

After you have looked at your web services, you might decide that the WS-I RSP default policy set most closely meets your needs. You would go to the administrative console and click **Services > Policy sets > Application policy sets** to access the Application policy sets collection. Locate the WS-I RSP default in the **Name** column of the table and click the box beside it (in the **Select** column). Click **Copy**. This opens the Policy set settings window. You might want to name your policy set by your company or division so you could provide a name like ABC WS-I RSP in the Name field. Because you know others in your organization might access and use it, you've chosen a name that is meaningful to those people too. You want to be sure everyone knows exactly what this copy of the WS-I RSP policy is used for, so you add a description in the **Description** field describing it. Now you want to customize the policy set so you edit the policy information by clicking the name of a policy to edit it.

When you identify the requirements of your web service, you might decide that none of the default policy sets meet your needs closely enough to use them as a template so you might decide to create your own policy set. You would first create the policy set with the name you choose to give it. As if you were reusing an existing template, you would go to the administrative console and click **Services > Policy sets > Application policy sets** and click **New**. The Policy set settings window opens but note that the Policy set name field is blank and there are not yet any associated policies in the table. Enter the name and add any policies necessary.

When you add policies to a policy set, the policies are set to their default values. You can then edit the policies to modify any attribute values that need to be changed and save the settings.

What to do next

If you are creating a new policy set without copying an existing policy set, you need to specify the policy information. If you are copying an existing policy set, you can either accept the default policies associated with the policy set or you can change the policies.

WS-I RSP default policy sets:

The Reliable Asynchronous Message Profile (WS-I RSP) default policy sets are based on the Reliable Asynchronous Message Profile specification. The WS-I RSP default policy sets include the WS-I RSP default policy set, the Lightweight Third-Party Authentication (LTPA) WS-I RSP default policy set and the Username WS-I RSP default policy set. You can use these policy sets to simplify your web services configuration.

The WS-I RSP default policy sets are composed of a set of policies to provide reliable and secure web services. The WS-I RSP default policy sets use the WS-Addressing, WS-ReliableMessaging, and WS-Security specifications. Use the WS-I RSP default policy set, the LTPA WS-I RSP default policy set, or the Username WS-Security WS-I RSP default policy set as provided with the application server. To customize the policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

The WS-I RSP default policy sets include the following policies:

WS-Addressing policy

You can use the WS-Addressing policy to enable the addressing capability of the WS-Addressing specification.

WS-ReliableMessaging policy

You can use the WS-ReliableMessaging policy to specify the quality of service for reliable delivery.

WS-Security policy

The WS-Security policy in the WS-I RSP default policy set provides the following security:

- Message integrity through digital signature that includes signing the body, time stamp, WS-Addressing headers and WS-ReliableMessaging headers using the WS-SecureConversation and WS-Security specifications.
- Confidentiality through encryption that includes encrypting the body, signature elements, using the WS-SecureConversation and WS-Security specifications.
- Traditional RSA cryptography is used to secure a request to a Trust Server to obtain a Secure Context Token (SCT). Thereafter, the conversation is secured using symmetric keys derived from the SCT.

The application server provides additional policy sets that you can use or customize. To use the following default policy sets, you must import the policy sets from the default repository. Read about importing policy sets using the administrative console for more information.

The following WS-I RSP default policy sets exist:

WS-I RSP default

This policy set provides:

- Reliable message delivery to the intended receiver by enabling WS-ReliableMessaging.
- Message integrity through digital signature that includes signing the body, time stamp, WS-Addressing headers and WS-ReliableMessaging headers using the WS-SecureConversation and WS-Security specifications.
- Confidentiality through encryption that includes encrypting the body, signature elements, using the WS-SecureConversation and WS-Security specifications.

LTPA WS-I RSP default

This policy set provides the WS-I RSP default policy set and adds a Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

Username WS-I RSP default

This policy set provides the WS-I RSP default policy set and adds a username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

SecureConversation default policy sets:

The SecureConversation default policy sets are based on the Web Services Secure Conversation Language (SecureConversation) standard that establishes a secure context, based on shared keys for the client and server to use for a series of messages. This standard provides a framework to define how to secure the message exchange across organizations. The SecureConversation default policy sets include the SecureConversation policy set, the Lightweight Third-Party Authentication (LTPA) SecureConversation policy set, and the Username SecureConversation policy set.

The SecureConversation default policy sets are based on the WS-SecureConversation, the WS-Security, and the WS-Addressing specifications. Use the SecureConversation policy set, the LTPA SecureConversation policy set, or the Username SecureConversation policy set as provided with the application server. To customize the policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

The WS-SecureConversation specification alone does not provide a complete security solution. The WS-SecureConversation is built on the WS-Security and WS-Trust specifications to provide secure communication across one or more messages. Specifically, this specification defines mechanisms for establishing and sharing security contexts, and deriving keys from established security contexts or any shared secret.

WS-Security focuses on the message authentication model but not in a security context. The WS-SecureConversation specification defines mechanisms for establishing and sharing security contexts, and deriving keys from security contexts, to enable a secure conversation. By using the SOAP extensibility model, modular SOAP-based specifications are designed to be composed with each other to provide a rich messaging environment.

The following SecureConversation default policy sets exist:

SecureConversation

This policy set provides:

- Message integrity by digital signature that includes signing the body, timestamp, and WS-Addressing headers using WS-SecureConversation and WS-Security specifications.
- Message confidentiality by encryption that includes encrypting the body, signature and signature confirmation elements, using WS-SecureConversation and WS-Security specifications.

LTPA SecureConversation

This policy set provides the SecureConversation policy set and adds a Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

Username SecureConversation

This policy set provides the SecureConversation policy set and adds a username token included in the request message to authenticate the client to the service. The username token is encrypted in the request

WS-ReliableMessaging default policy sets:

The WS-ReliableMessaging default policy sets are pre-configured to provide reliable message exchange between web services. Two of these policy sets (WS-I RSP and WS-I RSP ND) are immediately available, and the rest are readily available for import from a default repository.

With WS-ReliableMessaging, you can make your SOAP over HTTP-based web services reliable without writing custom code. You can use the provided non-editable default policy sets without change, or you can create customized copies of them.

All the default policy sets that include the WS-ReliableMessaging policy also include the WS-Addressing policy. The WS-ReliableMessaging policy provides the ability to deliver a message reliably to its intended receiver. The WS-Addressing policy provides a transport-neutral way to uniformly address web services and messages, and WS-ReliableMessaging uses WS-Addressing to provide asynchronous request and reply capabilities.

Note: WS-ReliableMessaging Version 1.1 messaging requires WS-Addressing to be mandatory. If you use a policy set that includes WS-ReliableMessaging and WS-Addressing policies, and the WS-Addressing policy is configured as optional, then WebSphere Application Server overrides the WS-Addressing setting and automatically enables WS-Addressing.

The following default policy sets that include the WS-ReliableMessaging policy are immediately available, as described in Viewing policy sets using the administrative console:

WS-I RSP

This policy set enables WS-ReliableMessaging Version 1.1 and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent. Message integrity is provided by digitally signing the body, the time stamp, and the WS-Addressing headers. Message confidentiality is provided by encrypting the body and the signature. This policy set follows the WS-SecureConversation and WS-Security specifications.

WS-I RSP ND

This is the network deployment version of the WS-I RSP policy set. This policy set provides the WS-I RSP default policy set and adds a *managed non-persistent* quality of service. This in-memory quality of service option uses a messaging engine to manage the sequence state, and messages are written to disk if memory is low. This quality of service allows for the re-sending of messages that are lost in the network, and can also recover from server failure. However, state is discarded after a messaging engine restart so in this case you will lose messages.

The following additional default policy sets that include the WS-ReliableMessaging policy are readily available for import, as described in Importing policy sets using the administrative console:

LTPA WS-I RSP

This policy set provides the WS-I RSP default policy set and adds a Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

Username WS-I RSP

This policy set provides the WS-I RSP default policy set and adds a username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

WSReliableMessaging 1_0

This policy set enables both WS-ReliableMessaging Version 1.0 and WS-Addressing and uses the

minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

You can use this policy set with .NET-based web services.

WSReliableMessaging default

This policy set enables both WS-ReliableMessaging Version 1.1 and WS-Addressing and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

WSReliableMessaging persistent

This policy set enables both WS-ReliableMessaging and WS-Addressing and uses the maximum quality of service, *managed persistent*. This quality of service supports asynchronous web service invocations and uses a service integration messaging engine and message store to manage the sequence state. Messages are processed within transactions, are persisted at the web service requester server and at the web service provider server, and are recoverable in the event of server failure. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

Because this policy set specifies managed persistent quality of service, you have to define bindings to the service integration bus and messaging engine that you want to use to manage the WS-ReliableMessaging state. You can attach and bind a WS-ReliableMessaging policy set to a web service application by using the administrative console or the wsadmin tool.

WSAddressing default policy set:

The WSAddressing default policy set provides a transport-neutral way to uniformly address web services and messages.

The WSAddressing default policy set is based on the WS-Addressing specification. The WS-Addressing standard uses endpoint references and message addressing properties to facilitate the addressing of web services in a standard and interoperable way.

Use the WSAddressing default policy set as provided with the application server. To customize the policy set, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

To learn more about the WS-Addressing standard, read about Web Services Addressing support.

Web Services Security default policy sets:

The Web Services Security default policy sets are based on the WS-Security 1.0 and Web Services Addressing (WS-Addressing) specifications. The Web Services Security default policy sets include the WSSecurity default policy set, the Lightweight Third-Party Authentication (LTPA) WSSecurity policy set, the Username WSSecurity policy set, and the Kerberos V5 HTTPS default policy set. These default policy sets are used to build secure web services.

The Web Services Security default policy sets use the WS-Security 1.0 specification enhancements to SOAP messaging to provide quality of protection through message integrity, message confidentiality, and single message authentication. Providing quality of protection means to prevent the following potential threats to SOAP messages:

- The message being modified or read by antagonists.

- An antagonist sending messages to a service that are formed correctly, but lack the appropriate security claims to be processed.

The WS-Addressing specification defines XML 1.0 and XML Namespaces elements to identify web services endpoints and to secure end-to-end endpoint identification in messages.

You can use the WSSecurity default policy set, the LTPA WSSecurity policy set, the Username WSSecurity policy set, or the Kerberos V5 HTTPS default policy set as provided with the application server. To customize the other Web Services Security policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

Features and details of the default Web Services Security policy sets are as follows:

Kerberos V5 HTTPS default

This policy set provides message authentication with a Kerberos Version 5 token. Message integrity and confidentiality are provided by Secure Sockets Layer (SSL) transport security. This policy set follows the OASIS Kerberos Token Profile V1.1 and WS-Security specifications.

When you use this policy set, configure the basic authentication data and custom properties such as the `com.ibm.wsspi.wssecurity.krbtoken.targetServiceName` and `com.ibm.wsspi.wssecurity.krbtoken.targetServiceHost` custom properties in the client bindings. For more information, see the Authentication generator or consumer token settings and Protection token settings (generator or consumer) topics.

LTPA WSSecurity default

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.
- A Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

Username SecureConversation

This policy set provides:

- Message integrity through digital signature that includes signing the body, time stamp, and WS-Addressing headers using WS-SecureConversation and WS-Security specifications
- Message confidentiality through encryption that includes encrypting the body, signature and signature confirmation elements, using WS-SecureConversation and WS-Security specifications
- A username token included in the request message to authenticate the client to the service. The username token is encrypted in the request

Username WSSecurity default

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.
- A username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

WSSecurity default

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.

WSTransaction default policy sets:

The WSTransaction default policy sets are based on the WS-Transaction specification and provide transactional integrity for web services. The WSTransaction default policy sets include the WSTransaction policy set and the SSL WSTransaction policy set.

You can use the WSTransaction default policy sets to make your SOAP over HTTP-based web services interoperable and coordinate atomic transactions or business activities without writing custom code. Use the WSTransaction policy set or the SSL WSTransaction policy set as provided with the application server. To customize the policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

The WSTransaction default policy sets are:

WSTransaction

Use this policy set to coordinate distributed transactional work atomically and interoperably, by using the WS-AtomicTransaction specification. Also, use this policy set to coordinate loosely coupled business processes that are distributed across the heterogeneous web service environment, with the ability to compensate actions if a failure occurs in the business activity, by using the WS-BusinessActivity specification.

SSL WSTransaction

Use this policy set to coordinate distributed transactional work atomically, interoperably and securely, by using the WS-AtomicTransaction specification and SSL Transport security. Also, use this policy set to coordinate loosely coupled business processes, with the ability to compensate actions if a failure occurs in the business activity, securely, by using the WS-BusinessActivity specification and SSL Transport security.

WSHTTPS default policy set:

The WSHTTPS default policy set provides SSL transport security for the HTTP protocol with web services applications.

The WSHTTPS default policy set is provided with the application server and it contains the HTTP transport policy, the SSL transport policy and the WS-Addressing policy.

You can use the WSHTTPS default policy set as provided with the application server. You cannot edit the WSHTTPS default policy set. You can create a copy of the default policy set and then configure custom policy settings and bindings to meet your needs. Alternatively, you can create a new policy set and specify the policies for it.

Copy of default policy set and bindings settings:

Use this page to copy a policy set that you select from a list of available policy sets.

To view this administrative console page:

1. Click **Services > Policy sets > Application policy sets**.
2. Select the policy set that you want to copy, and click **Copy**.
3. Enter a name for the copy of the policy set in the **Name** field.
4. [Optional] Enter a description for the copy of the policy set in the **Description** field.

Name:

Specifies the name of the policy set. Use this field to enter a name for the copy of the policy set.

Description:

Specifies a description of the policy set that you want to copy.

Transfer attachments:

If the policy set that you want to copy is attached to one or more applications, services, or endpoints, then the check box option for **Attach this policy set in place of the original for all attached applications, services, endpoints, and operations**, is available. The default setting for this check box is cleared. You can perform the following actions:

1. Select the **Attach this policy set in place of the original for all attached applications, services, endpoints, and operations** check box to move the attachments to a new policy set. Selecting the check box detaches the original policy set and attaches the replacement policy set in its place.
2. Select **Copy bindings** if you want to copy the bindings of the policy set that is currently attached.
3. [Optional] Select **Restore default bindings** if you want to restore the default bindings.

Configuring the WS-Addressing policy

When working with policy sets in the administrative console, you can add and configure policies to enable standard addressing of web services.

Before you begin

You can specify policies for custom policy sets. The provided default policy sets cannot be edited. You must create a copy of the default policy set or create a completely new policy set in order to specify the policies for it.

About this task

Adding a WS-Addressing policy enables the support for WS-Addressing. This support provides a standard way to address Web services and include addressing information in messages. Adding a WS-Addressing policy is equivalent to configuring the WSDL file for the web service to specify that WS-Addressing should be used.

To specify or configure the policies associated with a policy set, use the administrative console.

Procedure

1. In the navigation pane of the administrative console, click **Services > Policy sets > Application policy sets > policy_set_name > [Policies] WS-Addressing**. The WS-Addressing settings pane is displayed.
2. Select **WS-Addressing is mandatory** to specify that WS-Addressing information must be included in SOAP message headers. For servers, this setting means that the server returns a fault if it receives a message that does not contain a WS-Addressing header. For clients, this setting means that WS-Addressing headers are always added to SOAP messages. If you have enabled WS-Policy, this requirement is communicated between servers and clients that support WS-Policy.
3. In the **Messaging style** box, select the message exchange pattern to use:
 - **Synchronous and asynchronous**. The targeting of response messages is not restricted.
 - **Synchronous only**. Response messages must be targeted at the WS-Addressing anonymous URI.
 - **Asynchronous only**. Response messages must not be targeted at the WS-Addressing anonymous URI.
4. Click **OK**.
5. Save your changes to the master configuration.

Results

After you have included the WS-Addressing policy in a policy set, the associated policy set uses this policy to address web services.

WS-Addressing policy settings:

Use this page to define the appropriate WS-Addressing policy assertions for this policy set.

To view this administrative console page, click **Services > Policy sets > Application policy sets > *policy_set_name* > [Policy] WS-Addressing**, when the policy set includes the WS-Addressing policy type.

You can configure the WS-Addressing policy type for both client-side and provider-side policy sets. If you enable WS-Policy, this configuration is communicated between servers and clients that support WS-Policy.

WS-Addressing is mandatory:

Specifies whether a WS-Addressing SOAP header is included on messages.

Information

Data type

Default

Range

Value

Check box

Cleared

Cleared

WS-Addressing is not mandatory. Servers will not generate a fault if they receive a message that does not contain a WS-Addressing header. Clients might not include WS-Addressing headers in SOAP messages, for example, if WS-Policy is enabled and the server does not specify that WS-Addressing is mandatory.

Selected

WS-Addressing is mandatory. Servers return a fault if they receive a message that does not contain a WS-Addressing header. Clients always include WS-Addressing headers in SOAP messages.

Messaging style:

Specifies the messaging style supported by this policy set.

Use the radio buttons to configure the messaging style.

- Select **Synchronous and asynchronous** to specify that there is no restriction on the targeting of response messages.
- Select **Synchronous only** to specify that response messages must be targeted at the WS-Addressing anonymous URI. You might want to use this messaging style in the following situations:
 - The SOAP headers are not signed, and WS-Security is not enabled. Specifying the synchronous message exchange pattern prevents the server sending messages to a third party, thereby preventing the server from potentially taking part in a Denial of Service attack.
 - Clients with a NAT device between themselves and the endpoint. In this configuration, non-anonymous URIs cannot be routed. Use this setting to prevent the client from sending a message containing a ReplyTo endpoint reference with a non-anonymous URI.

- Select **Asynchronous only** to specify that response messages must not be targeted at the WS-Addressing anonymous URI. This setting does not mean that all non-anonymous URIs are supported, therefore a server can return a fault if it receives a response endpoint reference that it cannot process. You might want to use this messaging style if the endpoint has a very long-running invocation time, and you do not want to hold the connection open while waiting for a response.

The following table shows how the messaging style options correspond to WS-Policy assertions.

Table 113. WS-Addressing messaging style and WS-Policy. This table provides a mapping between messaging style options and WS-Policy assertions.

Messaging style	WS-Policy mapping
Synchronous and asynchronous	wsam:AnonymousResponses or wsam:NonAnonymousResponses
Synchronous only	wsam:AnonymousResponses
Asynchronous only	wsam:NonAnonymousResponses

Information	Value
Required	No
Data type	Radio button

Attaching a policy set to a service artifact

Attach a policy set to a service artifact, such as an application, service, endpoint or operation, to define the quality of services that are supported. Policy sets can define the policies for WS-Addressing, WS-Security, WS-ReliableMessaging, WS-Transaction, HTTP transport, Java Messaging Service (JMS) transport, and Secure Sockets Layer (SSL) transport.

Before you begin

Before you can start this task, you must deploy an application containing web services. Also, if none of the default policy sets contain the necessary policy definitions, then you must create a custom policy set with the necessary definitions.

About this task

Develop a web service that contains each of the necessary artifacts, and deploy your web services application into your application server instance. Now you can attach policy sets to your service artifacts, such as an application, service, or endpoint.

To attach a policy set to a service artifact, perform the following steps:

Procedure

1. Open the administrative console.
2. To attach a policy set to a service provider, click **Applications > Enterprise applications > *application_name* > Service provider policy sets and bindings**.
To attach a policy set to a service client, click **Applications > Enterprise applications > *application_name* > Service client policy sets and bindings**.
3. Select the check box for the service artifact.
4. Select **Attach** to display a list of available policy sets to attach. Select a policy set from the list.
5. Click **Save**, to save your changes to the master configuration.
6. [Optional] To see what attachments are defined for a given policy set, select **Services > Policy sets > Application policy sets > *policy_set_name* > Attached applications**.

Results

When you finish these steps, a policy set is attached to the service artifact.

Example

If you have the application, `app1` and you want to attach the policy set, `WSSecurity default`, then perform the following steps:

1. Locate the `app1` application in the **Applications > Enterprise applications** collection.
2. Click the `app1` application.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** link.
4. Select the check box for the service artifact where the policy set is to be attached.
5. Click **Attach**. Select `WSSecurity default` policy set.
6. Click **Save**, to save your changes to the master configuration.

What to do next

You can create custom bindings for policy set attachments. Read about creating custom bindings for policy set attachments.

You can configure the service client or service provider to share their policies. Read about using WS-Policy to exchange policies in a standard format.

Configuring a service provider to share its policy configuration

A WebSphere Application Server service provider can share its policy configuration in published Web Services Description Language (WSDL), or WSDL that is obtained by using an HTTP GET request or the Web Services Metadata Exchange (WS-MetadataExchange) GetMetadata request.

Before you begin

You have developed a web services service provider that contains all the necessary artifacts and deployed your web services application into your application server instance. You have attached the policy sets and managed the associated bindings.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the topic about learning about WS-Policy.

About this task

You can make the policy configuration of a Java API for XML-Based Web Services (JAX-WS) service endpoint available to share in the following ways:

- Include the policy configuration of the service provider in the WSDL. The WSDL is then available to publish, or to obtain by using an HTTP GET request.
- Enable the Web Services Metadata Exchange (WS-MetadataExchange) protocol so that the policy configuration of the service provider is included in the WSDL and is available to a WS-MetadataExchange GetMetadata request. An advantage of using the WS-MetadataExchange protocol is that you can apply message-level security to WS-MetadataExchange GetMetadata requests by using a suitable system policy set.

If the service provider application uses multipart WSDL, all the WSDL must be local to the web service application. For more information about multipart WSDL, see the topic about WSDL.

You must configure a service provider to share its policy configuration because by default the policy configuration is not available in its WSDL. You can configure the service provider to include the policy configuration in its WSDL, to use WS-MetadataExchange so that the policy configuration is available, or both. This topic describes how to configure a service provider to share its policy configuration by using the administrative console. You can also configure a service provider to share its policy configuration by using wsadmin commands or Rational Application Developer tools.

You can configure a service provider to share its policy configuration at application or service level. The policy configuration that is represented by the policy sets attached to any lower levels will also be shared. Policy sets that are attached at lower levels override the policy set configuration attached at a higher level.

Procedure

1. From the navigation pane of the administrative console, click **Applications > Application Types > WebSphere enterprise applications > service_provider_application_instance > [Web services properties] Service provider policy sets and bindings**.
2. In the row for the application or service where the provider policy that you want to share is attached, click the link in the Policy sharing column. The link is either **Enabled** or **Disabled**. The Policy Sharing pane is displayed.
3. To include the policy configuration of the service provider in its WSDL so that it can be either published or obtained by using an HTTP GET request, select **Exported WSDL**.
4. To enable WS-MetadataExchange and make the policy configuration of the service provider available to a WS-MetadataExchange GetMetadata request, select **WS-MetadataExchange request**.
5. Optional: If you select **WS-MetadataExchange request** and you want to use message-level security, select **Attach a system policy set to the WS-MetadataExchange**, then select a suitable policy set and binding from the drop-down lists. See *Configuring security for a WS-MetadataExchange request*.
6. Click **OK** and save your changes to the master configuration.

Results

The policy configuration of the service provider is available to its clients. The WSDL of the service provider contains the current policy configuration in WS-PolicyAttachments format so that it is available to other clients, service registries, or services that support the Web Services Policy (WS-Policy) specification. The link in the Policy Sharing column on the Service provider policy sets and bindings pane changes to **Enabled**.

If the policy configuration cannot be shared, an error that describes the problem is written to the service provider error log, and the following policy is attached to the WSDL of the service provider:

```
<wsp:Policy>
<wsp:ExactlyOne>
</wsp:ExactlyOne>
</wsp:Policy>
```

This policy notifies the client that there is no acceptable policy configuration for the service. Other aspects of the WSDL are unaffected.

A service provider might not be able to share its policy configuration because the configuration cannot be expressed in the standard WS-PolicyAttachments format. One reason might be because multiple incompatible policies are defined for a particular attach point. Another reason might be because there is not enough binding information to generate the standard policy. Policy configuration might include bootstrap policy, for example, the policy to access a WS-Trust service, so the bootstrap policy must also be expressed in WS-PolicyAttachments format.

Configuring a service provider to share its policy configuration using wsadmin scripting:

A WebSphere Application Server service provider can share its policy configuration in published Web Services Description Language (WSDL), or WSDL that is obtained by using an HTTP GET request or the Web Services Metadata Exchange (WS-MetadataExchange) GetMetadata request.

Before you begin

You have developed a web services service provider that contains all the necessary artifacts and deployed your web services application into your application server instance. You have attached the policy sets and managed the associated bindings.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the topic about learning about WS-Policy.

About this task

You can make the policy configuration of a Java API for XML-Based Web Services (JAX-WS) service endpoint available to share in the following ways:

- Include the policy configuration of the service provider in the WSDL. The WSDL is then available to publish, or to obtain by using an HTTP GET request.
- Enable the Web Services Metadata Exchange (WS-MetadataExchange) protocol so that the policy configuration of the service provider is included in the WSDL and is available to a WS-MetadataExchange GetMetadata request. An advantage of using the WS-MetadataExchange protocol is that you can apply message-level security to WS-MetadataExchange GetMetadata requests by using a suitable system policy set.

If the service provider application uses multipart WSDL, all the WSDL must be local to the web service application. For more information about multipart WSDL, see the topic about WSDL.

You must configure a service provider to share its policy configuration because by default the policy configuration is not available in its WSDL. You can configure the service provider to include the policy configuration in its WSDL, to use WS-MetadataExchange so that the policy configuration is available, or both. This topic describes how to configure a service provider to share its policy configuration by using wsadmin commands. You can also use the administrative console or Rational Application Developer tools.

You can configure a service provider to share its policy configuration at application or service level. The policy configuration that is represented by the policy sets attached to any lower levels will also be shared. Policy sets that are attached at lower levels override the policy set configuration attached at a higher level.

Procedure

1. Start the wsadmin scripting client if it is not already running.
2. Use the **SetProviderPolicySharingInfo** command. For example:

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WebServiceProviderApplication
-resource WebService:/WebServiceProvider.war:{http://example_path/}Service1
-sharePolicyMethods [httpGet ]]')
```

3. Save your changes to the master configuration.

To save your configuration changes, enter the following command:

```
AdminConfig.save()
```

Results

The policy configuration of the service provider is available to its clients. The WSDL of the service provider contains the current policy configuration in WS-PolicyAttachments format so that it is available to other clients, service registries, or services that support the Web Services Policy (WS-Policy) specification.

If the policy configuration cannot be shared, an error that describes the problem is written to the service provider error log, and the following policy is attached to the WSDL of the service provider:

```
<wsp:Policy>
<wsp:ExactlyOne>
</wsp:ExactlyOne>
</wsp:Policy>
```

This policy notifies the client that there is no acceptable policy configuration for the service. Other aspects of the WSDL are unaffected.

A service provider might not be able to share its policy configuration because the configuration cannot be expressed in the standard WS-PolicyAttachments format. One reason might be because multiple incompatible policies are defined for a particular attach point. Another reason might be because there is not enough binding information to generate the standard policy. Policy configuration might include bootstrap policy, for example, the policy to access a WS-Trust service, so the bootstrap policy must also be expressed in WS-PolicyAttachments format.

What to do next

Optionally, you can publish the WSDL files.

setProviderPolicySharingInfo command:

Use the **setProviderPolicySharingInfo** command to set how an application or service that is a web service provider can share its policy configuration with other clients, service registries, or services that support the WS-Policy specification. You can set or remove this information about how a provider policy is shared.

To run the command, use the AdminTask object of the wsadmin scripting client.

 The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available policy set management administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('PolicySetManagement')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the **setProviderPolicySharingInfo** command to set how an application, or a service in an application, shares its policy configuration with clients, service registries, or services that support the WS-Policy specification. The policy configuration is shared in WS-PolicyAttachments format.

The policy configuration of the resource can be shared with clients through a WS-MetadataExchange request, through Web Services Description Language (WSDL) exported by a ?WSDL HTTP Get request, or through both methods.

Target object

None.

Required parameters

-applicationName

The name of the application for which you want to set how the provider policy is shared. (String)

-resource

The name of the resource for which you want to set how the provider policy is shared. For all resources in an application, specify `WebService:/.` For a service in an application, specify `WebService:/module:{namespace}service_name`. Endpoints or operations inherit the settings of the parent application or service. (String)

Optional parameters

-sharePolicyMethods

Specifies how the policy configuration of the resource can be shared. (String array)

Enter either or both of the following values:

httpGet

The resource can share its policy configuration through WSDL that is obtained by a ?WSDL HTTP Get request.

wsMex The resource can share its policy configuration through a WS-MetadataExchange request.

-wsMexProperties

Specifies that message-level security is required for WS-MetadataExchange requests and specifies the settings that provide the message-level security. (Properties)

Enter the following values, following each value with the setting that you require for that value:

wsMexPolicySetName

The name of the system policy set that specifies message-level security when the resource shares its policy configuration through a WS-MetadataExchange request. Specify a system policy set that contains only WS-Security policies, only WS-Addressing policies, or both. The default policy set is `SystemWSSecurityDefault`.

wsMexPolicySetBinding

The name of the general binding for the policy set attachment when the resource shares its policy configuration through a WS-MetadataExchange request. Specify a general binding that is scoped to the global domain, or scoped to the security domain of this service. If you do not specify this property, the default binding is used.

This parameter is valid only when you specify `wsMex` for the `sharePolicyMethods` parameter.

-remove

Specifies whether the information about how the provider policy is shared is removed from the resource. (Boolean)

This parameter takes the following values:

true The information about how the provider policy is shared is removed from the resource.

false This value is the default. The information about how the provider policy is shared is not removed from the resource.

Examples

The following example removes the information about how the provider policy is shared from the WSSampleServices application:

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WSSampleServices  
-resource WebService:/ -remove true]')
```

The following example enables policy sharing, using WSDL exported by a ?WSDL HTTP Get request, for the EchoService service in the WSSampleServices application:

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WSSampleServices  
-resource WebService:/WSSampleServicesSei.war:{http://example_path/}EchoService  
-sharePolicyMethods [httpGet ]]')
```

The following example enables policy sharing, using a WS-MetadataExchange request with message-level security, for the WSSampleServices application. Message level security is provided by the SystemWSSecurityDefault policy set and the “Provider sample” general binding.

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WSSampleServices  
-resource WebService:/ -sharePolicyMethods [wsMex ]  
-wsMexProperties [ [wsMexPolicySetName [SystemWSSecurityDefault]]  
[wsMexPolicySetBinding [Provider sample]] ]]')
```

getProviderPolicySharingInfo command:

Use the **getProviderPolicySharingInfo** command to find out whether an application or service that is a web service provider can share its policy configuration, and list the properties that apply to sharing that configuration.

To run the command, use the AdminTask object of the wsadmin scripting client.

 The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available policy set management administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('PolicySetManagement')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the **getProviderPolicySharingInfo** command to find out how a web services application, or a service in a Web services application, shares its policy configuration with clients, service registries, or services that support the WS-Policy specification. The policy configuration is shared in WS-PolicyAttachments format.

The command returns properties that show whether the policy configuration of the resource can be shared with clients through a WS-MetadataExchange request or through Web Services Description Language (WSDL) that is obtained by a ?WSDL HTTP Get request.

Target object

None.

Required parameters

-applicationName

The name of the application for which you want to find out how it shares its policy configuration. The application must be a service provider. (String)

Optional parameters

-resource

The name of the resource for which you want to find out how it shares its policy configuration. If you specify this parameter, only the properties for that resource are returned. To retrieve information for the application, specify `WebService:/.` Alternatively, you can specify a service, endpoint or operation. However, policy sets are attached only at the application or service level, so the properties returned for an endpoint or operation are the settings that are inherited from the service. (String)

Return value

Returns a list of properties that include the resource name and that show whether the policy configuration of the resource can be shared. The following properties can be returned:

wsMexPolicySetName

The name of the policy set that specifies message-level security when the resource shares its policy configuration through a WS-MetadataExchange request. This property is returned if the value of the `sharePolicyMethods` property is `wsMex` and a policy set to provide message-level security was specified.

wsMexPolicySetBinding

The name of the binding that is applied when the resource shares its policy configuration through a WS-MetadataExchange request. This property is returned if the value of the `sharePolicyMethods` property is `wsMex` and a binding to provide message-level security was specified.

resource

The resource that you specified.

directSetting

How the properties apply to the resource. Valid values for this property are:

true

The properties apply directly to the resource.

false

The properties are inherited from the parent application or service.

sharePolicyMethods

How the policy configuration of the resource can be shared. Valid values for this property are:

HttpGet

The resource shares its policy configuration through an HTTP Get request.

wsMex

The resource shares its policy configuration through a WS-MetadataExchange request.

Example

The following command displays the policy sharing configuration properties for the `EchoService` service in the `WSSampleServices` application. The provider is configured to share its policy through an HTTP Get

request, and a WS-MetadataExchange request with message-level security. Message-level security for the WS-MetadataExchange request is provided by using the SystemWSSecurityDefault policy set and the “Provider sample” general binding.

```
AdminTask.getProviderPolicySharingInfo(['-applicationName', 'WSSampleServices',  
'-resource', 'WebService:/SampleServicesSei.war:{http://example_path/}EchoService'])  
.  
.  
[ [wsMexPolicySetName SystemWSSecurityDefault] [wsMexPolicySetBinding [Provider sample]]  
[resource WebService:/SampleServicesSei.war:{http://example_path/}EchoService/]  
[directSetting true] [sharePolicyMethods [httpGet wsMex]] ]
```

Policy sharing settings:

Use this pane to view and change whether the policy configuration of a web services service provider is shared. You can configure the service provider to include the policy configuration in its Web Services Description Language (WSDL) so that it can be accessed using an HTTP Get request, or published. You can also make the policy configuration available to a Web Services Metadata Exchange (WS-MetadataExchange) request.

To view this administrative console page for an application or service, complete the following steps. The application must be a web services service provider.

1. Click **Applications > Application Types > WebSphere enterprise applications > *service_provider_application_name* > [Web Services Properties] Service provider policy sets and bindings.**
2. Select the link in the Policy Sharing column for the application or service you require. The link is available if the application or service has a policy set attached.

To view this administrative console page for a service, complete the following steps.

1. Click **Services > Service providers > *service_name*.**
2. Select the link in the Policy Sharing column for the service. The link is available if the service has a policy set attached.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Exported WSDL:

Select **Exported WSDL** to include the policy configuration of the service provider in the WSDL. The policy configuration is in WS-PolicyAttachments format in the WSDL so that it is then available to other clients, service registries, or services that support the Web Services Policy (WS-Policy) specification. The policy configuration will be available in published WSDL, or a client can use an HTTP Get request that is targeted at the target URL followed by ?WSDL to obtain the provider policy.

WS-MetadataExchange request:

Select **WS-MetadataExchange** to make the policy configuration of the service provider available to a WS-MetadataExchange GetMetadata request. The policy configuration is in WS-PolicyAttachments format in the WSDL so that it is then available to other clients, service registries or services that support the Web Services Policy (WS-Policy) specification and the WS-MetadataExchange GetMetadata request.

When **WS-MetadataExchange** is selected, the **Attach a system policy set to the WS-MetadataExchange** option is available.

Attach a system policy set to the WS-MetadataExchange:

Select **Attach a system policy set to the WS-MetadataExchange** to set message-level security for the WS-MetadataExchange request. By default, this option is not selected and the transport policy of the application is used. This option is available only when **WS-MetadataExchange** is selected.

When **Attach a system policy set to the WS-MetadataExchange** is selected, the **Policy set** and **Binding** lists are available.

Policy set:

Select the policy set you require from the list to provide message-level security for the WS-MetadataExchange request. You can select from system policy sets that contain only WS-Security policies, only WS-Addressing policies, or both. The default policy set is SystemWSSecurityDefault.

System policy sets are used for system messages that are not business-related, for example, messages that apply qualities of service (QoS), including the messages that are defined in the WS-MetadataExchange protocol.

Note that any transport policy of the application is always used.

This option is available only when **Attach a system policy set to the WS-MetadataExchange** is selected.

Binding:

Select the binding you require from the list to provide message-level security for the WS-MetadataExchange request. You can select from general bindings that are scoped to the global domain, or scoped to the security domain of this service.

This option is available only when **Attach a system policy set to the WS-MetadataExchange** is selected.

Configuring the client policy to use a service provider policy

An application that is a web service client can obtain the policy configuration of a web service provider and use this information to establish a policy configuration that is acceptable to both the client and the service provider.

Before you begin

You have developed a web service client that contains all the necessary artifacts, and deployed your web services application into your application server instance. If you require them, you have attached the policy sets and managed the associated bindings.

The service provider must publish its policy in its Web Services Description Language (WSDL) and that policy must contain its policy configuration at run time in WS-PolicyAttachments format. The client must be able to support those provider policies.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the WS-Policy topic.

About this task

You can administer the client to configure itself dynamically at run time, based on the policy of the service provider in the standard WS-PolicyAttachments format. You can administer the client to apply dynamically the provider policy at the application or service or service reference level. By default, endpoints and

operations inherit their policy configuration from the relevant service. However, it is possible to configure a service reference to override the service, in which case the endpoints and operations inherit their policy configuration from the service reference.

If the provider policy uses multipart WSDL, you can use an HTTP GET request to obtain the policy of the provider, but you cannot use the WS-MetadataExchange protocol. For more information about multipart WSDL, see the topic about WSDL.

Policy intersection is the comparison of a client policy and a provider policy to determine whether they are compatible, and the calculation of a new policy, known as the effective policy, that complies with both their requirements and capabilities.

This topic describes how to configure the client policy to use a service provider policy by using the administrative console. You can also configure the client policy to use a service provider policy by using wsadmin commands.

Procedure

1. From the navigation panel of the administrative console, click **Applications > Application Types > WebSphere enterprise applications > service_client_application_instance > [Web services properties] Service client policy sets and bindings**.
2. In the row for the application or service where you want to apply the policy, click the link in the Policies Applied column. The Policies Applied panel is displayed.
3. Select one of the following options from the drop-down list:
 - Provider policy only. Configure the client based solely on the policy of the service provider. This option is available when a client policy set is not attached.
 - Client and provider policy. Configure the client based on both the client policy set and the policy of the service provider. This option is available when a client policy set is attached.

The other options in the list do not apply to this task.

4. Use the radio buttons to select which method to employ to obtain the provider policy: an HTTP GET request (see step 5) or a WS-MetadataExchange request (see step 6).
5. Optional: To obtain the provider policy by using an HTTP GET request, click **HTTP GET request**. By default, the HTTP GET request is targeted at the URL for the service endpoint followed by ?WSDL. For example:

`http://myhost:9080/WSSampleSei/EchoService?WSDL`

When the policy set attach point is at the application level you cannot change this value.

- a. Optional: If you are applying a policy to a service and the provider policy is located at the service endpoint, ensure that **Use the default request target** is selected.
 - b. Optional: If you are applying a policy to a service and the provider policy is not located at the service endpoint, click **Specify request target**, then enter the URL for the location of the provider policy in the field. For example, you might change the target of the HTTP GET request if the provider policy is located in a repository.
 - c. Optional: If you select **HTTP GET request** as the method to be used to obtain the provider policy and if you select **Specify request target** and you want to configure transport-level security, select **Attach a system policy set to the HTTP GET request**, then select a suitable policy set and binding from the drop-down lists. Select the policy set you require from the Policy set list to provide transport-level security for the HTTP GET request. Select from system policy sets that contain solely HTTP transport policies, solely SSL transport policies, or both; the policy set cannot contain other policy types. Select the binding you require from the Binding list for the HTTP GET request. You can select from general bindings that are scoped to the global domain or scoped to the security domain of this service.
6. Optional: To obtain the provider policy by using a Web Services Metadata Exchange (WS-MetadataExchange) GetMetadata request, click **WS-MetadataExchange request**.

- a. Optional: If you select **WS-MetadataExchange request** and want to use message-level security, select **Attach a system policy set to the WS-MetadataExchange request**, then select a suitable policy set and binding from the drop-down lists. See *Configuring security for a WS-MetadataExchange request*.
7. Click **OK**.
8. Save your changes to the master configuration.

Results

The web application client-side policy is calculated when it is required at run time, based either on the policy of the service provider, or on the client policy set and the policy of the service provider, depending on which option you selected. This calculated policy is known as the “effective policy” and is cached as a runtime configuration. The effective policy is used for subsequent outbound web service requests to the endpoint or operation for which the dynamic policy calculation was performed. The policy set configuration of the client does not change.

The provider policy that the client holds for a service is refreshed the first time that the web service is invoked after the application is loaded. After that, the provider policy is refreshed when the application restarts, or if the application explicitly invokes a refresh. When the provider policy is refreshed, the effective policy is recalculated.

Configuring the client policy to use a service provider policy by using wsadmin scripting:

An application that is a web service client can obtain the policy configuration of a web service provider and use this information to establish a policy configuration that is acceptable to both the client and the service provider.

Before you begin

You have developed a web service client that contains all the necessary artifacts, and deployed your web services application into your application server instance. If you require them, you have attached the policy sets and managed the associated bindings.

The service provider must publish its policy in its Web Services Description Language (WSDL) and that policy must contain its policy configuration at run time in WS-PolicyAttachments format. The client must be able to support those provider policies.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the WS-Policy topic.

About this task

You can administer the client to configure itself dynamically at run time, based on the policy of the service provider in the standard WS-PolicyAttachments format. You can administer the client to dynamically apply the provider policy at the application or service or service reference level.

Note: If you specify client dynamic policy control at the service reference level, you must use the new name-value paired list format of the resource string. If you are not specifying client dynamic policy control at service reference level, you can use either format.

Table 114. How to specify policy control at different levels of the application. For each applicable level of the application, the table lists the relevant string format command and name-value pair format command needed to specify policy control and summarizes the associated behavior.

Level	String format	Name-value pair list format (NEW)	Behavior
Type	"WebService:/"	"type=WebService:/"	Indicates all artifacts in the application

Table 114. How to specify policy control at different levels of the application (continued). For each applicable level of the application, the table lists the relevant string format command and name-value pair format command needed to specify policy control and summarizes the associated behavior.

Level	String format	Name-value pair list format (NEW)	Behavior
Service	"WebService:/myModule:{namespace}myService"	"type=WebService:/,module=myModule,service={namespace}myService"	Indicates all artifacts within the web service
Endpoint (under this service)	"WebService:/myModule:{namespace}myService/endpointA"	"type=WebService:/,module=myModule,service={namespace}myService,endpoint=endpointA"	Indicates all operations for this endpoint (under the service)
Operation (under this service)	"WebService:/myModule:{namespace}myService/endpointA/operation1"	"type=WebService:/,module=myModule,service={namespace}myService,endpoint=endpointA,operation=operation1"	Indicates a specific single operation (under the service)
Service reference	[Not possible]	"type=WebService:/,module=myModule,service={namespace}myService,serviceRef=myServiceRef"	Indicates all artifacts within the web service reference
Endpoint (under this service reference)	[Not possible]	"type=WebService:/,module=myModule,service={namespace}myService,serviceRef=myServiceRef,endpoint=endpointA"	Indicates all operations for this endpoint (under the service reference)
Operation (under this service reference)	[Not possible]	"type=WebService:/,module=myModule,service={namespace}myService,serviceRef=myServiceRef,endpoint=endpointA,operation=operation1"	Indicates a specific single operation (under the service reference)

If the provider policy uses multipart WSDL, you can use an HTTP GET request to obtain the policy of the provider, but you cannot use the WS-MetadataExchange protocol. For more information about multipart WSDL, see the topic about WSDL.

Policy intersection is the comparison of a client policy and a provider policy to determine whether they are compatible, and the calculation of a new policy, known as the effective policy, that complies with both their requirements and capabilities.

This topic describes how to configure the client policy to use a service provider policy by using wsadmin commands. You can also configure the client policy to use a service provider policy by using the administrative console.

Procedure

1. Start the wsadmin scripting client if it is not already running.
2. Use the **SetClientDynamicPolicyControl** command. For example:

```
AdminTask.setClientDynamicPolicyControl('[-applicationName WebServiceClientApplication
-resource WebService:/ClientApplication.war:{http://example_path/}Service1
-acquireProviderPolicyMethod [httpGet ]
-httpGetProperties [httpGetTargetURI http://example_path]]')
```

3. Save your changes to the master configuration.

To save your configuration changes, enter the following command:

```
AdminConfig.save()
```

Results

The web application client-side policy is calculated when it is required at run time, based either on the policy of the service provider, or on the client policy set and the policy of the service provider, depending on which option you selected. This calculated policy is known as the “effective policy” and is cached as a runtime configuration. The effective policy is used for subsequent outbound web service requests to the endpoint or operation for which the dynamic policy calculation was performed. The policy set configuration of the client does not change.

The provider policy that the client holds for a service is refreshed the first time that the web service is invoked after the application is loaded. After that, the provider policy is refreshed when the application restarts, or if the application explicitly invokes a refresh. When the provider policy is refreshed, the effective policy is recalculated.

Configuring the client policy to use a service provider policy from a registry:

An application that is a web service client can obtain the policy configuration of a web service provider from a registry, such as WebSphere Service Registry and Repository (WSRR), and use this information to establish a policy configuration that is acceptable to both the client and the service provider.

Before you begin

You have developed a web service client that contains all the necessary artifacts, and deployed your web services application into your application server instance. If you require them, you have attached the policy sets and managed the associated bindings.

The Web Services Description Language (WSDL) for the policy of the service provider, and its corresponding policies and policy attachments, are stored in a registry such as WSRR. That policy must contain its policy configuration in WS-PolicyAttachments format. The client must be able to support those provider policies.

The registry must support the use of HTTP GET requests to publish WSDL that contains WS-Policy attachments, for example WSRR Version 6.2 or later.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the WS-Policy topic.

About this task

You can administer the client to configure itself dynamically at run time, based on the policy of a service provider that is held in a registry. You can administer the client at the service or service reference level to dynamically apply the provider policy that it obtains from a registry. By default, endpoints and operations inherit their policy configuration from the relevant service. However, it is possible to configure a service reference to override the service, in which case the endpoints and operations inherit their policy configuration from the service reference. You cannot administer the client to apply dynamically the provider policy that it obtains from a registry at the application level.

You can configure the client policy to use a service provider policy that is stored in a registry by using the administrative console. You can also configure the client policy to use a service provider policy that is stored in a registry by using wsadmin commands.

Procedure

1. From the navigation pane of the administrative console, click **Applications > Application Types > WebSphere enterprise applications**.
2. Click the web service client application that you want to configure.
3. Click **[Web services properties] Service client policy sets and bindings**.
4. In the row for the service where you want to apply the policy, click the link in the Policies Applied column. You cannot apply the policy at application level. The Policies Applied pane is displayed.
5. Select one of the following options from the drop-down list:
 - Provider policy only. Configure the client based solely on the policy of the service provider. This option is available when a client policy set is not attached.
 - Client and provider policy. Configure the client based on both the client policy set and the policy of the service provider. This option is available when a client policy set is attached.

The other options in the list do not apply to this task.

6. Click **HTTP GET request**.
7. Click **Specify request target**, then enter the URL for the location of the provider policy in the field, that is, the address in the repository for the WSDL and policy. For information about using WSRR to

retrieve a WSDL document with embedded policies, and therefore obtain the required URL, see the WSRR documentation. The following example shows a typical URL:

```
https://www.wsrr.host/WSRR/6.2/PolicyService/  
WSDL?bsrURI=3b9b493b-278f-4f64.ba3f.dabd30da3f7e
```

8. Click **OK**.
9. Optional: If there is a secure connection that uses the Secure Sockets Layer (SSL) protocol between the client and the registry, ensure that trust is established between the application server and the registry server. To access the registry, the client uses the SSL transport policy that is part of its service-level application policy. For example, for WSRR, you can enter the URL for the WSRR server in a browser window. If the WSRR server is not already trusted, a message is displayed stating that the security certificate is not trusted. To establish trust, use the following steps:
 - a. Retrieve and store the X509 certificate from the WSRR server. Use the options on the message to view details of the certificate and save those details to a file, using distinguished encoding rules (DER) encoded binary format.
 - b. Find out the key store that the client uses, that is, the key store that is shown by the SSL security transport bindings of the client application policy set. See *Configuring the SSL transport policy*. For example, the key store might be the default trust store for the node.
 - c. Add the signer certificate that you saved in step a. to the key store that the client uses. See *Adding a signer certificate to a keystore*.
10. Optional: To access the registry, the client uses the transport policy that is part of its service-level application policy. If the registry requires authentication using the HTTP protocol, configure a valid user name and password as part of the application-level transport policy binding configuration. It is advisable to secure any authorization credentials, because they are used for interactions with both the web service endpoint and the registry.
 - a. Ensure that the client has a policy set that contains the HTTP transport policy attached to the application or service level. See the relevant steps in *Managing policy sets and bindings for service clients at the application level using the administrative console*.
 - b. Configure the HTTP transport client bindings for the binding named *Client sample* and enter the user name and password that the registry requires to authenticate outbound service requests. See the relevant steps in *Configuring the HTTP transport policy*.
11. Save your changes to the master configuration.

Results

The web application client-side policy is calculated when it is required at run time, based either on the policy of the service provider, or on the client policy set and the policy of the service provider, depending on which option you selected. This calculated policy is known as the “effective policy” and is cached as a runtime configuration. The effective policy is used for subsequent outbound web service requests to the endpoint or operation for which the dynamic policy calculation was performed. The policy set configuration of the client does not change.

The provider policy that the client holds for a service is refreshed the first time that the web service is invoked after the application is loaded. After that, the provider policy is refreshed when the application restarts, or if the application explicitly invokes a refresh. When the provider policy is refreshed, the effective policy is recalculated.

Policies applied settings:

Use this panel to view and change whether the policy configuration of a WebSphere Application Server service client is configured dynamically, based on the policies supported by its service provider. You can view or change how the client obtains the policy of the service provider; the client can use an HTTP GET request or a Web Services Metadata Exchange (WS-MetadataExchange) request. You can specify a policy set and binding to provide message-level security for WS-MetadataExchange requests or to specify HTTP transport and SSL transport configuration for HTTP GET requests.

To view this administrative console page for an application or service, complete the following steps. The application must be a web services service client.

1. Click **Applications > Application Types > WebSphere enterprise applications > *service_client_application_name* > [Web Services Properties] Service client policy sets and bindings.**
2. Select the link in the **Policies Applied** column for the application or service you require.

To view this administrative console page for a service, complete the following steps:

1. Click **Services > Service clients > *service_name*.**
2. Select the link in the **Policies Applied** column for the service. The link is available if the service or the parent application has a policy set attached.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Apply the following policies:

Specifies whether the client policy is based on the policy of the service provider, and how that policy is used.

Select from the following options:

- Client policy only. Configure the client based solely on the client policy set. Do not use the policy of the service provider. This option is available when a client policy set is attached to the resource.
- Client and provider policy. Configure the client based on both the client policy set and the policy of the service provider. This option is available when a client policy set is attached to the resource.
- Inherit application attachment. Inherit the setting of the parent application. This option is available for a service when a client policy set is not attached to the service. If there is a policy set attached to the parent application, the inherited properties are displayed on this panel, but you cannot change them. If there is no policy set attached to the parent application, when you return to the Service clients policy sets and bindings panel, the Policies applied column shows a value of **None**.
- Provider policy only. Configure the client based solely on the policy of the service provider. This option is available when a client policy set is not attached to the resource.

HTTP GET request:

Click **HTTP GET request** to obtain the policy of the service provider by using an HTTP GET request. The policy configuration must be in WS-PolicyAttachments format in the WSDL of the service provider.

This option is available when **Apply the following policies** is set to Client and provider policy or Provider policy only.

By default, the HTTP GET request is targeted at the URL for each service endpoint followed by ?WSDL.

Use the default request target:

When you apply a policy to a service, click **Use the default request target** to target the HTTP GET request at the URL for each service endpoint followed by ?WSDL.

If the attach point is for the service, then you can either select this default request target or you can choose to specify an alternative request target using the **Specify request target** option.

If the attach point is for the application then the default request target will be used.

Specify request target:

When you apply a policy to a service, click **Specify request target** to change the target for acquiring provider policy using an HTTP GET request. Enter the URL for the location of the provider policy in the field.

This option is available when **HTTP GET request** is selected and you apply a policy to a service.

When you apply a policy to an application, this option is not available.

Attach a system policy set to the HTTP GET request:

Select **Attach a system policy set to the HTTP GET request** to set HTTP transport and SSL transport configuration for the HTTP GET request. This option is available when **HTTP GET request** is selected as the method to be used to obtain the provider policy and when **Specify request target** is selected and completed.

If you do not specify a policy set you will inherit the HTTP transport and SSL transport configuration from the application.

Policy set (for the HTTP GET request):

Select the policy set you require from the list to provide HTTP transport and SSL transport configuration for the HTTP GET request. Select from system policy sets that contain solely HTTP transport policies, solely SSL transport policies, or both; the policy set cannot contain other policy types.

This option is available when **Attach a system policy set to the HTTP GET request** is selected and the **Specify request target** is selected and completed.

Binding (for the HTTP GET request):

Select the binding you require from the list for the HTTP GET request. You can select from **Global Default Bindings** or **General client/provider policy set bindings**, which are specific to the individual service.

This option is available when **Attach a system policy set to the HTTP GET request** is selected and the **Specify request target** is selected and completed.

The value of **Default** will result in the Global Default Binding being used.

WS-MetadataExchange request:

Click **WS-MetadataExchange** to obtain the policy of the service provider by using a WS-MetadataExchange GetMetadata request. The policy configuration must be in WS-PolicyAttachments format in the WSDL of the service provider.

This option is available when **Apply the following policies** is set to Client and provider policy or Provider policy only.

Attach a system policy set to the WS-MetadataExchange request:

Select **Attach a system policy set to the WS-MetadataExchange request** to set message-level security for the WS-MetadataExchange request. By default, this option is not selected and the transport policy of the application is used. This option is available when **WS-MetadataExchange request** is selected.

When **Attach a system policy set to the WS-MetadataExchange request** is selected, the **Policy set** and **Binding** lists are available. If you select **Attach a system policy set to the WS-MetadataExchange request**, you must also select a policy set and a binding.

Policy set (for the WS-MetadataExchange request):

Select the policy set you require from the list to provide message-level security for the WS-MetadataExchange request. You can select from system policy sets that contain only WS-Security policies, only WS-Addressing policies, or both. The default policy set is SystemWSSecurityDefault.

System policy sets are used for system messages that are not business-related, for example, messages that apply qualities of service (QoS), including the messages that are defined in the WS-MetadataExchange protocol.

Note that any transport policy of the application is always used.

This option is available when **Attach a system policy set to the WS-MetadataExchange** is selected.

Binding (for the WS-MetadataExchange request):

Select the binding you require from the list to provide message level security for the WS-MetadataExchange request. You can select from **Global Default Bindings** or **General client/provider policy set bindings**, which are specific to the individual service.

This option is available when **Attach a system policy set to the WS-MetadataExchange** is selected.

The value of **Default** will result in the Global Default Binding being used.

Enabling Web Services Addressing support for JAX-WS applications using deployment descriptors

For JAX-WS applications, you can enable WS-Addressing support during the packaging of either a service or client application, by editing the deployment descriptor for that application.

About this task

To modify WS-Addressing behavior by using deployment descriptors, add an <addressing> element to the deployment descriptor file for the application. The <addressing> element has optional child elements as described in the following table.

The <addressing> element functions in the same way as the Addressing annotation. The child elements of the <addressing> annotation function in the same way as the parameters of the Addressing annotation.

Table 115. Child elements of the addressing deployment descriptor element. The table lists the different child elements with their possible values and a description of each one.

Element name	Possible values	Description
enabled	true (default) false	Whether WS-Addressing support is enabled.
required	true false (default)	Whether WS-Addressing headers are required.
responses	All (default) ANONYMOUS NON_ANONYMOUS	Whether to use a synchronous or an asynchronous message exchange pattern. Specify ANONYMOUS to send messages in a synchronous message pattern; use NON_ANONYMOUS to send messages in an asynchronous message exchange pattern.

Procedure

- To modify the behavior of the WS-Addressing support in the service application, add the `<addressing>` element, and optional child elements as required, to the service deployment descriptor under the `<port-component>` element within the `<webservice-description>` element. In the following example, the Addressing deployment descriptor fragment specifies that WS-Addressing is enabled and required, and that the asynchronous message exchange pattern is used.

```
<port-component>
  <port-component-name>MyPort1</port-component-name>
  <addressing>
    <enabled>true</enabled>
    <required>true</required>
    <responses>NON_ANONYMOUS</responses>
  </addressing>
  <service-impl-bean>
    <servlet-link>MyPort1ImplBean</servlet-link>
  </service-impl-bean>
</port-component>
```

- To modify the behavior of the WS-Addressing support in the client application, add the `<addressing>` element, and optional child elements as required, to the client deployment descriptor under the `<port-component-ref>` element within the `<service-ref>` element. For example, the following deployment descriptor fragment indicates that WS-Addressing is enabled:

```
<service-ref>
  <service-ref-name>service/MyPortComponentRef</service-ref-name>
  <service-interface>com.example.MyService</service-ref-interface>
  <port-component-ref>
    <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
    <addressing>
      <enabled>true</enabled>
    </addressing>
  </port-component-ref>
</service-ref>
```

Results

WS-Addressing properties are now included in the SOAP message header, and are processed by the server on receipt of the message.

Enabling Web Services Addressing support for JAX-WS applications using addressing annotations

For JAX-WS applications, you can enable WS-Addressing support during development of a service application, by using addressing annotations in the code. You can also use this method in a client application that uses an injected web service proxy reference.

About this task

Use one of the following addressing annotations in your service code:

- `Addressing` - use this annotation if you want to use the 2005/08 WS-Addressing specification.
- `SubmissionAddressing` - use this annotation if you want to use the 2004/08 WS-Addressing specification.

On clients, use the `Addressing` annotation only; the `SubmissionAddressing` annotation is not supported. You must specify the `Addressing` annotation in combination with the `WebServiceRef` annotation. The `WebServiceRef` annotation specifies a reference to the web service proxy that is injected by the client container.

Annotation settings override settings in the WSDL document. Annotation settings might differ from WSDL settings if you create the WSDL document manually rather than generating it from the code.

Specify up to three optional parameters for each annotation:

Table 116. Parameters for the addressing annotations. The table lists the different parameters with their possible values and a description of each one.

Parameter name	Possible values	Description
enabled	true (default) false	Whether WS-Addressing support is enabled.
required	true false (default)	Whether WS-Addressing headers are required.
responses	Responses.ALL (default) Responses.ANONYMOUS Responses.NON_ANONYMOUS	Whether to use a synchronous or an asynchronous message exchange pattern. Specify Responses.ANONYMOUS to send messages in a synchronous message pattern; use Responses.NON_ANONYMOUS to send messages in an asynchronous message exchange pattern. Note: This parameter is not supported on the SubmissionAddressing annotation.

Note: You can use the Addressing annotation only with a SOAP (1.1 or 1.2) over HTTP binding. If you use the class with another binding, such as XML over HTTP, an exception is thrown on clients, and on servers the web service fails to deploy.

Procedure

- To modify the behavior of the WS-Addressing support programmatically in the service application, use one of the addressing annotations, with optional parameters as required, in the code. In the following example, the Addressing annotation is used with no parameters, so the default settings apply.

```
import javax.xml.ws.soap.Addressing;

@Addressing
@WebService(endpointInterface =
    "org.apache.axis2.jaxws.calculator.Calculator",
    serviceName = "CalculatorService",
    portName = "CalculatorServicePort",
    targetNamespace = "http://calculator.jaxws.axis2.apache.org")
```

In the following example, the SubmissionAddressing annotation is used with parameters that specify that WS-Addressing is enabled and required. The responses attribute is not supported on this annotation.

```
import com.ibm.websphere.wsaddressing.jaxws21.SubmissionAddressing;

@SubmissionAddressing(enabled=true, required=true)
@WebService(endpointInterface =
    "org.apache.axis2.jaxws.calculator.Calculator",
    serviceName = "CalculatorService",
    portName = "CalculatorServicePort",
    targetNamespace = "http://calculator.jaxws.axis2.apache.org")
```

- To enable WS-Addressing support on clients that use an injected web service proxy reference, use the Addressing annotation, with optional parameters as required, in combination with the WebServiceRef annotation. The SubmissionAddressing annotation is not supported for this method.

For example, the following code fragment specifies that WS-Addressing is enabled and that the synchronous message exchange pattern is used:

```
public class MyClientApplication {

    // Enable Addressing for a port-component-ref resource injection.
    @Addressing(enabled=true, responses=Responses.ANONYMOUS)
    @WebServiceRef(MyService.class)
    private MyPortType myPort;
    ...
}
```

Results

If you use an addressing annotation in the service application, the server processes any WS-Addressing headers that conform to the relevant specification in inbound SOAP messages. If you specify that WS-Addressing is required, and an inbound SOAP message does not include any WS-Addressing headers, or includes WS-Addressing headers that do not conform to the specification indicated by the

annotation, the server returns a fault message. For example, if a client sends a message that includes 2004/08 WS-Addressing headers, and the server requires 2005/08 headers, the server returns a fault message.

If you use the Addressing annotation and generate a WSDL document from the code, a UsingAddressing element and WS-Policy assertions are created in the WSDL document. Clients that use this WSDL document will include WS-Addressing information in their messages. The SubmissionAddressing annotation is not understood by current WSDL generation tools. However, the WSDL document does not distinguish between the 2005/08 specification and the 2004/08 specification, so if you want to generate a WSDL document from code that contains a SubmissionAddressing annotation, use both the Addressing and SubmissionAddressing annotations together.

If you specify the responses attribute, the corresponding message exchange pattern will be used.

Enabling Web Services Addressing support for JAX-WS applications using addressing features

For JAX-WS applications, you can enable WS-Addressing support during development of a client application, by using addressing features in the code.

About this task

Use one of the following addressing feature classes in your client code:

- AddressingFeature - use this class if you want to send messages that include WS-Addressing headers that conform to the 2005/08 WS-Addressing specification
- SubmissionAddressingFeature - use this class if you want to send messages that include WS-Addressing headers that conform to the 2004/08 WS-Addressing specification

If you use both feature classes, the specification that is used depends on the type of endpoint reference that you also specify. For example, if you specify a W3CEndpointReference object, the specification that is used is the 2005/08 specification. If you specify an endpoint reference whose type conflicts with that indicated by the feature class, for example a W3CEndpointReference object with a SubmissionAddressingFeature instance, an error is thrown. If you do not specify an endpoint reference, the default specification is the 2005/08 specification.

Specify up to three optional parameters for each addressing feature instance:

Table 117. Parameters for the addressing features. The table lists the different addressing feature parameters as well as their possible values and a description of each one.

Parameter name	Possible values	Description
enabled	true (default) false	Whether WS-Addressing support is enabled.
required	true false (default)	Whether WS-Addressing headers are required.
responses	Responses.All (default) Responses.ANONYMOUS Responses.NON_ANONYMOUS	Whether to use a synchronous or an asynchronous message exchange pattern. Specify Responses.ANONYMOUS to send messages in a synchronous message pattern; use Responses.NON_ANONYMOUS to send messages in an asynchronous message exchange pattern. Note: This parameter is not supported for the SubmissionAddressingFeature class.

Note: You can use the addressing feature classes only with a SOAP (1.1 or 1.2) over HTTP binding. If you use the class with another binding, such as XML over HTTP, an exception is thrown on clients, and on servers the web service fails to deploy.

Procedure

Create an instance of one of the addressing feature classes, with parameters as required. For example, to specify that WS-Addressing is enabled and required, and that the 2005/08 specification and the asynchronous message exchange pattern is used, use the following code:

```
AddressingFeature feat = new AddressingFeature(true, true, AddressingFeature.Responses.NON_ANONYMOUS);
```

To specify that WS-Addressing is disabled for the 2004/08 specification, use the following code:

```
SubmissionAddressingFeature feat = new SubmissionAddressingFeature(false);
```

Results

If you specify that WS-Addressing is enabled, the client includes WS-Addressing headers in SOAP messages. The headers conform to the WS-Addressing specification indicated by the type of feature class used. If the server does not use annotations, or uses policy sets to enable WS-Addressing, the server accepts both the 2005/08 and 2004/08 specifications.

If you specify that WS-Addressing is required and the client receives a message that does not include WS-Addressing headers, the client returns a fault.

If you specify the responses attribute, the corresponding message exchange pattern will be used.

Enabling Web Services Addressing support for JAX-WS applications using WS-Policy

For JAX-WS applications, you can enable WS-Addressing support during the development of a client or service application by adding WS-Policy assertions into the WSDL document.

About this task

The JAX-WS 2.2 specification introduces functionality that enables WS-Policy assertions in the application WSDL document to be mapped to and from Java annotations in the code.

There are several ways of enabling WS-Addressing support for JAX-WS applications. The method of using WS-Policy will be effective unless it is overridden by another method with greater precedence, such as if you are using AddressingFeature classes or using Addressing annotations. See the parent topic: Enabling Web Services Addressing support for JAX-WS applications for full details about the order of precedence used by WebSphere Application Server.

Note: WebSphere Application Server version 8 supports the JAX-WS 2.2 specification. One of the differences between the JAX-WS 2.1 and JAX-WS 2.2 specifications is that whereas the presence of WS-Policy in an application's WSDL was formerly ignored, if WS-Addressing support is defined within the WS-Policy, this will now be used by WebSphere Application Server in the configuration of the application. As the presence of WS-Policy in an application's WSDL is now checked for WS-Addressing configuration, you may notice a change in behavior in applications formerly run in previous versions of WebSphere Application Server.

If you add an Addressing annotation to your provider code and use the **wsgen** command-line tool to generate the WSDL document, it will contain WS-Policy assertions specifying the WS-Addressing support. However, if you are looking at the published WSDL document for the provider service, it is possible that policy defined in policy sets is showing, as this would overwrite any annotations defined in the code.

If you are using an existing WSDL document to create Java code, when WebSphere Application Server reads the WSDL, if any WS-Policy assertions specifying WS-Addressing support are present, the generated Java code will contain Addressing annotations.

Procedure

- To enable WS-Addressing support on clients, use WS-Policy assertions in the code, with optional attributes as required. The `wsam:Addressing` assertion indicates that WS-Addressing is required. If you want to indicate that WS-Addressing is supported but not mandatory, add the `wsp:Optional` attribute. In the following example, WS-Addressing is supported, but is not mandatory and the messaging format to use has not been specified.

```
<wsp:Policy>
  <wsam:Addressing wsp:Optional="true">
    <wsp:Policy/>
  </wsam:Addressing>
</wsp:Policy>
```

This example is equivalent to the policy set configuration of WS-Addressing being set to non-mandatory and the messaging style being set to synchronous and asynchronous.

- To specify the message exchange pattern to be employed, use the `wsam:AnonymousResponses` assertion for synchronous message exchanges and the `wsam:NonAnonymousResponses` assertion for asynchronous message exchanges. In the following example, WS-Addressing support is set as mandatory and a synchronous message exchange pattern has been specified.

```
<wsp:Policy>
  <wsam:Addressing>
    <wsp:Policy>
      <wsam:AnonymousResponses/>
    </wsp:Policy>
  </wsam:Addressing>
</wsp:Policy>
```

This example is equivalent to the policy set configuration of WS-Addressing being set to required and the messaging style being set to synchronous only.

For more information, see the [Web Services Addressing 1.0 - Metadata specification document](#).

Results

If you add WS-Addressing annotations to the application code specifying that WS-Addressing is enabled, when you generate the WSDL it will contain WS-Policy assertions.

When WS-Policy assertions specifying WS-Addressing support are included in the WSDL, WS-Addressing headers are included in the generated SOAP messages.

If you specify that WS-Addressing is required and an inbound SOAP message is received that does not include any WS-Addressing headers, an exception occurs.

Web Services Addressing annotations

The WS-Addressing specification provides transport-neutral mechanisms to address web services and to facilitate end-to-end addressing. If you have a JAX-WS application you can use Java annotations in your code to specify WS-Addressing behavior at run time.

You can use WS-Addressing annotations to enable WS-Addressing support, to specify whether WS-Addressing information is required in incoming messages, to control the message exchange pattern the service supports, and to specify actions to be associated with a web service operation or fault response.

The following WS-Addressing annotations are supported in WebSphere Application Server. These annotations are defined in the JAX-WS 2.2 specification unless otherwise stated. The JAX-WS 2.2 specification supersedes and includes functions within the JAX-WS 2.1 specification. See the [Java API for XML-Based Web Services 2.2 specification](#) for full details.

javax.xml.ws.Action

Specifies the action that is associated with a web service operation.

- When following a bottom-up approach to developing JAX-WS web services, you can generate a WSDL document from Java application code using the `wsgen` command-line tool. However, for this attribute to be added to the WSDL operation, you must also specify the `@Addressing` annotation on the implementation class. The result in the generated WSDL document is that the Action annotations will have the `wsam:Action` attribute on the input message and output message elements of the `wsdl:operation`. Alternatively, if you do not want to use the `@Addressing` annotation you can supply your own WSDL document with the Action attribute already defined.
- When following a top-down approach to developing JAX-WS web services, you can generate Java application code from an existing WSDL document using the `wsimport` command-line tool. In such cases, the resulting Java code will contain the correct Action and FaultAction annotations.

If this action is not specified in either code annotations or in the WSDL document, the default action pattern as defined in the Web Services Addressing 1.0 Metadata specification is used. Refer to this specification for full details.

Note: Whilst the WebSphere Application Server runtime environment supports the deprecated `wsaw:Action` attribute, if you try to generate Java code from an old WSDL document containing the deprecated `wsaw:Action` attribute, this attribute will be ignored.

javax.xml.ws.FaultAction

Specifies the action that is added to a fault response. When you use this annotation with a particular method, the WS-Addressing FaultAction extension attribute is added to the fault element of the WSDL operation that corresponds to that method. For this attribute to be added to the WSDL operation, you must also specify the Addressing annotation on the implementation class. If you do not want to use the Addressing annotation you can supply your own WSDL document with the Action attribute already defined. This annotation must be contained within an Action annotation.

WSDL documents generated from Java application code containing the WS-Addressing FaultAction annotation will have the `wsam:Action` attribute on the `fault` message element of the `wsdl:operation`.

Note: To ensure that any custom Exception classes you write are successfully mapped to the generated WSDL document, extend the `java.lang.Exception` class instead of the `java.lang.RuntimeException` class.

javax.xml.ws.soap.Addressing

Specifies that this service is to enable WS-Addressing support. You can use this annotation only on the service implementation bean; you cannot use it on the service endpoint interface.

com.ibm.websphere.wsaddressing.jaxws21.SubmissionAddressing

This annotation is part of the IBM implementation of the JAX-WS specification. This annotation specifies that this service is to enable WS-Addressing support for the 2004/08 WS-Addressing specification. You can use this annotation only on the service implementation bean; you cannot use it on the service endpoint interface.

For more information about the Addressing and SubmissionAddressing annotations, including code examples, see [Enabling Web Services Addressing support for JAX-WS applications using addressing annotations](#).

The following example code uses the Action annotation to define the invoke operation to be invoked (input), and the action that is added to the response message (output). The example also uses the FaultAction annotation to specify the action that is added to a response message if a fault occurs:

```
@WebService(name = "Calculator")
public interface Calculator {
    ...
    @Action(
        input="http://calculator.com/inputAction",
        output="http://calculator.com/outputAction",

```

```

        fault = { @FaultAction(className=AddNumbersException.class,
                               value="http://calculator.com/faultAction")
        }
    }
    public int add(int value1, int value2) throws AddNumbersException {
        return value1 + value2;
    }
}

```

If you use a tool to generate service artifacts from code, the WSDL tags that are generated from the preceding example are as follows:

```

<definitions targetNamespace="http://example.com/numbers" ...>
    ...
    <portType name="AddPortType">
        <operation name="Add">
            <input message="tns:AddInput" name="Parameters"
                wsam:Action="http://calculator.com/inputAction"/>
            <output message="tns:AddOutput" name="Result"
                wsam:Action="http://calculator.com/outputAction"/>
            <fault message="tns:AddNumbersException" name="AddNumbersException"
                wsam:Action="http://calculator.com/faultAction"/>
        </operation>
    </portType>
    ...
</definitions>

```

Web Services Addressing security

It is essential that communications that use Web Services Addressing (WS-Addressing) are adequately secured and that a sufficient level of trust is established between the communicating parties. You can achieve secure communications through the signing of WS-Addressing message-addressing properties and the encryption of endpoint references.

Undertake these actions for both the supported addressing namespaces, <http://www.w3.org/2005/08/addressing> and <http://schemas.xmlsoap.org/ws/2004/08/addressing>, even if you intend to use only one of those namespaces.

Signing of WS-Addressing message-addressing properties

You can use an assembly tool to specify the message-addressing properties, and therefore the WS-Addressing message elements, that require signing, or that require signature verification on inbound requests. The receiver of the message might rely on the presence of this verifiable signature to determine that the outbound message originated from a trusted source. Similarly, the lack of a verifiable signature that is associated with the specified inbound message addressing properties causes the rejection of the message with a SOAP fault.

Encryption of endpoint references

You can encrypt endpoint references as part of the SOAP header or SOAP body. Alternatively, you can remove the need for encryption by not including sensitive information in the address or reference parameters properties of the endpoint reference.

Use of the synchronous message exchange pattern

This method applies to JAX-WS applications only.

If you do not secure the WS-Addressing information in the SOAP message by using one or more of the previous methods, and you do not have WS-Security enabled, the ReplyTo and FaultTo elements of the SOAP message could be used to send messages to a third party, potentially taking part in a Denial of Service attack. To prevent such attacks, apply a WS-Addressing policy type and configure it to specify synchronous messaging only. You should also enable WS-Policy so that this requirement is communicated to clients.

Invoking JAX-WS web services asynchronously

Java API for XML-Based Web Services (JAX-WS) provides support for invoking web services using an asynchronous client invocation. JAX-WS provides support for both a callback and polling model when calling web services asynchronously. Both the callback model and the polling model are available on the Dispatch client and the Dynamic Proxy client.

Before you begin

Develop a JAX-WS Dynamic Proxy or Dispatch client. When developing Dynamic Proxy clients, after you generate the portable client artifacts from a Web Services Description Language (WSDL) file using the **wsimport** command, the generated service endpoint interface (SEI) does not have asynchronous methods included in the interface. Use JAX-WS bindings to add the asynchronous callback or polling methods on the interface for the Dynamic Proxy client. To enable asynchronous mappings, you can add the `jaxws:enableAsyncMapping` binding declaration to the WSDL file. For more information on adding binding customizations to generate an asynchronous interface, see chapter 8 of the JAX-WS specification.

Note: When you run the **wsimport** tool and enable asynchronous invocation through the use of the JAX-WS `enableAsyncMapping` binding declaration, ensure that the corresponding response message your WSDL file does not contain parts. When a response message does not contain parts, the request acts as a two-way request, but the actual response that is sent back is empty. The **wsimport** tool does not correctly handle a void response. To avoid this scenario, you can remove the output message from the operation which makes your operation a one-way operation or you can add a `<wsdl:part>` to your message. For more information on the usage, syntax and parameters for the **wsimport** tool, see the **wsimport** command for JAX-WS applications documentation.

About this task

An asynchronous invocation of a web service sends a request to the service endpoint and then immediately returns control to the client program without waiting for the response to return from the service. JAX-WS asynchronous web service clients consume web services using either the callback approach or the polling approach. Using a polling model, a client can issue a request and receive a response object that is polled to determine if the server has responded. When the server responds, the actual response is retrieved. Using the callback model, the client provides a callback handler to accept and process the inbound response object. The `handleResponse()` method of the handler is called when the result is available. Both the polling and callback models enable the client to focus on continuing to process work without waiting for a response to return, while providing for a more dynamic and efficient model to invoke web services. Polling invocations are valid from Enterprise JavaBeans (EJB) clients or Java Platform, Enterprise Edition (Java EE) application clients. Callback invocations are valid only from Java EE application clients.

Using the callback asynchronous invocation model

To implement an asynchronous invocation that uses the callback model, the client provides an `AsyncHandler` callback handler to accept and process the inbound response object. The client callback handler implements the `javax.xml.ws.AsyncHandler` interface, which contains the application code that is run when an asynchronous response is received from the server. The `javax.xml.ws.AsyncHandler` interface contains the `handleResponse(javax.xml.ws.Response)` method that is called after the run time has received and processed the asynchronous response from the server. The response is delivered to the callback handler in the form of a `javax.xml.ws.Response` object. The response object returns the response content when the `get()` method is called. Additionally, if an error was received, then an exception is returned to the client during that call. The response method is then invoked according to the threading model used by the executor method, `java.util.concurrent.Executor` on the client's `javax.xml.ws.Service` instance that was used to create the Dynamic Proxy or Dispatch client instance. The executor is used to invoke any asynchronous callbacks registered by the application. Use the `setExecutor` and `getExecutor` methods to modify and retrieve the executor configured for your service.

Using the polling asynchronous invocation model

Using the polling model, a client can issue a request and receive a response object that can subsequently be polled to determine if the server has responded. When the server responds, the actual response can then be retrieved. The response object returns the response content when the `get()` method is called. The client receives an object of type `javax.xml.ws.Response` from the `invokeAsync` method. That `Response` object is used to monitor the status of the request to the server, determine when the operation has completed, and to retrieve the response results.

Using an asynchronous message exchange

By default, asynchronous client invocations do not have asynchronous behavior of the message exchange pattern on the wire. The programming model is asynchronous; however, the exchange of request or response messages with the server is not asynchronous. To use an asynchronous message exchange, the `com.ibm.websphere.webservices.use.async.mep` property must be set on the client request context with a boolean value of `true`. When this property is enabled, the messages exchanged between the client and server are different from messages exchanged synchronously. With an asynchronous exchange, the request and response messages have WS-Addressing headers added that provide additional routing information for the messages. Another major difference between asynchronous and synchronous message exchange is that the response is delivered to an asynchronous listener that then delivers that response back to the client. For asynchronous exchanges, there is no timeout that is sent to notify the client to stop listening for a response. To force the client to stop waiting for a response, issue a `Response.cancel()` method on the object returned from a polling invocation or a `Future.cancel()` method on the object returned from a callback invocation. The cancel response does not affect the server when processing a request.

Procedure

1. Determine if you want to implement the callback method or the polling method for the client to asynchronously invoke the web service.
2. (Optional) Configure the client request context. Add the

```
com.ibm.websphere.webservices.use.async.mep
```

property to the request context to enable asynchronous messaging for the web services client. Using this property requires that the service endpoint supports WS-Addressing which is supported by default for the application server. The following example demonstrates how to set this property:

```
Map<String, Object> rc = ((BindingProvider) port).getRequestContext();  
rc.put("com.ibm.websphere.webservices.use.async.mep", Boolean.TRUE);
```

3. To implement the asynchronous callback method, perform the following steps.
 - a. Find the asynchronous callback method on the SEI or `javax.xml.ws.Dispatch` interface. For an SEI, the method name ends in *Async* and has one more parameter than the synchronous method of type `javax.xml.ws.AsyncHandler`. The `invokeAsync(Object, AsyncHandler)` method is the one that is used on the `Dispatch` interface.
 - b. (Optional) Add the `service.setExecutor` methods to the client application. Adding the executor methods gives the client control of the scheduling methods for processing the response. You can also choose to use the `java.concurrent.Executors` class factory to obtain packaged executors or implement your own executor class. See the JAX-WS specification for more information on using executor class methods with your client.
 - c. Implement the `javax.xml.ws.AsyncHandler` interface. The `javax.xml.ws.AsyncHandler` interface only has the `handleResponse(javax.xml.ws.Response)` method. The method must contain the logic for processing the response or possibly an exception. The method is called after the client run time has received and processed the asynchronous response from the server.
 - d. Invoke the asynchronous callback method with the parameter data and the callback handler.
 - e. The `handleResponse(Response)` method is invoked on the callback object when the response is available. The `Response.get()` method is called within this method to deliver the response.
4. To implement the polling method,

- a. Find the asynchronous polling method on the SEI or `javax.xml.ws.Dispatch` interface. For an SEI, the method name ends in *Async* and has a return type of `javax.xml.ws.Response`. The `invokeAsync(Object)` method is used on the `Dispatch` interface.
 - b. Invoke the asynchronous polling method with the parameter data.
 - c. The client receives the object type, `javax.xml.ws.Response`, that is used to monitor the status of the request to the server. The `isDone()` method indicates whether the invocation has completed. When the `isDone()` method returns a value of `true`, call the `get()` method to retrieve the response object.
5. Use the `cancel()` method for the callback or polling method if the client needs to stop waiting for a response from the service. If the `cancel()` method is invoked by the client, the endpoint continues to process the request. However, the wait and response processing for the client is stopped.

Results

You have enabled your JAX-WS web service client to asynchronously invoke and consume web services. See the JAX-WS specification for additional information regarding the asynchronous client APIs.

Example

The following example illustrates a web service interface with methods for asynchronous requests from the client.

```
@WebService
public interface CreditRatingService {
    // Synchronous operation.
    Score getCreditScore(Customer customer);
    // Asynchronous operation with polling.
    Response<Score> getCreditScoreAsync(Customer customer);
    // Asynchronous operation with callback.
    Future<?> getQuoteAsync(Customer customer,
        AsyncHandler<Score> handler);
}
```

Using the callback method

The callback method requires a callback handler that is shown in the following example. When using the callback procedure, after a request is made, the callback handler is responsible for handling the response. The response value is a response or possibly an exception. The `Future<?>` method represents the result of an asynchronous computation and is checked to see if the computation is complete. When you want the application to find out if the request is completed, invoke the `Future.isDone()` method. Note that the `Future.get()` method does not provide a meaningful response and is not similar to the `Response.get()` method.

```
CreditRatingService svc = ...;
Future<?> invocation = svc.getCreditScoreAsync(customerTom,
    new AsyncHandler<Score>() {
        public void handleResponse (
            Response<Score> response)
        {
            score = response.get();
            // process the request...
        }
    }
);
```

Using the polling method

The following example illustrates an asynchronous polling client:

```
CreditRatingService svc = ...;
Response<Score> response = svc.getCreditScoreAsync(customerTom);

while (!response.isDone()) {
    // Do something while we wait.
}

score = response.get();
```

Enabling Web Services Addressing support for JAX-RPC applications

The Web Services Addressing (WS-Addressing) support provides mechanisms to address web services and provide addressing information in messages. To enable the WS-Addressing support for JAX-RPC applications, either configure the Web Services Description Language (WSDL) file for a service that runs on WebSphere Application Server, or use the WS-Addressing application programming interface (API) or system programming interface (SPI) to add WS-Addressing properties in a WebSphere Application Server client.

About this task

Complete this task to enable the WS-Addressing support, either as a service provider or as a client of a service provided by another party. This task also describes how to disable the WS-Addressing support, which can improve performance for those applications that do not use WS-Addressing or any protocol that depends on the WS-Addressing support.

If you are creating a web service, you can enable the WS-Addressing support during development of the service, by including the `UsingAddressing` extensibility element in the WSDL binding element for the service. This element contains a **required** attribute that has a value of either `false`, which specifies that WS-Addressing information is accepted but not required in incoming messages, or `true`, which specifies that WS-Addressing information is required in incoming messages. The default value is `false`. Messages from WebSphere Application Server clients always include WS-Addressing information if your service WSDL file includes the `UsingAddressing` element, regardless of the value of the **required** attribute.

If you are creating a client application to use a service from another provider, you might not have access to the WSDL file for the service, or the service might use a version of WSDL that does not support the `UsingAddressing` element (if the service is not running on a current version of this product). However, you can still enable WS-Addressing support, during run time, by setting WS-Addressing properties on the JAX-RPC stub or call object that you use to communicate with the service.

The following table summarizes the behavior of the WS-Addressing support in each of the scenarios mentioned previously.

Table 118. The behavior of the WS-Addressing support in the product. The table details the resulting behavior of different `UsingAddressing` settings when an application server client sends a message.

	The WSDL for the service specifies <code>UsingAddressing required = "false"</code>	The WSDL for the service specifies	The WSDL for the service does not specify <code>UsingAddressing</code>
A client sends a message that contains WS-Addressing information	The WS-Addressing information is processed by the product.	The WS-Addressing information is processed by the product.	The WS-Addressing information is processed by the product.
A non-WebSphere Application Server client sends a message that does not contain WS-Addressing information	The message is accepted.	The service returns a fault.	The message is accepted.
A WebSphere Application Server client sends a message, without specifying addressing properties	The message automatically contains the mandatory WS-Addressing information, as defined in the WS-Addressing specification. The information is processed by the product.	The message automatically contains the mandatory WS-Addressing information, as defined in the WS-Addressing specification. The information is processed by the product.	WS-Addressing information is not added. The message is accepted.

Procedure

- To enable WS-Addressing support from the server by configuring the WSDL file, complete the following steps:
 1. Ensure that the WSDL file for the service contains the `UsingAddressing` extensibility element on the binding element. If you generated the WSDL file by using the Java2WSDL tool, this element is

automatically added for you. If you created the WSDL file yourself, for use with the WSDL2Java tool, you must add the extensibility element. The UsingAddressing element has a **required** attribute with a default value of false. For example:

```
<wsdl:binding name="TestServiceSoapBinding" type="intf:TestService">
  <wsaw:UsingAddressing wsdl:required="false"
    xmlns:wsaw="http://www.w3.org/2006/05/addressing/wsdl"/>
  <wsdlsoap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http"/>
  <wsdl:operation name="invokeInstance">
    ...
  </wsdl:operation>
</wsdl:binding>
```

This code indicates that the endpoint will process WS-Addressing information, but that this information is not required.

2. Optional: To specify that WS-Addressing information is required, change the value of the **required** attribute to true. If the endpoint receives a message that does not contain the mandatory WS-Addressing elements within the message header, the endpoint returns a fault message, as defined in the WS-Addressing specification.

WebSphere Application Server clients always send WS-Addressing conformant messages to endpoints with bindings that specify the UsingAddressing element.

- To enable WS-Addressing support from a WebSphere Application Server client, use the IBM proprietary WS-Addressing API or SPI to associate one or more WS-Addressing properties with the JAX-RPC stub or call object that is used to send messages to the endpoint.

These properties become message-addressing properties (MAPs) in the SOAP message header. If the node that receives the message is a WebSphere Application Server node, it processes the incoming MAPs in accordance with the WS-Addressing specification, even if the service does not have a UsingAddressing element in its WSDL file.

Use this method when communicating with endpoints that use earlier versions of the WS-Addressing specification (for example: <http://schemas.xmlsoap.org/ws/2004/08/addressing>) that do not support the UsingAddressing element, or when the WSDL file for the target endpoint is not available to the client.

Results

WS-Addressing properties are now included in the SOAP message header, and are processed by the server on receipt of the message.

Disabling Web Services Addressing support

The Web Services Addressing (WS-Addressing) support provides mechanisms to address web services and provide addressing information in messages. WS-Addressing support is disabled by default on clients. The method for disabling WS-Addressing support on servers depends on whether your application is based on JAX-RPC or JAX-WS.

About this task

You do not have to disable WS-Addressing support even if your application does not require it, because in most cases WS-Addressing support does not have a negative impact on the running of applications. For JAX-RPC applications, disabling WS-Addressing support can be risky as this action also disables support for other specifications such as Web Services Atomic Transactions.

Procedure

- Disable WS-Addressing support for JAX-WS service providers using one of the following ways:
 - Use both the Addressing and SubmissionAddressing annotations in the service code, with the **enabled** parameter set to false; for example:

```
import javax.xml.ws.soap.Addressing;
```

```
@Addressing(enabled=false)
@SubmissionAddressing(enabled=false)
@WebService(...)
```

- Use the `<webservice-description>/<port-component>/<addressing>` deployment descriptor element in the deployment descriptor for the service application; for example:

```
<port-component>
  <port-component-name>MyPort1</port-component-name>
  <addressing>
    <enabled>false</enabled>
  </addressing>
  <service-impl-bean>
    <servlet-link>MyPort1ImplBean</servlet-link>
  </service-impl-bean>
</port-component>
```

- You do not have to take any action to disable WS-Addressing support for JAX-WS clients, because WS-Addressing support is disabled by default. However, you can programmatically specify that WS-Addressing is disabled by using one of the following ways:
 - Use both the `AddressingFeature` and `SubmissionAddressingFeature` classes in the client code, with the `enabled` parameter set to `false`; for example:

```
AddressingFeature feat = new AddressingFeature(false);
SubmissionAddressingFeature feat = new AddressingFeature(false);
```

- Use the `Addressing` annotation for an injected web services proxy reference; for example:

```
public class MyClientApplication {
  // Disable Addressing for a port-component-ref resource injection.
  @Addressing(enabled=false)
  @WebServiceRef(MyService.class)
  private MyPortType myPort;
  ...
}
```

- Use the `<service>/<port-component>/<addressing>` deployment descriptor; for example:

```
<service-ref>
  <service-ref-name>service/MyPortComponentRef</service-ref-name>
  <service-interface>com.example.MyService</service-ref-interface>
  <port-component-ref>
    <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
    <addressing>
      <enabled>false</enabled>
    </addressing>
  </port-component-ref>
</service-ref>
```

- To disable WS-Addressing support for JAX-RPC service providers or clients, set the `com.ibm.ws.wsaddressingAndDependentsDisabled` system property to `true`. For example:

```
java -Dcom.ibm.ws.wsaddressingAndDependentsDisabled=true ... application_name
```

Attention: Use this property with care because applications might require WS-Addressing message addressing properties to function correctly. Setting this property also disables support for the following specifications, which depend on the WS-Addressing support: Web Services Atomic Transactions, Web Services Business Agreement, Web Services Notification and Web Services Reliable Messaging.

Results

By completing this task, you disabled the WS-Addressing support. Disabling WS-Addressing on clients prevents WebSphere Application Server sending WS-Addressing message addressing properties in the SOAP header of outbound web service messages. Disabling WS-Addressing on servers additionally prevents WebSphere Application Server processing WS-Addressing MAPs in incoming SOAP headers.

Chapter 29. Developing web services - Invocation framework (WSIF)

The Web Services Invocation Framework (WSIF) is a Web Services Description Language (WSDL)-oriented Java™ API. You use this API to invoke web services dynamically, regardless of the service implementation format (for example enterprise bean) or the service access mechanism (for example Java Message Service (JMS)). Using WSIF, you can move away from the usual web services programming model of working directly with the SOAP APIs, towards a model where you interact with representations of the services. You can therefore work with the same programming model regardless of how the service is implemented and accessed.

Using WSIF to invoke web services

You invoke a web service dynamically by using the WSIF API directly.

About this task

You specify the location of the Web Services Description Language (WSDL) file for the service, the name of the operation to invoke, and any operation arguments. All other information needed to access the web service (the abstract interface, the binding, and the service endpoint) is available through the WSDL.

This kind of invocation does not require stub classes and does not need a separate compilation cycle.

Note: You should not use WSIF for new applications in WebSphere Application Server, unless you are supporting an existing WSIF configuration. You should instead adopt a more recent open standard, such as the Java API for XML-Based Web Services (JAX-WS) programming model.

For more information about using the Web Services Invocation Framework (WSIF) to invoke web services, see the following topics:

Procedure

- “Linking a WSIF service to the underlying implementation of the service.”
- “Developing a WSIF service” on page 1179.
- “Using complex types” on page 1187.
- “Using WSIF to bind a JNDI reference to a web service” on page 1188.
- “Example: Passing SOAP messages with attachments by using WSIF” on page 1190.
- “Interacting with the Java EE container in WebSphere Application Server” on page 1192.
- “Invoking a WSDL-based web service through the WSIF API” on page 1193.
- “Running WSIF as a client” on page 1199

Linking a WSIF service to the underlying implementation of the service

A Web Services Invocation Framework (WSIF) service is linked to the underlying service through a WSIF provider. A provider is an implementation of a Web Services Description Language (WSDL) binding that can run a WSDL operation through a binding-specific protocol. Providers implement the interface between the WSIF API and the implementation of a service.

About this task

Providers are pluggable within the WSIF framework, and are registered according to the namespace of the WSDL extension that they implement. Some providers use the Java Platform, Enterprise Edition (Java EE) programming model to use Java EE services. If a provider is available, but its required class libraries are not, then the provider is disabled.

To use the providers that are supplied with WebSphere Application Server, see the following topics:

Procedure

- Link a WSIF service to a SOAP over HTTP service.
- Link a WSIF service to a JMS-provided service (SOAP over JMS, or native JMS).
- Link a WSIF service to a local Java application.
- Write the WSDL extension that lets your WSIF service invoke an enterprise bean.

Linking a WSIF service to a SOAP over HTTP service

The SOAP provider allows WSIF stubs and dynamic clients to invoke SOAP services. Add Web Services Description Language (WSDL) extensions to your web service WSDL file so that the service can use the SOAP provider.

Before you begin

Note: The current WSIF default SOAP provider (the IBM Web Service SOAP provider) does not fully interoperate with services that are running on the former (Apache SOAP) provider. This is because the IBM Web Service SOAP provider is designed to interoperate fully with a JAX-RPC compliant web service, and Apache SOAP cannot provide such a service. For more information see “WSIF SOAP provider: working with existing applications.”

About this task

The Web Services Invocation Framework (WSIF) SOAP provider supports SOAP 1.1 over HTTP.

The SOAP provider is JSR 101/109 compliant and uses Web Services for Java EE for parsing and creating SOAP messages.

The SOAP provider supports:

- SOAP-ENC encoding.
- RPC style and Document style SOAP messages.
- SOAP messages with attachments.

The SOAP provider is not transactional.

The SOAP provider does not support the WSIF synchronous timeout. The SOAP provider uses the default client timeout value that is set for Web Services for Java EE.

To link a WSIF service to a SOAP over HTTP service, you write extensions to the service WSDL file.

Procedure

- Optional: If you have a web service that you expect multiple clients to use to connect over SOAP, before you deploy the service set up your application deployment descriptor file `dds.xml` to handle multiple connections. For more information, see the troubleshooting tip Using WSIF with multiple clients causes a SOAP parsing error.
- Write the WSDL extension that lets your WSIF service access a SOAP over JMS service.

Note: The WSDL binding extension for SOAP over JMS varies only slightly from the SOAP over HTTP binding.

- Write the WSDL extensions for SOAP attachments.

WSIF SOAP provider: working with existing applications:

The current WSIF default SOAP provider (the IBM Web Service SOAP provider) does not fully interoperate with services that are designed to run on the former (Apache SOAP) provider. This is because the IBM Web Service SOAP provider is designed to interoperate fully with a JAX-RPC compliant web service, and Apache SOAP cannot provide such a service.

About this task

As a result of the change from the Apache SOAP provider to the IBM Web Service SOAP provider, previous WSIF clients might not work in either of the following cases:

1. The web service uses any of the following parameter types: `xsd:date`, `xsd:dateTime`, `xsd:hexBinary` or `xsd:QName`. For more information, see the **Type Mappings** section of WSIF - Known restrictions.
2. The web service was built upon the Apache SOAP provider.

To get your existing services working again, you have two options:

Procedure

- Change the default WSIF SOAP provider back to the former Apache SOAP provider (in which case any future invocations to a JAX-RPC compliant web service will not work if that web service uses parameter types `xsd:date`, `xsd:dateTime`, `xsd:hexBinary` or `xsd:QName`).
- Modify your web services to use the IBM Web Service SOAP provider.

Changing the default WSIF SOAP provider:

The WSIF default SOAP provider (the IBM Web Service SOAP provider) is designed to interoperate fully with a JAX-RPC compliant web service, and therefore the default provider does not fully interoperate with services that are running on the former (Apache SOAP) provider. To get your existing services working again, you can either modify your web services to use the current IBM Web Service SOAP provider, or you can change the WSIF default provider back to Apache SOAP as described in this topic.

About this task

WSIF uses a properties file named `wsif.properties` to choose what SOAP provider to use. The SOAP provider is a node-wide setting, so all servers on the node must be restarted for any changes to take effect. The `wsif.properties` file is shipped in the `com.ibm.ws.runtime.jar` file that is located in the `app_server_root/plugins` directory (where `app_server_root` is the root directory for your installation of IBM WebSphere Application Server), and the “as shipped” properties file is accessed in this location by being put on the class path. However when you make changes to the file, you do not replace the original copy in the `com.ibm.ws.runtime.jar` file. Instead, you save the modified version in the `app_server_root/lib/properties` directory.

To change the WSIF default SOAP provider back to Apache SOAP, complete the following steps:

Procedure

1. Extract the `wsif.properties` file from the `com.ibm.ws.runtime.jar` file that is located in the `app_server_root/plugins` directory (where `app_server_root` is the root directory for your installation of IBM WebSphere Application Server).
2. Open the `wsif.properties` file in a text editor.
3. Remove the leading “#” character from the following lines:

```
# wsif.provider.default.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=1
# wsif.provider.uri.1.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=
# http://schemas.xmlsoap.org/wsdl/soap/
#
```

After the update, the preceding lines should look like this:

```
wsif.provider.default.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=1
wsif.provider.uri.1.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=
http://schemas.xmlsoap.org/wsdl/soap/
#
```

4. Save the updated `wsif.properties` file in the `app_server_root/lib/properties` directory.
5. Stop then restart all application servers on the node.

Example

Modifying web services to use the IBM Web Service SOAP provider:

The current WSIF default SOAP provider (the IBM Web Service SOAP provider) is designed to interoperate fully with a JAX-RPC compliant web service, and therefore the current default provider does not fully interoperate with services that are running on the former (Apache SOAP) provider. To get your existing services working again, you can either modify your web services to use the current IBM Web Service SOAP provider as described in this topic, or you can change the WSIF default provider back to Apache SOAP.

About this task

To modify an existing web service, use the assembly tool to complete the following steps and thereby generate new deployment artifacts for access to the service from the IBM Web Service provider:

Procedure

1. Import into the Workspace the project that contains your existing web services.
2. For every existing SOAP service in the project, repeat the following steps :
 - a. From the pop-up menu for `your_service.wsdl`, select **Generate Deploy Code**.
 - b. In the Generate Deploy Code window, change the **Inbound Binding Type** from SOAP to IBM Web Service.
 - c. Click **Finish**.
3. Export the EAR file that contains all of the deployment artifacts for the IBM Web Service web service.

Linking a WSIF service to a JMS-provided service

The JMS providers enable a WSIF service to be invoked through either SOAP over JMS, or native JMS. Add Web Services Description Language (WSDL) extensions to your web service WSDL file so that the service can use the JMS providers.

About this task

The Java Message Service (JMS) is an API for transport technology. The mapping to a JMS destination is defined during deployment and maintained by the container.

The JMS destination endpoint for a web service can be realized in any of the following ways:

- The JMS destination for the queue can be the web service implementation.
- The JMS destination can be (but is not required to be) associated with a message-driven bean by the EJB container, thereby allowing the message-driven bean to be the web service implementation.
- For SOAP over JMS, the JMS destination can unwrap the JMS message and route the SOAP message to a web service that is implemented as a stateless session bean.

The JMS destination endpoint must respect the interaction model expected by the client and defined by the WSDL. It must return a response if one is required.

When the JMS destination endpoint creates the JMS response message the following rules must be followed:

- The response message must be sent to `JMSReplyTo` from the incoming request.

- The JMSCorrelationID value of the response message must be set to the JMSMessageID value from the request message.
- The response must be sent with a deliveryMode value equal to the JMSDeliveryMode value of the request message.
- The response must be sent with a priority value equal to the JMSPriority value of the request message.
- The TimeToLive/JMSExpiration value must be set to a value that equals the JMSExpiration value of the request message.

The client does not see any of these headers. The container receives the JMS message and (for SOAP over JMS) removes the SOAP message to send to the client.

To link a WSIF service to a JMS-provided service, use the following information and code examples:

Procedure

- Link your WSIF service to a SOAP over JMS service.
- Link a WSIF service to a service provided at a JMS destination.
- Enable a WSIF client to invoke a web service through JMS.

Writing the WSDL extension that lets your WSIF service access a SOAP over JMS service:

You can write a Web Services Description Language (WSDL) extension that enables your Web Services Invocation Framework (WSIF) service to access a SOAP service that uses the Java Message Service (JMS) as its transport mechanism.

Before you begin

This topic assumes that you chose and configured a JMS provider when you installed WebSphere Application Server (either the default messaging provider, or another provider such as the WebSphere MQ messaging provider). If not, do so now as described in Choosing a messaging provider.

About this task

If a SOAP message contains only XML, it can be carried on the Java Message Service (JMS) transport mechanism with the JMS message body type **TextMessage**. The SOAP message, including the SOAP envelope, is wrapped with a JMS message and put on the appropriate queue. The container receives the JMS message and removes the SOAP message to send to the client.

Use the following procedure, and associated code fragments, to help you to write the Web Services Description Language (WSDL) extension that enables your WSIF service to access a SOAP over JMS service.

Note: You can also use this procedure as a guide to writing the WSDL binding extension for SOAP over HTTP, because the SOAP over JMS binding is almost identical to the SOAP over HTTP binding.

Procedure

- Select the SOAP over JMS binding.

You set the transport attribute of the <soap:binding> tag to indicate that JMS is used. If you also set the style attribute to rpc (Remote Procedure Call), then the Web Services Invocation Framework (WSIF) assumes that an operation is invoked on the web service endpoint:

```
<soap:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/jms"/>
```

- Set the JMS address.

Note: See also the alternative method for specifying the JMS address that is given in the next step.

For SOAP over JMS, the `<wsdl:port>` tag must contain a `<jms:address>` element. This element provides the information required for a client to connect correctly to the web service by using the JMS programming model. Typically, it is the stubs generated to support the SOAP over JMS binding that act as the JMS client. Alternatively, the web service client can use the JMS programming model directly.

The `<jms:address>` element takes this form:

```
<jms:address
  destinationStyle="queue"
  jmsVendorURI="http://ibm.com/ns/mqseries"?
  initialContextFactory="com.ibm.NamingFactory"?
  jndiProviderURL="iiop://something:900/wherever"?
  jndiConnectionFactoryName="orange"
  jndiDestinationName="fred">
  <jms:propertyValue name="targetService" type="xsd:string"
    value="StockQuoteServicePort"/>
</jms:address>
```

where attributes marked with a question mark (?) are optional.

The optional `jmsVendorURI` attribute is a string that uniquely identifies the JMS implementation. WSIF ignores this URI, which is used by the client developer and perhaps the client implementation to determine if it has access to the correct JMS provider in the client runtime environment.

The optional attributes `initialContextFactory` and `jndiProviderURL` can only be omitted if the runtime environment has a default Java Naming and Directory Interface (JNDI) provider configured.

The `jndiConnectionFactoryName` attribute gives the name of a JMS `ConnectionFactory` object, which can be looked up within the JNDI context given by the `jndiContext` attribute. This `ConnectionFactory` object is used to create a JMS connection to the JMS provider instance that owns the queue. In a simple configuration, the same `ConnectionFactory` object is used by the server message listener and by the clients. However the server and the clients can use different `ConnectionFactory` objects, provided that they all create connections to the same JMS provider instance.

The `value` attribute of the `targetService <jms:propertyValue>` element is the name of the port component for the target service as defined in the `<port-component-name>` element of the `webservices.xml` file for the target service.

- Set the JMS address (alternative method).

For the SOAP over JMS provider you can instead specify the JMS address using the `<soap:address>` tag in the following format:

```
jms:[queue|topic]?<property>=<value>&amp;<property>=<value>&amp;...
```

where the specification of `queue` or `topic` corresponds to the JMS address `destinationStyle` attribute.

Table 119. Properties that are valid for use with the `<soap:address>` tag. Column 1 specifies the property name, column 2 describes the property, and column 3 specifies the corresponding JMS address value.

Property name	Property description	Corresponding JMS address value
destination	The JNDI name of the destination queue or topic	jndiDestinationName
connectionFactory	The JNDI name of the connection factory.	jndiConnectionFactory
targetService	The name of the port component of the target service	targetService jms:propertyValue within jms:address
JNDI-related properties (optional):		
initialContextFactory	The name of the initial context factory.	initialContextFactory
jndiProviderURL	The JNDI provider URL	jndiProviderURL
JMS-related properties (optional):		
deliveryMode	An indication as to whether the request message should be persistent or not. The valid values are <code>DeliveryMode.NON_PERSISTENT</code> (default) and <code>DeliveryMode.PERSISTENT</code>	JMSDeliveryMode

Table 119. Properties that are valid for use with the <soap:address> tag (continued). Column 1 specifies the property name, column 2 describes the property, and column 3 specifies the corresponding JMS address value.

Property name	Property description	Corresponding JMS address value
password	The password to be used to gain access to the connection factory.	JMSPassword
priority	The JMS priority associated with the request message. Valid values are 0 to 9. The default value is 4.	JMSDeliveryMode
replyTo	The JNDI destination queue to which reply messages should be sent.	JMSReplyTo
timeToLive	The lifetime (in milliseconds) of the request message. A value of 0 indicates an infinite lifetime.	JMSTimeToLive
userid	The userid to be used to gain access to the connection factory.	JMSUserid

Here is an example of this format:

<jms:address> format:

```
<wsdl:port name="StockQuoteServicePort"
    binding="sqi:StockQuoteSoapJMSBinding">
    <jms:address destinationStyle="queue"
        jndiConnectionFactoryName="myQCF"
        jndiDestinationName="myQ"
        initialContextFactory="com.ibm.NamingFactory"
        jndiProviderURL="iiop://something:900/">
        <jms:propertyValue name="targetService"
            type="xsd:string"
            value="StockQuoteServicePort"/>
    </jms:address>
</wsdl:port>
```

<soap:address> format:

```
<wsdl:port name="StockQuoteServicePort"
    binding="sqi:StockQuoteSoapJMSBinding">
    <soap:address location="jms:/queue?connectionFactory=myQCF&destination
=myQ&initialContextFactory=com.ibm.NamingFactory&jndiProviderURL
=iiop://something:900/&targetService=StockQuoteServicePort" />
</wsdl:port>
```

- Set the JMS headers and properties.

You use the <jms:property> tag to set the JMS headers and properties. This tag maps either a message part, or a literal value, into a JMS property:

```
<jms:property name="Priority" {part="requestPriority" | value="fixedValue"}/>
```

If the <jms:property> has a literal value, then it can also be nested within the <jms:address> tag:

```
<jms:property name="Priority" value="fixedValue" />
```

This form of the <jms:property> tag is also used in the native JMS binding.

Example of a WSDL that defines a SOAP over JMS binding

```
<!-- Example: SOAP over JMS Text Message -->
<?xml version="1.0" encoding="UTF-8"?>
<wsdl:definitions
    name="StockQuoteInterfaceDefinitions"
    targetNamespace="urn:StockQuoteInterface"
    xmlns:tns="urn:StockQuoteInterface"
    xmlns:xsd="http://www.w3.org/2000/10/XMLSchema"
    xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
    xmlns:jms="http://schemas.xmlsoap.org/wsdl/jms/"
    xmlns:wSDL="http://schemas.xmlsoap.org/wsdl/">
```

```

<wsdl:message name="GetQuoteInput">
  <part name="symbol" type="xsd:string"/>
</wsdl:message>
<wsdl:message name="GetQuoteOutput">
  <part name="value" type="xsd:float"/>
</wsdl:message>

<wsdl:portType name="StockQuoteInterface">
  <wsdl:operation name="GetQuote">
    <wsdl:input message="tns:GetQuoteInput"/>
    <wsdl:output message="tns:GetQuoteOutput"/>
  </wsdl:operation>
</wsdl:portType>

<wsdl:binding name="StockQuoteSoapJMSBinding" type="tns:StockQuoteInterface">
  <soap:binding style="rpc"
    transport="http://schemas.xmlsoap.org/soap/jms"/>
  <wsdl:operation name="GetQuote">
    <soap:operation soapAction="urn:StockQuoteInterface#GetQuote"/>
    <wsdl:input>
      <soap:body use="encoded" namespace="urn:StockQuoteService"
        encodingStyle="http://schemas.xmlsoap.org/soap/encoding"/>
    </wsdl:input>
    <wsdl:output>
      <soap:body use="encoded" namespace="urn:StockQuoteService"
        encodingStyle="http://schemas.xmlsoap.org/soap/encoding"/>
    </wsdl:output>
  </wsdl:operation>
</wsdl:binding>
<wsdl:service name="StockQuoteService">
  <wsdl:port name="StockQuoteServicePort"
    binding="sqi:StockQuoteSoapJMSBinding">
    <jms:address destinationStyle="queue"
      jndiConnectionFactoryName="myQCF"
      jndiDestinationName="myQ"
      initialContextFactory="com.ibm.NamingFactory"
      jndiProviderURL="iiop://something:900"/>

    <jms:propertyValue name="targetService"
      type="xsd:string"
      value="StockQuoteServicePort"/>

  </jms:address>
  </wsdl:port>
</wsdl:service>
</wsdl:definitions>

```

Writing the WSDL extensions that let your WSIF service access a service at a JMS destination:

Using the native Java Message Service (JMS) provider, Web Services Invocation Framework (WSIF) clients can treat a service that is available at a JMS destination as a Web service. Use this information, and associated code fragments, to help you to write the Web Services Description Language (WSDL) extensions.

Before you begin

This topic assumes that you chose and configured a JMS provider when you installed WebSphere Application Server (either the default messaging provider, or another provider such as the WebSphere MQ messaging provider). If not, do so now as described in [Choosing a messaging provider](#).

About this task

The WSDL extensions for JMS are identified with the namespace prefix `jms`. For example, `<jms:binding>`.

The supported operations are either one-way operations (send for JMS point-to-point messaging, or publish for JMS publish and subscribe messaging) or request-response operations (send and receive for JMS point-to-point messaging). The WSDL operations therefore specify either an input message only, or an input and an output message.

Operations that describe message interfaces with a native JMS binding do not have fault messages. No assumptions are made about the message schema or the semantics of message properties, therefore no distinction can be made between output and fault messages.

Use the following procedure, and associated code fragments, to help you to write the Web Services Description Language (WSDL) extensions that enable your WSIF service to access an underlying service at a JMS destination.

Procedure

- Set the JMS message body type.

You use the `<jms:binding>` extension to specify the JMS message body type:

```
<wsdl:binding ... >
  <jms:binding type="messageBodyType" />
  ...
</wsdl:binding>
```

where *messageBodyType* is either `ObjectMessage` or `TextMessage`.

- Specify the parts to use for the input and output messages.

For JMS text messages and JMS object messages created from one or more WSDL message parts, you use the `<jms:input>` and `<jms:output>` extensions to specify the message parts to use for the JMS messages:

```
<wsdl:input ... >
  <jms:input parts="part1 part2 ..." />
</wsdl:input>
```

```
<wsdl:output ... >
  <jms:output parts="part1 part2 ..." />
</wsdl:output>
```

In the next example, the WSDL message has just one part that contains the complete message body. This message body might result from a mapping of some other representation (see the next step “Map the data types”).

```
<wsdl:input ... >
  <jms:input parts="part1" />
</wsdl:input>
```

If no parts are defined, then all the message parts are used.

- Map the data types.

You use the `<format>` extensions to map data types:

```
<wsdl:binding ... >
  <jms:binding type="..." />

  <format:typeMapping encoding="Java" style="Java">
    <format:typeMap typeName="..." formatType="targetType"/>
  </format:typemapping>
  ...
</wsdl:binding>
```

The value of *targetType* is dependent on the JMS message body type (see the step “Set the JMS message body type”). For JMS object messages, the target data type implements the `java.io.Serializable` class. For JMS text messages, the target data type is always `java.lang.String`.

The `<format>` extensions are also used in other bindings that deal with Java interfaces.

- Set the JMS headers and properties.

JMS does not make assumptions about message headers. For example, if the JMS provider is MQSeries then each JMS message carries an RFH2 header. However you can access data in this message header indirectly, by getting and setting JMS message properties.

When you want your application to pass a property into the Web Services Invocation Framework (WSIF) as a part on the WSIF message, you use a `<jms:property>` tag. When you want to hard code a property value into the WSDL, you use a `<jms:propertyValue>` tag. The `<jms:propertyValue>` tag contains a specification of a literal value and its associated XML schema type.

You can specify `<jms:property>` and `<jms:propertyValue>` extensions within the `<wsdl:input>` tag in the binding operation, and also within the `<jms:address>` tag. For the `<wsdl:output>` tag in the binding operation, you can only specify the `<jms:property>` extension. Property values that are set in the `<jms:property>` tag take precedence over values set in the `<jms:propertyValue>` tag, and property values that are set in the binding operation (in the `<input>` and `<output>` tags) take precedence over values set in the `<jms:address>` tag.

Here is an example of the `<jms:property>` and `<jms:propertyValue>` tags nested within the `<input>` and `<output>` tags:

```
<wsdl:input ... >
    <jms:property name="propertyName" part="partName" />
    <jms:propertyValue name="propertyName"
        type="xsdType" value="actualValue" />
</wsdl:input>
<wsdl:output ... >
    <jms:property name="propertyName" part="partName" />
</wsdl:output>
```

where *propertyName* identifies the JMS property that is associated with the header field, and *partName* identifies the message part that is associated with the property.

The JMS property identified by *propertyName* can be user-defined, or it can be one of the following predefined header fields:

Table 120. Predefined JMS message header fields.

Column 1 specifies the header field value, and column 2 specifies the data type for that header field value.

Value	Java type
JMSMessageId	java.lang.String
JMSTimeStamp	long
JMSCorrelationId	byte [] or java.lang.String
JMSReplyTo	javax.jms.Destination
JMSDestination	javax.jms.Destination
JMSDeliveryMode	int
JMSRedelivered	boolean
JMSType	java.lang.String
JMSExpiration	long
JMSTimeToLive	long

See the JMS specification for restrictions that apply when setting JMS header field values. Attempts to set restricted values are ignored.

For application-defined JMS message properties, the Java types used in the native JMS binding implementation (used for calls to the corresponding JMS methods) are derived from the XML schema type in the abstract interface (<wsdl:part> tag), and from the type mapping information in the format binding (<format:typemap> tag).

- Handle transactions.

Independent of other JMS properties, the asynchronous processing of request-response operations has implications for callers running in a transaction scope. The send request part and the receive response part are separated into two transactions, because the send needs to be committed in order for the request message to become visible. Implementations that process WSDL for asynchronous request-response operations (such as WSIF) must therefore take the following additional actions:

- They must ensure that the send request transaction returns a correlation ID to the user, and provides a callback with which users can pass in the response message to process the receive response transaction.
- They might implement their own response message listener in order to recognize the arrival of response messages, and to manage the correlation to the request message.

Example 1: JMS Text Message

The JMS text message contains a `java.lang.String`. In this example, the WSDL message contains only one part that represents the whole message body:

```
<wsdl:definitions ... >

  <!-- simple or complex types for input and output message -->
  <wsdl:types> ... </wsdl:types>

  <wsdl:message name="JmsOperationRequest"> ... </wsdl:message>
  <wsdl:message name="JmsOperationResponse"> ... </wsdl:message>

  <wsdl:portType name="JmsPortType">
    <wsdl:operation name="JmsOperation">
      <wsdl:input name="Request"
        message="tns:JmsOperationRequest"/>
      <wsdl:output name="Response"
        message="tns:JmsOperationResponse"/>
    </wsdl:operation>
  </wsdl:portType>

  <wsdl:binding name="JmsBinding" type="JmsPortType">
    <jms:binding type="TextMessage" />

    <format:typemapping style="Java" encoding="Java">
      <format:typemap name="xsd:String" formatType="String" />
    </format:typemapping>

    <wsdl:operation name="JmsOperation">
      <wsdl:input message="JmsOperationRequest">
        <jms:input parts="requestMessageBody" />
      </wsdl:input>
      <wsdl:output message="JmsOperationResponse">
        <jms:output parts="responseMessageBody" />
      </wsdl:output>
    </wsdl:operation>
  </wsdl:binding>

  <wsdl:service name="JmsService">
    <wsdl:port name="JmsPort" binding="JmsBinding">
      <jms:address destinationStyle="queue"
        jndiConnectionFactoryName="myQCF"
        jndiDestinationName="myDestination"/>
    </wsdl:port>
  </wsdl:service>
</wsdl:definitions>
```

```

    </wsdl:port>
  </wsdl:service>

</wsdl:definitions>

```

As an extension to the previous JMS message example, the following example WSDL describes a request-response operation in which specific JMS property values of the request and response message are set for the request message and retrieved from the response message.

The JMS properties in the request message are set according to the values in the input message. Likewise, selected JMS properties of the response message are copied to the corresponding values of the output message. The direction of the mapping is determined by the appearance of the `<jms:property>` tag in the input or output section, respectively.

```

<wsdl:definitions ... >

  <!-- simple or complex types for input and output message -->
  <wsdl:types> ... </wsdl:types>

  <wsdl:message name="JmsOperationRequest">
    <wsdl:part name="myInt" type="xsd:int"/>
    ...
  </wsdl:message>

  <wsdl:message name="JmsOperationResponse">
    <wsdl:part name="myString" type="xsd:String"/>
    ...
  </wsdl:message>

  <wsdl:portType name="JmsPortType">
    <wsdl:operation name="JmsOperation">
      <wsdl:input name="Request"
        message="tns:JmsOperationRequest"/>
      <wsdl:output name="Response"
        message="tns:JmsOperationResponse"/>
    </wsdl:operation>
  </wsdl:portType>

  <wsdl:binding name="JmsBinding" type="JmsPortType">
    <!-- the JMS message type might be any of the above -->
    <jms:binding type="..." />

    <format:typemapping style="Java" encoding="Java">
      <format:typemap name="xsd:int" formatType="int" />
      ...
    </format:typemapping>

    <wsdl:operation name="JmsOperation">
      <wsdl:input message="JmsOperationRequest">
        <jms:property message="tns:JmsOperationRequest" parts="myInt" />
        <jms:propertyValue name="myLiteralString"
          type="xsd:string" value="Hello World" />
        ...
      </wsdl:input>
      <wsdl:output message="JmsOperationResponse">
        <jms:property message="tns:JmsOperationResponse" parts="myString" />
        ...
      </wsdl:output>
    </wsdl:operation>
  </wsdl:binding>

  <wsdl:service name="JmsService">
    <wsdl:port name="JmsPort" binding="JmsBinding">
      <jms:address destinationStyle="queue"
        jndiConnectionFactoryName="myQCF"
        jndiDestinationName="myDestination"/>
    </wsdl:port>
  </wsdl:service>

```

```
</wsdl:port>
</wsdl:service>

</wsdl:definitions>
```

Enabling a WSIF client to invoke a web service through JMS:

The ways in which the Web Services Invocation Framework (WSIF) interacts with the Java Message Service (JMS), and the steps to take to enable a service to be invoked through JMS by a WSIF client application.

Before you begin

This topic assumes that you chose and configured a JMS provider when you installed WebSphere Application Server (either the default messaging provider, or another provider such as the WebSphere MQ messaging provider). If not, do so now as described in *Choosing a messaging provider*.

About this task

Here are the ways in which WSIF interacts with JMS:

- WSIF only supports input JMS properties.
- WSIF needs two queues when invoking an operation: one for the request message and one for the reply.
- The replyTo queue is by default a temporary queue, which WSIF creates on behalf of the application. You can specify a permanent queue by setting the **JMSReplyTo** property to the JNDI name of a queue.
- WSIF uses the default values for properties set by the JMS implementation.

To enable a service to be invoked through JMS by a WSIF client application, complete the following steps:

Procedure

1. Use the administrative console to create and configure a queue connection factory and a queue destination for your chosen messaging provider.

For more information, see *Configuring resources for the default messaging provider*, *Configuring JMS resources for the WebSphere MQ messaging provider* or *Managing messaging with a third-party messaging provider*.

Note: In WebSphere MQ and some other JMS implementations, messages are persistent by default. The WSIF replyTo temporary queue is of type `temporary dynamic` by default, which means that your JMS provider cannot write a persistent response message to this queue. If you are using the WebSphere MQ messaging provider, create a temporary model queue that is of type `permanent dynamic`, then pass this model as the **tempmodel** of your queue connection factory. This ensures that persistent messages are written to a temporary replyTo queue that is of type `permanent dynamic`.

2. Use the administrative console to add the new queue destination to the list of JMS destination names for your application server. Ensure that the **Initial State** is started.
3. Put the JNDI names of the queue destination and queue connection factory, as well as your JNDI configuration, in the Web Services Description Language (WSDL) file.
4. Optional: If your client is running on an application server that has been migrated from WebSphere Application Server Version 5, you might get basic authentication errors and therefore have to modify your security settings. For more information see *Web Services Invocation Framework troubleshooting tips*.

JMS message header: The TimeToLive property reference:

The range of permitted values for the `TimeToLive` property of a JMS message that WSIF puts onto a queue.

The JMS message header property `JMSTimeToLive` is of type `long`. It sets the time to live of a message put onto a queue, in milliseconds. A value of 0 means live indefinitely.

The factors that determine the time to live of a JMS message are as follows:

- For a one-way (input only) operation, the default time to live is 0, so the message remains on the queue indefinitely or until the server end-processes the message. The `JMSTimeToLive` value, if specified in the service endpoint URL or the JMS Address, is used for one-way messages. The client never waits for a response to a one-way operation and so it never times out. During a one-way operation, the client fails only if the queue itself is unavailable.
- For a two-way (request and response) operation the `JMSTimeToLive` value, if specified in the service endpoint URL or the JMS Address, is used for two-way messages. When the time to live is not specified, the default value is determined by the client response timeout setting.

Writing the WSDL extension that lets your WSIF service invoke a method on a local Java object

Using the Web Services Invocation Framework (WSIF) Java provider, WSIF can invoke Java code. This means that, in a thin-client environment such as a Java virtual machine (JVM) or Tomcat test runtime environment, you can define shortcuts to local Java programs. Use this procedure to help you to write the Web Services Description Language (WSDL) extension that links your WSIF service to a local Java application.

Before you begin

The WSIF Java provider is not intended for use in a Java Platform, Enterprise Edition (Java EE) environment. There is a difference between a client using the WSIF Java provider to invoke a Java component, and implementing a web service as a Java component on the server side.

About this task

The WSIF Java binding exploits the format binding for type mapping. Using the format binding, your WSDL can define the mapping between XML schema types and Java types.

The WSIFJava provider requires the targeted Java classes to be on the class path of the client. The Java method is invoked synchronously, in-process, in-thread, with the current thread and Object Request Broker (ORB) contexts.

The WSIF Java provider is not transactional.

The WSIF Java provider does not support the WSIF synchronous timeout. The Java provider will not time out waiting for a Java method to complete.

Use the following procedure, and associated code fragments, to help you to specify the WSDL extension that enables your WSIF service to invoke a method on a local Java object.

Procedure

- Specify the Java binding.

To use the Java provider, you need the following binding specified in the WSDL file:

```
<!-- Java binding -->
<binding .... >
  <java:binding />
  <format:typeMapping style="Java" encoding="Java"/>?
  <format:typeMap name="qname" formatType="nmtoken"/>*
</format:typeMapping>
```

```

<operation>*
  <java:operation
    methodName="nmtoken"
    parameterOrder="nmtoken"
    returnPart="nmtoken"?
    methodType="instance|constructor" />
    <input name="nmtoken"? />?
    <output name="nmtoken"? />?
    <fault name="nmtoken"? />?
  </operation>
</binding>

```

In this example:

- A question mark (?) means optional, and an asterisk (*) means 0 or more.
 - The name attribute of the <format:typeMap> element is a qualified name of a simple or complex type used by one of the Java operations.
 - The formatType attribute of the <format:typeMap> element is the fully qualified class name for the Java class to which the element specified by name maps.
 - The methodName attribute of the <java:operation> element is the name of the method on the Java object that is called by the operation.
 - The parameterOrder attribute of the <java:operation> element contains a white space-separated list of part names that define the order in which they are passed to the Java object method.
 - The methodType attribute of the <java:operation> element must be set to either instance or constructor. The value specifies whether the method that is invoked on the object is an instance method or a constructor for the object.
- Specify the <java:address> element.

The className attribute of the <java:address> element specifies the fully qualified class name of the object containing the method to invoke:

```

<service ... >
  <port>*
    <java:address
      className="nmtoken"/>
    </port>
  </service>

```

Writing the WSDL extension that lets your WSIF service invoke an enterprise bean

Using the EJB provider, WSIF clients can invoke enterprise beans through Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP). Use this information, and associated code fragments, to help you to write the Web Services Description Language (WSDL) extension that links your WSIF service to a service implemented as an enterprise bean.

Before you begin

Although you can use the EJB provider for EJB(IIOP)-based web service invocation, it is recommended that you instead invoke RMI-IIOP web services by using JAX-RPC.

The EJB client JAR file must be available in the client runtime environment with the current provider.

The EJB provider does not support the WSIF synchronous timeout. The EJB provider will not time out waiting for a Java method to complete.

About this task

Your WSIF client can invoke an enterprise bean by using RMI-IIOP, with the current security and transaction contexts. If the EJB provider is invoked within a transaction, the transaction is passed to the onward service and the standard EJB transaction attribute applies.

If there are multiple implementations of the service, it is up to the service providers to make sure that every implementation offers the same semantics. For example, for transactions, the bean deployer must specify TX_REQUIRES_NEW to force a new transaction.

Use the following procedure, and associated code fragments, to help you to write the Web Services Description Language (WSDL) extension that enables your WSIF service to invoke an enterprise bean.

Procedure

- Specify the EJB binding.

```
<!-- EJB binding -->
<binding .... >
  <ejb:binding />
  <format:typeMapping style="Java" encoding="Java"/>?
  <format:typeMap name="qname" formatType="nmtoken"/>*
</format:typeMapping>
<operation>*
  <ejb:operation
    methodName="nmtoken"
    parameterOrder="nmtoken"
    returnPart="nmtoken"?
    interface="remote|home" />
    <input name="nmtoken"? />?
    <output name="nmtoken"? />?
    <fault name="nmtoken"? />?
  </operation>
</binding>
```

In this example:

- A question mark (?) means optional, and an asterisk (*) means 0 or more.
 - The name attribute of the <format:typeMap> element is a qualified name of a simple or complex type used by one of the EJB operations.
 - The formatType attribute of the <format:typeMap> element is the fully qualified class name for the Java class to which the element specified by name maps.
 - The methodName attribute of the <ejb:operation> element is the name of the method on the enterprise bean that is called by the operation.
 - The parameterOrder attribute of the <ejb:operation> element contains a white space-separated list of part names that define the order in which they are passed to the EJB method.
 - The interface attribute of the <ejb:operation> element must be set to either remote or home. The value specifies the interface of the enterprise bean on which the method named by the methodName attribute is accessible.
- Specify the <ejb:address> element.

```
<service ... >
  <port>*
    <ejb:address
      className="nmtoken"
      jndiName="nmtoken"
      initialContextFactory="nmtoken" ?
      jndiProviderURL="nmtoken" ? />
    </port>
  </service>
```

In this example:

- The className attribute of the <ejb:address> element specifies the fully qualified class name of the home interface class of the enterprise bean.
- The jndiName attribute of the <ejb:address> element specifies the full Java Naming and Directory Interface (JNDI) name that is used to look up the enterprise bean.
- The initialContextFactory attribute of the <ejb:address> element is optional and specifies the initial context factory class.
- The jndiProviderURL attribute of the <ejb:address> element is optional and specifies the JNDI provider web address.

Developing a WSIF service

A Web Services Invocation Framework (WSIF) service is a web service that uses WSIF.

About this task

To develop a WSIF service, develop the web service (or use an existing web service), then develop the WSIF client based on the Web Services Description Language (WSDL) document for that Web service.

There are also two pre-built WSIF samples available for download from the WebSphere Application Server samples page of the developerWorks website:

- The Address Book sample.
- The Stock Quote sample.

For more information about using the pre-built samples, see the documentation that is included in the developerWorks download package. Note that these samples were written to work with WebSphere Application Server Version 5.

To develop a WSIF service, complete the following steps:

Procedure

1. Implement the web service.

Use web services tools to discover, create, and publish the web service. You can develop Java bean, enterprise bean, and URL web services. You can use web service tools to create skeleton Java code and a sample application from a WSDL document. For example, an enterprise bean can be offered as a Web service, and use Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) as the access protocol. Or you can use a Java class as a web service, with native Java invocations as the access protocol.

 You can use the WebSphere Development Studio for System i (WDS) to create a web service from a Java application. Using the web service wizard, you generate a binding WSDL document and a service WSDL document from the Java bean. You can then deploy the web service to a web server, generate a client proxy to the web service, and generate a sample application that accesses the service through the client proxy. You can test the service, publish it by using the IBM UDDI Explorer, and then discover the service in the IBM UDDI Test Registry.

2. Develop the WSIF client.

Use the following information to help you develop a WSIF client:

- “Example: Using WSIF to invoke the AddressBook sample web service dynamically” gives example code to show how you define a web service in WSDL.
- “Linking a WSIF service to the underlying implementation of the service” on page 1163 describes the available providers, and gives example code of how their WSDL extensions are coded.
- “Invoking a WSDL-based web service through the WSIF API” on page 1193 defines the main interfaces that your client uses to support the invocation of Web services defined in WSDL.

The AddressBook sample is written for synchronous interaction. If you are using a JMS provider, your WSIF client might have to act asynchronously. WSIF provides two main features that meet this requirement:

- A correlation service that assigns identifiers to messages so that the request can match up with the (eventual) response.
- A response handler that picks up the response from the web service at a later time.

For more information, see “WSIFOperation - Asynchronous interactions reference” on page 1197.

Example: Using WSIF to invoke the AddressBook sample web service dynamically

This is example code for dynamic invocation of the AddressBook sample web service by using WSIF:

```

try {
    String wsdlLocation="clients/addressbook/AddressBookSample.wsdl";

    // The starting point for any dynamic invocation using wsif is a
    // WSIFServiceFactory. Create one through the newInstance
    // method.
    WSIFServiceFactory factory = WSIFServiceFactory.newInstance();

    // Once you have a factory, you can use it to create a WSIFService object
    // corresponding to the AddressBookService service in the wsdl file.
    // Note: because you only have one service defined in the wsdl file, you
    // do not have to use the namespace and name of the service and can pass
    // null instead. This also applies to the port type, although values have
    // been used below for illustrative purposes.
    WSIFService service = factory.getService(
        wsdlLocation,    // location of the wsdl file
        null,            // service namespace
        null,            // service name
        "http://www.ibm.com/namespace/wsif/samples/ab", // port type namespace
        "AddressBookPT" // port type name
    );

    // The AddressBook.wsdl file contains the definitions for two complexType
    // elements within the schema element. Map these complexTypes
    // to Java classes. These mappings are used by the Apache SOAP provider
    service.mapType(
        new javax.xml.namespace.QName(
            "http://www.ibm.com/namespace/wsif/samples/ab/types",
            "address"),
        Class.forName("com.ibm.www.namespace.wsif.samples.ab.types.WSIFAddress"));
    service.mapType(
        new javax.xml.namespace.QName(
            "http://www.ibm.com/namespace/wsif/samples/ab/types",
            "phone"),
        Class.forName("com.ibm.www.namespace.wsif.samples.ab.types.WSIFPhone"));
    // You now have a WSIFService object. The next step is to create a WSIFPort
    // object for the port you want to use. The getPort(String portName) method
    // allows us to generate a WSIFPort from the port name.
    WSIFPort port = null;

    if (portName != null) {
        port = service.getPort(portName);
    }
    if (port == null) {
        // If no port name was specified, attempt to create a WSIFPort from
        // the available ports for the port type specified on the service
        port = getPortFromAvailablePortNames(service);
    }

    // Once you have a WSIFPort, you can create an operation. Execute
    // the addEntry operation and therefore attempt to create a WSIFOperation
    // corresponding to it. The addEntry operation is overloaded in the wsdl i.e.
    // there are two versions of it, each taking different parameters (parts).
    // This overloading requires that you specify the input and output message
    // names for the operation in the createOperation method so that the correct
    // operation can be resolved.
    // Because the addEntry operation has no output message, you use null for its name.
    WSIFOperation operation =
        port.createOperation("addEntry", "AddEntryWholeNameRequest", null);

    // Create messages to use in the execution of the operation. This should
    // be done by invoking the createXXXXXMessage methods on the WSIFOperation.
    WSIFMessage inputMessage = operation.createInputMessage();
    WSIFMessage outputMessage = operation.createOutputMessage();
    WSIFMessage faultMessage = operation.createFaultMessage();

    // Create a name and address to add to the addressbook

```

```

String nameToAdd="Chris P. Bacon";
WSIFAddress addressToAdd =
    new WSIFAddress (1,
        "The Waterfront",
        "Some City",
        "NY",
        47907,
        new WSIFPhone (765, "494", "4900"));

// Add the name and address to the input message
inputMessage.setObjectPart("name", nameToAdd);
inputMessage.setObjectPart("address", addressToAdd);

// Execute the operation, obtaining a flag to indicate its success
boolean operationSucceeded =
    operation.executeRequestResponseOperation(
        inputMessage,
        outputMessage,
        faultMessage);

if (operationSucceeded) {
    System.out.println("Successfully added name and address to addressbook\n");
} else {
    System.out.println("Failed to add name and address to addressbook");
}

// Start from fresh
operation = null;
inputMessage = null;
outputMessage = null;
faultMessage = null;

// This time you will lookup an address from the addressbook.
// The getAddressFromName operation is not overloaded in the
// wsdl and therefore you can specify the operation name
// without any input or output message names.
operation = port.createOperation("getAddressFromName");

// Create the messages
inputMessage = operation.createInputMessage();
outputMessage = operation.createOutputMessage();
faultMessage = operation.createFaultMessage();

// Set the name to find in the addressbook
String nameToLookup="Chris P. Bacon";
inputMessage.setObjectPart("name", nameToLookup);

// Execute the operation
operationSucceeded =
    operation.executeRequestResponseOperation(
        inputMessage,
        outputMessage,
        faultMessage);

if (operationSucceeded) {
    System.out.println("Successful lookup of name '"+nameToLookup+"' in addressbook");

    // You can get the address that was found by querying the output message
    WSIFAddress addressFound = (WSIFAddress) outputMessage.getObjectPart("address");
    System.out.println("The address found was:");
    System.out.println(addressFound);
} else {
    System.out.println("Failed to lookup name in addressbook");
}

} catch (Exception e) {

```

```

        System.out.println("An exception occurred when running the sample:");
        e.printStackTrace();
    }
}

```

The preceding code refers to the following Sample method:

```

WSIFPort getPortFromAvailablePortNames(WSIFService service)
    throws WSIFException {
    String portChosen = null;

    // Obtain a list of the available port names for the service
    Iterator it = service.getAvailablePortNames();
    {
        System.out.println("Available ports for the service are: ");
        while (it.hasNext()) {
            String nextPort = (String) it.next();
            if (portChosen == null)
                portChosen = nextPort;
            System.out.println(" - " + nextPort);
        }
    }
    if (portChosen == null) {
        throw new WSIFException("No ports found for the service!");
    }
    System.out.println("Using port " + portChosen + "\n");

    // An alternative way of specifying the port to use on the service
    // is to use the setPreferredPort method. Once a preferred port has
    // been set on the service, a WSIFPort can be obtained through getPort
    // (no arguments). If a preferred port has not been set and more than
    // one port is available for the port type specified in the WSIFService,
    // an exception is thrown.
    service.setPreferredPort(portChosen);
    WSIFPort port = service.getPort();
    return port;
}

```

The web service uses the following classes:

WSIFAddress:

```

public class WSIFAddress implements Serializable {

    //instance variables
    private int streetNum;
    private java.lang.String streetName;
    private java.lang.String city;
    private java.lang.String state;
    private int zip;
    private WSIFPhone phoneNumber;

    //constructors
    public WSIFAddress () { }

    public WSIFAddress (int streetNum,
                        java.lang.String streetName,
                        java.lang.String city,
                        java.lang.String state,
                        int zip,
                        WSIFPhone phoneNumber) {
        this.streetNum = streetNum;
        this.streetName = streetName;
        this.city = city;
        this.state = state;
        this.zip = zip;
        this.phoneNumber = phoneNumber;
    }
}

```

```

    }

    public int getStreetNum() {
        return streetNum;
    }

    public void setStreetNum(int streetNum) {
        this.streetNum = streetNum;
    }

    public java.lang.String getStreetName() {
        return streetName;
    }

    public void setStreetName(java.lang.String streetName) {
        this.streetName = streetName;
    }

    public java.lang.String getCity() {
        return city;
    }

    public void setCity(java.lang.String city) {
        this.city = city;
    }

    public java.lang.String getState() {
        return state;
    }

    public void setState(java.lang.String state) {
        this.state = state;
    }

    public int getZip() {
        return zip;
    }

    public void setZip(int zip) {
        this.zip = zip;
    }

    public WSIFPhone getPhoneNumber() {
        return phoneNumber;
    }

    public void setPhoneNumber(WSIFPhone phoneNumber) {
        this.phoneNumber = phoneNumber;
    }
}

```

WSIFPhone:

```

public class WSIFPhone implements Serializable {

    //instance variables
    private int areaCode;
    private java.lang.String exchange;
    private java.lang.String number;

    //constructors
    public WSIFPhone () { }

    public WSIFPhone (int areaCode,
                      java.lang.String exchange,
                      java.lang.String number) {
        this.areaCode = areaCode;
    }
}

```

```

        this.exchange = exchange;
        this.number = number;
    }

    public int getAreaCode() {
        return areaCode;
    }

    public void setAreaCode(int areaCode) {
        this.areaCode = areaCode;
    }

    public java.lang.String getExchange() {
        return exchange;
    }

    public void setExchange(java.lang.String exchange) {
        this.exchange = exchange;
    }

    public java.lang.String getNumber() {
        return number;
    }

    public void setNumber(java.lang.String number) {
        this.number = number;
    }
}

```

WSIFAddressBook:

```

public class WSIFAddressBook {
    private Hashtable name2AddressTable = new Hashtable();

    public WSIFAddressBook() {
    }

    public void addEntry(String name, WSIFAddress address)
    {
        name2AddressTable.put(name, address);
    }

    public void addEntry(String firstName, String lastName, WSIFAddress address)
    {
        name2AddressTable.put(firstName+" "+lastName, address);
    }

    public WSIFAddress getAddressFromName(String name)
        throws IllegalArgumentException
    {
        if (name == null)
        {
            throw new IllegalArgumentException("The name argument must not be " +
                "null.");
        }
        return (WSIFAddress)name2AddressTable.get(name);
    }
}

```

The following code is the corresponding WSDL file for the web service:

```

<?xml version="1.0" ?>

<definitions targetNamespace="http://www.ibm.com/namespace/wsif/samples/ab"
    xmlns:tns="http://www.ibm.com/namespace/wsif/samples/ab"
    xmlns:typens="http://www.ibm.com/namespace/wsif/samples/ab/types"

```

```

</service>
</definitions>

```

Using complex types

WSIF supports user-defined complex types through the mapping of complex types to Java classes. You can specify this mapping manually or automatically.

About this task

Any calls to the WSIFService mapType and mapPackage methods used for manual mapping override any equivalent mapping information that is produced automatically. This override helps to maintain backwards compatibility, and also accommodates less standard mappings.

To map your user-defined complex types to Java classes, complete either of the following steps:

- Manually map complex types.
- Automatically map complex types.

Procedure

- Manually map complex types.

The method to use when you create these mappings manually depends on the provider. For the Java and EJB providers, the mappings are specified in the Web Services Description Language (WSDL) file in the binding element. The following example provides the syntax for specifying the mapping:

```
<binding .... >
  <ejb:binding|java:binding/>
    <format:typeMapping style="Java" encoding="Java"/>?
      <format:typeMap typeName="qname" formatType="nmtoken"/>*
    </format:typeMapping>
  ...
</binding>
```

In this example:

- A question mark (“?”) means “optional” and an asterisk (“*”) means “0 or more”.
- The `format:typeMap` **typeName** attribute is a qualified name of a complex type or simple type used by one of the operations.
- The `format:typeMap` **formatType** attribute is the fully qualified class name for the Java class to which the element specified by **typeName** maps.

If you use the Apache SOAP provider then you specify the mapping of a complex type to a Java class in the client code through two methods on the `org.apache.wsif.WSIFService` interface:

```
public void mapType(QName elementType, Class javaType)
and
public void mapPackage(String namespaceURI, String packageName)
```

Use the **mapType** method to specify a mapping between an XML schema element and a Java class. The method takes a `QName` representing the complex type or simple type, and the corresponding Java class to which it maps.

Use the **mapPackage** method to specify a more general mapping between a namespace and a Java package. Any custom, complex or simple type whose namespace matches that of the mapping is mapped to a Java class in the corresponding package. The name of the class is derived from the name of the complex type using standard XML to Java naming conventions.

- Automatically map complex types.

For complex types defined in the WSDL, where a generated bean is used to represent this type in Java, the Web Services Invocation Framework (WSIF) programming model requires that a call is made to the `WSIFService.mapType()` method. This call tells WSIF the package and class name of the bean representing the XML schema type that is identified with a `QName`. To make things easier, the `WSIFService.mapPackage()` method provides a mechanism to specify a wildcard version of this, where any class within a specified package is mapped to the namespace of a `QName`. This is a mechanism for manually mapping an XML schema type to a Java class and back again (one mapping entry provides a bidirectional mapping).

There are many ways to convert a `QName` representing an XML schema type name to a Java package name and class. To enable automatic type mapping, set the `WSIF_FEATURE_AUTO_MAP_TYPES` feature on the `WSIFServiceFactory` instance:

```
WSIFServiceFactory factory = WSIFServiceFactory.newInstance();
factory.setFeature(WSIFConstants.WSIF_FEATURE_AUTO_MAP_TYPES, new Boolean(true));
```

WSIF maps types by converting the URI part of the XML schema type `QName` to a package name, and converting the local part to a class name. WSIF does this mapping by using the `WSIFUtils` methods `getPackageNameFromNamespaceURI` and `getJavaClassNameFromXMLName`.

Using WSIF to bind a JNDI reference to a web service

You can use the Web Services Invocation Framework (WSIF) to bind a reference to a web service, then look up the reference by using JNDI.

About this task

You access a web service through information provided in the Web Services Description Language (WSDL) document for the service. If you do not know where to find the WSDL document for the service,

but you know that it has been registered in a UDDI registry, then you look it up in the registry. Java programs access Java objects and resources in a similar manner, but using a JNDI interface.

The code fragments in the following steps show how, by using WSIF, you can bind a reference to a web service then look up the reference by using JNDI.

Procedure

- Specify the argument values for the web service.

The web service is represented in WSIF by an instance of the `org.apache.wsif.naming.WSIFServiceRef` class. This simple Referenceable object has the following constructor:

```
public WSIFServiceRef(
    String WSDL,
    String sNS,
    String sName,
    String ptNS,
    String ptName)
{
    [...]
}
```

In this example

- *WSDL* is the location of the WSDL file containing the definition of the service.
- *sNS* is the full namespace for the service definition (you can specify null if only one service is defined in the WSDL file).
- *sName* is the local name for the service definition (you can specify null if only one service is defined in the WSDL file).
- *ptNS* is the full namespace for the port type within the service that you want to use (you can specify null if only one port type is available for the service).
- *ptName* is the local name for the port type (you can specify null if only one port type is available for the service).

For example, if the WSDL file for the web service is available from the web address `http://myServer/WSDL/Example.WSDL` and contains the following service and port type definitions:

```
<definitions targetNamespace="http://hostname/namespace/example"
    xmlns:abc="http://hostname/namespace/abc"
[...]
    <portType name="ExamplePT">
        <operation name="exampleOp">
            <input name="exampleInput" message="tns:ExampleInputMsg"/>
        </operation>
    </portType>
[...]
    <service name="abc:ExampleService">
[...]
    </service>
[...]
</definitions>
```

You can specify the following argument values for the `WSIFServiceRef` class:

- *WSDL* is `http://myServer/WSDL/Example.WSDL`
 - *sNS* is `http://hostname/namespace/abc`
 - *sName* is `ExampleService`
 - *ptNS* is `http://hostname/namespace/example`
 - *ptName* is `ExamplePT`
- Bind the service by using JNDI.
- To bind the service reference in the naming directory by using JNDI, you can use the `com.ibm.websphere.naming.JndiHelper` class in WebSphere Application Server:

```
[...]
import com.ibm.websphere.naming.JndiHelper;
import org.apache.wsif.naming.*;
```

```
[...]
try {
    Context startingContext = new InitialContext();
    WSIFServiceRef ref = new WSIFServiceRef("http://myServer/WSDL/Example.WSDL",
        "http://hostname/namespace/abc"
        "ExampleService",
        "http://hostname/namespace/example",
        "ExamplePT");

    JndiHelper.recursiveRebind(startingContext,
        "myContext/mySubContext/myServiceRef", ref);

}
catch (NamingException e) {
    // Handle error.
}
[...]
```

- Look up the service by using JNDI.

The following code fragment shows the lookup of a service by using JNDI:

```
[...]
try {
[...]
```

```
    InitialContext ic = new InitialContext();
    WSIFService myService =
        (WSIFService) ic.lookup("myContext/mySubContext/myServiceRef");
[...]
```

```
}
catch (NamingException e) {
    // Handle error.
}
[...]
```

Example: Passing SOAP messages with attachments by using WSIF

Information and example code for using the Web Services Invocation Framework (WSIF) SOAP provider to pass attachments within a MIME multipart/related message in such a way that the SOAP processing rules for a standard SOAP message are not changed. This includes how to write the Web Services Description Language (WSDL) extensions for SOAP attachments, and how to work with types and type mappings.

The W3C SOAP Messages with Attachments document describes a standard way to associate a SOAP message with one or more attachments in their native format (for example GIF or JPEG) by using a multipart MIME structure for transport. It defines specific use of the “Multipart/Related” MIME media type, and rules for the use of URI references to entities bundled within the MIME package. It thereby outlines a technique for carrying a SOAP 1.1 message within a MIME multipart/related message in such a way that the SOAP processing rules for a standard SOAP message are not changed.

WSIF supports passing attachments in a MIME message using the SOAP provider to link a WSIF service to a SOAP over HTTP service. The attachment is a `javax.activation.DataHandler` object. The `mime:multipartRelated`, `mime:part` and `mime:content` tags are used to describe the attachment in the WSDL.

- “Example: Writing the WSDL extensions for SOAP attachments”
- “Example: Using WSIF to pass SOAP attachments” on page 1191
- “SOAP attachments - Working with types and type mappings” on page 1192
- “SOAP attachments - scenarios that are not supported” on page 1192

Example: Writing the WSDL extensions for SOAP attachments

The following example WSDL illustrates a simple operation that has one attachment called `attach`:

```
<binding name="MyBinding" type="tns:abc" >
  <soap:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/http"/>
  <operation name="MyOperation">
```

```

<soap:operation soapAction=""/>
<input>
  <mime:multipartRelated>
    <mime:part>
      <soap:body use="encoded" namespace="http://mynamespace"
        encodingStyle="http://schemas.xmlsoap.org/soap/encoding"/>
    </mime:part>
    <mime:part>
      <mime:content part="attch" type="text/html"/>
    </mime:part>
  </mime:multipartRelated>
</input>
</operation>
</binding>

```

In this type of WSDL extension:

- There must be a part attribute (in this example attch) on the input message for the operation (in this example MyOperation). There can be other input parts to MyOperation that are not attachments.
- In the binding input there must either be a <soap:body> tag or a <mime:multipartRelated> tag, but not both.
- For MIME messages, the <soap:body> tag is inside a <mime:part> tag. There must only be one <mime:part> tag that contains a <soap:body> tag in the binding input and that must not contain a <mime:content> tag as well, because a content type of text/xml is assumed for the <soap:body> tag.
- There can be multiple attachments in a MIME message, each described by a <mime:part> tag.
- Each <mime:part> tag that does not contain a <soap:body> tag contains a <mime:content> tag that describes the attachment itself. The type attribute inside the <mime:content> tag is not checked or used by the Web Services Invocation Framework (WSIF). It is there to suggest to the application that uses WSIF what the attachment contains. Multiple <mime:content> tags inside a single <mime:part> tag means that the backend service expects a single attachment with a type specified by one of the <mime:content> tags inside that <mime:part> tag.
- The parts="..." attribute (optional) inside the <soap:body> tag is assumed to contain the names of all the MIME parts as well as the names of all the SOAP parts in the message.

Example: Using WSIF to pass SOAP attachments

The following code fragment can invoke the service described by the example WSDL in “Example: Writing the WSDL extensions for SOAP attachments” on page 1190:

```

import javax.activation.DataHandler;
. . .
DataHandler dh = new DataHandler(new FileDataSource("myimage.jpg"));
WSIFServiceFactory factory = WSIFServiceFactory.newInstance();
WSIFService service = factory.getService("my.wsdl", null, null, "http://mynamespace", "abc");
WSIFOperation op = service.getPort().createOperation("MyOperation");
WSIFMessage in = op.createInputMessage();
in.setObjectPart("attch", dh);
op.executeInputOnlyOperation(in);

```

The associated type mapping in the DeploymentDescriptor.xml file depends upon your SOAP server. For example if you use Tomcat with SOAP 2.3, then the DeploymentDescriptor.xml file contains the following type mapping:

```

<isd:mappings>
<isd:map encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"
  xmlns:x="http://mynamespace"
  qname="x:datahandler"
  javaType="javax.activation.DataHandler"
  java2XMLClassName="org.apache.soap.encoding.soapenc.MimePartSerializer"
  xml2JavaClassName="org.apache.soap.encoding.soapenc.MimePartSerializer" />
</isd:mappings>

```

In this case, the backend service is invoked with the following signature:

```
public void MyOperation(DataHandler dh);
```

You can also use stubs to pass attachments into the Web Services Invocation Framework (WSIF):

```
DataHandler dh = new DataHandler(new FileDataSource("myimage.jpg"));
WSIFServiceFactory factory = WSIFServiceFactory.newInstance();
WSIFService service = factory.getService("my.wsdl", null, null, "http://mynamespace", "abc");
MyInterface stub = (MyInterface)service.getStub(MyInterface.class);
stub.MyOperation(dh);
```

Attachments can also be returned from an operation, but only one attachment can be returned as the return parameter.

SOAP attachments - Working with types and type mappings

By default, attachments are passed into WSIF as `DataHandler` objects. If the part on the message that is the `DataHandler` object maps to a `<mime:part>` tag in the WSDL, then WSIF automatically maps the fully qualified name of the WSDL type to the `DataHandler` class and sets up that type mapping with the SOAP provider.

In your WSDL, you might have defined a schema for the attachment (for instance as a `binary[]` type). WSIF silently ignores this mapping and treats the attachment as a `DataHandler` object, unless you explicitly issue a `mapType()` method. WSIF lets the SOAP provider set the MIME content type based on the type of the `DataHandler` object, instead of the type attribute specified for the `<mime:content>` tag in the WSDL.

SOAP attachments - scenarios that are not supported

The following scenarios are not supported:

- Using DIME.
- Passing in `javax.xml.transform.Source` and `javax.mail.internet.MimeMultipart`.
- Using the `mime:mimeXml` WSDL tag.
- Nesting a `mime:multipartRelated` tag inside a `mime:part` tag.
- Using types that extend `DataHandler`, `Image`, and so on.
- Using types that contain `DataHandler`, `Image`, and so on.
- Using Arrays or Vectors of `DataHandlers`, `Images`, and so on.
- Using multiple in/out or output attachments.

The MIME headers from the incoming message are not preserved for referenced attachments. The outgoing message contains new MIME headers for `Content-Type`, `Content-Id` and `Content-Transfer-Encoding` that are created by WSIF.

Interacting with the Java EE container in WebSphere Application Server

How, and to what extent, WSIF interacts with the Java EE container that is provided in WebSphere Application Server.

About this task

You can interact with a container in any of the following ways:

Procedure

- Use the application server administrative console to define web services to WebSphere Application Server. This task is described in “Using WSIF to bind a JNDI reference to a web service” on page 1188. As part of the definition of a service, the administrator might define a “preferred port”.
- Use the Web Services Invocation Framework (WSIF) to make log and trace calls to the J2EE services in WebSphere Application Server, as described in Tracing and logging WSIF.

- Use WSIF providers to access Java Platform, Enterprise Edition (Java EE) services. For example, use the EJB provider to access the Java Naming and Directory Interface (JNDI) and make calls to remote enterprise beans.
- Use WSIF to wrap the use of container services so that, when WSIF is run in an unmanaged (thin) environment, the operation can succeed.

Invoking a WSDL-based web service through the WSIF API

The Web Services Invocation Framework (WSIF) provides a Java API for invoking web services, independent of the format of the service, or the transport protocol through which it is invoked.

Before you begin

WSIF includes an EJB provider for EJB invocation that uses the Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP). However, for EJB(IIOP)-based web service invocation, invoke RMI-IIOP Web services using JAX-RPC instead.

Ensure that your application uses only one thread to call WSIF.

About this task

The WSIF API supports the invocation of Web Services Description Language (WSDL)-defined web services. WSIF is intended for use in both WSIF clients and web service intermediaries.

The WSIF API is driven by the abstract service description in WSDL; it is completely independent of the binding used. This independence makes the API more natural to work with because it uses WSDL terms to refer to message parts, operations, and other items.

The WSIF API was designed for the WSDL usage model:

1. Select a port that supports the port type that you need.
2. Invoke the operation by providing the necessary abstract input message consisting of the required parts, without worrying about how the message is mapped to a specific binding protocol.

Other web service APIs, for example SOAP APIs, are not designed on WSDL, but for a specific binding protocol with its associated syntax; for example, target URIs and encoding styles.

The main WSIF API interfaces are described in the following procedure. For additional technical details of the WSIF API, see the generated API documentation that is supplied with WSIF (see the Apache WSIF website).

Procedure

- Create a message for sending to a port through the WSIFMessage interface.

In WSDL, a message describes the abstract type of the input or output to an operation. The corresponding WSIF class is `WSIFMessage`, which represents in memory the input or output of an operation. The `WSIFMessage` interface separates the representation of the data from the abstract type defined by WSDL.

A `WSIFMessage` class is a container for a set of named parts. `WSIFMessage` classes can be sent between Java Virtual Machines (JVMs).

1. Choose whether to represent the WSIF message at run time as a Java class or as XML.

There are two natural ways to represent a WSDL message in a runtime environment:

- The generated Java class, based on a WSDL to Java mapping such as that provided by a Java API for XML-based remote procedure call (JAX-RPC).
- The XML representation of the data, for example using SOAP Encoding.

Each option offers benefits in different scenarios. The Java class is the natural approach when WSIF is used in a standard Java client. However, in other scenarios where WSIF is used in an intermediary, it might be more efficient to keep a WSDL message in the SOAP encoded format. The style used to define messages must be consistent within the message, so all the parts in one message must be consistent. A string - `getRepresentationStyle()` - always returns `null`. This indicates that parts on this `WSIFMessage` class are represented as Java objects.

2. Get and set the parts of the WSIF message.

You add parts to a `WSIFMessage` class with the `setObjectPart` or `setTypePart` methods. Each part is named. Part names within a message are unique. If you set a part more than once, the last setting is the one that is used.

You retrieve parts by name from a `WSIFMessage` class with the `getObjectPart` or `getTypePart` methods. If the named part does not exist, the method returns a `WSIFException` error.

You can use iterators to retrieve parts from the message through the `getParts()` and `getPartNames()` methods.

The order in which you set the parts is not important, but the message implementation might be more efficient if the parts are set in the parameter order specified by WSDL.

`WSIFMessage` classes are cloneable and serializable. If the parts set are not cloneable, the implementation can try to clone them using serialization. If the parts are not serializable either, then a `CloneNotSupportedException` exception is thrown if cloning is attempted.

3. Set the WSIF message name.

In addition to the containing parts, a `WSIFMessage` class also has a message name. This is required for operation overloading, which is supported by WSDL and WSIF.

For more information about the `WSIFMessage` interface (</wsi/org/apache/wsif/WSIFMessage.html>) see the generated API documentation that is supplied with WSIF.

- Find a port factory or service through the `WSIFService` interface and the `WSIFServiceFactory` class.

The `WSIFService` interface is a port factory that models and supports the WSDL approach in which a service is available on one or more ports. The factory hides the implementation of the port. WSIF supports dynamic ports that are based on a particular protocol and transport and configured using the WSDL at run time. For example, the dynamic SOAP port can invoke any SOAP service based on the WSDL description of that service, so you can hide and modify the set of available ports at run time.

To find a service from a WSDL document at a web address, or from a code-generated code base, use the `WSIFServiceFactory` class.

- Invoke an operation through the `WSIFPort` interface and the `WSIFOperation` interface.

A `WSIFPort` interface handles the details of invoking an operation. The port provides access to the implementation of the service.

A WSDL document can provide many different WSDL bindings, and these bindings can drive multiple ports. The client can choose a port, the service stub can choose a port, or WSIF can choose a default port.

The port offers an interface to retrieve an `Operation` object. A `WSIFOperation` interface offers the ability to run the given operation.

If the port is serialized and deserialized at a later time, WSIF ensures that the client provides the correct information to the server to identify the instance. If the server instance is no longer available, the server must decide whether to create a fault or provide a new instance. That behavior can depend on the type of service. For example, for an enterprise bean, the `WSIFPort` interface stores the EJB Home and uses it to select the bean before each invocation. The client is responsible for serializing or maintaining the port instance if it requires instance support. The client must create a new operation and messages for each invocation.

WSIFService interface

The `WSIFService` interface can generate an instance of the `WSIFOperation` interface to use for a particular invocation of a service operation.

The Web Services Invocation Framework (WSIF) service stores a list of providers that can each generate a WSIF operation for a particular Web Services Description Language (WSDL) binding. This service looks up providers by the provider type. For example, the service knows about one provider that handles SOAP ports, and other providers that handle Java ports that you define. In a managed environment, the container can configure the WSIFService interface.

For more information about the WSIFService interface, see the generated API documentation that is supplied with WSIF (see the Apache WSIF website).

A WSIFService implementation can choose a preferred port based on a number of criteria. The WSIFService implementation can set the preferred port, or it can be set by calling the setPreferredPort method.

The getPort method returns an instance of the WSIFPort class that is used to invoke a service on the port. Variants of the getPort method are used to define the characteristics of the port to be created:

- the getPort method with no arguments returns the preferred port.
- the getPort method with a string argument returns the port named by the string containing the WSDL identifier for the selected port.

The return value is null if the port name is not valid.

If a port is chosen (either by the WSIFService implementation, or by the setPreferredPort method), then the WSIFService implementation validates that the relevant provider exists and is configured. If the provider fails this validation check, the WSIFService interface chooses any other port for which a provider is defined. For example, if the preferred port is SOAP over JMS but the JMS libraries are not available, then WSIF chooses another port. If no preferred port is set, or the preferred port is not available, the WSIF implementation chooses the first available port listed in the WSDL.

The getAvailablePortNames() method returns, as an iteration of strings, the list of WSDL port names filtered by the set of available providers.

The getDefinition() method returns the WSDL definition for the service. If the WSDL definition is not available, this method returns null.

WSIFServiceFactory class

To find a service from a Web Services Description Language (WSDL) document at a web address, or from a code-generated code base, you can use the WSIFServiceFactory class.

Note: When you create a WSIFService interface from a WSIFServiceFactory class, you can specify a ClassLoader object to use in locating the WSDL file. You must specify this object when the WSDL file is in a JAR file. In such a case, specify the location of the WSDL file relative to the root of the JAR file, and use forward slashes (/) with the preceding slash removed.

For example:

```
com/myCompany/wsd1/MyWSDLFile.wsd1
```

rather than

```
/com/myCompany/wsd1/MyWSDLFile.wsd1
```

For more information about the WSIFServiceFactory class, see the generated API documentation that is supplied with WSIF (see the Apache WSIF website).

The WSIFServiceFactory class returns null if no service is found with that identifier.

WSIFPort interface

The port implements a factory method for the WSIFOperation interface.

For detailed information about the WSIFPort interface, see the generated API documentation that is supplied with WSIF (see the Apache WSIF website).

The createOperation(String) method returns a new instance of a WSIFOperation object. If the operationName value is not valid, or the operation is overloaded, the method throws an exception.

The createOperation(String, String, String) method supports overloaded Web Services Description Language (WSDL) operations. You can overload based on the input parameters, but not on the output parameters.

The client must call the close method when a port is no longer in use. In many cases, where the transport is sessionless, such as HTTP, this has no effect. However, if the port is using a session-based protocol such as MQSeries, Java Message Service (JMS), or External Call Interface (ECI), this supports the port in caching an open connection to the server and then closing it as required. Responsibly-written applications will call the close method if appropriate.

WSIFOperation interface

You use the WSIFOperation interface to invoke a service, based on a particular binding.

The WSIFOperation interface is the runtime representation of an operation. This interface provides methods to create input, output, and fault messages, and to invoke the operation.

For more information about the WSIFOperation interface, see the generated API documentation that is supplied with WSIF (see the Apache WSIF website).

createInputMessage, createOutputMessage and createFaultMessage

These are factory methods to create the messages required by the invocation methods. All invocation methods require an input message.

executeRequestResponseOperation

This method invokes “In Out” operations.

executeInputOnlyOperation

This method invokes “In only” operations.

executeRequestResponseOperation

If this method is used for invocation, an output and a fault message are instantiated and passed on the call to the method. If the method returns true, the output message contains the response message. If the message returns false, a fault occurred and is returned in the fault message.

executeRequestResponseAsync

This method allows “In Out” operations to be invoked with the reply handled by using an alternative thread. Use of this method is discussed further in “WSIFOperation - Asynchronous interactions reference” on page 1197.

setContext and getContext

Use of these methods is discussed in “WSIFOperation - Context.”

All of the **executeNnnn** methods fail with an exception if there is an error in processing the request in the WSIF provider.

Setting the timeouts for synchronous and asynchronous operations is discussed in “WSIFOperation - Synchronous and asynchronous timeouts reference” on page 1198.

WSIFOperation - Context:

Although Web Services Description Language (WSDL) does not define context, a number of uses of the Web Services Invocation Framework (WSIF) require the ability to pass context to the port that is invoking the service.

For example, a SOAP over HTTP port might require an HTTP user name and password. This information is specific to the invocation, but is not a parameter of the service. In general, context is defined as a set of name-value pairs. However, because web services tend to define the types of data by using XML schema types, WSIF represents the name-value pairs of the context by using the same representation that WSIFMessage classes use; that is, a set of named parts, each of which equates to an instance of an XML schema type.

You use the WSIFOperation interface setContext and getContext methods to pass context information to the binding. The port implementation can use this context, for example to update a SOAP header. There is no definition of how a port can use the context.

The parameter of the setContext and getContext methods is a WSIFMessage interface, and this interface has named parts defining the context information. The WSIFConstants class defines constants for the part names that can be set in a context WSIFMessage interface.

The following code fragment shows how to set the user name and password for HTTP basic authentication:

```
// set a basic authentication header
WSIFMessage headers = new WSIFDefaultMessage();
headers.setObjectPart( WSIFConstants.CONTEXT_HTTP_USER, "user name" );
headers.setObjectPart( WSIFConstants.CONTEXT_HTTP_PSWD, "password" );
operation.setContext( headers );
```

The WSIFOperation interface ignores context parts that it does not support. For example, the previous code is ignored by the WSIF Java provider.

The WSIFConstants class includes the following constants that can be used for context part names:

- CONTEXT_HTTP_USER
- CONTEXT_HTTP_PSWD
- CONTEXT_SOAP_HEADERS

The HTTP header values are expected to be of type String, and the SOAP header value is expected to be of type java.util.List, which should contain entries of type org.w3c.dom.Element.

WSIFOperation - Asynchronous interactions reference:

The Web Services Invocation Framework (WSIF) supports asynchronous operation. In this mode of operation, the client puts the request message as part of one transaction, and carries on with the thread of execution. The response message is then handled by a different thread, with a separate transaction.

Asynchronous operation is supported by the WSIF providers for SOAP over JMS and native JMS.

The WSIFPort class uses the supportsAsync method to test whether asynchronous operation is supported.

An asynchronous operation is initiated with the WSIFOperation interface executeRequestResponseAsync method. This method lets a Remote Procedure Call (RPC) method be invoked asynchronously. The method returns before the operation is completed, and the thread of execution continues.

The response to the asynchronous request is processed by the WSIFOperation interface fireAsyncResponse or processAsyncResponse methods.

To initiate the request, there are two forms of the executeRequestResponseAsync method:

- public WSIFCorrelationId executeRequestResponseAsync
 (WSIFMessage input, WSIFResponseHandler handler)
- public WSIFCorrelationId executeRequestResponseAsync (WSIFMessage input)

executeRequestResponseAsync(WSIFMessage input, WSIFResponseHandler handler)

This method takes an input message and a `WSIFResponseHandler` handler. The handler is invoked on another thread when the operation completes. When using this method, the client listener calls the `fireAsyncResponse` method, which then calls the `WSIFResponseHandler` interface `executeAsyncResponse` method.

For more information about the `WSIFResponseHandler` interface, see the generated API documentation that is supplied with WSIF (see the Apache WSIF website).

executeRequestResponseAsync(WSIFMessage input)

This method only takes an input message, and does not use a response handler. The client listener processes the response by calling the `WSIFOperation` interface `processAsyncResponse` method. This process updates the `WSIFMessage` output and fault messages with the result of the request.

WSIF supports correlation between the asynchronous request and response. When the request is sent, the `WSIFOperation` object is serialized into the `WSIFCorrelationService` object. The `executeRequestResponseAsync` methods return a `WSIFCorrelationId` object that identifies the serialized `WSIFOperation` object. The client listener can use this to match a response to a particular request.

The correlation service is located with the `WSIFCorrelationServiceLocator` class `getCorrelationService()` method in the `org.apache.wsif.utils` package.

In a managed container a default correlation service is defined in the default Java Naming and Directory Interface (JNDI) namespace by using the name: `java:comp/wsif/WSIFCorrelationService`. If this correlation service is not available, WSIF uses the `WSIFDefaultCorrelationService`.

For more information about the `WSIFCorrelationService` interface, see the generated API documentation that is supplied with WSIF.

This is the correlator ID:

```
public interface WSIFCorrelator extends Serializable {
    public String getCorrelationId();
}
```

The client must implement its own response message listener or message data base so that it can recognize the arrival of response messages. This client implementation manages the correlation of the response message to the request and call of one of the asynchronous response processing methods. As an example of the requirement for a client listener, the following code fragment shows what can be in the `onMessage` method of a Java Message Service (JMS) listener:

```
public void onMessage(Message msg) {
    WSIFCorrelationService cs = WSIFCorrelationServiceLocator.getCorrelationService();
    WSIFCorrelationId cid = new JmsCorrelationId( msg.getJMSCorrelationID() );
    WSIFOperation op = cs.get( cid );
    op.fireAsyncResponse( msg );
}
```

WSIFOperation - Synchronous and asynchronous timeouts reference:

When you use the Web Services Invocation Framework (WSIF) with the Java Message Service (JMS) you can set timeouts for synchronous and asynchronous operations.

Default values for these timeouts are defined in the `wsif.properties` file:

```
# maximum number of milliseconds to wait for a response to a synchronous request.
# Default value if not defined is to wait forever.
wsif.syncrequest.timeout=10000

# maximum number of seconds to wait for a response to an async request.
# if not defined or invalid defaults to no timeout
wsif.asyncrequest.timeout=60
```

If you use these default values, a synchronous request (such as a WSIFOperation interface executeRequestResponseOperation method call) times out after ten seconds, and an asynchronous request (such as a WSIFOperation interface executeRequestResponseAsync method call) times out after sixty seconds.

Note:

The code that processes both of these timeout values uses milliseconds as its unit of time. The WSIFProperties class getAsyncTimeout method multiplies the wsif.asyncrequest.timeout value by 1000, to convert the value from seconds to milliseconds.

You can override these default values for a given request by writing a WSDL extension that sets a JMS property on the operation request with the <jms:property> and <jms:propertyValue> WSDL elements. Set the name of the property to be the name of the timeout from the WSIF properties file.

The following example sets synchronous requests to time out after two minutes (120 seconds):

```
<jms:propertyValue name="wsif.syncrequest.timeout" type="xsd:string" value="120000"/>
```

and the following example disables asynchronous timeouts (a value of zero means wait forever):

```
<jms:propertyValue name="wsif.asyncrequest.timeout" type="xsd:string" value="0"/>
```

When an asynchronous timeout expires, no listener or message data base waiting for the response is notified. The asynchronous timeout is only used to tell the correlation service that the stored WSIFOperation can be deleted. For more information about the correlation service, see “WSIFOperation - Asynchronous interactions reference” on page 1197.

Running WSIF as a client

You can run the Web Services Invocation Framework (WSIF) in the Application Client for WebSphere Application Server, and in similar clients from other suppliers.

Procedure

To simplify the process of launching client applications in the Application Client for WebSphere Application Server, use the launchClient tool as described in “Running a Java EE client application with launchClient” on page 1809.

Chapter 30. Developing web services - Notification (WS-Notification)

WS-Notification enables web services to use the publish and subscribe messaging pattern. You use publish and subscribe messaging to publish one message to many subscribers. In this pattern a producing application inserts (publishes) a message (event notification) into the messaging system having marked it with a topic that indicates the subject area of the message. Consuming applications that have subscribed to the topic in question, and have appropriate authority, all receive an independent copy of the message that was published by the producing application.

Developing applications that use WS-Notification

You can code a single application to undertake several WS-Notification tasks. These topics provide sample code for common tasks that your WS-Notification applications can perform.

Before you begin

Most of these examples use the Java API for XML-based remote procedure call (JAX-RPC) APIs and WebSphere Application Server APIs and SPIs. These JAX-RPC examples can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS
- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

If you have an existing Version 6.1 WS-Notification configuration, and you want to use WS-Notification with policy sets, work through the following tasks:

1. Migrating a Version 6.1 WS-Notification configuration from WebSphere Application Server Version 6.1 to Version 7.0 or later.
2. Preparing a migrated Version 6.1 WS-Notification configuration for reliable notification.
3. Configuring WS-Notification for reliable notification.

Your applications can also use WS-Notification to receive event notifications generated by other clients of the service integration bus such as JMS clients. This is described in *Topology for WS-Notification* as an entry or exit point to the service integration bus and *Providing access for WS-Notification applications to an existing bus topic space*. For information about developing applications for a mixed clients solution, including cross-streaming from a JMS client, see *Interacting with JMS message types*.

About this task

A single application can be coded to undertake several WS-Notification tasks. Use the examples to help you code these tasks into your WS-Notification applications.

For an overview of how applications can use the notification broker, see *WS-Notification: How client applications interact at runtime*.

WS-Notification applications divide into two broad types: those that expose a Web service endpoint (for example a WS-Notification consumer application that receives notifications of stock valuation changes),

and those that do not expose a web service endpoint (for example applications that generate notifications of stock valuation changes). For broad guidance on the steps you take to develop each of these application types, see the following topics:

- “Writing a WS-Notification application that exposes a web service endpoint.”
- “Writing a WS-Notification application that does not expose a web service endpoint” on page 1203.

Rather than receiving all messages on a topic to which you have subscribed, your consuming application can use XML Path (XPath) selectors to filter the messages based upon the contents of each message as described in “Filtering the message content of publications” on page 1204.

The code examples listed in this topic use the following WebSphere Application Server APIs and SPIs:

```
com.ibm.websphere.sib.wsn.AbsoluteOrRelativeTime;  
com.ibm.websphere.sib.wsn.CreatePullPoint;  
com.ibm.websphere.sib.wsn.CreatePullPointResponse;  
com.ibm.websphere.sib.wsn.Filter;  
com.ibm.websphere.sib.wsn.GetMessages;  
com.ibm.websphere.sib.wsn.GetMessagesResponse;  
com.ibm.websphere.sib.wsn.NotificationMessage;  
com.ibm.websphere.sib.wsn.TopicExpression;  
com.ibm.websphere.webservices.soap.IBMSOAPFactory;  
com.ibm.websphere.wsaddressing.EndpointReference;  
com.ibm.websphere.wsaddressing.WSConstants;  
com.ibm.wsspi.wsaddressing.EndpointReferenceManager;
```

Procedure

- For examples of client applications, see the following topics:
 1. “Example: Subscribing a WS-Notification consumer” on page 1205.
 2. “Example: Pausing a WS-Notification subscription” on page 1208.
 3. “Example: Publishing a WS-Notification message” on page 1209.
 4. “Example: Creating a WS-Notification pull point” on page 1211.
 5. “Example: Getting messages from a WS-Notification pull point” on page 1212.
 6. “Example: Registering a WS-Notification publisher” on page 1213.
- For example XML code illustrating message content filtering by using XPath selectors, see “Filtering the message content of publications” on page 1204.
- For an example WSDL document describes a web service that implements the NotificationConsumer portType, see “Example: Creating a Notification consumer web service skeleton” on page 1215.

Writing a WS-Notification application that exposes a web service endpoint

Write a Java EE application, containing a web service definition, that can be deployed to the application server and act as a NotificationProducer, NotificationConsumer or demand-based publisher.

Before you begin

This task assumes that you have the following resources:

- An installed and functioning copy of IBM Rational Application Developer, Rational Software Architect or equivalent tooling.
- The WSDL file for the endpoint that is to be exposed.

About this task

To write a WS-Notification application that exposes a Web service endpoint, follow the method provided by your tooling for creating a web service implementation from a WSDL file. For example in Rational Software Architect there is a wizard in the Tutorials Gallery under “Create and deploy a WS-I compliant web service

and an enterprise bean skeleton from a WSDL document by using the WebSphere Application Server runtime environment". This wizard guides you through the following steps for writing a JAX-RPC application. The steps are very similar for writing a JAX-WS application. For an example of a JAX-WS NotificationConsumer client application that exposes a web service endpoint, see Writing JAX-WS applications for WS-Notification.

Procedure

1. Create a Dynamic Web Project.
2. Import and validate the WSDL file.
3. Create the web service. Select **File > New > Other > Web services > Web service wizard > Skeleton EJB web service**.
4. Implement the business methods in the generated EJB class. The methods you choose depend upon the type of endpoint that you are exposing (NotificationProducer, NotificationConsumer or demand based publisher).
5. Export the application.

What to do next

You are now ready to deploy the application to WebSphere Application Server as described in Installing enterprise application files with the console. In the Select installation options panel, ensure that the **Deploy web services** option is enabled.

Writing a WS-Notification application that does not expose a web service endpoint

Write a Java EE application that can be run outside of the application server to make web service invocations against an external web service. This application acts as a lightweight publisher, or a pull type consumer by invoking web service operations against another web service such as the NotificationBroker provided by WebSphere Application Server.

Before you begin

This task assumes that you have the following resources:

- An installed and functioning copy of IBM Rational Application Developer, Rational Software Architect or equivalent tooling.
- Knowledge of where to find the WSDL file for the service that is to be invoked.

About this task

To write a WS-Notification application that does not expose a web service endpoint, follow the method provided by your tooling for creating a web service implementation from a WSDL file. As an illustration, the following steps describe the method provided by Rational Software Architect for writing a JAX-RPC application. The steps are very similar for writing a JAX-WS application. For examples of JAX-WS publisher and subscriber client applications that do not expose a web service endpoint, see Writing JAX-WS applications for WS-Notification.

Procedure

1. Get the WSDL files for the service that you want to invoke. If the target service is the notification broker service that was generated by WebSphere Application Server, use the administrative console to publish the WSDL files for the service to a compressed file.
2. Create a Dynamic Web Project with a name of your choice.
3. Choose **File > New > Other > Web services > Web services Client**.
4. Select **Java Proxy**.

5. Enter or select the WSDL you obtained earlier.
6. Choose a Client Type of “Application Client” or “Java” depending upon your requirements.
7. Select your required security configuration.
8. Click **Finish**.
9. Use the generated proxy and stubs to make calls against the remote web service. For detailed coding examples, see “Developing applications that use WS-Notification” on page 1201.

What to do next

You are now ready to deploy the application for use in the Java EE application client container as described in “Running a Java EE client application with launchClient” on page 1809.

Filtering the message content of publications

Rather than receiving all messages on a topic to which you have subscribed, your consuming application can use XML Path (XPath) selectors to filter the messages based upon the contents of each message. This content-based subscription gives you greater flexibility in defining the type of information that you want to receive, and your applications do not need to handle their own filtering. Performance is improved because messages that are not relevant are not sent unnecessarily from the server to the application.

About this task

The WS-Notification publish and subscribe messaging model is topic-based. Each publication is classified as belonging to one of a fixed set of topics. Publishers label each publication with a topic name and consumers subscribe to all publications on a particular topic. For example a stock trading notification system might define a topic for each issue: Publishers post information labeled with the appropriate issue as the topic name, and subscribers subscribe to information regarding some issue.

You can use XPath selectors to filter messages for a given topic, by using a Boolean expression that is evaluated over the XML message content of the message body. For example, a subscriber to a topic-based publish and subscribe system for stock trading might use XPath selectors to specify constraints against three message attributes at the same time:

- issue name
- price
- volume of shares

The resultant Boolean statement might be as follows:

```
(issue="IBM") and (price<120) and (volume>1000)
```

You code your XPath 1.0 message content filters in the subscribing applications, by using XML Path (XPath) language, Version 1.0..

Note: If your subscriber applications use message content filtering, and are coded to specify the XPath Version 1.0 SelectorDomain, they can also filter publications from other WS-Notification providers that are of type JMS TextMessage or BytesMessage. For more information about these JMS message types, see Topology for WS-Notification as an entry or exit point to the service integration bus.

To filter the message content of publications by using XPath selectors, complete the following steps.

Procedure

1. Create a new application that subscribes a WS-Notification consumer.
2. Code an XPath message content filter in the subscribing application. For example code for doing this, see “Example: Subscribing a WS-Notification consumer” on page 1205. For an example of message content filter usage, see the example at the end of this task.

3. Code error handling for cases where the filter is not valid.
4. Invoke the application.

Example

This example XML code illustrates message content filtering by using XPath selectors. In this example a business, represented by a NotificationConsumer application, wants to be notified of bank transfers of over \$1,000,000. The monitoring application subscribes on behalf of the NotificationConsumer specifying a valid XPath Version 1.0 message content filter, in the following WS-Notification subscribe message:

```
<wsnt:Subscribe>
  <wsnt:ConsumerReference>
    wsa:EndpointReference
  </wsnt:ConsumerReference>
  <wsnt:Filter>
    [ <wsnt:TopicExpression Dialect="xsd:anyURI">
      {any} ?
    </wsnt:TopicExpression> |
    <wsnt:ProducerProperties Dialect="xsd:anyURI">
      {any} ?
    </wsnt:ProducerProperties> |
    <wsnt:MessageContent Dialect="xsd:anyURI">
      /bankTransfer[value %gt; 1,000,000]
    </wsnt:MessageContent> |
    {any} *
    ] *
  </wsnt:Filter> ?
  <wsnt:InitialTerminationTime>
    [xsd:dateTime | xsd:duration]
  </wsnt:InitialTerminationTime> ?
  <wsnt:SubscriptionPolicy>
    [ <wsnt:UseRaw/> |
      {any}
    ] *
  </wsnt:SubscriptionPolicy> ?
  {any}*
</wsnt:Subscribe>
```

The WS-Notification service stores the subscription and its filter.

Another WS-Notification application then publishes a notification in which the message body contains the following information:

```
<bankTransfer origin="123456 87654321" target="224466 88664422">
  <originName>IBM Corporation</originName>
  <targetName>Matt Roberts</targetName>
  <date>02/02/2006</date>
  <value currency="USD">100,000,000</value>
</bankTransfer>
```

The WS-Notification service in the application server matches this publication to the earlier subscription and delivers the notification to the consumer specified in the subscription.

Example: Subscribing a WS-Notification consumer

Use this task to write the code for a JAX-RPC client acting in the publisher registration role, registering a publisher (producer) application with a broker, based on the example code extract provided.

About this task

This example is based on using the Java API for XML-based remote procedure calls (JAX-RPC) APIs with code generated by using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

In WebSphere Application Server there are two implementations of the WS-Notification service: Version 6.1 and Version 7.0. This JAX-RPC example can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS
- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

The article Writing JAX-WS applications for WS-Notification includes an example of a JAX-WS subscriber client application.

Raw subscriptions:

In this example, the first optional code block shows you how to create a *raw subscription*. This concept is defined in section 4.2 of the Web Services Base Notification specification.

In the normal case, a wrapped subscription causes the Notify operation of the NotificationConsumer to be driven when matching event notifications become available. If the Subscriber instead creates a raw subscription, then only the application specific content of the event notification (that is, the contents of the NotificationMessage element) are sent to the target consumer endpoint. Note that the web service endpoint specified in the ConsumerReference of the Subscribe request that also specifies **UseRaw** (that is, a raw subscription request) does not have to implement the NotificationConsumer port type because the Notify operation will not be used to deliver event notifications.

This means that the consumer must be able to accept operations for each of the types of application content that will be published on the specified topic. This pattern allows WS-Notification to invoke a group of existing web service applications that are not WS-Notification aware, but that want to receive the same information.

JAX-WS supports action-based dispatch, and JAX-WS raw consumer applications must accept the <http://docs.oasis-open.org/wsn/bw-2/NotificationConsumer/Notify> action URI. For more information, see the troubleshooting tip A JAX-WS application that is a raw consumer of brokered notifications must recognize a notification broker SOAP action.

To write the code for a JAX-RPC client acting in the publisher registration role, registering a publisher (producer) application with a broker, complete the following steps, referring to the example code extract for further information.

Procedure

1. Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation.
2. Get a stub for the port on which you want to invoke operations.
3. Create the ConsumerReference. This either contains the address of the consumer web service that is being subscribed to, or a reference to a pull point. Specifying a pull point EPR indicates that the consumer is to use pull-based notifications.
4. Create the filter. This provides the name of the topic to which you want to subscribe the consumer.

5. Create a topic expression and add it to the filter. The prefixMappings are mappings between namespace prefixes and their corresponding namespaces for prefixes used in the expression.
6. Create an XPath 1.0 message content filter. For example you could select a subset of the available messages in the topic, based upon salary level. For an example of message content filter usage, see "Filtering the message content of publications" on page 1204.
7. Create the InitialTerminationTime. This is the time when you want the subscription to terminate. For example, you could set a time of 1 year in the future.
8. Create the Policy information.
9. Optional: Construct a policy indicating that the consumer is to receive raw style notifications.
10. Create holders to hold the multiple values returned from the broker:
 - The subscription reference
 - The current time at the broker
 - The termination time for the subscription
 - Any additional elements
11. Invoke the Subscribe operation by calling the associated method on the stub.
12. Get the returned values:
 - An endpoint reference for the subscription that has been created. This is required for subsequent lifetime management of the subscription, for example pausing the subscription.
 - The current time at the broker.
 - The termination time of the subscription.
 - Any other information.

Example

The following example code describes a subscriber client application that can subscribe a consumer application with a broker:

```
// Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");

// Get a stub for the port on which you want to invoke operations
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);

// Create the ConsumerReference. This contains the address of the consumer web service that is being
// subscribed, or alternatively is a reference to a pull point (see alternative below). Specifying a
// pull point EPR indicates that the consumer is to use pull-based notifications.
EndpointReference consumerEPR =
    EndpointReferenceManager.createEndpointReference(new URI("http://myserver.mycom.com:9080/Consumer"));

/*
// Alternative ConsumerReference for pull-based notifications:
EndpointReference consumerEPR = pullPointEPR;
*/

// Create the Filter. This provides the name of the topic to which you want to subscribe the consumer
Filter filter = new Filter();

// Create a topic expression and add it to the filter. The prefixMappings are mappings between namespace
// prefixes and their corresponding namespaces for prefixes used in the expression
Map prefixMappings = new HashMap();
prefixMappings.put("abc", "uri:example");
TopicExpression exp =
    new TopicExpression(TopicExpression.SIMPLE_TOPIC_EXPRESSION, "abc:ExampleTopic", prefixMappings);
filter.addTopicExpression(exp);

//Create an XPath 1.0 message content filter
//This example selects a subset of the available messages in the topic, based upon salary level
String filterExpression = "/company/department/employee/salary > 10000";
URI xpathURI = new URI("http://www.w3.org/TR/1999/REC-xpath-19991116");
```

```

QueryExpression qexp =
    new QueryExpression(xpathURI, filterExpression);

filter.addMessageContentExpression(qexp);

// Create the InitialTerminationTime. This is the time when you want the subscription to terminate.
// For example, set a time of 1 year in the future.
Calendar cal = Calendar.getInstance();
cal.add(Calendar.YEAR, 1);
AbsoluteOrRelativeTime initialTerminationTime = new AbsoluteOrRelativeTime(cal);

// Create the Policy information
SOAPElement[] policyElements = null;

/*
Optional
-----
The following lines show how to construct a policy indicating that the consumer is to
receive raw style notifications:

    javax.xml.soap.SOAPFactory soapFactory = javax.xml.soap.SOAPFactory.newInstance();
    SOAPElement useRawElement = null;

    if (soapFactory instanceof IBMSOAPFactory) {
        // You can use the value add methods provided by the IBMSOAPFactory API to create the SOAPElement
        // from an XML string.
        String useRawElementXML = "<mno:UseRaw xmlns:mno=\"http://docs.oasis-open.org/wsn/b-2\"/>";
        useRawElement = ((IBMSOAPFactory) soapFactory).createElementFromXMLString(useRawElementXML);
    } else {
        useRawElement = soapFactory.createElement("UseRaw", "mno", "http://docs.oasis-open.org/wsn/b-2");
    }

    policyElements = new SOAPElement[] { useRawElement };
*/

// Create holders to hold the multiple values returned from the broker:
// The subscription reference
EndpointReferenceTypeHolder subscriptionRefHolder = new EndpointReferenceTypeHolder();

// The current time at the broker
CalendarHolder currentTimeHolder = new CalendarHolder();

// The termination time for the subscription
CalendarHolder terminationTimeHolder = new CalendarHolder();

// Any additional elements
AnyArrayHolder anyOtherElements = new AnyArrayHolder();

// Invoke the Subscribe operation by calling the associated method on the stub
stub.subscribe(consumerEPR,
    filter,
    initialTerminationTime,
    policyElements,
    anyOtherElements,
    subscriptionRefHolder,
    currentTimeHolder,
    terminationTimeHolder);

// Get the returned values:
// An endpoint reference for the subscription that has been created. It is required for
// subsequent lifetime management of the subscription, for example pausing the subscription
com.ibm.websphere.wsaddressing.EndpointReference subscriptionRef = subscriptionRefHolder.value;

// The current time at the broker
Calendar currentTime = currentTimeHolder.value;

// The termination time of the subscription
Calendar terminationTime = terminationTimeHolder.value;

// Any other information
SOAPElement[] otherElements = anyOtherElements.value;

```

Example: Pausing a WS-Notification subscription

Use this task to write the code for a JAX-RPC client acting in the subscriber role, pausing a subscription for a consumer application, based on the example code extract provided.

About this task

This example is based on using the Java API for XML-based remote procedure calls (JAX-RPC) APIs with code generated by using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

In WebSphere Application Server there are two implementations of the WS-Notification service: Version 6.1 and Version 7.0. This JAX-RPC example can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS
- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

Procedure

1. Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation. The PauseSubscription operation belongs to the SubscriptionManager service.
2. Get a stub for the port on which you want to invoke operations.
3. Associate the request with the subscription you want to pause. The subscriptionEPR is the EndpointReference returned by the invocation of the Subscribe operation.
4. Create any optional information.
5. Invoke the PauseSubscription operation by calling the associated method on the stub.

Example

The following example code describes a JAX-RPC client acting in the subscriber role, pausing a subscription for a consumer application:

```
// Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation.
// The PauseSubscription operation belongs to the SubscriptionManager service
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup("java:comp/env/services/SubscriptionManager");

// Get a stub for the port on which you want to invoke operations
SubscriptionManager stub = (SubscriptionManager) service.getPort(SubscriptionManager.class);

// Associate the request with the subscription you want to pause. The subscriptionEPR is the
// EndpointReference returned by the invocation of the Subscribe operation
((Stub) stub)._setProperty(WSConstants.WSADDRESSING_DESTINATION_EPR, subscriptionEPR);

// Create any optional information
SOAPElement[] optionalInformation = new SOAPElement[] {};

// Invoke the PauseSubscription operation by calling the associated method on the stub
SOAPElement[] additionalReturnedInformation = stub.pauseSubscription(optionalInformation);
```

Example: Publishing a WS-Notification message

Use this task to write the code for a publisher client application that can publish a notification message to a broker, based on the example code extract provided.

About this task

This example is based on using the Java API for XML-based remote procedure calls (JAX-RPC) APIs with code generated by using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

In WebSphere Application Server there are two implementations of the WS-Notification service: Version 6.1 and Version 7.0. This JAX-RPC example can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS
- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

The article Writing JAX-WS applications for WS-Notification includes an example of a JAX-WS publisher client application.

To write the code for a publisher client application that can publish a notification message to a broker, complete the following steps, referring to the example code extract for further information.

Procedure

1. Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation.
2. Get a stub for the port on which you want to invoke operations.
3. Create the message contents for a notification message.
4. Create a notification message from the contents.
5. Add a topic expression to the notification message. The topic expression must indicate to which topic or topics the message corresponds.
6. Create any optional information.
7. Optional: If the broker requires publisher client applications to register, associate the request with a particular publisher registration. The registrationEPR is the ConsumerReference EndpointReference returned by the broker in relation to an invocation of the RegisterPublisher operation.
8. Invoke the Notify operation by calling the associated method on the stub.

Example

The following example code represents a publisher client application that can publish a notification message to a broker:

```
// Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");

// Get a stub for the port on which you want to invoke operations
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);

// Create the message contents for a notification message
SOAPElement messageContents = null;
javax.xml.soap.SOAPFactory soapFactory = javax.xml.soap.SOAPFactory.newInstance();
if (soapFactory instanceof IBMSOAPFactory) {
    // You can use the value add methods provided by the IBMSOAPFactory API to create the SOAPElement
    // from an XML string.
    String messageContentsXML = "<xyz:MyData xmlns:xyz=\"uri:mynamespace\">Some data</xyz:MyData>";
```

```

    messageContents = ((IBMSOAPFactory) soapFactory).createElementFromXMLString(messageContentsXML);
} else {
    // Build up the SOAPElement using the standard javax.xml.soap APIs
    messageContents = soapFactory.createElement("MyData", "xyz", "uri:mynamespace");
    messageContents.addTextNode("Some data");
}

// Create a notification message from the contents
NotificationMessage message = new NotificationMessage(messageContents);

// Add a topic expression to the notification message indicating to which topic or topics the
// message corresponds
Map prefixMappings = new HashMap();
prefixMappings.put("abc", "uri:example");
TopicExpression exp =
    new TopicExpression(TopicExpression.SIMPLE_TOPIC_EXPRESSION, "abc:ExampleTopic", prefixMappings);
message.setTopic(exp);

// Create any optional information
SOAPElement[] optionalInformation = new SOAPElement[] {};

/*
Optional
-----
The following line will cause the request to be associated with a particular publisher registration.
You must do this if the broker requires publishers to register. The registrationEPR is the
ConsumerReference EndpointReference returned by the broker in relation to an invocation of the
RegisterPublisher operation.

    ((Stub) stub)._setProperty(WSAConstants.WSADDRESSING_DESTINATION_EPR, consumerReferenceEPR);
*/

// Invoke the Notify operation by calling the associated method on the stub
stub.notify(new NotificationMessage[] { message }, optionalInformation);

```

Example: Creating a WS-Notification pull point

Use this task to write the code for a JAX-RPC subscriber client. This client creates a pull point for use by consumer applications that use pull style notifications.

About this task

This example is based on using the Java API for XML-based remote procedure calls (JAX-RPC) APIs with code generated by using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

In WebSphere Application Server there are two implementations of the WS-Notification service: Version 6.1 and Version 7.0. This JAX-RPC example can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS
- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

To write the code for a JAX-RPC client acting in the subscriber role, creating a pull point for use by a consumer application that is to use pull style notifications, complete the following steps, referring to the example code extract for further information.

Procedure

1. Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation.
2. Get a stub for the port on which you want to invoke operations.
3. Create the request information.
4. Invoke the CreatePullPoint operation by calling the associated method on the stub.
5. Retrieve the reference to the pull point from the response.
6. Retrieve any additional information from the response.

Example

The following example code describes a JAX-RPC client acting in the subscriber role, creating a pull point for use by a consumer application that is to use pull style notifications:

```
// Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");

// Get a stub for the port on which you want to invoke operations
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);

// Create the request information.
SOAPElement[] optionalInformation = null;
CreatePullPoint cpp = new CreatePullPoint(optionalInformation);

// Invoke the CreatePullPoint operation by calling the associated method on the stub
CreatePullPointResponse response = stub.createPullPoint(cpp);

// Retrieve the reference to the pull point from the response
EndpointReference pullPointEPR = response.getPullPoint();

// Retrieve any additional information from the response
SOAPElement[] additionalInformation = response.getElements();
```

Example: Getting messages from a WS-Notification pull point

Use this task to write the code for a JAX-RPC client acting in the pull style consumer role, requesting messages from a pull point, based on the example code extract provided.

About this task

This example is based on using the Java API for XML-based remote procedure calls (JAX-RPC) APIs with code generated by using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

In WebSphere Application Server there are two implementations of the WS-Notification service: Version 6.1 and Version 7.0. This JAX-RPC example can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS
- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

To write the code for a JAX-RPC client acting in the pull style consumer role, requesting messages from a pull point, complete the following steps, referring to the example code extract for further information.

Procedure

1. Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation.
2. Get a stub for the port on which you want to invoke operations.
3. Associate the request with a pull point. The pullPointEPR is the EndpointReference returned from invoking the CreatePullPoint operation.
4. Specify the number of messages you want to retrieve.
5. Create any optional information.
6. Create the request information.
7. Invoke the GetMessages operation by calling the associated method on the stub.
8. Get the messages returned from the response.

Example

The following example code describes a JAX-RPC client acting in the pull style consumer role, requesting messages from a pull point:

```
// Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");

// Get a stub for the port on which you want to invoke operations
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);

// Associate the request with a pull point. The pullPointEPR is the EndpointReference returned
// from invoking the CreatePullPoint operation
((Stub) stub)._setProperty(WSConstants.WSADDRESSING_DESTINATION_EPR, pullPointEPR);

// Specify the number of messages you want to retrieve
Integer numberOfMessages = new Integer(2);

// Create any optional information
SOAPElement[] optionalInformation = new SOAPElement[] {};

// Create the request information
GetMessages request = new GetMessages(numberOfMessages, optionalInformation);

// Invoke the GetMessages operation by calling the associated method on the stub
GetMessagesResponse response = stub.getMessages(request);

// Get the messages returned from the response
NotificationMessage[] messages = response.getMessages();
```

Example: Registering a WS-Notification publisher

Use this task to write the code for a subscriber client application that can subscribe a consumer application with a broker, based on the example code extract provided.

About this task

This example is based on using the Java API for XML-based remote procedure calls (JAX-RPC) APIs with code generated by using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

In WebSphere Application Server there are two implementations of the WS-Notification service: Version 6.1 and Version 7.0. This JAX-RPC example can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS

- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

To write the code for a subscriber client application that can subscribe a consumer application with a broker, complete the following steps, referring to the example code extract for further information.

Procedure

1. Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation.
2. Get a stub for the port on which you want to invoke operations.
3. Create a reference for the publisher (producer) being registered. This contains the address of the producer web service.
4. Create a list (array) of topic expressions to describe the topics to which the producer publishes messages.
5. Indicate that you do not want the publisher to use demand based publishing.
6. Set a value for the initial termination time of the registration. For example, you could set a value 1 year in the future.
7. Create holders to hold the multiple values returned from the broker:
 - **PublisherRegistrationReference** defines the endpoint reference for use in lifetime management of the registration.
 - **ConsumerReference** defines the endpoint reference for use in subsequent publishing of messages.
8. Invoke the RegisterPublisher operation by calling the associated method on the stub.
9. Retrieve the PublisherRegistrationReference.
10. Retrieve the ConsumerReference.

Example

The following example code represents a JAX-RPC client acting in the publisher registration role, registering a publisher (producer) application with a broker.

```
// Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");

// Get a stub for the port on which you want to invoke operations
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);

// Create a reference for the publisher (producer) being registered. This contains the address of the
// producer web service.
EndpointReference publisherEPR =
    EndpointReferenceManager.createEndpointReference(new URI("http://myserver.mysom.com:9080/Producer"));

// Create a list (array) of topic expressions to describe the topics to which the producer publishes
// messages. For this example you add one topic
Map prefixMappings = new HashMap();
prefixMappings.put("abc", "uri:mytopics");
TopicExpression topic =
    new TopicExpression(TopicExpression.SIMPLE_TOPIC_EXPRESSION, "abc:xyz", prefixMappings);
TopicExpression[] topics = new TopicExpression[] {topic};

// Indicate that you do not want the publisher to use demand based publishing
Boolean demand = Boolean.FALSE;

// Set a value for the initial termination time of the registration. For example, set a value 1 year in
// the future
Calendar initialTerminationTime = Calendar.getInstance();
initialTerminationTime.add(Calendar.YEAR, 1);

// Create holders to hold the multiple values returned from the broker:
// PublisherRegistrationReference: An endpoint reference for use in lifetime management of
// the registration
```

```

EndpointReferenceTypeHolder pubRegMgrEPR = new EndpointReferenceTypeHolder();

// ConsumerReference: An endpoint reference for use in subsequent publishing of messages
EndpointReferenceTypeHolder consEPR = new EndpointReferenceTypeHolder();

// Invoke the RegisterPublisher operation by calling the associated method on the stub
stub.registerPublisher(publisherEPR, topics, demand, initialTerminationTime, null, pubRegMgrEPR, consEPR);

// Retrieve the PublisherRegistrationReference
EndpointReference registrationEPR = pubRegMgrEPR.value;

// Retrieve the ConsumerReference
EndpointReference consumerReferenceEPR = consEPR.value;

```

Example: Creating a Notification consumer web service skeleton

Use this example when creating a web service that implements the NotificationConsumer portType defined by the Web Services Base Notification specification.

About this task

This task provides two code examples:

- An example WSDL document that describes a web service that implements the NotificationConsumer portType defined by the Web Services Base Notification specification.
- A basic implementation of the Service Endpoint Interface (SEI) generated from the preceding WSDL document using the WSDL2Java tool.

Note: The article Writing JAX-WS applications for WS-Notification also includes an example of a consumer Web service.

Procedure

If you are creating a Notification consumer web service skeleton, see the following code examples.

Example

The following example WSDL document describes a web service that implements the NotificationConsumer portType defined by the Web Services Base Notification specification:

```

<?xml version="1.0" encoding="utf-8"?>

<wsdl:definitions xmlns="http://schemas.xmlsoap.org/wsdl/"
  xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:wsn-bw="http://docs.oasis-open.org/wsn/bw-2"
  xmlns:wsdlsoap="http://schemas.xmlsoap.org/wsdl/soap/"
  xmlns:tns="uri:example.wsn/consumer"
  targetNamespace="uri:example.wsn/consumer">

  <wsdl:import namespace="http://docs.oasis-open.org/wsn/bw-2"
    location="http://docs.oasis-open.org/wsn/bw-2.wsdl" />

  <wsdl:binding name="NotificationConsumerBinding" type="wsn-bw:NotificationConsumer">
    <wsdlsoap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http" />
    <wsdl:operation name="Notify">
      <wsdlsoap:operation soapAction="" />
      <wsdl:input>
        <wsdlsoap:body use="literal" />
      </wsdl:input>
    </wsdl:operation>
  </wsdl:binding>

  <wsdl:service name="NotificationConsumerService">
    <wsdl:port name="NotificationConsumerPort" binding="tns:NotificationConsumerBinding">
      <wsdlsoap:address location="http://myserver.mycom.com:9080/Consumer" />
    </wsdl:port>
  </wsdl:service>

```

```
</wsdl:port>
</wsdl:service>

</wsdl:definitions>
```

The following example shows a basic implementation of the Service Endpoint Interface (SEI) generated from the preceding WSDL document using the WSDL2Java tool:

```
public class ConsumerExample implements NotificationConsumer {

    public void notify(NotificationMessage[] notificationMessage, SOAPElement[] any)
        throws RemoteException {
        // Process each NotificationMessage
        for (int i=0; i<notificationMessage.length; i++) {
            NotificationMessage message = notificationMessage[i];

            // Get the contents of the message
            SOAPElement messageContent = message.getMessageContents();

            // Get the expression indicating which topic the message is associated with
            TopicExpression topic = message.getTopic();

            // Get a reference to the producer (this value is optional and so might be null)
            EndpointReference producerRef = message.getProducerReference();

            // Get a reference to the subscription (this value is optional and so might be null)
            EndpointReference subscriptionRef = message.getSubscriptionReference();

            // User defined processing ...

        }
    }
}
```

Chapter 31. Developing web services - Reliable messaging (WS-ReliableMessaging)

To configure a web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent.

Developing a reliable web service application

Develop a Java API for XML-Based Web Services (JAX-WS) provider or requester application that can compose with a WS-ReliableMessaging-enabled policy set.

Before you begin

At any stage - that is, before or after you have built your reliable web service application, or configured your policy sets - you can set a property that configures endpoints to only support clients that use reliable messaging. This setting is reflected by WS-Policy if engaged.

About this task

You can develop a Java API for XML-Based Web Services (JAX-WS) web service requester application that sends messages reliably, or a web service provider application that requires reliable messaging. Your client application can also take programmatic control of WS-ReliableMessaging sequences.

Procedure

1. Develop your JAX-WS web service application.

For a Web service requester application that sends messages reliably:

- a. Get an implementation WSDL document, and select the SOAP over HTTP binding. The WSDL should be WS-I Basic Profile compliant.
- b. Build the JAX-WS application from the WSDL implementation document.
- c. (Optional) Enable transaction support for outbound (requester) one-way message sends. For more information, see “Providing transactional recoverable messaging through WS-ReliableMessaging” on page 1220.
- d. (Optional) Use the `waitUntilSequenceCompleted` method on the `sequenceManager` to ensure that reliable messaging state is released after the client finishes messaging, as described in the “Controlling WS-ReliableMessaging sequences programmatically” on page 1218 topic.
- e. (Optional) If you want to use in-order delivery (that is, you want WS-ReliableMessaging to make messages available to your requester application in the order that they were sent), then you must also configure your requester application to poll for the messages in the order in which it should receive them. For more information, see `Configuring the WS-ReliableMessaging policy`.

For a web service provider application that requires reliable messaging:

- a. Write or get an interface WSDL document that describes the service interface. The document should be compliant with the WS-I Basic Profile.
 - b. Write or get an implementation WSDL document, and select the SOAP over HTTP binding. The WSDL should remain WS-I Basic Profile compliant.
 - c. Build the JAX-WS application from the WSDL implementation document.
2. Enable your client application to take programmatic control of WS-ReliableMessaging sequences.
This helps manage resources on the server, for example by removing sequences after a client application has finished messaging. You can add code to create sequences, send acknowledgement

requests, close sequences, terminate sequences and wait until sequences are complete. For more information, including example code, see “Controlling WS-ReliableMessaging sequences programmatically.”

What to do next

You are now ready to configure a policy set instance to enable WS-ReliableMessaging.

Controlling WS-ReliableMessaging sequences programmatically

Your client application can use the `WSRMSequenceManager`, part of the WebSphere Application Server SPI for reliable messaging, to gain programmatic control over reliable messaging sequences. This helps manage resources on the server, for example by removing sequences after a client application has finished messaging. You can add code to create sequences, send acknowledgement requests, close sequences, terminate sequences and wait until sequences are complete.

Before you begin

The WebSphere Application Server SPI for reliable messaging always uses the static policy set configuration that is applied to the client from which the SPI is called. It does not use any alternative policy set that is subsequently configured by WS-Policy to meet the requirements of a WS-Policy intersection.

About this task

By closing sequences programmatically, you limit the number of open sequences a single client has to support in a single JVM at one time.

For your client application to gain programmatic control over reliable messaging sequences, it needs access to a `WSRMSequenceManager` instance. Use the following code fragment to achieve this:

```
import com.ibm.wsspi.wsrp.WSRMSequenceManager;
import com.ibm.wsspi.wsrp.WSRMSequenceManagerFactory;
.....

// Get the factory
WSRMSequenceManagerFactory factory = WSRMSequenceManagerFactory
    .getInstance();

// Get the sequence manager instance
WSRMSequenceManager sequenceManager = factory.createWSRMSequenceManager();
```

All `WSRMSequenceManager` methods take the following parameters:

- The client instance object. This is either a **Dispatch client** instance, or the **Dynamic proxy client**. For details of the client types, see the JAX-WS client programming model topic.
- The **Port QName** instance for the target endpoint.

To control WS-ReliableMessaging sequences programmatically, add code to your client application as described in the following steps:

Procedure

- Add code to create a sequence.

To set the available properties use the following methods:

```
/**
 * Sets the target provider endpoint.
 * A null value will cause a NullPointerException when the WSRMSequenceProperties object is used.
 *
 * @param providerEndPoint The target service endpoint URI
 */
public void setTargetEndpointUri(String providerEndPoint);

/**
 * This is used to indicate that a response flow is required between the provider and requester and the response
 * flow will be established at create sequence time
```

```

*
* By calling this method it will indicate that a response flow is required.
*/
public void setUseOfferedSequenceId();

/**
* Set the Soap version for RM protocol messages.
* The default value for this property is WSRMSequenceProperties.SOAP_11
*
* @param soapVersion
*/
public void setSoapVersion(int soapVersion);

/**
* If the Sequence Acknowledgement messages are to be sent back asynchronously call this method.
*
*/
public void useAsyncTransport();

```

To create the reliable messaging sequence use the `createNewWSRMSequence` method on the `WSRMSequenceManager`:

```

/**
* Initiates a new sequence handshake between this client and the target EPR specified in the
* WSRMSequenceProperties instance.
*
* This sequence will only be valid for the client issuing the createNewWSRMSequence call.
*
* When returning from this call, there is no guarantee that the sequence has been established.
*
* @throws NullPointerException if the sequenceProperties object is null, or the target EPR is null
*
* @param clientObject The JAX-WS Dispatch instance, or the Dynamic Proxy client instance.
* @param sequenceProperties The properties for creating the reliable messaging sequence
* @throws WSRMNotEnabledException
* @throws WSRMSequenceAlreadyExistsException
*/
public void createNewWSRMSequence(Object clientObject, QName portQName, WSRMSequenceProperties sequenceProperties)

throws WSRMNotEnabledException,
        WSRMSequenceAlreadyExistsException;

```

- Add code to send an acknowledgment request.

To send an acknowledgment request for a `WS-ReliableMessaging` sequence, use the following method on the `WSRMSequenceManager`:

```

/**
* Sending an acknowledgement request sends the ACK requested message to the specified target endPointUri.
* The target will respond with a range of messages that can be acknowledged for the current reliable messaging
* sequence.
*
* @param clientObject The JAX-WS Dispatch instance, or the Dynamic Proxy client instance.
* @param portQName
* @param endPointUri The target endpoint uri
* @throws WSRMNotEnabledException
* @throws WSRMSequenceUnknownException
* @throws WSRMSequenceTerminatedException
* @throws WSRMSequenceClosedException
*/
public void sendAcknowledgementRequest(Object clientObject, QName portQName, String endPointUri)

throws WSRMNotEnabledException,
        WSRMSequenceUnknownException,
        WSRMSequenceTerminatedException,
        WSRMSequenceClosedException;

```

- Add code to close a sequence.

To close a `WS-ReliableMessaging` sequence use the following method on the `WSRMSequenceManager`:

```

/**
* Closes the web services reliable messaging session from this application to
* the endpoint url specified.
*
* Throws a WSRMSequenceTerminatedException if the session between this application
* and the target endpoint url is already closed
*
* Throws a WSRMSequenceTerminatedException when the session between this application
* and the target endpoint has already been terminated.
*
* Throws WSRMSequenceUnknownException exception when either reliable messaging is not engaged to
* the specified endpoint url or the sequence has previously been terminated and removed.
*
* @param clientObject The JAX-WS Dispatch instance, or the Dynamic Proxy client instance.
* @param endPointUri The target endpoint url
*
* @throws WSRMNotEnabledException

```

```

* @throws WSRMSequenceUnknownException
* @throws WSRMSequenceClosedException
* @throws WSRMSequenceTerminatedException
*/
public void closeSequence(Object clientObject, QName portQName, String endPointUri)

throws WSRMNotEnabledException,
        WSRMSequenceUnknownException,
        WSRMSequenceClosedException,
        WSRMSequenceTerminatedException;

```

- Add code to terminate a sequence.

To terminate a WS-ReliableMessaging sequence use the following method on the `WSRMSequenceManager`:

```

/**
 * Terminates web services reliable messaging session from this application to
 * the endpoint url specified.
 *
 * Throws a WSRMSequenceTerminatedException when the session between this application
 * and the target endpoint has already been terminated.
 *
 * Throws WSRMSequenceUnknownException exception when either reliable messaging is not engaged to
 * the specified endpoint url or the sequence has previously been terminated and removed.
 *
 * @param clientObject The JAX-WS Dispatch instance, or the Dynamic Proxy client instance.
 * @param endPointUri The target endpoint url
 * @throws WSRMNotEnabledException
 *
 * @throws WSRMSequenceTerminatedException
 * @throws WSRMSequenceUnknownException
 */
public void terminateSequence(Object clientObject, QName portQName, String endPointUri) throws WSRMNotEnabledException;

```

- Add code to wait for a sequence to complete.

To wait for a reliable messaging sequence to complete, you use a method call that ensures that all messages have been sent and acknowledged by the target service. After the sequence is completed, it is terminated and cleaned up.

There are two ways of using the `waitUntilSequenceCompleted` method:

```

public boolean waitUntilSequenceCompleted(Object clientObject,
QName portQName, String endPointUri, long waitTime)

```

This method call waits for the specified **waitTime** for the reliable messaging sequence to complete. If the sequence does not complete in the specified time, the method returns false. If the sequence does complete in time, the method returns true.

```

public boolean waitUntilSequenceCompleted(Object clientObject,
QName portQName, String endPointUri)

```

This method call does not return until the reliable messaging sequence is completed.

Providing transactional recoverable messaging through WS-ReliableMessaging

If your WS-ReliableMessaging application runs inside the web container and uses a managed quality of service, you can use WS-ReliableMessaging to provide transactional recoverable messaging.

About this task

The WS-ReliableMessaging transactional model is as follows:

- On the web service requester side, the transaction is between the application and the local managed store.
- The WS-ReliableMessaging protocol delivers the message to the web service provider side, where a different transaction is used between the second managed store and the application being dispatched.

For the outbound (requestor) case on a one-way message send, if the `enableTransactionalOneWay` property is set to true, then the send is performed under any transactional context currently held by the application thread. (Note that transactions are not supported under an outbound two-way message exchange).

For the inbound (provider) case, if the `inOrderDelivery` property is set to `true`, then an inbound message is dispatched to the application under a transaction. For an inbound two-way message exchange, the response is also generated under that transaction and is not sent until that transaction has committed.

Note:

WS-ReliableMessaging transactions do not use the WS-AtomicTransactions protocol. The relationship between these two protocols is as follows:

- WS-AtomicTransactions and WS-ReliableMessaging are mutually exclusive when WS-ReliableMessaging is being used, with a managed store, to provide transactional recoverable messaging.
- If WS-ReliableMessaging is configured to use an in-memory store, then there are cases where a WS-AtomicTransaction can be flowed between the reliable messaging source and the reliable messaging destination for two-way invocations. In this situation, WS-ReliableMessaging only protects against network failures, not against server failure.

For more information, see WS-AtomicTransactions.

To provide transactional recoverable messaging through WS-ReliableMessaging, work through the steps described in Adding assured delivery to web services through WS-ReliableMessaging and also complete the following additional steps:

Procedure

- To enable transactional messaging for outbound (requester) one-way message sends, when you develop your JAX-WS web service application set the `enableTransactionalOneWay` property to `Boolean.TRUE` (or the string `true`) in the `jaxWS` request context map.
- To enable transactional messaging for inbound (provider) one-way and two-way message exchanges, when you configure your WS-ReliableMessaging policy either use the administrative console to select the option **Deliver messages in the order that they were sent** or use the `wsadmin` tool to set the `inOrderDelivery` property to `true`.

Configuring endpoints to only support clients that use WS-ReliableMessaging

By default, when a WS-ReliableMessaging enabled policy set is attached to an endpoint, the server supports clients that use reliable messaging and clients that do not use reliable messaging. In this version of the product, you can configure endpoints to only support clients that use reliable messaging.

About this task

You configure endpoints to only support clients that use reliable messaging by setting a property in either of the following ways:

- Set a property when packaging the application.
- Set a property as a JVM argument for the server.

This setting is reflected by WS-Policy if engaged. For information about how to engage WS-Policy, see Using WS-Policy to exchange policies in a standard format.

Procedure

- When packaging the application, configure endpoints to only support clients that use reliable messaging by setting the `strictlyEnforceWSRM` property in the `META-INF/MANIFEST.MF` of a WAR file or EJB module.

- Using a JVM argument for the server, configure endpoints to only support clients that use reliable messaging by defining the Java virtual machine custom property `com.ibm.ws.websvcs.rm.strictlyEnforceWSRM` on the server. For more information, see [Configuring the JVM](#).

Chapter 32. Developing web services - RESTful services

You can use Java API for RESTful Web Services (JAX-RS) to develop services that follow Representational State Transfer (REST) principles. RESTful services are based on manipulating resources. Resources can contain static or dynamically updated data. By identifying the resources in your application, you can make the service more useful and easier to develop.

Planning JAX-RS web applications

Planning to use JAX-RS to enable RESTful services

By using the Java API for RESTful Web Services (JAX-RS) API, application developers can quickly develop RESTful applications. When planning to use JAX-RS to enable RESTful services, consider how to best implement the capabilities and characteristics of a RESTful application with JAX-RS.

Before you begin

Read the overview of JAX-RS information to learn about REST services and the advantages of using JAX-RS to build RESTful services.

About this task

JAX-RS is a programming model that provides a mechanism for developing services that follow Representational State Transfer (REST) principles. Using JAX-RS, development of RESTful services is simplified.

JAX-RS is a Java API for developing REST applications quickly. While JAX-RS provides a faster way for developing web applications than servlets, the primary goal of JAX-RS is to build RESTful services. JAX-RS 1.0 defines a server-side component API to build REST applications. IBM JAX-RS provides an implementation of the JAX-RS (JSR 311) specification.

By using JAX-RS technology, REST applications are simpler to develop, simpler to consume, and simpler to scale when compared to other types of distributed systems. Many popular and widely used Internet services have successfully provided RESTful APIs to their applications. Third parties have used various REST APIs to build their own businesses and applications.

Due to the simple consumption of RESTful services, you can write clients in many languages on different platforms. Most languages require no third-party libraries as long as there is a method to use an HTTP connection. Because of the pervasiveness of web browsers, the most prevalent clients are typically web browsers. For example, many Web 2.0 properties use a JavaScript framework such as Dojo toolkit for developing a client in a browser in conjunction with a RESTful server-side application that provides the data for the client.

Procedure

1. Review existing business and middleware applications in your environment to determine which services you want to implement as REST services.
2. Define the resources in your RESTful applications.
3. Determine the URL patterns, operations, and media type formats to use for each resource.
 - a. Define the URI patterns for resources in RESTful applications.
 - b. Define the client capabilities for RESTful applications using HTTP methods .
 - c. Define the HTTP headers and response codes for RESTful applications using HTTP methods.

Results

You have a design plan for using JAX-RS to implementing REST services.

Defining the resources in RESTful applications

You can use Java API for RESTful Web Services (JAX-RS) to develop services that follow Representational State Transfer (REST) principles. RESTful services are based on manipulating resources. Resources can contain static or dynamically updated data. By identifying the resources in your application, you can make the service more useful and easier to develop.

Before you begin

After you have identified the application that you want to expose as a RESTFUL service, you must first define the resources for your RESTful application. When defining the resources for your application, consider the type of data do you want to expose. Perhaps you already have a relational database that contains information that you want to expose to users using REST technology. Do you already have a set of Java classes defined for accessing that data?

For example, consider the case of an application defined to support a book store. This application currently has a database with several tables that define the various items in the collection of books and the inventory of each book. In this example, there are a number of ways to represent the data in the database in a RESTful application. One approach is to consider each table as an individual resource, so that each of the verbs in the RESTful request maps to the actions that the database supports on that table such as select, insert, update, delete. This example is a simple approach to creating a RESTful application. This approach using the book store example is also used in the documentation that describes defining URL patterns for resources, resource methods, HTTP headers and response codes, media types, and parameters for request representations to resources

In support of this database for the book store application, there might already be existing code that is responsible for accessing the database and retrieving the data from each table. Even though the rows in each of the tables logically represents each resource, the accessor classes are used to define the resources. The implementing JAX-RS applications documentation provides more details on how these classes are incorporated into your JAX-RS application.

Alternately, you might have more static content that does not reside in a database that you want to distribute as resources. Whether it is a collection of documents in various formats or a resource-based facade for other remote systems, using JAX-RS, you can distribute content from multiple sources.

About this task

Resources are the basic building block of a RESTful service. Examples of a resource from an online book store application include a book, an order from a store, and a collection of users.

Resources are addressable by URLs and HTTP methods can perform operations on resources. Resources can have multiple representations using different formats such as XML and JSON. You can use HTTP headers and parameters to pass additional information that is relevant to the request and response.

With JAX-RS, you can annotate existing or new Plain Old Java objects (POJO) with JAX-RS specific annotations. JAX-RS annotated resource classes and the annotated methods are invoked depending on the URI patterns. You can use the annotated resource classes after these resource classes are added to the list of resources returned by the overridden methods in the JAX-RS application class.

Procedure

1. Identify the types of resources in the application.
2. (optional) Identify existing Java classes that you can use as resource classes.

3. Create new Java classes for resources that do not have an existing Java class.

Results

You have defined the content that you want to expose as a collection of resources in your application.

What to do next

Based on the resources that you have defined, read about defining URL patterns for resources, resource methods, HTTP headers and response codes, media types, and parameters for request representations to resources to learn more about additional steps you can take to define the resources for your JAX-RS application.

Defining the URI patterns for resources in RESTful applications

Representational State Transfer (REST) services are based on manipulating resources. Resources for RESTful services are addressable, and URLs are the primary way of achieving addressability in REST.

Before you begin

Identify the resources in the application that you want to expose as a RESTful service.

About this task

URLs are used to specify the location of a resource. Interaction between the server and client is based on issuing HTTP operations to URLs. Defining URL patterns is important because URLs often have a long lifetime so that clients can directly address a resource long after the resource is initially discovered.

URLs are typically used when you enter addresses to web browsers, such as `http://www.ibm.com/` or `http://www.example.com/bookstore/books/ISBN123`. Although URLs are not required to be understandable by users, RESTful services that provide logical URLs in understandable patterns enable client application developers to work efficiently.

RESTful clients use URLs to manipulate resources. Each resource must have its own unique URL. Some URL patterns have a collection path with a unique identifier appended. For example, you can use `http://www.example.com/bookstore/books` as the collection resource URL, `http://www.example.com/bookstore/books/ISBN123` as a unique book resource URL, and you can use `http://www.example.com/bookstore/books/ISBN123/authors` to retrieve a collection resource describing ISBN123 authors.

The application developer must carefully consider the granularity of URLs because it can affect usage of the application and performance. For example, you can include the author information of a book as part of the book resource or you can define the author information as a unique resource with its own URL that is referenced in the book resource. Depending on the reuse of resources, it might be more efficient to define a separate resource for the author information that is referenced in a hyperlink of the book resource for cases when the author writes a different book.

After an initial URL is given to a client, subsequent related requests are discoverable by parsing the current resource. In the book example, a GET request to `http://www.example.com/bookstore/books/` retrieves a list of book URLs that can include `http://www.example.com/bookstore/books/ISBN123`.

Because systems rely on resources being available, URLs typically have longevity. Because HTTP has built-in status codes for redirection, such as the 301 moved permanently code and the 307 temporarily redirected code, users and clients with caches often reuse previously discovered URLs first. You can additionally consider including a version identifier in the URL pattern, such as `http://www.example.com/bookstore/v2/books/ISBN123`. Like the planning involved to define an interface using Java code, be sure to carefully choose your URL patterns because of expected longevity.

In Java API for RESTful Web Services (JAX-RS), you must add `@Path` annotations to the Java class files or the Java methods to define the relative URL of the resource. You can use JAX-RS subresource locators and subresource methods to define resources. Use parameters, such as the path parameter or matrix parameter, in the URL to identify the resource.

The value in the `@Path` annotation defines the relative part of the full URL to your resource. The base URL is derived from the domain, port, application module context root, and any URL pattern mappings in the `web.xml` file of the application module. For example, if the domain is `www.example.com`, the port is `9060`, the module context root is `example`, the servlet URL pattern is `store/*`, and the value of the `@Path` annotation is `/bookstore/books`. The full URL is: `http://www.example.com:9060/example/store/bookstore/books`.

Procedure

1. Identify the types of resources in the application. Suppose that you have two types of resources, a `BooksCollection` and an individual `Book` object which have the following class definitions:

```
public class BooksCollection {
    public BooksCollection() {
        /* no argument constructor */
    }
}

public class Book {
    public Book(String ISBN) {
        /* This constructor has an argument that will be annotated with a JAX-RS annotation.
        See the JAX-RS specification for information on valid constructors. */
    }
}
```

As defined in the JAX-RS specification, by default, resource instances are created per request. For the JAX-RS runtime environment to create a resource instance, you must have either a constructor with no argument or a constructor with only JAX-RS annotated parameters present.

2. Add a `@javax.ws.rs.Path` annotation to each resource class. For each `@javax.ws.rs.Path` annotation, set the value as the part of the URL after the base URL of the application.

```
/*
 * BooksCollection.java
 * This Java class represents the books collection URL at /bookstore/books.
 */
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
}
```

After completing the application, you can use the resource by visiting `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books`. For this URL, specify the context root value as the part of the URL after the context module. Specify the servlet path as any URL patterns in the `web.xml` file, if it exists.

3. (optional) Determine if a resource needs to use part of the URL as a parameter. If a resource needs to use part of the URL as a parameter, such as an identifier, you can use the `@javax.ws.rs.Path` annotation with a regular expression. You can then add a `@javax.ws.rs.PathParam` annotation in either the resource constructor or the resource method.

```
/*
 * Book.java represents individual books.
 */
@javax.ws.rs.Path("/bookstore/books/{bookID}")
public class Book {
    public Book(@javax.ws.rs.PathParam("bookID") String ISBN) {
    }
}
```

When an HTTP request is made to `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books/ISBN_number`, a `Book` instance is created with `ISBN_number` passed in to the `ISBN` parameter of the constructor.

For more information about other possible parameters, read about defining parameters for requests to resources in RESTful applications.

4. Create the `javax.ws.rs.core.Application` subclass to define to the JAX-RS runtime environment which classes are part of the JAX-RS application. The resource classes are returned in the `getClasses()` method; for example:

```
public class BookApplication extends javax.ws.rs.core.Application {
    public Set<Class<?>> getClasses() {
        Set<Class<?>> classes = new HashSet<Class<?>>();
        classes.add(BooksCollection.class);
        classes.add(Book.class);
        return classes;
    }
}
```

By defining the `javax.ws.rs.core.Application` subclass, classes returned from its methods are registered to the JAX-RS runtime environment. When configuring the `web.xml` file, you must specify the `javax.ws.rs.core.Application` subclass as a parameter to the servlet or filter. For more information, read about configuring the `web.xml` file for JAX-RS applications.

Results

You have created a URL to identify your resources for your RESTful service. By considering issues with URL patterns early in the application design, the RESTful service increases its usability and value over an extended time.

What to do next

The resource at the defined URL exists. However, the resource does not yet have any methods to handle HTTP method actions such as GET, POST, PUT, or DELETE. See the defining resource methods for RESTful applications to learn more about defining capabilities of resources using supported HTTP methods.

Defining resource methods for RESTful applications

Individual resources can define their capabilities using supported HTTP methods. In Representational State Transfer (REST) services, the supported methods are GET, PUT, DELETE, and POST. All operations are typically conducted by using one of the predefined HTTP methods with a resource.

Before you begin

Understand the predefined HTTP methods and their known attributes. Some HTTP methods are meant to be safe, meaning that issuing the request does not change the resource, or idempotent, meaning that multiple invocations of the operation do not change the result. While HTTP methods are defined to have certain attributes, the service implementation follows the definitions. See the HTTP method definitions information to learn more about the common set of methods for HTTP.

About this task

Clients use HTTP methods to perform certain operations. Unlike other distributed systems where unique interfaces are defined by each system, RESTful systems based on HTTP mainly rely on predefined methods. The four most common methods are GET, PUT, DELETE, and POST. Resources are not required to permit all HTTP methods for all clients.

The HTTP GET method retrieves a resource representation. It is safe and idempotent. Repeated GET requests do not change any resources.

The HTTP PUT method is often used to update resources or to create a new entity at a known URL. When a resource must be updated or created, an HTTP PUT method is issued at the resource URL with the new resource data as the request entity, also known as the message body. The HTTP PUT method is

idempotent so multiple identical PUT requests with the same entity to the same URL yields the same result as if only one PUT request was issued. This method assumes that no other relevant requests were made.

The HTTP DELETE method removes a resource at a given URL. It is also idempotent.

The HTTP POST method is often used when creating a resource in a collection when the final resource URL is not known. For instance, an administrator issues a POST request to a /users collection resource that creates a user with a unique ID such as 1234567890. The unique ID is then used as part of the URL path to describe the new user resource, such as /users/1234567890. It is not safe and is not idempotent. In this case, the multiple POST requests to the /users collection can continue creating a new unique ID and adding this new ID to the users collection even if the user has the same information.

Because most RESTful services use well-known HTTP methods that provide expected results, you can more easily create clients. RESTful service developers can take advantage of the expected behaviors of HTTP methods. Resource methods can also use parameters, such as path parameters, query parameters, or matrix parameters to identify the resource. Read about defining the use of parameters for request representations to resources to learn more.

(optional) If you have a sub-resource method and a sub-resource locator method that have an @Path annotation with the same value in the same resource class, the sub-resource locator is not considered when determining the method to invoke by default. This is in compliance with the JAX-RS specification.

Use the `wink.searchPolicyContinuedSearch` property with a value of `true` to modify this behavior. This results in sub-resource locators being used if no sub-resource methods match the request.

To enable the property, include a properties file in the WEB-INF directory of the module that has the `wink.searchPolicyContinuedSearch` property and value specified. In the `web.xml` file of the application module, include an `init-param` element with the `propertiesLocation` value for the `param-name` element. The `param-value` element specifies the location of the properties file, for example, `WEB-INF/my_wink.properties`.

The following example illustrates the `web.xml` file:

```
<servlet>
  ...
  ...
  <init-param>
    <param-name>propertiesLocation</param-name>
    <param-value>/WEB-INF/my_wink.properties</param-value>
  </init-param>
</servlet>
```

The following example illustrates the `WEB-INF/my_wink.properties` properties file:

```
wink.searchPolicyContinuedSearch=true
```

Procedure

1. Identify the types of resources in the application.

For each resource class, identify an existing method or create a method that you want to invoke for each supported HTTP method. Methods that respond to HTTP requests are also known as resource methods. For each resource method in the resource class, annotate the Java method with a single JAX-RS HTTP method annotation such as `@javax.ws.rs.GET`, `@javax.ws.rs.POST`, `@javax.ws.rs.DELETE` or `@javax.ws.rs.PUT`. For example, if an HTTP GET method is supported by the `BooksCollection` class, then you can create and annotate a method like the following snippet:

```
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBooksCollection() {
        String str = /* Construct a String representation of the resource. */
        return str;
    }
}
```

When issuing an HTTP GET request to `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books` URL using a web browser or another HTTP client, the previous `getBooksCollection()` method is invoked.

2. Ensure that the resource supports the required HTTP methods.

Each resource typically has multiple resource methods; for example:

```
@javax.ws.rs.Path("/bookstore/books/{bookID}")
public class Book {
    /* This is a database key. */
    private String ISBN;

    public Book(@javax.ws.rs.PathParam("bookID") String ISBN) {
        this.ISBN = ISBN;
    }

    @javax.ws.rs.GET
    public String retrieveSpecificBookInformation() {
        /* This code retrieves a book resource based on the ISBN key. */
    }

    @javax.ws.rs.PUT
    public String updateBookInformation(String updatedBookInfo) {
        /* This code updates the book resource based on ISBN key and the entity (message body) sent
        in the request that is stored in updatedBookInfo. */
    }

    @javax.ws.rs.DELETE
    public void removeBook() {
        /* This code deletes a book resource based on ISBN key. */
    }
}
```

When issuing an HTTP GET request to the `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books/<isbn_number>` URL using a web browser or another HTTP client, the `retrieveSpecificBookInformation()` method is invoked. Sending an HTTP PUT request to the same URL invokes the `updateBookInformation` method and any content in the request message body is passed as the value of the `updatedBookInfo` object. Finally, sending an HTTP DELETE request to the same URL invokes the `removeBook()` method.

Note: According to the JAX-RS specification, you must not put multiple HTTP method annotations, such as `@javax.ws.rs.POST` or `@javax.ws.rs.PUT` on the same resource method. Because HTTP methods have uniquely defined semantics, do not use a resource method for multiple HTTP methods.

Results

You have defined valid operations for the resources.

Defining the HTTP headers and response codes for RESTful applications

HTTP headers and status codes are useful to help intermediary and client programs understand information about requests and responses for applications. HTTP headers contain metadata information. HTTP status codes provide status information about the response.

Before you begin

See the HTTP 1.1 specification to become familiar with HTTP headers and HTTP status codes.

About this task

HTTP headers contain metadata information such as security authentication information, the user agent that is used, and cache control metadata. Standard HTTP headers are defined in the HTTP specification; however, you can use custom HTTP headers, if necessary.

You can read HTTP headers from the request and set the headers in the response. There are a set of common request and response headers, but there are also unique request and unique response headers. JAX-RS provides the `HttpHeaders` injectable interface and the `@HeaderParam` parameter annotation for reading HTTP headers. If a `javax.ws.rs.core.Response` object is returned from a resource method, you can set HTTP headers on the response. Also, you can set HTTP headers when an entity is written using the `MessageBodyWriter` interface.

You can set HTTP response status codes to help client programs understand the response. While responses can contain an error code in XML or other format, client programs can quickly and more easily understand an HTTP response status code. The HTTP specification defines several status codes that are typically understood by clients.

Procedure

- To read a specific request header, add a `@javax.ws.rs.HeaderParam` annotated parameter.

```
@javax.ws.rs.Path("/bookstore/books/{bookID}")
public class Book {
    @javax.ws.rs.GET
    public String retrieveSpecificBookInformation(@javax.ws.rs.HeaderParam("User-Agent") String theUserAgent) {
        /* The book ID was sent in a HTTP request header with the name "bookID". */
    }
}
```

- To read any request header, use the `@javax.ws.rs.core.Context javax.ws.rs.core.HttpHeaders` injected object.

```
@javax.ws.rs.Path("/bookstore/books/{bookID}")
public class Book {
    @javax.ws.rs.GET
    public String retrieveSpecificBookInformation(@javax.ws.rs.core.Context HttpHeaders requestHeaders) {
        /* Call methods on "requestHeaders" to get any request header sent by the client. */
        List<String> bookIdValues = requestHeaders.getRequestHeader("User-Agent");
    }
}
```

- To set a response status code or header, return a `javax.ws.rs.core.Response` object and build the response with the appropriate status code and headers.

```
@javax.ws.rs.Path("/bookstore/books/{bookID}") public class Book {
    @javax.ws.rs.GET public javax.ws.rs.core.Response retrieveSpecificBookInformation() {
        return Response.status(200).header("responseHeaderValue", "responseHeaderValue").header("anotherResponseHeaderName", "foo").build();
    }
}
```

Results

You have used HTTP headers to read request headers and set response status codes and headers for JAX-RS web applications.

Defining media types for resources in RESTful applications

Resources are represented by multiple formats. XML, JavaScript Object Notation (JSON), Atom, binary formats such as PNG, JPEG, GIF, plain text, and proprietary formats are used to represent resources. Representational State Transfer (REST) provides the flexibility to represent a single resource in multiple formats.

Before you begin

Define the resources in the JAX-RS web application.

About this task

Resources have representations. A resource representation is the content in the HTTP message that is sent to, or returned from the resource using the URI. Each representation that a resource supports has a corresponding media type. For example, if a resource is going to return content formatted as XML, you can use `application/xml` as the associated media type in the HTTP message.

Depending on the requirements of your application, resources can return representations in a preferred single format or in multiple formats. For example, resources that are accessed using JavaScript clients might prefer JSON representations because JSON is easy to consume.

JAX-RS provides `@Consumes` and `@Produces` annotations to declare the media types that are acceptable for a resource method to read and write.

JAX-RS also maps Java types to and from resource representations using entity providers. A `MessageBodyReader` entity provider reads a request entity and deserializes the request entity into a Java type. A `MessageBodyWriter` entity provider serializes from a Java type into a response entity.

Table 121. Standard entity providers and basic Java types. This table includes the standard entity providers and basic Java types that are included in the JAX-RS runtime environment, along with the corresponding supported content types.

Java type	MessageBodyReader	MessageBodyWriter	Supported Content types
byte[]	X	X	*/*
java.io.InputStream	X	X	*/*
java.io.Reader	X	X	*/*
java.lang.String	X	X	*/*
java.io.File	X	X	*/*
javax.activation.DataSource	X	X	*/*
javax.xml.transform.Source	X	X	text/xml, application/xml, application/*+xml
javax.ws.rs.core.MultivaluedMap	X	X	application/x-www-form-urlencoded
JAXB types	X	X	text/xml, application/xml, application/*+xml
javax.ws.rs.core.StreamingOutput		X	*/*

If a `String` value is used as the request entity parameter, the `MessageBodyReader` entity provider deserializes the request body into a new `String`. If a JAXB type is used as the return type on a resource method, the `MessageBodyWriter` serializes the Java Architecture for XML Binding (JAXB) object into a response body.

If you need a custom mapping from a Java type to a specific representation, see the information for using an application-defined entity provider.

If your client can handle multiple formats and you want the server to determine the best resource representation to return, read about using content negotiation in JAX-RS applications to serve multiple content types.

The specifications for XML, JSON, and Atom provide details regarding the formats of resource representations for applications. See the specifications to learn more about the formats of resource representations.

Procedure

1. Determine the resource representation format such as XML, JSON, or ATOM to use for either the request or the response.
2. Add the `@Consumes` and `@Produces` annotations appropriately to the resource method.
3. If the resource needs to read the content of the request, add a request entity parameter to the resource method. The request entity parameter is a single Java parameter on the method that does not have an annotation.

4. If the resource method returns content in the response, return a Java object that is writable by a JAX-RS entity provider. This Java object is mapped to the response entity in the HTTP response. The returned object must be a JAX-RS supported Java type or wrapped in a `javax.ws.rs.core.Response` or `javax.ws.rs.core.GenericEntity` type.

Results

You have mapped the request entities to the resource method entity parameter and any response objects that are returned are mapped to the response entity for the resource representation.

Example

The following example illustrates defining XML as the resource representation for a RESTful bookstore application.

1. Identify the resource methods that you want to read the request entity or return a response entity.

In the `retrieveSpecificBookInformation` method example that follows, there is no request entity that is read. However, there is a response object that is returned. This object wraps a JAXB object that contains the entity information. Adding the `@Produces` annotation on the resource method with a media type of `application/xml` indicates that the resource method always returns an XML representation with a media type of `application/xml`.

Clients that have an Accept HTTP request header value compatible with the `application/xml` media type invoke the method correctly.

Clients that do not have an Accept HTTP header value compatible with the `application/xml` media type automatically receive a 406 Not Acceptable response status which indicates that the server cannot produce an acceptable response.

The following example identifies the resource methods that read the request entity or return a response entity:

```
/*
 * Book.java
 * This class represents individual books. The @Produces annotation specifies a media type of application/xml.
 */
@Path("/bookstore/books/{bookID}")
public class Book {
    @GET
    @Produces("application/xml")
    public javax.ws.rs.core.Response retrieveSpecificBookInformation(@PathParam("bookID") String theBookID,
        @Context javax.ws.rs.core.HttpHeaders headers) {
        /* ... */
        return
            Response.ok(/* JAXB object to represent response body entity */).expires(/* Expires response header value*/).header("CustomHeaderName", "CustomHeaderValue").build();
    }
    @PUT
    public String updateBookInformation(@PathParam("bookID") String theBookID, String theRequestEntity,
        @javax.ws.rs.HeaderParam("Content-Length") String contentLengthHeader) { /* ... */ }

    @DELETE
    public void removeBook(@PathParam("bookID") String theBookID) { /* ... */ }
}
```

2. Identify the resource methods that need to consume the request information.

In the following snippet, the PUT method on the book resource accepts the request entity content if a media type of `text/plain` is sent, as defined in the `@Consumes` annotation. This method returns content with a `text/plain` representation as specified in the `@Produces` annotations.

If a client does not send a message with a `Content-Type` value of `text/plain`, then the PUT resource method is not invoked. If `Content-Type: application/xml` is sent in the HTTP request headers, the `updateBookInformation` Java method is not be called.

The DELETE method neither reads a request entity nor returns a response entity; therefore, it does not require either an `@Consumes` or an `@Produces` annotation.

The following example identifies the resource methods that consume the request information:

```
/*
 * Book.java
 * This class represents represent individual books with custom headers.
 */
@Path("/bookstore/books/{bookID}")
public class Book {
    @GET
    @Produces("application/xml")
    public javax.ws.rs.core.Response retrieveSpecificBookInformation(@PathParam("bookID") String theBookID, @Context javax.ws.rs.core.HttpHeaders headers) {
```

```

    /* ... */
    return Response.ok(/* JAXB object to represent response body entity */.expires(/* Expires response header value).header("CustomHeaderName", "CustomHeaderValue").build());
}
@PUT
@Consumes("text/plain")
@Produces("text/plain")
public String updateBookInformation(@PathParam("bookID") String theBookID, String theRequestEntity, @javax.ws.rs.HeaderParam("Content-Length") String contentLengthHeader) {
    /* ... */
    String responseEntity = /* a plain text representation */;
    return responseEntity;
}

@DELETE
public void removeBook(@PathParam("bookID") String theBookID) { /* ... */ }
}

```

What to do next

See the JAX-RS specification for a list of all the standard media formats that are supported for representations.

Advanced users might consider defining custom mappings of Java types to representations or using content negotiation for clients to negotiate preferred resource representations. To learn more about these options, see the using custom defined entity formats information or the serving multiple content types with content negotiation information.

Defining parameters for request representations to resources in RESTful applications

Parameters are used to pass and add additional information to a request. You can use parameters as part of the URL or in the headers. Path parameters, matrix parameters, query parameters, header parameters, and cookie parameters are useful for passing in additional information to a request.

About this task

Multiple parameters types exist. Java API for RESTful Web Services (JAX-RS) enables easy access to all the types of parameters using annotated injected parameters.

You can use any basic Java primitive type including `java.lang.String` as parameters, as well as Java types with a constructor that uses a single `String` or a `valueOf(String)` static method. Additionally, you can use `List`, `SortedSet`, and `Set` interfaces where the generic type is one of the previously mentioned types, such as a `Set` when a parameter can have multiple values. If you need to parse requests, then use `String` as the parameter type to enable you to complete basic inspection and customization of error path responses.

JAX-RS provides the following annotations to use on resource method parameters to specify that the resource method can be invoked with correct parameter values.

javax.ws.rs.PathParam annotation

Path parameters are part of the URL. For example, the URL can include `/collection/{item}`, where `{item}` is a path parameter that identifies the item in the collection. Because path parameters are part of the URL, they are essential in identifying the request.

If parts of the URL are parameters, you can use a `@javax.ws.rs.PathParam` annotated parameter; for example:

```

@javax.ws.rs.Path("/bookstore/books/{bookId}")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getSpecificBookInfo(@javax.ws.rs.PathParam("bookId") String theBookId) {
        /* theBookId would contain the next path segment after /bookstore/books/ */
    }
}

```

In this example, requests to `/bookstore/books/12345` assigns the value of 12345 to the `theBookId` variable.

javax.ws.rs.MatrixParam annotation

Matrix parameters are part of the URL. For example, if the URL includes the path segment, /collection;itemID=itemIDValue, the matrix parameter name is itemID and itemIDValue is the value.

You can read matrix parameters with a `@javax.ws.rs.MatrixParam` annotated parameter; for example:

```
@javax.ws.rs.Path("/bookstore/books")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBookCollectionInfo(@javax.ws.rs.MatrixParam("page") int page, @javax.ws.rs.MatrixParam("filter") String filter) {
        /* This statement uses the page and filter parameters. */
    }
}
```

In this example, requests to /bookstore/books;page=25;filter=test invoke the `getBookCollectionInfo` parameter so that the value for the page variable is set to 25 and the value for filter variable is set to test.

javax.ws.rs.QueryParam annotation

Query parameters are appended to the URL after a “?” with name-value pairs. For instance, if the URL is `http://example.com/collection?itemID=itemIDValue`, the query parameter name is `itemID` and `itemIDValue` is the value. Query parameters are often used when filtering or paging through HTTP GET requests.

You can read query parameters with a `@javax.ws.rs.QueryParam` annotated parameter; for example:

```
@javax.ws.rs.Path("/bookstore/books")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBookCollectionInfo(@javax.ws.rs.QueryParam("page") int page, @javax.ws.rs.QueryParam("filter") String filter) {
        /* This statement uses the page and filter parameters. */
    }
}
```

In this example, requests to /bookstore/books;page=25;filter=test invoke the `getBookCollectionInfo` parameter so that the value for the page variable is set to 25 and the value for filter variable is set to test.

javax.ws.rs.HeaderParam annotation

Header parameters are HTTP headers. While there are pre-defined HTTP headers, you can also use custom headers. Headers often contain control metadata information for the client, intermediary, or server.

If a HTTP request header must be read, use the `@javax.ws.rs.HeaderParam` annotation; for example:

```
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBookCollectionInfo(@javax.ws.rs.HeaderParam("Range") String rangeValue) {
        /* The rangeValue variable contains the value of the HTTP request header "Range" */
    }
}
```

In this example, requests to /bookstore/books/ with a Range HTTP request header value of `bytes=0-499` invokes the method with `bytes=0-499` as the value for the `rangeValue` variable.

javax.ws.rs.CookieParam annotation

Cookie parameters are special HTTP headers. While cookies are associated with storing session identification or stateful data that is not accepted as RESTful, cookies can contain stateless information.

If an HTTP cookie is sent, such as `mycustomid=customvalue123`, you can retrieve the value of the `mycustomid` variable using the following example:

```
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.GET
```

```

public String getBookCollectionInfo(@javax.ws.rs.CookieParam("mycustomid") String mycustomid) {
    /* The cookie value is passed to the mycustomid variable. */
}
}

```

javax.ws.rs.FormParam annotation

Form parameters are used when submitting a HTML form from a browser with a media type of `application/x-www-form-urlencoded`. The form parameters and values are encoded in the request message body in the form like the following: `firstParameter=firstValue &secondParameter=secondValue`. The `javax.ws.rs.FormParam` annotation enables easy access to individual form parameter values.

If a form is submitted and the entity value is `firstName=Bob&lastName=Smith`, you can retrieve the values of the form parameters using the following example:

```

@javax.ws.rs.Path("/customer")
public class Customer {
    @javax.ws.rs.POST
    public String postCustomerInfo(@javax.ws.rs.FormParam("firstName") String firstName, @javax.ws.rs.FormParam("lastName") String lastName) {
        /* firstName would be "Bob" and secondName would be "Smith" */
    }
}

```

Note: You can either use a single unannotated parameter to represent the message body or use multiple `FormParam` annotated parameters, but not both. Because the `FormParam` requires the request message body to be read and the message body is represented as a byte stream, the message body cannot be read again. The following code is not valid:

```

@javax.ws.rs.Path("/bookstore/books")
public class BooksCollection {
    @javax.ws.rs.POST
    public String postSpecificBookInfo(@javax.ws.rs.FormParam("bookId") String theBookId, String theRequestEntity) {
        /* This code is invalid. Can only use FormParam or a request entity parameter like "String theRequestEntity" and not both */
    }
}

```

Choose one of the following ways to define variables to read parameters.

Procedure

- Add a parameter to the resource method by using an appropriate JAX-RS parameter annotation on the method to identify the type of parameter. You can read multiple types of parameters from a request; for example:

```

@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBookCollectionInfo(@javax.ws.rs.QueryParam("page") int page, @javax.ws.rs.QueryParam("filter") String filter) {
        /* This statement uses the page and filter parameters. */
    }
}

```

Issuing an HTTP GET request using a web browser or other HTTP client, such as `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books?page=10&filter=FilterValue`, invokes the `getBookCollectionInfo()` method with the page set to 10 and filter set to `FilterValue`.

- Add the parameter annotation on the fields, JavaBeans properties, and constructor arguments; for example:

```

@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.QueryParam("page") int page;

    String filter;

    @javax.ws.rs.QueryParam("filter")
    public void setFilter(String filter) {
        this.filter = filter;
    }

    @javax.ws.rs.GET
    public String getBookCollectionInfo() {
        /* This statement uses the page and filter parameters. */
    }
}

```

Issuing an HTTP GET request using a web browser or other HTTP client, such as `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books?page=10&filter=FilterValue`, also invokes the `getBookCollectionInfo()` method with the page set to 10 and filter set to `FilterValue`.

Results

Your resource methods are defined so that they can be invoked with appropriate parameter values.

Example

Defining exception mappers for resource exceptions and errors

Java API for RESTful Web Services (JAX-RS) applications can produce exceptions and errors. The default behavior is to use the exception handling functionality of application container such as JavaServer Pages (JSP) error pages. However, you can customize the error handling and send specific responses back when an exception or error occurs.

About this task

JAX-RS resource methods, like any Java method, can throw checked and unchecked exceptions. By default, an unchecked runtime exception or error occurs in the container again. A checked exception is wrapped in a `ServletException` for resources running in the web container. Therefore, a developer can use error handling facilities such as JSP error pages to handle exceptions thrown from a JAX-RS application.

JAX-RS introduced the exception, `javax.ws.rs.WebApplicationException`. A developer can specify a specific error class name or `javax.ws.rs.core.Response` object when creating a `WebApplicationException`. When the `WebApplicationException` is thrown, the information included in the exception by way of a status class name or `Response` object is used to serialize a response.

If you cannot throw the exception, `WebApplicationException`, in your code and you cannot use the error handling facilities in the web container, but you want to use a custom error response, then you can create a customized JAX-RS `javax.ws.rs.ext.ExceptionMapper` class to map exceptions to HTTP error responses.

The following procedure illustrates how to write a custom `ExceptionMapper` class.

Procedure

1. Create a class that implements the `javax.ws.rs.ext.ExceptionMapper` class and annotate the class with the `javax.ws.rs.ext.Provider` annotation. This step assumes that your JAX-RS resource can throw the exception, `MyCustomException`, in its methods. The following example illustrates a simple `ExceptionMapper` class:

```
import javax.ws.rs.core.Response;
import javax.ws.rs.ext.ExceptionMapper;
import javax.ws.rs.ext.Provider;

@Provider
public class CustomExceptionMapper implements ExceptionMapper<MyCustomException> {

    public Response toResponse(MyCustomException exception) {
        return null;
    }

}
```

2. In the `toResponse(MyCustomException)` method, return a `Response` object that contains the customized error response. The following example illustrates a customized `ExceptionMapper.toResponse(MyCustomException)` method:

```
@Provider
public class CustomExceptionMapper implements ExceptionMapper<MyCustomException> {

    public Response toResponse(MyCustomException exception) {
        return Response.status(500).entity("Unfortunately, the application cannot
```

```

        process your request at this time.").type("text/plain").build());
    }
}

```

You can have additional code where you log an error, inspect the exception thrown, or use more complex logic.

3. Package the compiled custom `ExceptionHandler` class with your web application project. If you rely on the annotation scanning capabilities to find all of your JAX-RS classes in your web application, no additional steps are required. However, if you return all of the relevant JAX-RS resource classes and providers in a JAX-RS application subclass method, then you must also add the custom `ExceptionHandler` class to the returned set. The following example illustrates a preexisting `javax.ws.rs.core.Application` subclass:

```

import java.util.HashSet;
import java.util.Set;

import javax.ws.rs.core.Application;

public class MyApplication extends Application {

    @Override
    public Set<Class<?>> getClasses() {
        Set<Class<?>> classes = new HashSet<Class<?>>();
        classes.add(CustomExceptionHandler.class);
        /* add your additional JAX-RS classes here */
        return classes;
    }
}

```

When exceptions occur in your JAX-RS resource methods, you can customize the HTTP error response so that a user cannot see a stack trace or potentially confidential data. Use an `ExceptionHandler` or the exception handling functionality in the web container to give more helpful responses if the application is not behaving correctly.

Results

You have written a custom `ExceptionHandler` to handle exceptions in your JAX-RS web application.

Developing JAX-RS web applications

Getting started with IBM JAX-RS

JAX-RS is a collection of interfaces and Java annotations that simplifies development of server-side REST applications. By using JAX-RS technology, Representational State Transfer (REST) applications are easier to develop and easier to consume when compared to other types of distributed systems.

About this task

JAX-RS is a Java API for developing REST applications quickly. While JAX-RS provides a faster way of developing web applications than servlets, the primary goal of JAX-RS is to build RESTful services. JAX-RS 1.0 defines a server-side component API to build REST applications. The IBM implementation of JAX-RS provides an implementation of the JAX-RS (JSR 311) specification.

Use this Getting Started guide to help you quickly develop and deploy a simple JAX-RS web application.

This procedure illustrates developing a simple Hello World service that is packaged inside a web application archive (WAR) module.

Procedure

1. Create a Java class. This class is used to represent a type of resource.

```
package com.ibm.jaxrs.sample;

public class HelloWorldResource {

}
```

2. Annotate the Java class with a `javax.ws.rs.Path` annotation. The value of the annotation is the relative part of the URL after the application context. The application context is fully defined during deployment. In JAX-RS terminology, this class is known as a root resource.

```
package com.ibm.jaxrs.sample;

@javax.ws.rs.Path("/helloworld")
public class HelloWorldResource {

}
```

3. Create a Java method that returns a Hello World! response. It is intended for the method to be invoked when an HTTP request is received.

```
package com.ibm.jaxrs.sample;

@javax.ws.rs.Path("/helloworld")
public class HelloWorldResource {

    public String sayHelloWorld() {
        return "Hello World!";
    }

}
```

4. Add a `javax.ws.rs.GET` annotation to the Java method.

Now, whenever an HTTP GET request is received by the application to the `/helloworld` path, the `sayHelloWorld` Java method is invoked. The response message body will contain Hello World! as its content.

```
package com.ibm.jaxrs.sample;

@javax.ws.rs.Path("/helloworld")
public class HelloWorldResource {

    @javax.ws.rs.GET
    public String sayHelloWorld() {
        return "Hello World!";
    }

}
```

The resource implementation is now complete.

5. You must create the JAX-RS `javax.ws.rs.core.Application` configuration subclass. This subclass needs to return the set of Java classes that is relevant to the JAX-RS runtime environment.

```
package com.ibm.jaxrs.sample;

public class HelloWorldAppConfig extends javax.ws.rs.core.Application {
    public Set<Class<?>> getClasses() {
        Set<Class<?>> classes = new HashSet<Class<?>>();
        classes.add(com.ibm.jaxrs.sample.HelloWorldResource.class);
        return classes;
    }
}
```

6. Create the `web.xml` web module configuration file.

The file tells the web container that the web module contains the IBM JAX-RS REST servlet. You must initialize the IBM JAX-RS Rest servlet with the application configuration class.

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_9" version="2.4" xmlns=http://java.sun.com/xml/ns/j2ee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd">
  <servlet>
    <servlet-name>HelloWorldApp</servlet-name>
    <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
    <init-param>
      <param-name>javax.ws.rs.Application</param-name>
      <param-value>com.ibm.jaxrs.sample.HelloWorldAppConfig</param-value>
    </init-param>
    <load-on-startup>1</load-on-startup>
  </servlet>
  <servlet-mapping>
    <servlet-name>HelloWorldApp</servlet-name>
    <url-pattern>/rest/*</url-pattern>
  </servlet-mapping>
</web-app>
```

See the servlet mapping that is specified in the previous example. The pattern is used to help determine the final URL of the RESTful service.

7. Add the `j2ee.jar` file to the classpath.

Get the `j2ee.jar` file from the `app_server_root/dev/JavaEE` directory and add the JAR file to the classpath. Compile the classes.

8. Assemble the web application.

By using the `jar` command-line tool that is included with the JDK, run the following command:

```
jar cvf helloworld-jaxrs.war *
```

This command creates a WAR file.

9. Deploy the application onto the application server.

When deploying the application, you might be prompted to provide a value for the context root of the module. The context root is used to define the application context.

When using the IBM JAX-RS servlet, the following URL defines the application context:

```
http://<your_hostname>:<your Web_container_port>/<context_root_of_web_application>/servlet_mapping_pattern
```

Root resource URLs that are specified by the `@javax.ws.rs.Path` values are relative to the application context root. Therefore, if the context root is defined as `myapplication` during deployment, the URL pattern is defined in the `web.xml` file as `/rest/*`, and the Java root resource class has a `@javax.ws.rs.Path` value of `/helloworld`. An example of the final URL is:

```
http://localhost:9080/myapplication/rest/helloworld
```

Now, you can send a client request to the final URL by using a web browser or any other HTTP client.

Results

You have developed and deployed a JAX-RS web application on the application server.

Setting up a development environment for JAX-RS applications

The application server provides command-line tools to develop web services clients and implementations that are based on the Java API for RESTful Web Services (JAX-RS) specification. You must set up your development environment before you start developing web services.

Before you begin

Before you can set up a web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information about installing the application server, read about installing your application server environment.

To develop JAX-RS applications, the JAX-RS libraries must be added to the class path definition. See the information for your assembly tools to understand how to include libraries on the class path for the JAX-RS application.

About this task

Set up a web services development environment by completing the following actions.

Procedure

Set up the environment.

 Run the `setupCmdLine` script on the Qshell command line from the `./profile_root/bin` directory.

Results

You have set up an environment so that you can develop RESTful web services.

What to do next

Develop your JAX-RS application and configure the `web.xml` file for the JAX-RS servlet.

Development and assembly tools

You can use an Integrated Development Environment to develop, assemble, and deploy Java Platform, Enterprise Edition (Java EE) modules for WebSphere Application Server.

The IBM Rational Application Developer for WebSphere Software product and the IBM WebSphere Application Server Developer Tools for Eclipse product are supported tools for integrated development environments.

This information center refers to the products as the *assembly tools*. However, you can use the products to do more than assemble modules. Use these tools in an integrated development environment to develop, assemble, and deploy Java EE modules.

The Rational Application Developer for WebSphere Software is a more extensive set of tools supporting enterprise development. This workbench has integrated support for WebSphere Application Server Version 6.1 and later. This workbench also supports both the OSGi and Java EE programming models, and contains wizards and visual editors to help you develop Web 2.0, Service Component Architecture (SCA), Java, and Java EE applications. This product contains code quality tools to help you analyze code and improve performance. This product integrates with Rational Team Concert to provide a team-based environment to help developers share information and work collaboratively. The Trial download for Rational Application Developer is available at <http://www.ibm.com/developerworks/downloads/r/rad/>.

IBM WebSphere Application Server Developer Tools for Eclipse is a lightweight set of tools for developing, assembling, and deploying Java EE applications to WebSphere Application Server Version 7.0 and 8.x. This workbench integrates with the application server to help you to quickly deploy and test applications. This product contains wizards and visual editors that support the Java EE programming model.

For documentation on the tools, see “Rational Application Developer documentation.” Topics on application assembly in this information center supplement that documentation.

Important: The assembly tools run on Windows and Linux Intel platforms. Users of WebSphere Application Server on all platforms must assemble their modules using an assembly tool installed on Windows or Linux Intel platforms. To install an assembly tool, follow instructions available with the tool.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

IBM i

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root

The default installation root directory for the Application Client for IBM WebSphere Application Server is the /QIBM/ProdData/WebSphere/AppClient/V85/client directory.

app_client_user_data_root

The default Application Client for IBM WebSphere Application Server user data root is the /QIBM/UserData/WebSphere/AppClient/V85/client directory.

app_client_profile_root

The default Application Client for IBM WebSphere Application Server profile root is the /QIBM/UserData/WebSphere/AppClient/V85/client/profiles/*profile_name* directory.

app_server_root

The default installation root directory for WebSphere Application Server is the /QIBM/ProdData/WebSphere/AppServer/V85/Base directory.

java_home

Table 122. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32-bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit
64-bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit

plugins_profile_root

The default Web Server Plug-ins profile root is the /QIBM/UserData/WebSphere/Plugins/V85/webserver/profiles/*profile_name* directory.

plugins_root

The default installation root directory for Web Server Plug-ins is the /QIBM/ProdData/WebSphere/Plugins/V85/webserver directory.

plugins_user_data_root

The default Web Server Plug-ins user data root is the /QIBM/UserData/WebSphere/Plugins/V85/webserver directory.

product_library

product_lib

This is the product library for the installed product. The product library for each Version 8.5 installation on the system contains the program and service program objects (similar to .exe, .dll, .so objects) for the installed product. The product library name is QWAS85x (where x is A, B, C, and so on). The product library for the first WebSphere Application Server Version 8.5 product installed on the system is QWAS85A. The *app_server_root*/properties/product.properties file contains the value for the product library of the installation, was.install.library, and is located under the *app_server_root* directory.

profile_root

The default directory for a profile named *profile_name* for WebSphere Application Server is the /QIBM/UserData/WebSphere/AppServer/V85/Base/profiles/*profile_name* directory.

shared_product_library

The shared product library, which contains all of the objects shared by all installations on the system, is QWAS85. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root

The default user data directory for WebSphere Application Server is the /QIBM/UserData/WebSphere/AppServer/V85/Base directory.

The profiles and profileRegistry subdirectories are created under this directory when you install the product.

The `user_data_root` directory contains the default locations for `WLP_USR_DIR` and `WLP_OUTPUT_DIR` when the Liberty profile is installed. These directories are `user_data_root/wlp/usr` and `user_data_root/wlp/output/servers`, respectively.

web_server_root

The default web server path is `/www/web_server_name`.

Configuring JAX-RS web applications

Configuring JAX-RS applications using JAX-RS 1.1 methods

You can configure Java API for RESTful Web Services (JAX-RS) applications in multiple ways depending on your needs. To take advantage of the Java Platform, Enterprise Edition (Java EE) 6 functionality, you can use the annotation scanning capabilities. By using annotation scanning, you can omit a `JAX-RS javax.ws.rs.core.Application` subclass or have a minimally defined `javax.ws.rs.core.Application` subclass.

About this task

The JAX-RS 1.1 specification supports several new ways to configure a JAX-RS application. You can use the built-in annotation scanning to help automatically configure the application. You can optionally add `javax.ws.rs.core.Application` subclasses to your application and then add the URL patterns required using either the `javax.ws.rs.ApplicationPath` annotation or a `web.xml` servlet definition. When using the IBM JAX-RS implementation, you do not have to specify the servlet class implementation because it is automatically added to the configuration of the web module by the time the JAX-RS application is started.

When using a `web.xml` file, you must use a Java Servlet 3.0 `web.xml` file.

Procedure

- Configure the JAX-RS application with only one JAX-RS default application in the `web.xml` file. Use this method if you only need one JAX-RS application and all resource classes are located after a single URL pattern. You can also specify security constraints with this method, if needed.
 1. Add all of your JAX-RS resource and provider classes to the `WEB-INF/classes` or `WEB-INF/lib` directory for your web application. You do not need to add a `javax.ws.rs.core.Application` subclass to your web application.
 2. In your `web.xml` file, add a servlet definition with `javax.ws.rs.core.Application` as the servlet name. You do not need to add a `servlet-class`. You must add a servlet URL pattern to the `web.xml` file. The application server runtime environment adds the specific IBM JAX-RS implementation to the configuration of the web module by the time the JAX-RS application is started; for example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns="http://java.sun.com/xml/ns/j2ee" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee
http://java.sun.com/xml/ns/j2ee/web-app_3_0.xsd"
version="3.0">
  <servlet>
    <servlet-name>javax.ws.rs.core.Application</servlet-name>
  </servlet>
  <servlet-mapping>
    <servlet-name>javax.ws.rs.core.Application</servlet-name>
    <url-pattern>/rest/*</url-pattern>
  </servlet-mapping>
</web-app>
```

The JAX-RS resources are now available at a URL such as:

`http://{hostname}:{port}/{context_root_of_Web_module}/{value_of_Web_xml_URL_pattern}/{value_of_@javax.ws.rs.Path}`

- Configure the JAX-RS application using the `javax.ws.rs.core.Application` subclass and the `web.xml` file. Use this method if you need multiple JAX-RS applications or require only specific resources in certain JAX-RS applications with specific URL patterns. You can also specify security constraints with this method, if needed.
 1. Create a `javax.ws.rs.core.Application` subclass. In your `javax.ws.rs.core.Application` subclass `getClasses()` or `getSingletons()` methods, return the relevant JAX-RS resources and providers. If

you return empty sets in both the `getClasses()` and `getSingletons()` methods, all the JAX-RS resource and provider classes that are found in the application are added to the JAX-RS application subclass; for example:

```
package com.example;

public class MyApplication extends javax.ws.rs.core.Application {

}
```

This example uses the default implementations of `javax.ws.rs.core.Application` subclass `getClasses()` and `getSingletons()` methods that return empty sets. Therefore, all relevant JAX-RS classes are assumed to be returned by the `javax.ws.rs.core.Application` subclass.

2. Add the `javax.ws.rs.core.Application` subclass to your web application.
3. Add a partial servlet definition in the `web.xml` file. The servlet name is the full name of the `javax.ws.rs.core.Application` subclass. Do not define the servlet-class. You must add a servlet URL pattern to the `web.xml` file. The application server runtime environment adds the specific IBM JAX-RS implementation to the configuration of the web module by the time the JAX-RS application is started; for example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns="http://java.sun.com/xml/ns/j2ee" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee
http://java.sun.com/xml/ns/j2ee/web-app_3_0.xsd"
  version="3.0">
  <servlet>
    <servlet-name>com.example.MyApplication</servlet-name>
  </servlet>
  <servlet-mapping>
    <servlet-name>com.example.MyApplication</servlet-name>
    <url-pattern>/rest/*</url-pattern>
  </servlet-mapping>
</web-app>
```

The JAX-RS resources are now available at a URL such as:

```
http://{hostname}:{port}/{context_root_of_Web_module}/{value_of_Web.xml_URL_pattern_for_Application_subclass}/{value_of_@javax.ws.rs.Path}
```

- Configure the JAX-RS application without a `web.xml` file. Use this method if you do not want to use a `web.xml` file. When you use this method, you cannot specify security constraints. To specify security constraints, you must use a `web.xml` file.
 1. Create a `javax.ws.rs.core.Application` subclass. In your `javax.ws.rs.core.Application` subclass `getClasses()` or `getSingletons()` methods, return the relevant JAX-RS resources and providers. If you return empty sets in both the `getClasses()` and `getSingletons()` methods, all the JAX-RS resource and provider classes that are found in the application are added to the JAX-RS application subclass; for example:

```
package com.example;

public class MyApplication extends javax.ws.rs.core.Application {

}
```

This example uses the default implementations of `javax.ws.rs.core.Application` subclass `getClasses()` and `getSingletons()` methods that return empty sets. Therefore, all relevant JAX-RS classes are assumed to be returned by the `javax.ws.rs.core.Application` subclass.

2. Add a `javax.ws.rs.ApplicationPath` annotation to the `javax.ws.rs.core.Application` subclass. The `ApplicationPath` annotation is supported with the JAX-RS 1.1 specification. The value of the `ApplicationPath` annotation is used as the servlet URL pattern which is equivalent to the servlet URL pattern in the `web.xml` file; for example:

```

package com.example;

@javax.ws.rs.ApplicationPath("rest")
public class MyApplication extends javax.ws.rs.core.Application {

}

```

3. Add the `javax.ws.rs.core.Application` subclass to your web application. When the application is started, the resources are available at the following URL:

```

http://{hostname}:{port}/{context_root_of_Web_module}/{value_of_@javax.ws.rs.ApplicationPath}/{value_of_@javax.ws.rs.Path}

```

Results

You have configured your JAX-RS application using JAX-RS 1.1 supported methods by taking advantage of annotation scanning to help automatically configure the application.

Configuring the web.xml file for JAX-RS servlets

The `web.xml` file contains information about the structure and external dependencies of web components in the module and describes how the components are used at run time. To enable the web container to run Java API for RESTful Web Services (JAX-RS) applications, you can configure the `web.xml` file to point directly to the IBM JAX-RS servlet. When using servlets, you can define a servlet path in the `web.xml` file that is appended to the base URL.

About this task

You can configure the `web.xml` file for your web application to enable the JAX-RS application code. You can specify an IBM specific JAX-RS servlet to use to run your JAX-RS code. The `web.xml` file provides configuration and deployment information for the web components that comprise a web application. Read about configuring the `web.xml` file for JAX-RS to learn more about this deployment descriptor file.

When using servlets, any servlet path that is defined in the `web.xml` is appended to the base URL. For example, if a root resource has a `@javax.ws.rs.Path` value of `myresource` and a servlet path of `myservletpath`, the final URL of the resource is `http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/myservletpath/myresource`.

Procedure

1. Open the `WEB-INF/web.xml` file.
2. Add the following servlet definition to the `WEB-INF/web.xml` file. In the following servlet, you must replace the *unique_servlet_name* with your unique servlet name. Also, replace the *Java_class_name* variable with the full Java package and class name of the `javax.ws.rs.core.Application` subclass.

```

<servlet>
  <servlet-name>unique_servlet_name</servlet-name>
  <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
  <init-param>
    <param-name>javax.ws.rs.Application</param-name>
    <param-value>Java_class_name </param-value>
  </init-param>
  <load-on-startup>1</load-on-startup>
</servlet>

```

3. (optional) If there are multiple JAX-RS application subclasses needed in the same web application, you must include an additional servlet initialization parameter, `requestProcessorAttribute`, in the servlet definition that you add to the `WEB-INF/web.xml` file. In the following servlet, you must replace the *unique_servlet_name* with your unique servlet name, the *Java_class_name* variable with the full Java package and class name of the `javax.ws.rs.core.Application` subclass, and the *unique_identifier* variable with a unique identifier.

```

<servlet>
  <servlet-name>unique_servlet_name_a</servlet-name>
  <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
  <init-param>
    <param-name>javax.ws.rs.Application</param-name>
    <param-value>Java_class_name_a </param-value>
  </init-param>
  <init-param>

```

```

        <param-name>requestProcessorAttribute</param-name>
        <param-value>unique_identifier_a</param-value>
    </init-param>
    <load-on-startup>1</load-on-startup>
</servlet>
<servlet>
    <servlet-name>unique_servlet_name_b</servlet-name>
    <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
    <init-param>
        <param-name>javax.ws.rs.Application</param-name>
        <param-value>Java_class_name_b</param-value>
    </init-param>
    <init-param>
        <param-name>requestProcessorAttribute</param-name>
        <param-value>unique_identifier_b </param-value>
    </init-param>
    <load-on-startup>1</load-on-startup>
</servlet>

```

4. Add servlet mappings in the WEB-INF/web.xml file for each servlet definition. The servlet path is appended to the context root of the web application.

```

<servlet-mapping>
    <servlet-name>servlet_name</servlet-name>
    <url-pattern>servlet_pattern_path</url-pattern>
</servlet-mapping>

```

For example, if the *servlet_pattern_path* is */restapi/**, all valid requests start at the following URL:
http://<your_hostname>:<your_Web_container_port>/<context_root_of_Web_application>/restapi/

Results

After editing the WEB-INF/web.xml file, the web application is configured for the JAX-RS application.

Example

The following example illustrates a WEB-INF/web.xml file that configures a servlet path for a JAX-RS application. The servlet path that is defined in the web.xml file is appended to the base URL.

```

<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_9" version="2.4"
xmlns=http://java.sun.com/xml/ns/j2ee
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd">

<servlet>
    <servlet-name>RestApplication1</servlet-name>
    <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
    <init-param>
        <param-name>javax.ws.rs.Application</param-name>
        <param-value>com.ibm.rest.sample.app1.MyApplication</param-value>
    </init-param>
    <init-param>
        <param-name>requestProcessorAttribute</param-name>
        <param-value>restApplication1ProcessorID</param-value>
    </init-param>
    <load-on-startup>1</load-on-startup>
</servlet>

<servlet>
    <servlet-name>OtherRestApplicationServlet</servlet-name>
    <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
    <init-param>
        <param-name>javax.ws.rs.Application</param-name>
        <param-value>com.ibm.rest.other.sample.OtherApplication </param-value>
    </init-param>
    <init-param>
        <param-name>requestProcessorAttribute</param-name>
        <param-value>otherRestApplicationID </param-value>
    </init-param>
    <load-on-startup>1</load-on-startup>
</servlet>

<servlet-mapping>
    <servlet-name> RestApplication1</servlet-name>
    <url-pattern>/rest/api/*</url-pattern>
</servlet-mapping>

<servlet-mapping>

```

```

        <servlet-name>OtherRestApplicationServlet /servlet-name>
        <url-pattern>/other/*</url-pattern>
    </servlet-mapping>
</web-app>

```

What to do next

Assemble the web application.

Configuring the web.xml file for JAX-RS filters

The web.xml file contains information about the structure and external dependencies of web components in the module and describes how the components are used at run time. To enable the web container to run Java API for RESTful Web Services (JAX-RS) applications, you can configure the web.xml file to define filters that indicate the possible URLs on which the filter can be invoked.

About this task

You can configure the web.xml file for your web application to enable the JAX-RS application code. You can specify an IBM specific JAX-RS filter to use to run your JAX-RS code. The web.xml file provides configuration and deployment information for the web components that comprise a web application. Read about configuring the web.xml file for JAX-RS to learn more about this deployment descriptor file.

When using servlets, any servlet path defined in the web.xml is appended to the base URL. Filters do not append a path to the resource base URL. Instead, filter URL mappings indicate the possible URLs on which the filter can be invoked. For instance, if a root resource has a `@javax.ws.rs.Path` value of `myresource`, the final URL of the resource is `http://<your_hostname>:<your_web_container_port>/<context_root_of_web_application>/myresource`. The URL mapping pattern for the filter must match `myresource` for the root resource to be served correctly. For this example, you can use `/*` or `/myresource` for the URL pattern. When there are multiple resources in the application, the URL pattern for the filter must match all of the resources. The `/*` pattern is a common value for the filter.

If the incoming request URL does not match any JAX-RS resources in the JAX-RS application, the request is passed to the rest of the filter chain. Depending on the application, you might want to use the filter behavior so that requests are served by the JAX-RS application, or if there is no JAX-RS resource available, the request can proceed to an underlying web container artifact, such as a JavaServer Pages (JSP). If the web container has no matching artifact, then the web container is responsible for the error response.

Procedure

1. Open the WEB-INF/web.xml file.
2. Define your filter in the WEB-INF/web.xml file. Add the following filter definition to the WEB-INF/web.xml file. Replace the *unique_filter_name* with your unique filter name. Also replace the *Java_class_name* variable with the full Java package and class name of the JAX-RS application Java subclass.

```

<filter>
    <filter-name>unique_filter_name</filter-name>
    <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
    <init-param>
        <param-name>javax.ws.rs.Application</param-name>
        <param-value>Java_class_name</param-value>
    </init-param>
</filter>

```

3. (optional) If there are multiple JAX-RS application subclasses needed in the same web application, you must include an additional filter initialization parameter, `requestProcessorAttribute`, in the filter definition that you add to the WEB-INF/web.xml file. In the following filter, replace the *unique_filter_name* with your unique filter name; replace the *Java_class_name* variable with the full Java package and the class name of the JAX-RS application Java subclass; replace the *unique_identifier* variable with a unique identifier.

```

<filter>
  <filter-name>unique_filter_name_a</filter-name>
  <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
  <init-param>
    <param-name>javax.ws.rs.Application</param-name>
    <param-value>Java_class_name_a</param-value>
  </init-param>

  <init-param>
    <param-name>requestProcessorAttribute</param-name>
    <param-value>unique_identifier_a</param-value>
  </init-param>
</filter>

<filter>
  <filter-name>unique_filter_name_b</filter-name>
  <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
  <init-param>
    <param-name>javax.ws.rs.Application</param-name>
    <param-value>Java_class_name_b</param-value>
  </init-param>

  <init-param>
    <param-name>requestProcessorAttribute</param-name>
    <param-value>unique_identifier_b</param-value>
  </init-param>
</filter>

```

4. Add filter mappings in the WEB-INF/web.xml file for each filter definition.

The URL pattern specified in the filter mapping defines to the container the valid URL patterns for invoking the `IBMRestFilter` filter. If an incoming request URL is compatible with the URL pattern, the `IBMRestFilter` is invoked. If the request URL does not match, the filter is not invoked. The request URLs always start at the context root for the filter. See the following example filter mappings:

```

<filter-mapping>
  <filter-name>filter_name</filter-name>
  <url-pattern>/*</url-pattern>
</filter-mapping>

```

For example, suppose you have the following two resources:

```

@javax.ws.rs.Path("myresource")
public class MyResource {

}

@javax.ws.rs.Path("myresource2")
public class MyResource2 {

}

```

You can reach the resources using the following URL:

```

http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/myresource
http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/myresource2

```

If you apply the following filter mapping:

```

<filter-mapping>
  <filter-name>filter_name</filter-name>
  <url-pattern>/myresource</url-pattern>
</filter-mapping>

```

you can use `MyResource` root resource by visiting the following URL:

```

http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/myresource

```

This URL invokes the `IBMRestFilter` filter and the URL can find the resource. Because the `/myresource` path matches with the URL pattern in the filter-mapping, the `IBMRestFilter` does get invoked and there is a root resource that has a matching `@Path` value.

However, suppose you visit the following URL:

```

http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/myresource2

```

the `IBMRestFilter` filter is not invoked because the URL pattern `/myresource` does not match `/myresource2`.

Results

After editing the WEB-INF/web.xml file to apply filters, the web application is configured for the JAX-RS application.

Example

The following example illustrates a WEB-INF/web.xml file that is configured to apply filters to a JAX-RS application. This example defines the RestApplication1 filter. If an incoming request URL matches a resource in the RestApplication1 filter, the response is generated from RestApplication1 filter. If the incoming request URL does not match a resource in the RestApplication1 filter but matches a resource in OtherRestApplicationFilter, then the response is generated from the OtherRestApplicationFilter filter. If the incoming URL does not match either filter, then the request can be served from another web container artifact, such as a JSP.

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_9" version="2.4"
xmlns=http://java.sun.com/xml/ns/j2ee
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd">

  <filter>
    <filter-name>RestApplication1</filter-name>
    <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
    <init-param>
      <param-name>javax.ws.rs.Application</param-name>
      <param-value>com.ibm.rest.sample.appl.MyApplication</param-value>
    </init-param>
    <init-param>
      <param-name>requestProcessorAttribute</param-name>
      <param-value>restApplication1ProcessorID</param-value>
    </init-param>
  </filter>
  <filter>
    <filter-name>OtherRestApplicationServlet</filter-name>
    <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
    <init-param>
      <param-name>javax.ws.rs.Application</param-name>
      <param-value>com.ibm.rest.other.sample.OtherApplication</param-value>
    </init-param>
    <init-param>
      <param-name>requestProcessorAttribute</param-name>
      <param-value>otherRestApplicationID </param-value>
    </init-param>
  </filter>

  <filter-mapping>
    <filter-name>RestApplication1</filter-name>
    <url-pattern>*/</url-pattern>
  </filter-mapping>

  <filter-mapping>
    <filter-name>OtherRestApplicationServlet</filter-name>
    <url-pattern>*/</url-pattern>
  </filter-mapping>
</web-app>
```

What to do next

Assemble the web application.

Implementing clients using the Apache Wink REST client

You can use the Apache Wink REST client to send requests and process responses from RESTful services. You can use the client API in Java programs to communicate with web services.

About this task

By default, the Apache Wink client uses the java.net.HttpURLConnection class from the Java runtime environment for issuing requests and processing responses. The Apache Wink client can also use Apache HttpClient 4.0 as the underlying client transport.

You can also use JAX-RS entity providers to help serialize request entities or deserialize response entities. The standard JAX-RS providers used in the JAX-RS server-side services are provided with the client.

You can configure the Apache Wink REST client programmatically or by setting Java Virtual Machine (JVM) properties.

To implement an Apache Wink REST client, you must first create an `org.apache.wink.client.ClientConfig` object that is then used to construct an `org.apache.wink.client.RestClient`. You can change the configuration settings for the `RestClient` object programmatically, or you can use JVM properties to modify the default `ClientConfig` object values.

To configure the configuration settings for the `RestClient` object programmatically, invoke the public methods of the `ClientConfig` object.

Note: After a `ClientConfig` object is used to construct a `RestClient` object, the `ClientConfig` object can no longer be modified. Attempting to do so results in an `org.apache.wink.client.ClientConfigException` error message.

Alternatively, you can configure the configuration settings for the `RestClient` object using JVM properties to modify the default `ClientConfig` object values. Use the following JVM properties to modify the default `ClientConfig` object values:

wink.client.readTimeout

This property specifies how long the `RestClient` object waits (in milliseconds) for a response to requests before timing out. A value of zero (0) means that the client waits for an unlimited amount of time and will not timeout.

The default value is 60,000 milliseconds.

wink.client.connectTimeout

This property specifies how long the `RestClient` object waits (in milliseconds) before timing out when attempting to connect to the target resource. A value of zero (0) means that the client waits for an unlimited amount of time and will not timeout.

The default value is 60,000 milliseconds.

You can programmatically alter any values for the `RestClient` object that you specify using JVM properties. The programmatic values take precedence over any JVM property values.

Procedure

1. Create an `org.apache.wink.client.ClientConfig` object.

The following code snippet illustrates how to create an `org.apache.wink.client.ClientConfig` object:

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ClientConfig();
```

.

If you use an Apache HTTP client as the underlying transport, create and use an `org.apache.wink.client.ApacheHttpClientConfig` object instead. You must also include the Apache HTTP client libraries in the classpath. The following code snippet illustrates how to create an `org.apache.wink.client.ApacheHttpClientConfig` object:

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ApacheHttpClientConfig();
```

2. (optional) Modify the default `ClientConfig` object values that you want to use for the `RestClient` object.
 - You can optionally modify the default configuration settings for the `RestClient` object programmatically. To specify the configuration settings for the `RestClient` object programmatically, invoke the public methods of the `ClientConfig` object; for example:

```
clientConfig.connectTimeout(30000);  
clientConfig.readTimeout(30000);
```

- If you are using the Thin Client for JAX-RS in a stand-alone unmanaged client runtime environment, you can optionally modify the configuration settings for the RestClient object using JVM properties. Set the custom JVM properties on the JVM under which the thin client is running.
- If you are not using the Thin Client for JAX-RS as a stand-alone client runtime environment, but you are using the RestClient object in an application that is intended for installation on the application server, you can optionally modify the configuration settings for the RestClient object using JVM properties. Set the custom JVM properties using the administrative console for your REST client code that is running within an application that is installed on the application server. See the Java virtual machine custom properties information for details on using the administrative console to set these custom JVM properties.

3. (optional) If you use a custom entity provider, add the entity provider using the client configuration.

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ClientConfig();

javax.ws.rs.core.Application app = new javax.ws.rs.core.Application() {
    public Set<Class<?>> getClasses() {
        Set<Class<?>> classes = new HashSet<Class<?>>();
        classes.add(MyCustomEntityProvider.class);
        return classes;
    }
};
clientConfig.applications(app);
```

4. Create a org.apache.wink.client.RestClient object with the client configuration.

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ClientConfig();

javax.ws.rs.core.Application app = new javax.ws.rs.core.Application() {
    public Set<Class<?>> getClasses() {
        Set<Class<?>> classes = new HashSet<Class<?>>();
        classes.add(MyCustomEntityProvider.class);
        return classes;
    }
};
clientConfig.applications(app);
```

```
org.apache.wink.client.RestClient client = new org.apache.wink.client.RestClient(clientConfig);
```

5. Create a org.apache.wink.client.Resource object with a URI from the REST client.

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ClientConfig();

javax.ws.rs.core.Application app = new javax.ws.rs.core.Application() {
    public Set<Class<?>> getClasses() {
        Set<Class<?>> classes = new HashSet<Class<?>>();
        classes.add(MyCustomEntityProvider.class);
        return classes;
    }
};
clientConfig.applications(app);

org.apache.wink.client.RestClient client = new org.apache.wink.client.RestClient(clientConfig);
```

```
org.apache.wink.client.Resource resource = client.resource("http://www.example.com/rest/api/book/123");
```

6. You can add request headers to the pending request by calling methods on the Resource object.

You can call a Java method such as post() with the request content as a parameter to send the request. In the following example, an HTTP POST request is made with a Content-Type header value of text/plain and an Accept header value of */*.

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ClientConfig();

javax.ws.rs.core.Application app = new javax.ws.rs.core.Application() {
    public Set<Class<?>> getClasses() {
        Set<Class<?>> classes = new HashSet<Class<?>>();
        classes.add(MyCustomEntityProvider.class);
        return classes;
    }
};
clientConfig.applications(app);

org.apache.wink.client.RestClient client = new org.apache.wink.client.RestClient(clientConfig);

org.apache.wink.client.Resource resource = client.resource("http://www.example.com/rest/api/book/123");
ClientResponse response = resource.contentType("text/plain").accept("*/*").post("The request body as a string");
```

Instead of calling resource.post("The request body as a string") with a String object, you can use any other object that has a class with a valid javax.ws.rs.ext.MessageBodyWriter object such as a JAXB annotated class, a byte[], or a custom class that has a custom entity provider.

7. Process the response by using the status code, response headers, or the response message body.

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ClientConfig();

javax.ws.rs.core.Application app = new javax.ws.rs.core.Application() {
    public Set<Class<?>> getClasses() {
        Set<Class<?>> classes = new HashSet<Class<?>>();
        classes.add(MyCustomEntityProvider.class);
        return classes;
    }
};
clientConfig.applications(app);

org.apache.wink.client.RestClient client = new org.apache.wink.client.RestClient(clientConfig);

org.apache.wink.client.Resource resource = client.resource("http://www.example.com/rest/api/book/123");

ClientResponse response = resource.contentType("text/plain").accept("*/*").post("The request body as a string");

System.out.println("The response code is: " + response.getStatusCode());
System.out.println("The response message body is: " + response.getEntity(String.class));
```

Instead of calling the `response.getEntity(String.class)` object with `String.class` file, you can use any other class that has a valid `javax.ws.rs.ext.MessageBodyReader` object, such as a JAXB annotated class, a `byte[]`, or a custom class that has a custom entity provider.

- (optional) Configure the client to transmit basic authentication security tokens. To configure basic authentication for your client, you can choose to manage the appropriate HTTP headers yourself, or more simply, you can use the provided `BasicAuthSecurityHandler` handler class. The `BasicAuthSecurityHandler` class simplifies the enablement of basic authentication in the Wink client application. To learn more about using the security client handler to perform basic HTTP authentication, see the securing JAX-RS applications within the web container information.

Results

You have implemented a JAX-RS client using the Apache Wink REST client that can issue requests to a JAX-RS application.

Implementing a client using the unmanaged RESTful web services JAX-RS client

WebSphere Application Server provides a thin Java Platform, Standard Edition 6 (Java SE 6) RESTful web services client runtime to enable application developers to quickly and easily create JAX-RS client applications. The Thin Client for JAX-RS with WebSphere Application Server is a stand-alone Java SE 6 client environment that enables running unmanaged JAX-RS RESTful web services client applications in a non-WebSphere environment to invoke JAX-RS RESTful web services that are hosted by the application server.

Before you begin

Note: You can use the Thin Client for JAX-RS with WebSphere Application Server as a stand-alone client run time in a pure Java SE environment. The Thin Client for JAX-RS running within WebSphere Application Server or WebSphere Application Client environments is not supported. In this version of the application server, other Thin Client run times provided with the application server can also reside in the CLASSPATH and coexist with the Thin Client for JAX-RS.

Before you set up a JAX-RS unmanaged client execution environment, obtain the Thin Client for JAX-RS Java archive (JAR) file. To obtain the Thin Client for JAX-RS, install WebSphere Application Server Version 8.5 or the Application Client for WebSphere Application Server Version 8.5. The Thin Client for JAX-RS JAR file, `com.ibm.jaxrs.thinclient_8.5.0.jar`, is located in the `app_server_root\runtimes` directory.

Copy the Thin Client for JAX-RS `com.ibm.jaxrs.thinclient_8.5.0.jar` file to other machines to create a lightweight client environment that enables communications with the product. Copies of the Thin Client for

JAX-RS are subject to the same terms and conditions of the license agreement for the WebSphere product where you obtained the Thin Client for JAX-RS. Refer to the license agreements for correct usage and other limitations.

The Thin Client for JAX-RS works with IBM Software Development Kits (SDKs) Version 6.0 and higher. The Thin Client for JAX-RS is also supported on non-IBM software development kits that are V6.0 and higher.

About this task

Set up a Thin Client for JAX-RS environment by completing the following steps.

Procedure

1. Configure the path. Enter the following command to add the Java bin directories to your path:
2. Configure the class path. Add the Thin Client for JAX-RS JAR file to the classpath definition; for example:

```
IBM i
```

```
export CLASSPATH=.:<your_JAX-RS_thin_client_install_directory>/com.ibm.jaxrs.thinclient_8.5.0.jar:  
<your_application_jars>;$CLASSPATH
```

3. Enter the following command to run your client application:

```
IBM i
```

```
$JAVA_HOME/bin/java <your_client_application>
```

Results

You have set up an unmanaged JAX-RS client runtime environment to invoke RESTful web services that are hosted on a WebSphere Application Server.

Migrating a Feature Pack for Web 2.0 JAX-RS application to WebSphere Version 8

When packaging an application for the Feature Pack for Web 2.0, you must manually make the Java API for RESTful Web Services (JAX-RS) run time available on the application CLASSPATH. A common way of doing this is placing the JAX-RS runtime Java archive (JAR) files in the WEB-INF/lib directory of the web archive (WAR) module. In Version 8, the JAX-RS runtime environment is native to the application server. It is no longer necessary to manually add the path of the runtime libraries on the CLASSPATH. Migrating Web 2.0 applications to the native runtime environment simplifies packaging and deployment, and allows for future updates to take advantage of Java Platform, Enterprise Edition (Java EE) integration features.

Before you begin

Identify Feature Pack for Web 2.0 JAX-RS applications to migrate to the native Version 8 JAX-RS runtime environment. Identify where the JAX-RS runtime JAR files have been made available to the application CLASSPATH. Two common methods are the WEB-INF/lib directory of the WAR module or by way of a shared library.

About this task

In WebSphere Version 8, the JAX-RS run time runs natively within the application server process. Unlike deploying JAX-RS applications with the Web 2.0 Feature Pack installed on WebSphere Version 7 or earlier, it is no longer necessary to package the JAX-RS runtime JAR files as an external library for the application.

To migrate Web 2.0 applications to the Version 8 runtime environment, simply remove the external JAX-RS runtime libraries. For example, if the runtime JAR files were placed in the WEB-INF/lib directory of the

WAR module, delete them from that directory before redeploying the application. No other changes are necessary. All other application configurations, such as `web.xml` configuration, are still valid in WebSphere Version 8.

Once the external JAX-RS runtime library is removed, the native runtime environment runs the JAX-RS application. There are advantages to this over Web 2.0 deployment. Application packaging and deployment are simplified since it is no longer necessary to add external libraries on the application CLASSPATH. Additionally, new Java EE integration features can be taken advantage of in future updates to the application. Examples are Enterprise JavaBeans (EJB) in a WAR and Java Contexts and Dependency Injection (JCDI) support.

Procedure

1. Remove external JAX-RS runtime libraries from the Feature Pack for Web 2.0 application.
2. Redeploy the application.

Results

You have migrated a Web 2.0 Feature Pack JAX-RS application to the native WebSphere Version 8 JAX-RS runtime environment.

Disabling the JAX-RS runtime environment

There are cases where you must disable the Java API for RESTful Web Services (JAX-RS) runtime environment. When disabling the JAX-RS runtime environment, JAX-RS features are not available, including base JAX-RS runtime capabilities, Enterprise JavaBeans (EJB) runtime integration, Java Contexts and Dependency Injection (JCDI) runtime integration, and Servlet 3.0 web container integration.

About this task

By disabling the JAX-RS runtime environment, any JAX-RS related processing of the application, including processing of classes with scanned JAX-RS annotations, EJB metadata, and JCDI bean enablement, is no longer performed. The JAX-RS runtime environment is not used to process requests and responses to and from the web container.

Note: Disabling the JAX-RS runtime environment does not disable Servlet 3.0 based annotation scanning for JAX-RS annotations such as `javax.ws.rs.Path`. To disable annotation scanning, set the `metadata-complete` attribute. If annotation scanning is disabled, it is disabled for all other components outside of JAX-RS.

The explicit plug points to the IBM JAX-RS runtime environment are the `com.ibm.websphere.jaxrs.server.IBMRestServlet` servlet class and the `com.ibm.websphere.jaxrs.server.IBMRestFilter` filter class. If you specify these classes as your `servlet-class` or `servlet-filter` in the web module's `web.xml` file, the IBM JAX-RS runtime environment is used to process requests to that servlet.

To disable the JAX-RS runtime environment from doing so, replace those classes with any other servlet or filter class that can handle expected requests to the servlet, or remove the servlet entirely from the `web.xml` file.

Note: Replacing the `IBMRestServlet` class with another might modify existing behavior in the application. Removing the servlet entirely results in requests not being processed.

Even if not explicitly using the `com.ibm.websphere.jaxrs.server.IBMRestServlet` or `com.ibm.websphere.jaxrs.server.IBMRestFilter` classes, the JAX-RS integration runtime environment may still process the application. For example, if the `web.xml` file of a web module is Servlet 3.0 based,

and appropriate conditions are met according to the JSR-311 specification, the JAX-RS integration runtime environment processes scanned classes with JAX-RS annotations and may inject a servlet that can handle requests to the JAX-RS resources in the application.

To disable this functionality, and other functionality such as EJB and JCDI integration, set the `com.ibm.websphere.jaxrs.server.DisableIBMJAXRSEngine` custom Java virtual machine (JVM) property on the application server with a value of `true`.

Procedure

1. Remove references to `IBMRestServlet` and `IBMRestFilter` from the `web.xml` file. The following example illustrates a sample `web.xml` file from an application that uses the IBM JAX-RS runtime environment:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns="http://java.sun.com/xml/ns/j2ee" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee http://java.sun.com/xml/ns/j2ee/web-app_3_0.xsd"
version="3.0">
  <servlet>
    <servlet-name>MyRestApplication1</servlet-name>
    <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
    <init-param>
      <param-name>javax.ws.rs.Application</param-name>
      <param-value>com.ibm.websphere.jaxrs.example.Application1</param-value>
    </init-param>
    <init-param>
      <param-name>requestProcessorAttribute</param-name>
      <param-value>MyRestApplication1RequestProcessorAttribute</param-value>
    </init-param>
    <load-on-startup>1</load-on-startup>
  </servlet>
  <servlet>
    <servlet-name>MyNonJAXRSApplication</servlet-name>
    <servlet-class>com.ibm.websphere.example.NonJAXRSServlet</servlet-class>
    <load-on-startup>1</load-on-startup>
  </servlet>
  <filter>
    <filter-name>MyRestApplication2</filter-name>
    <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
    <init-param>
      <param-name>javax.ws.rs.Application</param-name>
      <param-value>com.ibm.websphere.jaxrs.example.Application2</param-value>
    </init-param>
    <init-param>
      <param-name>requestProcessorAttribute</param-name>
      <param-value>MyRestApplication2RequestProcessorAttribute</param-value>
    </init-param>
  </filter>
  <servlet-mapping>
    <servlet-name>MyRestApplication1</servlet-name>
    <url-pattern>/jaxrsapp1/*</url-pattern>
  </servlet-mapping>
  <servlet-mapping>
    <servlet-name>MyNonJAXRSApplication</servlet-name>
    <url-pattern>/nonjaxrsapp/*</url-pattern>
  </servlet-mapping>
  <filter-mapping>
    <filter-name>MyRestApplication2</servlet-name>
    <url-pattern>/jaxrsapp2/*</url-pattern>
  </filter-mapping>
</web-app>
```

The following example illustrates how the `web.xml` file looks after removing the references to the `IBMRestServlet` and `IBMRestFilter` classes:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns="http://java.sun.com/xml/ns/j2ee" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee http://java.sun.com/xml/ns/j2ee/web-app_3_0.xsd"
version="3.0">
  <servlet>
    <servlet-name>MyNonJAXRSApplication</servlet-name>
    <servlet-class>com.ibm.websphere.example.NonJAXRSServlet</servlet-class>
    <load-on-startup>1</load-on-startup>
  </servlet>
  <servlet-mapping>
```

```
<servlet-name>MyNonJAXRSApplication</servlet-name>
<url-pattern>/nonjaxrsapp/*</url-pattern>
</servlet-mapping>
</web-app>
```

2. Set the `com.ibm.websphere.jaxrs.server.DisableIBMJAXRSEngine` custom JVM property on the application server with a value of `true`.
3. Restart the application server for the custom JVM property to take effect.

Results

You have disabled the JAX-RS runtime environment from processing your application.

Assembling JAX-RS web applications

After you develop the Java class files for your Java API for RESTful Web Services (JAX-RS) web application and edit the `web.xml` file to enable the JAX-RS servlet, you must assemble the application.

Before you begin

Identify the assembly tool to use to assemble your application. The web application is assembled into a web application archive (WAR) package. You can assemble the WAR package into an enterprise archive (EAR) package if required.

Before assembling the web application, ensure that you have customized the `web.xml` file to enable the JAX-RS servlet or filter configuration. To learn more, see the information about configuring the `web.xml` file for the JAX-RS application.

About this task

You must add the JAX-RS libraries to the web application in the `WEB-INF/lib` directory before you assemble the web application.

By packaging your JAX-RS application classes into the `WEB-INF/classes` directory of your WAR package and editing the `web.xml` file, you can use the built-in JAX-RS runtime environment.

Procedure

Create the WAR package using assembly tools.

1. Package your compiled JAX-RS Java classes into the `WEB-INF/classes` directory of your WAR package.
2. Package the `web.xml` file for your web application in the `WEB-INF/` directory into the WAR package.

Results

A WAR package is created that contains the web application. If needed, you can add the WAR package to an EAR package. The application server can deploy either the WAR or EAR packages.

What to do next

Deploy the web application.

Chapter 33. Developing web services - Security (WS-Security)

The Web Services Security specification defines core facilities for protecting the integrity and confidentiality of a message, and provides mechanisms for associating security-related claims with a message.

Developing applications that use Web Services Security

The Web Services Security specification provides a flexible framework for building secure web services to implement message content integrity and confidentiality. The Web Services Security service programming model supports this flexible framework by providing extension points to integrate new token formats, and methods to obtain keys needed for message protection. The application server programming model provides Web Services Security programming application programming interfaces (WSS API) for securing SOAP messages.

Configuring HTTP basic authentication for JAX-RPC web services programmatically

You can configure HTTP basic authentication for Java API for XML-based RPC (JAX-RPC) web services by programmatically modifying HTTP properties.

Before you begin

This task is one of three ways that you can configure HTTP basic authentication. You can also configure HTTP basic authentication with an assembly tool or with the administrative console.

If you programmatically configure HTTP basic authentication, the properties are configured in the Stub or Call instance. If you choose to configure HTTP basic authentication with the administrative console or an assembly tool, the Web Services Security binding information is modified. The values that are set programmatically take precedence over the values defined in the binding.

About this task

The HTTP basic authentication that is discussed in this topic is orthogonal to WS-Security and is distinct from basic authentication that WS-Security supports. WS-Security supports basic authentication token, not HTTP basic authentication.

Configure HTTP basic authentication programmatically with the following steps.

Procedure

Set the properties in the Stub or Call instance for a Web service or a web service client. You can set properties with the following constant names:

```
javax.xml.rpc.Call.USERNAME_PROPERTY  
javax.xml.rpc.Call.PASSWORD_PROPERTY  
javax.xml.rpc.Stub.USERNAME_PROPERTY  
javax.xml.rpc.Stub.PASSWORD_PROPERTY
```

Example

The following code enables you to configure basic authentication programmatically:

```
Properties prop = new Properties();  
InitialContext ctx = new InitialContext(prop);  
Service service = (Service)ctx.lookup("java:comp/env/service/StockQuoteService");  
QName portQName = new QName("http://httpchannel.test.wsft.ws.ibm.com", "StockQuoteHttp");  
StockQuote sq = (StockQuote)service.getPort(portQName, StockQuote.class);  
((javax.xml.rpc.Stub) sq)._setProperty(javax.xml.rpc.Stub.USERNAME_PROPERTY, "myUser");  
((javax.xml.rpc.Stub) sq)._setProperty(javax.xml.rpc.Stub.PASSWORD_PROPERTY, "myPwd");
```

Developing message-level security for JAX-WS web services

JAX-WS applications can be secured with Web Services Security in one of two ways. The application can be secured using policy sets, or through the use of the Web Services Security API (WSS API). The WSS API can only be used to secure a JAX-WS client application. The Web Services Security service programming interface (WSS SPI) provides additional programming interfaces for securing web services.

Web Services Security API programming model

The application server programming model provides Web Services Security programming application programming interfaces (WSS API) for securing SOAP messages.

The API programming model is an interface-based programming model that is based on Web Services Security Version 1.1 standards, but the design also includes support for Web Services Security Version 1.0 for securing SOAP messages. The WSS API programming model implementation is a simplified version, which is based on an early draft proposal of JSR-183, which is the JSR for defining Java API binding for Web Services Security. By design, because the application code is programmed to the interface, any application code that is programmed with the open source implementation should be able to run on the WebSphere Application Server with minimal changes or no changes at all.

The configuration model for web services has also been redesigned from a deployment descriptor model to a policy set model. Web Services Security can be enabled by either using a policy set that is configured by using the administrative console, or by using the WSS API for configuration. The functions provided by the policy set configurations are the same as the functions supported by the WSS API for the Web Services Security run time. However, the security policy that is defined using policy sets has a higher priority over the WSS API. When the WSS API and the policy set are both used in the application, the default behavior is for the security policy from the policy set to be enforced and the WSS API to be ignored. To use the WSS API in the application, you must make sure that there is no policy set attached to the application or to the application resources, or make sure there is no security policy in the attached policy set.

You can still use your existing JAX-RPC applications with Web Services Security; however, those applications cannot take advantage of the Web Services Security Version 1.1 functions, such as configuring the security policy using a policy set, OM filter performance improvements, WSS API, Web Services Secure Conversation (WS-SecureConversation), Kerberos token and the associated SHA-1 key for message protection and identity propagation, and Web Services Trust (WS-Trust) features.

In order to take advantage of the Web Services Security Version 1.1 functions, you must rewrite an existing JAX-RPC application as a JAX-WS application, manually re-configure the security constraints to a policy set, and perform code migration of the DOM-based SPIs to the OM-based SPIs.

For example, when using the JAX-WS programming model, the improved design of the pluggable token framework allows the same security implementation to be used for both the API and policy sets. The framework uses the JAAS Login Module and JAAS Callback Handler for token creation and token validation.

The following diagrams illustrate differences between the programming models.

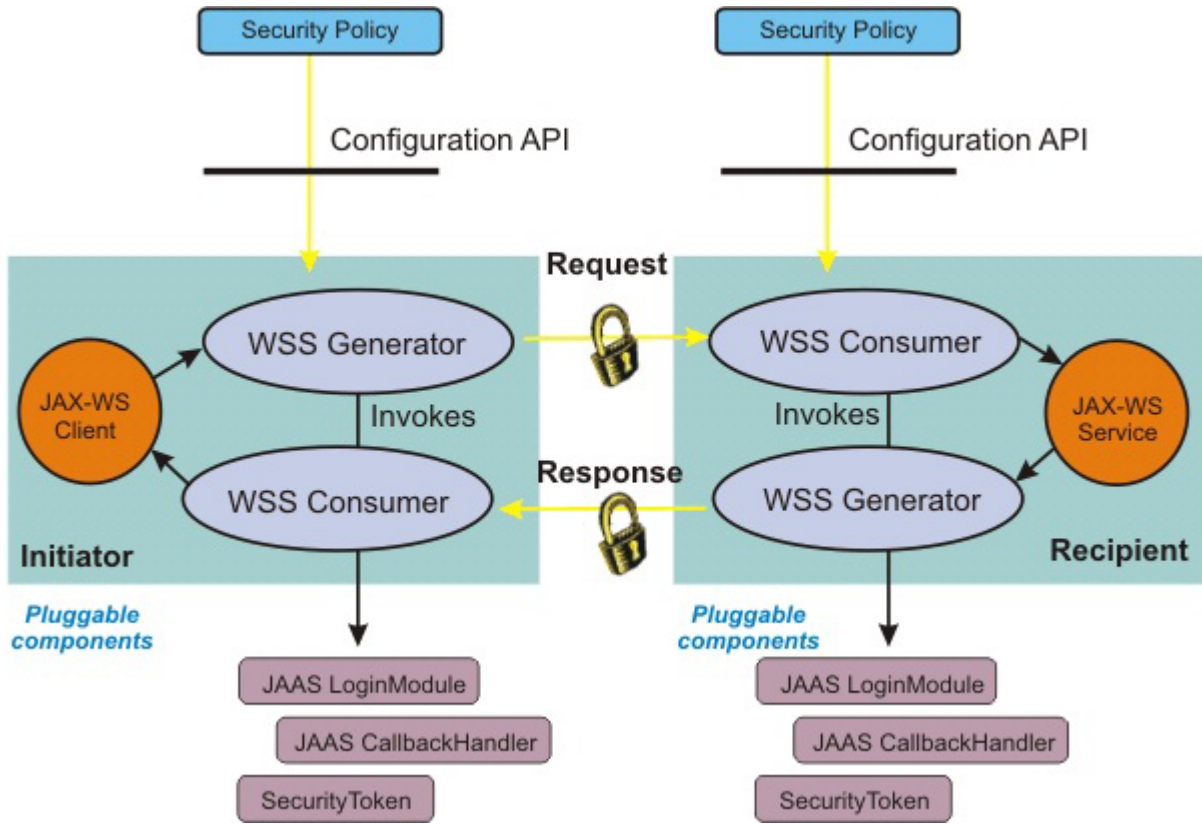

Figure 1. Pluggable token architecture using the JAX-WS programming model

Figure 2. Pluggable token architecture using the JAX-RPC programming model

What is supported when using the WSS APIs

The WSS API can only be used on the client. You can use the Java SE 6 client, the J2EE Application client, or a server client (a service provider acting as client) using the API to secure SOAP message with message-level security.

You should have Web Services Security (WSS) knowledge to use the WSS APIs. Before using the WSS API, keep in mind that the WSS API:

- Are Java-based interfaces.
- Are implemented by using a factory model (WSSFactory).
- Supports the WS-Security Version 1.0 and 1.1 standards, which include the Username and X.509 token profiles, Versions 1.0 and 1.1.
- Are very XML centric.
- Include an object-oriented design which simplifies the APIs.
- Are task oriented and allow common usage scenarios, such as: signing the body and encrypting the SOAP message body content.
- Are flexible and extensible, and they let you to extend the token type support.
- Are based on the provider framework and allow the use of different data models to be used, such as: AXIOM or DOM.
- Provides application programmer with better control and flexibility in applying WSS in their applications.

The default values for the WSS API are predefined and are part of the Web Services Security run time. Default values are provided for:

- The duration of the timestamp
- The signing algorithm, canonicalization algorithm, digest method, transform algorithm, security token reference method and signed parts such as the SOAP body, Web Services Addressing headers and the time stamp.
- The key encryption algorithm, data encryption algorithm, security token reference method, and encrypted parts such as the SOAP body content.

The signature validation has similar default values as the signature (signing information). Similarly, decryption has similar default values as encryption.

What is not supported when using the WSS APIs

The WSS API provided with the application server does not support the following function:

- The application programming model is JAX-WS, meaning JAX-RPC (JSR-109) applications are not supported.
- The WSS API is available in the synchronous message exchange of the JAX-WS client application. However, the WSS API are not supported for the asynchronous client.
- WSS API support is available only for the requester and not for the provider.
- The identity assertion semantic programming model is not supported in the WSS API because identity assertion is not part of the Web Services Security Version 1.0 standard. However, you can use the WSS API to add Identity Assertion semantic in the token processing.

WS-Trust and WS-SecureConversation scenarios

There are several ways to secure the WS-Trust SOAP messages:

- Using the bootstrap policy defined in the policy set.
- Using the WSS API, which supports WS-SecureConversation.
- Enabling dynamic policy for the provider so that the client can retrieve the provider-side policy at run time.

An application would use the WSS API to acquire a security context token for programmatic API-based secure conversation. The WebSphere Application Server trust service provides an application the ability to request a security token for access to a service. The scope and focus of the trust service is only for a WebSphere Application Server Security Context Token (SCT) for WS-SecureConversation.

The WS-SecureConversation and WS-Trust scenarios focus on the inter-operability functions, such as the configuration and runtime interaction of various components. You would use the WSS API to secure the bootstrap RST and RSTR to acquire the security context token from the trust service. After acquiring the security context token, a Derived Key Token is created by using the WSS API. Then the Derived Key Token can be used for signature and encryption.

There are two conditions when using the WSS API to secure the SOAP message with Web Services Security:

- Generation of the secure SOAP message, which is in the request generator application code.
- Consuming of the secured SOAP message, which is in the response consumer application code.

In both cases, a Java exception class `com.ibm.websphere.wssecurity.wssapi.WSSException` is provided if an error is encountered.

Web services client security context

When the JAX-WS client invokes web services, the current security context that is constructed by the security handler is stored in the RequestContext object. By default, the security context in the JAX-WS

web services client runtime environment is reconstructed for the next web services request invocation. You can preserve the security context for subsequent web services invocations. An example of this is a scenario where the security policy requires the client to send a username security token with the user name and password. When the client sends the first request to invoke the service, you are prompted to enter the required user name and password. The user name and password is saved in a Username SecurityToken token in a Subject in the security context. To avoid being prompted to enter the same user name and password again in subsequent request invocations, you can preserve the security context. There are two methods to preserve the security context: 1) configure the client run time to automatically preserve the client security context for subsequent request invocations; or 2) preserve the security context manually.

To configure the JAX-WS client run time environment to automatically preserve the security context, set the Java system property `com.ibm.websphere.wssecurity.context.management` to `true`. When this system property is `true`, the JAX-WS client run time copies the security context constructed by the security handler to the `RequestContext` automatically, and the context is used for subsequent request invocations.

To manually preserve the security context, use the following sample code:

```
// First request
Service svc = Service.create(...);
svc.addPort(...);
Dispatch<String> dispatch = svc.createDispatch(...);
Map<String, Object> requestContext = dispatch.getRequestContext();
String response = dispatch.invoke(body.toString());

Object securityContext = requestContext.get(com.ibm.wsspi.websvcs.Constants.WEBSPPHERE_SECURITY_CONTEXT);

// Subsequent request

Dispatch<String> dispatch = svc.createDispatch(...);
Map<String, Object> requestContext = dispatch.getRequestContext();
Object securityContext = requestContext.put(com.ibm.wsspi.websvcs.Constants.WEBSPPHERE_SECURITY_CONTEXT, securityContext);
```

Service Programming Interfaces (SPI)

The Web Services Security service programming interface (WSS SPI) provides programming interfaces for securing Web Services Security.

The Web Services Security specification provides a flexible framework for building secure web services to implement message content integrity and confidentiality. The specification does not define specific token formats, but instead associates separate profile documents that define various security token formats and semantics for using those tokens. The Web Services Security service programming model supports the flexible framework by providing extension points to integrate with new token formats, and with methods to obtain keys needed for message protection. Web Services Security uses this programming model to implement support for the standard X.509 token profile, the Username token profile, and the Kerberos token profiles. The programming model is also used to implement support for the LTPA security token, and for new security token types.

The Web Service Security run time token generation and token consuming Service Programming Interfaces (SPI) have been redesigned so that the same security token interface and JAAS Login Module implementation can be used for both the WSS API and the SPI. The WSS SPI for the service provider extends the security token types and provides keys and deriving keys for signing, signature verification, encryption and decryption.

The Web Services Security service programming model provides mechanisms to process custom security tokens, to use custom token in signing and encryption, and to retrieve encryption and signing keys. The Web Services Security service programming interfaces for the JAX-RPC run time, and for the JAX-WS run time, are similar, but not identical.

JAX-RPC run time

The plug-in programming interfaces for the JAX-RPC run time consist of the TokenGenerator, KeyLocator, and JAAS CallbackHandler for outbound message processing, and the TokenConsumer, KeyLocator, and JAAS LoginModule for inbound message processing.

Token Generator, KeyLocator, and Callback Handler

The TokenGenerator class is responsible for formatting the security token to the XML element. This class calls the CallbackHandler class that is specified in the TokenGeneratorConfig object, which obtains the security token input data, and then stores the resulting security token in the Subject object private credentials.

Token Consumer, KeyLocator and JAAS LoginModule

The KeyLocator class is responsible for obtaining the required key for signing and encrypting SOAP message elements from a key store that is specified by the KeyStoreConfig and the KeyLocatorConfig configuration. The TokenConsumer class extracts the token data from the XML security token representation, and stores it in the JAAS Subject using a JAAS LoginModule. The specified KeyLocator class is invoked to find the required key for verifying the digital signature and decrypting the SOAP message elements.

JAX-WS run time

The plug-in programming interfaces for the JAX-WS run time are based on the JAAS programming model for both inbound and outbound SOAP message processing. The JAAS LoginModule and CallbackHandler are responsible for processing the security tokens in SOAP messages. The Login Module and Callback Handler both retrieve and generate tokens, and store the SecurityToken objects in the run time. They replace the functionality of the TokenGenerator, TokenConsumer, and KeyLocator interfaces.

Due to the differences in the programming models, any WebSphere Application Server or custom SPI implementation from the Web Services Security Version 6.1 run time is not supported to run on the Web Services Security run time with the Version 6.1 Feature Pack for Web Services, or the Version 7.0 and later Web Services Security runtime. However, the Web Services Security Version 6.1 run time is supported simultaneously with the Version 6.1 Feature Pack for Web Services, meaning the Version 6.1 SPI implementations are still supported through the original run time. Before using the new Web Services Security run time, a code migration is required to reprogram the Version 6.1 DOM-based SPIs to the AXIOM-based SPIs in the Feature Pack for Web Services, before the SPI can be used.

Developing SAML applications

Use the SAML library application programming interface (API), the SAMLTokenFactory, to configure token parameters, create a SAML token, and bind the created token to a service request. The SAML trust client API provides helper functions that send WS-Trust SOAP requests to the specified external Security Token Service (STS).

About this task

The SAMLTokenFactory API creates SAML tokens through various method signatures. The API also instantiates runtime configuration objects related to the SAML token requester, as well as the recipient.

The WS-Trust Client API for SAML includes the WSSTrustClient class, the WSSTrustClientValidateResult class, and other configuration utility classes.

The following topics provide more information about developing SAML applications using the APIs.

WS-Trust client API:

The WS-Trust client application programming interface (API) includes the WSSTrustClient class, the WSSTrustClientValidateResult class, and other configuration utility classes. The WSSTrustClient class

provides helper functions that send WS-Trust SOAP requests to the specified external Security Token Service (STS) so that the STS can issue or validate one or more SAML assertions and other types of security tokens.

Overview

WebSphere Application Server includes WS-Trust client function, implemented through the `WSSTrustClient` class, that sends WS-Trust SOAP requests to a specified external Security Token Service (STS). Using the trust requests, the STS can issue one or more SAML assertions or other types of security tokens. The `WSSTrustClient` class supports the OASIS WS-Trust Version 1.3 specification, and also the WS-Trust Version 1.2 specification. In addition, the SOAP Version 1.1 and SOAP Version 1.2 specifications are supported by the function.

The sample code which follows demonstrates how a web services client uses the `WSSTrustClient` API to request a SAML bearer token. In the explanatory text which precedes the code sample, the term **SAML token** is used interchangeably with the term **SAML assertion**.

The `WSSTrustClient` class

You can copy the sample code into an assembly tool application, such as Rational Application Developer, and start using the code after completing the configuration steps. Use the `WSSTrustClient` class, together with other SAML APIs, to build useful SAML functions. Refer to the SAML API Javadoc for more information.

The `WSSTrustClient` class is an abstract class and has two concrete implementations: a WS-Trust Version 1.3 implementation and a WS-Trust v1.2 implementation. On line 50 of the code sample, the `SAMLWSTrustClientExample` web services client code invokes the `WSSTrustClient.getInstance(ProviderConfig)` method to retrieve the WS-Trust v1.3 implementation. The `getInstance()` method takes a single `ProviderConfig` object, which specifies configuration data that are relevant to the SAML token issuer. A `ProviderConfig` object is also instantiated in the sample code on line 32. The client code sends WS-Trust Version 1.3 request messages to a target STS endpoint. In the sample, the endpoint is `https://MyCompany/Trust/13/UsernameMixed`. To use the sample code, replace this example STS endpoint with the specific STS endpoint you plan to use.

Note: Starting with WebSphere Application Server Release 8, you can use the `com.ibm.websphere.wssecurity.wssapi.token.SAMLToken` class in Web Services Security (WSS) application programming interface (API). When there is no concern of confusion we use the term `SAMLToken` instead of using its complete package name. You can use WSS API to request `SAMLToken` processing from an external Security Token Service (STS), to propagate `SAMLTokens` in SOAP request messages, and to use a symmetric or asymmetric key identified by `SAMLTokens` to protect SOAP messages.

The WSS API SAML support complements the `com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory` and `com.ibm.websphere.wssecurity.wssapi.trust.WSSTrustClient` interfaces. `SAMLTokens` that are generated using the `com.ibm.websphere.wssecurity.wssapi.WSSFactory.newSecurityToken()` method can be processed by the `SAMLTokenFactory` and `WSSTrustClient` programming interfaces. Conversely, `SAMLTokens` that are generated by `SAMLTokenFactory` or returned by `WSSTrustClient` can be used in WSS API. Deciding which API to use in your application depends on your specific needs. WSS API SAML support is self contained in the sense that it provides functionality equivalent to that of the `SAMLTokenFactory` and `WSSTrustClient` interfaces as far as web services client applications are concerned. The `SAMLTokenFactory` interface has additional functions to validate `SAMLTokens` and to create the JAAS Subject that represents authenticated `SAMLTokens`. This validation is useful for the Web services provider side. When you develop applications to consume `SAMLTokens`, the `SAMLTokenFactory` programming interface is more suitable for you.

Example: Web services client code that uses the WSSTrustClient class

```

175.
176. }

```

WSSTrustClient class support for policy sets and bindings

The WS-Trust client function supports both application-specific bindings and general bindings for use with the trust client policy set and binding documents. In addition, general bindings and default bindings are supported if the application is running in the application server environment. General bindings are supported in the thin client environment, but default bindings are not.

Managing the policy set and bindings for the WS-Trust client API is similar to managing a policy set and bindings for a web services client. However, differences exist that are unique to the WS-Trust client. One difference is that the WS-Trust client does not use policy set attachments. Instead, the policy set name and binding name are specified in a ProviderConfig object, as shown in line 36 and line 37 of the sample code.

When the WS-Trust client looks for bindings, the way the client manages the search scope differs from the web services client. If you do not specify the `wstrustClientBindingScope` property for the trust client binding, the system first searches the application for an application-specific binding with the binding name that you specified. If a binding is found, it is used for the trust client request. If no application-specific binding is found, the system searches the available general bindings for a binding with the name that you specified. If a general binding is found, it is used for the trust client request. If no bindings with the specific name are found, then default bindings are used in a server environment. Default bindings are only used in a server environment. If the binding scope is specified, only that scope is used for the binding search.

Line 38 of the sample code, `providerConfig.setBindingScope("domain")`, indicates that the example uses general bindings. You can also set the binding scope to `application` to indicate that the sample code uses application-specific bindings. The example uses the general binding named **SamITCSample**. Both application-specific and general bindings are supported in the application server and the thin client environment. For more information about configuring the SamITCSample bindings when the application is installed on the application server, read about configuring policy sets and bindings to communicate with STS.

The `showProviderConfigDefaultValue(providerConfig)` code on line 34 of the sample code shows the default settings. The sample code includes a utility method that prints out the contents of `providerConfig`.

Line 51 of the sample code, `List<SecurityToken> securityTokens = client.issue(providerConfig, requesterConfig)`, sends an issue WS-Trust request. The second parameter on this line specifies the `RequesterConfig` object, and this parameter determines the content of the issue request. The code on line 41, `RequesterConfig requesterConfig = WSSTrustClient.newRequesterConfig(Namespace.WST13)`, instantiates a `RequesterConfig` object that is used to construct the trust request using the WS-Trust Version 1.3 namespace. A utility function is shown on line 43: `showRequestConfigDefaultValue(requesterConfig)`. This function displays the default settings for the `RequesterConfig` object. The code between lines 45 and 48 initializes the `RequesterConfig` to request a Version 1.1 SAML bearer token. This token is used to access the service endpoint using the SOAP 1.2 namespace. In the example, the service endpoint is `https://user.MyCompany.com:9443/WSSampleSei/EchoService12`.

JVM arguments support

Before executing the sample code, you must set up several Java Virtual Machine (JVM) arguments. The sample code implements the Username WSHTTPS default policy set, which has two requirements: 1) a Username token is sent to the STS; and 2) messages are protected using Secure Sockets Layer (SSL). To set up the environment to meet these requirements, first configure the `ssl.client.props` file to define a truststore. For step-by-step instructions, read about running an unmanaged web services JAX-WS client.

To meet the second requirement regarding SSL message protection, obtain a copy of the STS SSL X.509 certificate and inset it into the truststore. To do this, follow the steps in the topic, Using the `retrieveSigners` command in SSL, to enable server-to-server trust. Alternately, you can accept the STS certificate when

you send the first trust request to the STS if the `com.ibm.ssl.enableSignerExchangePrompt` property in the `profile_home/properties/ssl.client.props` file is set to true. For more information about this option, read about changing the signer auto-exchange prompt at the client.

In addition, you must specify the client JAAS configuration file so that the client runtime environment can locate the Username token LoginModule JAAS login configuration. Specify the parameter using this code: `-Djava.security.auth.login.config="%WAS_HOME%\properties\wsjaas_client.conf`. You must also include the thin client jar, for example `com.ibm.jaxws.thinclient_8.0.0.jar`, in the classpath. For more information, read about running an unmanaged web services JAX-WS client application.

Sample code execution

A prerequisite to executing the sample code is to set up an external STS endpoint to issue a SAML 1.1 bearer token for the specified web services as defined by the `RequesterConfiguration.RSTT.APPLIESTO_ADDRESS` property.

Executing the sample code generates a WS-Trust issue request message, as shown in the example:

```

177. <?xml version="1.0" encoding="UTF-8"?><soapenv:Envelope xmlns:soapenv="http://www.w3.org/2003/05/soap-envelope">
178.   <soapenv:Header>
179.     <wsa:To xmlns:wsa="http://www.w3.org/2005/08/addressing">https://user.MyCompany.com/Trust/13/UsernameMixed</wsa:To>
180.     <wsa:MessageID xmlns:wsa="http://www.w3.org/2005/08/addressing">urn:uuid:4951B6775950CAC92A1252458259166</wsa:MessageID>
181.     <wsa:Action xmlns:wsa="http://www.w3.org/2005/08/addressing">http://docs.oasis-open.org/ws-sx/ws-trust/200512/RST/Issue</wsa:Action>
182.   </soapenv:Header>
183.   <soapenv:Body>
184.     <wst:RequestSecurityToken xmlns:wst="http://docs.oasis-open.org/ws-sx/ws-trust/200512">
185.       <wst:TokenType>http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV1.1</wst:TokenType>
186.       <wst:RequestType>http://docs.oasis-open.org/ws-sx/ws-trust/200512/Issue</wst:RequestType>
187.       <wst:KeyType>http://docs.oasis-open.org/ws-sx/ws-trust/200512/Bearer</wst:KeyType>
188.       <wsp:AppliesTo xmlns:wsp="http://schemas.xmlsoap.org/ws/2004/09/policy">
189.         <wsa:EndpointReference xmlns:wsa="http://www.w3.org/2005/08/addressing">
190.           <wsa:Address>https://user.MyCompany.com:9443/WSSampleSei/EchoService12</wsa:Address>
191.         </wsa:EndpointReference>
192.       </wsp:AppliesTo>
193.     </wst:RequestSecurityToken>
194.   </soapenv:Body>
195. </soapenv:Envelope>

```

To view the WS-Trust request message, you must enable a client-side trace. Set the following JVM properties:

- `-DtraceSettingsFile=MyTraceSettings.properties`
- `-Djava.util.logging.manager=com.ibm.ws.bootstrap.WsLogManager`
- `-Djava.util.logging.configureByServer=true`

For more information about these properties, read about enabling trace on client and stand-alone applications. In addition to setting the JVM properties, you must also specify the trace setting, `com.ibm.ws.wssecurity.*=all=enabled`, in the `MyTraceSettings.properties` file. Look for `Trust Client outgoing request:` in the trace log file.

SAML token return

The code on line 51 of the sample code, `List<SecurityToken> securityTokens = client.issue(providerConfig, requesterConfig)`, returns a SAML token if the WS-Trust issue request is processed successfully. The code between lines 54 and 64 processes the returned SAML token. The utility function shown on line 58, `showSAMLToken((SAMLToken)token)`, displays the content of the received SAML token. The `showSAMLToken()` routine shows the SAML token as an XML document. An example of this XML document is provided in line 196 to line 233 of the sample code.

SAML token library APIs:

The SAML token library application programming interfaces (APIs) provide methods you can use to create, validate, parse, and extract SAML tokens.

Overview

The library implementation for SAML Version 1.1 and SAML Version 2.0 provides three types of subject confirmation: holder-of-key (HoK), bearer, and sender-vouches. You can use the SAML token library APIs to create, validate, and extract the attributes of a SAML HoK or bearer token. SAML token propagation from web services SOAP messages is also discussed. Sample code is provided to demonstrate the use of the APIs.

WebSphere Application Server with SAML provides default policy sets to support the bearer and HoK subject confirmation.

These sections discuss creating a SAML token using the SAML token library APIs:

1. "Configuration of token creation parameters" on page 1270
2. "SAML token factory instance creation" on page 1271
3. "SAML token creation" on page 1271
4. "Sample code" on page 1272

The SAMLTokenFactory API is the primary SAML token library programming interface. SAMLTokenFactory supports creating, parsing, and validating both SAML 1.1 and SAML 2.0 tokens. Using the SAMLTokenFactory API, you can create ProviderConfid, RequesterConfig, and ConsumerConfig configuration objects to define the required SAML token characteristics. Read the API documentation for more details.

You can perform additional operations on a SAML token after it is created, including:

- "SAML token validation" on page 1271
- "SAML token identity mapped to a subject" on page 1271
- "Parse assertion elements" on page 1272
- "SAML token attributes extraction" on page 1272

Note: Starting with WebSphere Application Server Release 8, you can use the `com.ibm.websphere.wssecurity.wssapi.token.SAMLToken` class in Web Services Security (WSS) application programming interface (API). When there is no concern of confusion we use the term SAMLToken instead of using its complete package name. You can use WSS API to request

SAMLToken processing from an external Security Token Service (STS), to propagate SAMLTokens in SOAP request messages, and to use a symmetric or asymmetric key identified by SAMLTokens to protect SOAP messages.

The WSS API SAML support complements the `com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory` and `com.ibm.websphere.wssecurity.wssapi.trust.WSSTrustClient` interfaces. SAMLTokens that are generated using the `com.ibm.websphere.wssecurity.wssapi.WSSFactory.newSecurityToken()` method can be processed by the `SAMLTokenFactory` and `WSSTrustClient` programming interfaces. Conversely, SAMLTokens that are generated by `SAMLTokenFactory` or returned by `WSSTrustClient` can be used in WSS API. Deciding which API to use in your application depends on your specific needs. WSS API SAML support is self contained in the sense that it provides functionality equivalent to that of the `SAMLTokenFactory` and `WSSTrustClient` interfaces as far as web services client applications are concerned. The `SAMLTokenFactory` interface has additional functions to validate SAMLTokens and to create the JAAS Subject that represents authenticated SAMLTokens. This validation is useful for the Web services provider side. When you develop applications to consume SAMLTokens, the `SAMLTokenFactory` programming interface is more suitable for you.

Configuration of token creation parameters

When you configure the token creation parameters, the configuration information relates to either the requesting entity, the issuing entity, or the receiving entity. In this example, configuration information is defined for the requesting and the issuing entities. For each type of supported subject confirmation, the SAML token library provides pre-configured attributes for the requesting entity. These attributes are used during the creation of the self-issued SAML token by the WebSphere runtime environment. A self-issued SAML token is one that is generated locally, instead of one that is requested from a Security Token Service (STS). If you need to customize the attributes for a default parameter, use the `RequesterConfig` parameter. For more information, read about the `RequesterConfig` parameter in the `SAMLTokenFactory` API topic.

First, set up the requestor configuration information:

```
// Setup the requester's configuration information (parameters needed
// to create the token specified as configuration properties).
// in this case we are using the configuration information to create a
// SAML token that contains a symmetric holder of key subject
// confirmation.
RequesterConfig requesterData =
    samlFactory.newSymmetricHolderOfKeyTokenGenerateConfig();
```

Next, set the recipient public key alias and optionally, the authentication method:

```
// Set recipient's public key alias
// (in this example we use SOAPRecipient), so the provider can encrypt secret
// key for the receiving end.
requesterData.setKeyAliasForAppliesTo("SOAPRecipient");

// Set the authentication method that took place. This is an optional
// parameter.
reqData.setAuthenticationMethod("Password");
```

Then set the issuer configuration attributes:

```
// Set issuer information by instantiating a default ProviderConfig.
// See javadocs for the SAMLTokenFactory class on the details of the
// default values and how to modify them.
ProviderConfig samlIssuerCfg =
    samlFactory.newDefaultProviderConfig("WebSphereSelfIssuer");
```

SAML token factory instance creation

Use the `SAMLTokenFactory` class, specifying the SAML token type, either Version 1.1 or Version 2.0. Set additional parameters for creating the SAML token.

Use the `SAMLTokenFactory` class with the SAML token type:

```
// Instantiate a token factory based on the version level of the token
// to use. In this example we use the SAML v1.1 token factory.
SAMLTokenFactory samlFactory =
SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSam1V11Token11);
```

Set additional parameters in the `CredentialConfig` object using the caller subject or the `runAsSubject`:

```
// Retrieve the caller subject or the runAsSubject (depending on your
// scenario) then use the Subject to get a CredentialConfig object
// using the SAML token library.
// This invocation requires the
// wssapi.SAMLTokenFactory.newCredentialConfig" Java Security
// permission.
CredentialConfig cred = samlFactory.newCredentialConfig(runAsSubject);
```

SAML token creation

Create the SAML token using the token factory:

```
// Now create the SAML token. This invocation requires the
// "wssapi.SAMLTokenFactory.newSAMLToken" Java Security permission.
SecurityToken samlToken =
    samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);
```

SAML token validation

An entity that receives a SAML token, such as a business service, can use the SAML token library API to validate the token before using it. For example, the service needs to validate the token before extracting the SAML attributes from the requester. An existing SAML assertion document can be validated using the configuration data from the consumer.

The following API code validates the token:

```
ConsumerConfig consumerConfig = samlFactory.newConsumerConfig();
XMLStructure xml =
try {
    SAMLToken token = samlFactory.newSAMLToken( consumerConfig, XMLStructure xml );
    // token successfully validated
} catch(WSSException e){
    // token failed validation
}
```

SAML token identity mapped to a subject

A SAML token can be used to create a subject. The name identifier in the SAML token is mapped to a user in the user registry to obtain the principal name for the subject.

```
Subject subject;
SAMLToken aSAMLToken = ...;
try {
    subject = samlFactory.newSubject(aSAMLToken);
} catch(WSSException e) {
}
```

Parse assertion elements

The recipient of a SAML token can parse and extract assertion elements from the SAML token using the SAMLToken APIs, which are included in the SAML token library API. For example, the token creation time can be extracted using this code:

```
Date dateCreated = samlToken.getSamlCreated();
```

Extract the name of the token issuer and the confirmation method as follows:

```
String confirmationMethpo = samlToken.getConfirmationMethod();
String issuerName = samlToken.getSAMLIssuerName();
```

If the extracted subject confirmation method is returned as holder-of-key confirmation, then you can use the following API to retrieve the bytes for the key material:

```
byte[] hokBytes = samlToken.getHolderOfKeyBytes();
```

For more information about all the SAML APIs, read the API documentation for the SAMLToken interface.

SAML token attributes extraction

Extract SAML attributes from the initiating entity (service requester) using the SAMLToken API, as shown in the following code snippets.

```
// Get all attributes
List<SAMLAttribute> allAttributes =
    ((SAMLToken) samlToken).getSAMLAttributes();

// Iterate over the attribute and process accordingly
Iterator<SAMLAttribute> iter = allAttributes.iterator();
while (iter.hasNext())
{
    SAMLAttribute anAttribute = iter.next();

    // Handle attributes
    String attributeName = anAttribute.getName();
    String[] attributeValues = anAttribute.getStringAttributeValue();
}
}
```

Sample code

The sample code demonstrates how to use the SAML token library APIs to accomplish some of the operations previously described. A JVM property that points to the location of the SAML properties file is a prerequisite for running this code. The SAML properties file, SAMLIssuerConfig.properties, must contain configuration attributes related to the issuer (provider) of the SAML token.

The default location of the SAMLIssuerConfig.properties file for the cell level is: *app_server_root/profiles/\$PROFILE/config/cells/\$CELLNAME/sts*.

For the server level, the default location is: *app_server_root/profiles/\$PROFILE/config/cells/\$CELLNAME/nodes/\$NODENAME/servers/\$SERVERNAME*.

```

Creating a SAML bearer token using the API:

Use the SAML library API to create a SAML bearer token.

About this task

This library allows you to create a SAML bearer token. You can use the SAML library API to create required SAML configuration objects, then use those configuration objects to generate a bearer SAML token.

Procedure

1. Create a SAMLTokenFactory instance using the SAML token version as a parameter.
 - a. Use the following line of code to import the method:

```
import com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory;
```

- b. Use one of these lines of code to create the instance, depending on the token version.
 - Add the following line of code to create a SAMLTokenFactory instance for a version 1.1 SAML token:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSam1V11Token11);
```

- Add the following line of code to create a SAMLTokenFactory instance for a version 2.0 SAML token:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSam1V11Token20);
```

2. After you create the instance, the SAMLTokenFactory is used to create a RequesterConfig instance, which determines how the token will be generated, according the authentication requirements of the requester. Use this line of code to create the RequesterConfig instance for the bearer token:

```
RequesterConfig reqData = samlFactory.newBearerTokenGenerateConfig();
```

The default RequestConfig instance is sufficient to generate a simple bearer token, but additional assertions can be included in the SAML token by customizing the RequesterConfig instance. For example, to include password authentication information in the token, use `setAuthenticationMethod`:

```
reqData.setAuthenticationMethod("password");
```

To disable signing in a SAML assertion, use the `setAssertionSignatureRequired` method, for example:

```
reqData.setAssertionSignatureRequired(false);
```

For more information, read about the SAML bearer assertion.

3. Use the SAMLTokenFactory to create a ProviderConfig instance, which describes the token issuer. The ProviderConfig instance specifies the SAML issuer name, as well as keystore and truststore information, which identifies the key for SAML encryption and signing. The ProviderConfig instance is created using property values from a property file. The property file specifies the default value of the ProviderConfig object. In a Java client environment, this property file is defined by a JVM system property, `com.ibm.webservices.wssecurity.platform.SAMLIssuerConfigDataPath`.

In the WebSphere Application Server runtime environment, the property file name is `SAMLIssuerConfig.properties`. The file can be located either under the server level configuration directory, or the cell level directory, in that order of precedence. An example of the server level path follows:

```
app_server_root/profiles/$PROFILE/config/cells/$CELLNAME/nodes/$NODENAME/servers/$SERVERNAME/SAMLIssuerConfig.properties
```

An example of the cell level path follows:

```
app_server_root/profiles/$PROFILE/config/cells/$CELLNAME/sts/SAMLIssuerConfig.properties
```

The JVM system property, `com.ibm.webservices.wssecurity.platform.SAMLIssuerConfigDataPath`, is ignored if the property is defined in server runtime environment. For a detailed description of all the properties, read about configuration of a SAML token during token creation.

Use the following line of code to create a default ProviderConfig instance:

```
ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig("any issuer name");
```

The issuer name is optional. If the issuer name is specified, the Issuer name appears in the SAML assertion. If the issuer name is not specified, a default issuer name property from the `SAMLIssuerConfig.properties` is used as the issuer name.

4. Optional: When creating a new SAML token, the SAMLTokenFactory uses either a JAAS subject or a CredentialConfig instance to populate the new SAML token. To use a JAAS subject to populate the token, use the `com.ibm.websphere.security.auth.WSSubject` `getCallerSubject()` API or the `getRunAsSubject()` API to obtain a JAAS subject that represents the requesting client, or the identity of the execution thread.

When you use the JAAS subject to create a new SAML token, the SAMLTokenFactory searches for a SAMLToken object in the subject `PrivateCredentials` list. If a SAMLToken object exists, the `NameId` or `NameIdentifier` are copied to the new SAML token. The SAMLTokenFactory also copies the SAML attributes and `AuthenticationMethod` from the existing SAML token to the new SAML token. The new

SAML token includes a new issuer name, new signing certificate, confirmation method, new KeyInfo for the holder-of-key confirmation method, and new NotBefore and NotOnAfter conditions. These token settings are determined by the configuration parameters in the ProviderConfig and RequesterConfig objects.

If there is no SAMLToken object in the subject, only the WSPPrincipal principal name is copied from the subject to the new SAML token. No other attributes in the subject are copied into the new SAML token. Similarly, the issuer name, signing certificate, confirmation method, KeyInfo for the holder-of-key, and NotBefore and NotOnOrAfter conditions are determined by configuration parameters in ProviderConfig and RequesterConfig objects.

Alternately, you can use the RunAsSubject method on the execution thread to create the SAML token. When using this method, do not pass the JAAS subject or the CredentialConfig object to the SAMLTokenFactory to create the SAML token. Instead, the content of the existing SAML token is copied to the new SAML token, as described previously.

Another method of creating a SAML token is to use a CredentialConfig object to populate the SAML NameId and Attributes programmatically. Use this method in the following circumstances:

- Custom SAML attributes must be included in the new SAML token.
- The SAML token is created manually instead of using the SAMLTokenFactory to populate the SAML token from a JAAS subject automatically.
- There is no existing SAML token in the subject.
- There is no JAAS subject available.

To create a CredentialConfig object without using the JAAS subject, use this line of code:

```
CredentialConfig cred = samlFactory.newCredentialConfig ();
```

There is no initial value provided for this CredentialConfig object, so you must use setter methods to populate the CredentialConfig object.

To populate the SAML NameIdentifier or NameID, use the following line of code:

```
cred.setRequesterNameID("any name");
```

The value of the *any name* variable is used as the principal name in the SAML token. The name appears in the assertion as the NameIdentifier in a SAML Version 1.1 token, or NameId in the SAML Version 2.0 token. For example, if the value of *any name* is Alice, the following assertion is generated in a SAML Version 1.1 token:

```
<saml:NameIdentifier>Alice</saml:NameIdentifier>
```

The following assertion is generated in a SAML Version 2.0 token:

```
<saml2:NameID>Alice</saml2:NameID>
```

To include SAML attributes in the <AttributeStatement> portion of an assertion, use this code:

```
SAMLAttribute samlAttribute = new SAMLAttribute("email" /* Name*/, new String[] {"joe@websphere"})
/*Attribute Values*/, null, "IBM WebSphere namespace" /* namespace*/, "email" /* format*/, "joe" /*friendly name */);
ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
al.add(samlAttribute);
sattribute = new SAMLAttribute("Membership", new String[] {"Super users", "Gold membership"}, null, null /* format*/, null, null );
al.add(samlAttribute );
cred.setSAMLAttributes(al);
```

This sample code generates the following <Attribute> assertions:

```
<saml:Attribute AttributeName="email" NameFormat="email" AttributeNamespace="IBM WebSphere namespace">
<saml:AttributeValue>joe@websphere</saml:AttributeValue>
</saml:Attribute>
<saml:Attribute AttributeName="Membership">
<saml:AttributeValue>Super users</saml:AttributeValue><saml:AttributeValue>Gold membership</saml:AttributeValue>
</saml:Attribute>
```

5. Generate a SAML bearer token using this line of code:

```
SAMLToken samlToken = samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);
```

This method requires the Java security permission wssapi.SAMLTokenFactory.newSAMLToken.

Complete code samples using lines of code from the previous steps are included in the Example section.

Example

Use this sample code to create a SAML version 1.1 bearer token from the subject:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSam1V11Token11);
RequesterConfig reqData = samlFactory.newBearerTokenGenerateConfig();
ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig("WebSphere Server");
Subject subject = com.ibm.websphere.security.auth.WSSubject.getRunAsSubject();
SAMLToken samlToken = samlFactory.newSAMLToken(subject, reqData, samlIssuerCfg);
```

Use this sample code to create a SAML version 1.1 bearer token without using the subject:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSam1V11Token11);
RequesterConfig reqData = samlFactory.newBearerTokenGenerateConfig();
reqData.setAuthenticationMethod("Password"); //Authentication method for Assertion
ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig(Self issuer);
CredentialConfig cred = samlFactory.newCredentialConfig ();
cred.setRequesterNameID("Alice"); // SAML NameIdentifier
//SAML attributes:
SAMLAttribute attribute = new SAMLAttribute
    ("email" /* Name*/, new String[] {"joe@websphere"})
    /*Attribute Values in String*/,null
    /*Attribute Values in XML */, "WebSphere" /* Namespace*/, "email" /* format*/, "joe" /*Friendly_name */);
ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
al.add(attribute);
attribute = new SAMLAttribute("Membership", new String[] {"Super users", "My team"}, null, null, null, null );
al.add(attribute);
cred.setSAMLAttributes(al);
SAMLToken samlToken = samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);
```

Creating a SAML holder-of-key token using the API:

The SAML holder-of-key token extends the security token public interface in WebSphere Application Server, and can be used as a protection token. WebSphere Application Server provides a SAML library API for SAML holder-of-key token creation.

About this task

SAML token creation requires three parameters:

- com.ibm.wsspi.wssecurity.saml.config.RequesterConfig
- com.ibm.wsspi.wssecurity.saml.config.ProviderConfig
- com.ibm.wsspi.wssecurity.saml.config.CredentialConfig

Follow the steps to create an instance for each of the parameters and then create a SAML holder-of-key token. As an alternative to CredentialConfig, you can also use javax.security.auth.Subject. For more information, read the API documentation.

Procedure

1. Create a com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory instance using the SAML token version as a parameter. The supported SAMLToken versions are <http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV1.1> and <http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV2.0>. The SAMLTokenFactory instance is a singleton and therefore is thread-safe. Use one of these lines of code to create the instance, depending on the token version.
 - Use the following line of code to create a com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory instance for a version 1.1 SAML token:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSam1V11Token11);
```

- Use the following line of code to create a `com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory` instance for a version 2.0 SAML token:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSam1V11Token20);
```

2. The `SAMLTokenFactory` instance is used to create a `RequesterConfig` instance, which determines how the token is generated, according to the authentication requirements of the requester. Use one of these lines of code to create the `RequesterConfig` instance, depending on whether you want the token to use a secret key (symmetric key) or a public key:

- Use the following line of code to create a default `RequesterConfig` for the SAML holder-of-key token using a secret key (symmetric key), which is included in the `SubjectConfirmation`:

```
RequesterConfig reqData = samlFactory.newSymmetricHolderOfKeyTokenGenerateConfig ();
```

You must also set the key alias for the target service so the provider can encrypt the secret key for the service:

```
reqData.setKeyAliasForAppliesTo("Soap Recipient");
```

- Use the following line of code to create a default `RequesterConfig` for the SAML holder-of-key token using a public key, which is included in the `SubjectConfirmation`:

```
RequesterConfig reqData = samlFactory.newAsymmetricHolderOfKeyTokenGenerateConfig ();
```

You must also set the key alias for the requester so the provider can extract the public key from the requester, and include the key in the `SubjectConfirmation`:

```
reqData.setKeyAliasForRequester("SOAP Initiator");
```

The default `RequesterConfig` instance is sufficient to generate a simple holder-of-key token, but additional assertions can be included in the SAML token by customizing the `RequesterConfig` instance. For example, to include password authentication information in the token, use `setAuthenticationMethod`:

```
reqData.setAuthenticationMethod("password");
```

3. Use the `SAMLTokenFactory` to create a `ProviderConfig` instance, which describes the token issuer. The `ProviderConfig` instance specifies the SAML issuer name, as well as keystore and truststore information, which identifies the key for SAML encryption and signing. The `ProviderConfig` instance is created using property values from a property file. The property file specifies the default value of the `ProviderConfig` object. In a Java client environment, this property file is defined by a JVM system property, `com.ibm.webservices.wssecurity.platform.SAMLIssuerConfigDataPath`.

In the WebSphere Application Server runtime environment, the property file name is `SAMLIssuerConfig.properties`. The file can be located either under the server level configuration directory, or the cell level directory, in that order of precedence. An example of the server level path follows:

```
app_server_root/profiles/$PROFILE/config/cells/$CELLNAME/nodes/$NODENAME/servers/$SERVERNAME/SAMLIssuerConfig.properties
```

An example of the cell level path follows:

```
app_server_root/profiles/$PROFILE/config/cells/$CELLNAME/sts/SAMLIssuerConfig.properties
```

The JVM system property, `com.ibm.webservices.wssecurity.platform.SAMLIssuerConfigDataPath`, is ignored if the property is defined in server runtime environment. For a detailed description of all the properties, read about configuration of a SAML token during token creation.

Use the following line of code to create a default `ProviderConfig` instance:

```
ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig("any issuer name");
```

The issuer name is optional. If the issuer name is specified, the issuer name appears in the SAML assertion. If the issuer name is not specified, a default issuer name property from the `SAMLIssuerConfig.properties` is used as the issuer name.

4. Optional: When creating a new SAML token, the `SAMLTokenFactory` uses either a `JAAS` subject or a `CredentialConfig` instance to populate the new SAML token. To use a `JAAS` subject to populate the

token, use the `com.ibm.websphere.security.auth.WSSubject` `getCallerSubject()` API or the `getRunAsSubject()` API to obtain a JAAS subject that represents the requesting client, or the identity of the execution thread.

When you use the JAAS subject to create a new SAML token, the `SAMLTokenFactory` searches for a `SAMLToken` object in the subject `PrivateCredentials` list. If a `SAMLToken` object exists, the `NameId` or `NameIdentifier` are copied to the new SAML token. The `SAMLTokenFactory` also copies the SAML attributes and `AuthenticationMethod` from the existing SAML token to the new SAML token. The new SAML token includes a new issuer name, new signing certificate, confirmation method, new `KeyInfo` for the holder-of-key confirmation method, and new `NotBefore` and `NotOnAfter` conditions. These token settings are determined by the configuration parameters in the `ProviderConfig` and `RequesterConfig` objects.

If there is no `SAMLToken` object in the subject, only the `WSPPrincipal` principal name is copied from the subject to the new SAML token. No other attributes in the subject are copied into the new SAML token. Similarly, the issuer name, signing certificate, confirmation method, `KeyInfo` for the holder-of-key, and `NotBefore` and `NotOnOrAfter` conditions are determined by configuration parameters in `ProviderConfig` and `RequesterConfig` objects.

Alternately, you can use the `RunAsSubject` method on the execution thread to create the SAML token. When using this method, do not pass the JAAS subject or the `CredentialConfig` object to the `SAMLTokenFactory` to create the SAML token. Instead, the content of the existing SAML token is copied to the new SAML token, as described previously.

Another method of creating a SAML token is to use a `CredentialConfig` object to populate the SAML `NameId` and `Attributes` programmatically. Use this method in the following circumstances:

- Custom SAML attributes must be included in the new SAML token.
- The SAML token is created manually instead of using the `SAMLTokenFactory` to populate the SAML token from a JAAS subject automatically.
- There is no existing SAML token in the subject.
- There is no JAAS subject available.

To create a `CredentialConfig` object without using the JAAS subject, use this line of code:

```
CredentialConfig cred = samlFactory.newCredentialConfig ();
```

There is no initial value provided for this `CredentialConfig` object, so you must use setter methods to populate the `CredentialConfig` object.

To populate the SAML `NameIdentifier` or `NameID`, use the following line of code:

```
cred.setRequesterNameID("any name");
```

The value of the `any name` variable is used as the principal name in the SAML token. The name appears in the assertion as the `NameIdentifier` in a SAML Version 1.1 token, or `NameId` in the SAML Version 2.0 token. For example, if the value of `any name` is `Alice`, the following assertion is generated in a SAML Version 1.1 token:

```
<saml:NameIdentifier>Alice</saml:NameIdentifier>
```

The following assertion is generated in a SAML Version 2.0 token:

```
<saml2:NameID>Alice</saml2:NameID>
```

To include SAML attributes in the `<AttributeStatement>` portion of an assertion, use this code:

```
SAMLAttribute samlAttribute = new SAMLAttribute("email" /* Name*/, new String[] {"joe@websphere"})
/*Attribute Values*/, null, "IBM WebSphere namespace" /* namespace*/, "email" /* format*/, "joe" /*friendly name */);
ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
al.add(samlAttribute)
sattribute = new SAMLAttribute("Membership", new String[] {"Super users", "Gold membership"}, null, null /* format*/, null, null );
al.add(samlAttribute );
cred.setSAMLAttributes(al);
```

This sample code generates the following `<Attribute>` assertions:

```

<saml:Attribute AttributeName="email" NameFormat="email" AttributeNamespace="IBM WebSphere namespace">
<saml:AttributeValue>joe@websphere</saml:AttributeValue>
</saml:Attribute>
<saml:Attribute AttributeName="Membership">
<saml:AttributeValue>Super users</saml:AttributeValue><saml:AttributeValue>Gold membership</saml:AttributeValue>
</saml:Attribute>

```

5. Generate a SAML holder-of-key token using this line of code:

```
SAMLToken samlToken = samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);
```

This method requires the Java security permission `wssapi.SAMLTokenFactory.newSAMLToken`. Complete code samples using lines of code from the previous steps are included in the Example section.

Example

Use this sample code to create a SAML version 1.1 holder-of-key token using a secret key (symmetric key) from the subject.

```

import com.ibm.wsspi.wsssecurity.saml.config.RequesterConfig;
import com.ibm.wsspi.wsssecurity.saml.config.ProviderConfig;
import com.ibm.wsspi.wsssecurity.saml.config.CredentialConfig ;
import com.ibm.websphere.wsssecurity.wssapi.token.SAMLTokenFactory

SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSam1V11Token11);

RequesterConfig reqData = samlFactory.newSymmetricHolderOfKeyTokenGenerateConfig();

//Map "AppliesTo" to key alias, so library knows how to encrypt the Symmetric Key
reqData.setKeyAliasForAppliesTo("SOAPRecipient");

ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig(IssuerUri);

Subject subject = com.ibm.websphere.security.auth.WSSubject.getRunAsSubject();

SAMLToken samlToken = samlFactory.newSAMLToken(subject, reqData, samlIssuerCfg);

```

Use this sample code to create a SAML version 2.0 holder-of-key token using a public key from the subject:

```

//User expression on how SAML should be created, default provided
RequesterConfig reqData = samlFactory.newAsymmetricHolderOfKeyTokenGenerateConfig();

//Choose a public key to be included in SAML
reqData.setKeyAliasForRequester("SOAPInitiator");

//Get issuer key store so can sign or encrypt assertion, issuer name
ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig("any_issuer");

//Get JAAS Subject so the factory can populate principal and attributes to SAML
Subject subject = com.ibm.websphere.security.auth.WSSubject.getRunAsSubject();

SAMLToken samlToken = samlFactory.newSAMLToken(subject, reqData, samlIssuerCfg);

```

Use this sample code to create a SAML version 2.0 holder-of-key token using a secret key (symmetric key):

```

SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance (SAMLTokenFactory.WssSam1V20Token11);

RequesterConfig reqData = samlFactory.newSymmetricHolderOfKeyTokenGenerateConfig ();
//Map "AppliesTo" to key alias so library knows how to encrypt the Symmetric Key
reqData.setKeyAliasForAppliesTo("SOAPRecipient");

ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig(null);

CredentialConfig cred = samlFactory.newCredentialConfig ();
cred.setRequesterNameID("any_name");

SAMLToken samlToken = samlFactory.newSAMLToken(subject, reqData, samlIssuerCfg);

```

Creating a SAML sender-vouches token using the API:

Use the SAML library API to create a SAML sender-vouches token, which includes the sender-vouches confirmation method. The sender-vouches confirmation method is used when a server needs to propagate the client identity or behavior of the client.

About this task

When SAML function is installed on a WebSphere server, a SAML library API is provided. Use the library to create a SAML sender-vouches token. You can use the SAML library API to create required SAML configuration objects. Then, use those configuration objects to generate a SAML sender-vouches token.

Procedure

1. Create a SAMLTokenFactory instance using the SAML token version as a parameter.

- a. Use the following line of code to import the method:

```
import com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory;
```

- b. Use one of these lines of code to create the instance, depending on the token version.

- Add the following line of code to create a SAMLTokenFactory instance for a version 1.1 SAML token:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSam1V11Token11);
```

- Add the following line of code to create a SAMLTokenFactory instance for a version 2.0 SAML token:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSam1V11Token20);
```

2. After you create the instance, the SAMLTokenFactory is used to create a RequesterConfig instance, which determines how the token will be generated, according the authentication requirements of the requester. Use this line of code to create the RequesterConfig instance for the sender-vouches token:

```
RequesterConfig reqData = samlFactory.newSenderVouchesTokenGenerateConfig();
```

The default RequestConfig instance is sufficient to generate a simple sender-vouches token, but additional assertions can be included in the SAML token by customizing the RequesterConfig instance. For example, to include password authentication information in the token, use the method, `setAuthenticationMethod`:

```
reqData.setAuthenticationMethod("password");
```

The trust validation for a sender-vouches assertion is the responsibility of the sender, not the issuer, so the Enveloped-Signature element is not required in the assertion. To remove the Enveloped-Signature element from the SAML assertion, use the `setAssertionSignatureRequired` method; for example:

```
reqData.setAssertionSignatureRequired(false);
```

3. Use the SAMLTokenFactory API to create a ProviderConfig instance, which describes the token issuer. The ProviderConfig instance specifies the SAML issuer name, as well as keystore and truststore information, which identifies the key for SAML encryption and signing. The ProviderConfig instance is created using property values from a property file. The property file specifies the default value of the ProviderConfig object. In a Java client environment, this property file is defined by a JVM system property, `com.ibm.webservices.wssecurity.platform.SAMLIssuerConfigDataPath`.

In the WebSphere Application Server runtime environment, the property file name is `SAMLIssuerConfig.properties`. The file can be located either under the server level configuration directory, or the cell level directory, in that order of precedence. See the following example of the server-level path:

```
app_server_root/profiles/$PROFILE/config/cells/$CELLNAME/nodes/$NODENAME/servers/$SERVERNAME/SAMLIssuerConfig.properties
```

See the following example of the cell-level path:

```
app_server_root/profiles/$PROFILE/config/cells/$CELLNAME/sts/SAMLIssuerConfig.properties
```

The JVM system property, `com.ibm.webservices.wssecurity.platform.SAMLIssuerConfigDataPath`, is ignored if the property is defined in server runtime environment. For a detailed description of all the properties, read about configuration of a SAML token during token creation.

Use the following line of code to create a default ProviderConfig instance:

```
ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig("any issuer name");
```

The issuer name is optional. If the issuer name is specified, the Issuer name appears in the SAML assertion. If the issuer name is not specified, a default issuer name property from the `SAMLIssuerConfig.properties` is used as the issuer name.

4. Optional: When creating a new SAML token, the `SAMLTokenFactory` uses either a Java Authentication and Authorization Service (JAAS) subject or a `CredentialConfig` instance to populate the new SAML token. To use a JAAS subject to populate the token, use the `com.ibm.websphere.security.auth.WSSubject` `getCallerSubject()` API or the `getRunAsSubject()` API to obtain a JAAS subject that represents the requesting client, or the identity of the execution thread.

- When you use the JAAS subject to create a new SAML token, the `SAMLTokenFactory` API searches for a `SAMLToken` object in the subject `PrivateCredentials` list. If a `SAMLToken` object exists, the `NameId` or `NameIdentifier` objects are copied to the new SAML token. The `SAMLTokenFactory` also copies the SAML attributes and `AuthenticationMethod` method from the existing SAML token to the new SAML token. The new SAML token includes a new issuer name, new signing certificate, confirmation method, new `KeyInfo` for the holder-of-key confirmation method, and new `NotBefore` and `NotOnAfter` conditions. These token settings are determined by the configuration parameters in the `ProviderConfig` and `RequesterConfig` objects.

If there is no `SAMLToken` object in the subject, only the `WSPPrincipal` principal name is copied from the subject to the new SAML token. No other attributes in the subject are copied into the new SAML token. Similarly, the issuer name, signing certificate, confirmation method, `KeyInfo` for the holder-of-key, and `NotBefore` and `NotOnOrAfter` conditions are determined by configuration parameters in `ProviderConfig` and `RequesterConfig` objects.

Alternately, you can use the `RunAsSubject` method on the execution thread to create the SAML token. When using this method, do not pass the JAAS subject or the `CredentialConfig` object to the `SAMLTokenFactory` to create the SAML token. Instead, the content of the existing SAML token is copied to the new SAML token, as described previously.

- Another method of creating a SAML token is to use a `CredentialConfig` object to populate the SAML `NameId` and `Attributes` programmatically. Use this method in the following circumstances:
 - Custom SAML attributes must be included in the new SAML token.
 - The SAML token is created manually instead of using the `SAMLTokenFactory` to populate the SAML token from a JAAS subject automatically.
 - There is no existing SAML token in the subject.
 - There is no JAAS subject available.

- a. To create a `CredentialConfig` object without using the JAAS subject, use this line of code:

```
CredentialConfig cred = samlFactory.newCredentialConfig ();
```

There is no initial value provided for this `CredentialConfig` object, so you must use setter methods to populate the `CredentialConfig` object.

- b. To populate the SAML `NameIdentifier` or `NameID`, use the following line of code:

```
cred.setRequesterNameID("any name");
```

The value of the parameter passed to the `setRequesterNameID()` method is used as the principal name in the SAML token. The name appears in the assertion as the `NameIdentifier` in a SAML Version 1.1 token, or `NameId` in the SAML Version 2.0 token. For example, if the value of the parameter passed to the `setRequesterNameID()` method is `Alice`, the following assertion is generated in a SAML Version 1.1 token:

```
<saml:NameIdentifier>Alice</saml:NameIdentifier>
```

The following assertion is generated in a SAML Version 2.0 token:

```
<saml2:NameID>Alice</saml2:NameID>
```

- c. To include SAML attributes in the `<AttributeStatement>` portion of an assertion, use this code:

```

SAMLAttribute samlAttribute = new SAMLAttribute("email" /* Name*/, new String[] {"joe@websphere"})
/*Attribute Values*/, null, "IBM WebSphere namespace" /* namespace*/, "email" /* format*/, "joe" /*friendly name */);
ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
al.add(samlAttribute)
sattribute = new SAMLAttribute("Membership", new String[] {"Super users", "Gold membership"}, null, null /* format*/, null, null );
al.add(samlAttribute );
cred.setSAMLAttributes(al);

```

This sample code generates the following <Attribute> assertions:

```

<saml:Attribute AttributeName="email" NameFormat="email" AttributeNamespace="IBM WebSphere namespace">
<saml:AttributeValue>joe@websphere</saml:AttributeValue>
</saml:Attribute>
<saml:Attribute AttributeName="Membership">
<saml:AttributeValue>Super users</saml:AttributeValue><saml:AttributeValue>Gold membership</saml:AttributeValue>
</saml:Attribute>

```

5. Generate a SAML sender-vouches token using this line of code:

```

SAMLToken samlToken = samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);

```

This method requires the Java security permission `wssapi.SAMLTokenFactory.newSAMLToken`.

Complete code samples using lines of code from the previous steps are included in the Example section.

Example

Use this sample code to create a SAML version 1.1 sender-vouches token from the subject:

```

SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSam1V11Token11)
RequesterConfig reqData = samlFactory.newSenderVouchesTokenGenerateConfig();
ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig("WebSphere Server");
Subject subject = com.ibm.websphere.security.auth.WSSubject.getRunAsSubject();
SAMLToken samlToken = samlFactory.newSAMLToken(subject, reqData, samlIssuerCfg);

```

Use this sample code to create a SAML version 1.1 sender-vouches token without using the subject:

```

SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSam1V11Token11);
RequesterConfig reqData = samlFactory.newSenderVouchesTokenGenerateConfig();
reqData.setAuthenticationMethod("Password"); //Authentication method for Assertion
ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig(Self issuer);
CredentialConfig cred = samlFactory.newCredentialConfig ();
cred.setRequesterNameID("Alice"); // SAML NameIdentifier
//SAML attributes:
SAMLAttribute attribute = new SAMLAttribute
("email" /* Name*/, new String[] {"joe@websphere"})
/*Attribute Values in String*/,null
/*Attribute Values in XML */, "WebSphere" /* Namespace*/, "email" /* format*/, "joe" /*Friendly_name */);
ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
al.add(attribute);
attribute = new SAMLAttribute("Membership", new String[] {"Super users", "My team"}, null, null, null, null );
al.add(attribute);
cred.setSAMLAttributes(al);
SAMLToken samlToken = samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);

```

Propagation of SAML tokens using the API:

The SAML propagation function is useful for applications that interact across multiple servers. The propagation feature communicates token information from the originating server downstream to other servers.

You can propagate SAML tokens using administrative commands, or programmatically using the SAML application programming interface (API). Propagation through administrative commands is discussed in the topics Propagating SAML tokens and SAML token propagation methods.

Programmatic propagation of SAML tokens is achieved through a combination of explicit programming and use of the Web Services Security runtime environment. For example, you can extract the SAMLToken from the `org.apache.axis2.jaxws.BindingProvider` object. The token is then used for outbound calls. In this

example, since WebSphere security is not required, programmatically propagating the SAML token allows you to exploit SAML security at the application level. Furthermore, the SAML token can be communicated downstream using any protocol.

Use the following sample code to extract the SAMLToken on the client side after the first request is completed.

Create a Dispatch object and invoke the request:

```
javax.xml.ws.Dispatch dispatch = ...;
dispatch.invoke();
```

Obtain a response context and extract the SAMLToken:

```
Map<String, Object> responseContext = dispatch.getResponseContext();
SAMLToken samlToken =
    (SAMLToken ) responseContext.get(com.ibm.wsspi.wssecurity.saml.config.SamlConstants.
    SAMLTOKEN_OUT_MESSAGECONTEXT);
```

The following sample code shows how to reuse a SAMLToken for subsequent web services requests.

The web services client program creates a dispatch instance to invoke a service:

```
javax.xml.ws.Dispatch dispatch = ...;
```

The web services client then uses this code to pass a SAMLToken to the Web Services Security handler:

```
Map<String, Object> requestContext = dispatch.getRequestContext();
requestContext.put(com.ibm.wsspi.wssecurity.saml.config.SamlConstants.
    SAMLTOKEN_IN_MESSAGECONTEXT, samlToken);
```

The web services provider (receiver) can use the following code to extract a SAMLToken from an incoming web services request.

Extract a SAMLToken from the requestContext:

```
Subject subject = (Subject) context.get(com.ibm.wsspi.wssecurity.core.Constants.WSSECURITY_TOKEN_WSSSUBJECT);
SAMLToken samlToken = null;
try
{
    samlToken = (SAMLToken) AccessController.doPrivileged(
        new java.security.PrivilegedExceptionAction() {
            public Object run() throws
                java.lang.Exception
            {
                final java.util.Iterator authIterator =
                    subject.getPrivateCredentials(SAMLToken.class)
                    .iterator();
                if ( authIterator.hasNext() ) {
                    final SAMLToken token = (SAMLToken)
                        authIterator.next();

                    return token;
                }
                return null;
            }
        });
} catch (Exception ex) {
    // Error handling
```

Extract the SAML attributes:

```
List<SAMLAttribute> allAttributes;
allAttributes = ((SAMLToken) samlToken).getSAMLAttributes();
```

The web services client runtime environment can cache the SAML token. On subsequent client requests within the application, the security runtime environment retrieves the SAML token from the cache for use with the target.

Web services client token cache for SAML:

When a SAML token is initially requested, the web services runtime environment automatically caches the SAMLToken. As a result of this automatic client token caching function, subsequent web services requests can use the SAMLToken from the previous request.

The web services client token cache for SAML enables web services clients to reuse SAML tokens when accessing business services. Reusing valid SAML tokens reduces traffic to the Security Token Service (STS) and also reduces the performance impact of sending WS-Trust request messages. There are several requirements for a token to be considered valid and therefore available for caching and reuse.

In order for a SAML token to be reused, the expiration time of the token must be equivalent to, or greater than, the current time. A cache cushion is added to the current time when comparing the token expiration time with the current time so that the token does not expire immediately after it is sent.

In addition, a token is valid only if it is sent again to the same business service. The SAML function in WebSphere Application Server does not verify the AudienceRestriction condition for the SAML token. Therefore, a practical way to ensure that the SAML token is reused for the right audience is to reuse the token only for the same web service that originally used the token. If an assertion contains the OneTimeUse assertion, the SAML token is not cached.

To take advantage of the SAMLToken cache, the application and SAMLToken must meet the following requirements:

- The SAMLToken must have a relatively long expiration time, with at least 5 minutes remaining in the token lifetime after the first request is completed. The WS-Security runtime environment validates the cached SAMLToken expiration time against a predefined cache cushion. The cached token is valid only if the remaining token lifetime is greater than the cushion value. The default cushion value is 5 minutes. This value can be configured using the custom property, cacheCushion. To override the default cache cushion, edit the CallbackHandler custom property for the SAMLToken generator. Add the cacheCushion property and set the cache cushion value in milliseconds. If the cached SAMLToken lifetime is within the cache cushion limit, a new SAMLToken is requested. For example, you can change the cache cushion to 3 minutes or 180000 milliseconds.

Custom property name	Value
cacheCushion	180000

- The SAML token cannot contain the OneTimeUse assertion.
- If the SAML token is encrypted, make sure that the STS communicates the token expiration time outside the encrypted token, and that the SAML token does not include the OneTimeUse assertion.

When you do not want to reuse the same SAMLToken for subsequent requests, you can disable the client side SAMLToken cache with the cacheToken custom property. To disable the client side SAMLToken cache, modify the custom property in the CallbackHandler for the SAMLToken generator. Add the cacheToken property and set the value to false.

Custom property name	Value
cacheToken	false

Securing web services applications using the WSS APIs at the message level

Standards and profiles address how to provide protection for messages that are exchanged in a web service environment. Web Services Security is a message-level standard that is based on securing SOAP messages through XML digital signature, confidentiality through XML encryption, and credential propagation through security tokens.

Before you begin

To secure web services, you must consider a broad set of security requirements, including authentication, authorization, privacy, trust, integrity, confidentiality, secure communications channels, delegation, and auditing across a spectrum of application and business topologies. One of the key requirements for the security model in today's business environment is the ability to interoperate between formerly incompatible security technologies in heterogeneous environments. The complete Web Services Security protocol stack and technology roadmap is described in the web services roadmap.

About this task

The Organization for the Advancement of Structured Information Standards (OASIS) Web Services Security: SOAP Message Security Version 1.1 specification is the basic messaging transport for all web services. SOAP 1.2 adds extensions to the existing SOAP 1.1 extensions so that you can build secure web services. Attachments can be added to SOAP messages by using Message Transmission Optimization Mechanism (MTOM) and XML-binary Optimized Packaging (XOP) instead of the SOAP with Attachments (SWA) profile.

The OASIS Web Services Security (WS-Security) Version 1.1 specification is the building block that is used in conjunction with other web service and application-specific protocols to accommodate a wide variety of security models. Web Services Security for WebSphere Application Server is based on specific standards that are included in the OASIS Web Services Security Version 1.1 specification and profiles.

The Version 1.1 specification defines additional facilities for protecting the integrity and confidentiality of a message. The Version 1.1 specification also provides the mechanisms for associating security-related claims with the message. The Web Services Security Version 1.1 standards that are supported by WebSphere Application Server include the signature confirmation, encrypted header elements, the Username Token Profile and the X.509 Token Profile. The Username Token Profile and the X.509 Token Profile have been updated as Version 1.1 profiles. For the X.509 Certificate Token Profile, one new type of security token reference is the Thumbprint reference, which is specified in the binding.

XML Schema, Part 1 and Part 2 are specifications that explain how schemas are organized in XML documents. The two WS-Security Version 1.0 schemas have been updated to the Version 1.1 specifications plus a new Version 1.1 schema has been added. Note that the Version 1.1 schema does not replace the Version 1.0 schema but instead builds upon it by defining an additional set of capabilities within a Version 1.1 namespace.

You can use the following methods to configure Web Services Security and to define policy types to secure the SOAP messages:

- **Use the administrative console to configure policy sets.**

This method uses the bootstrap policy that is defined in the policy set. You can use policy sets, or assertions about how services are defined, to simplify your security configuration for web services. You can use the administrative console to create, modify, and delete custom policy sets. A set of default policy sets are available.

For example, you can define the bootstrap policy in the policy set to secure the Web Services Trust (WS-Trust) SOAP messages.

You can also use the administrative console to perform policy set management tasks and to secure web services using encryption, signing information, and security tokens.

The following steps high-level steps describe how to configure WebSphere Application Server to use WS-Security and to secure the SOAP messages using the administrative console. The generator and consumer tasks that are discussed in the following steps use WS-Security Versions 1.0 and 1.1.

- Create and configure the application policy sets or the system policy sets for trust service.
- Define the policy types to be used to secure the SOAP messages when creating and configuring the policy sets.

- Configure the policy set binding. Select either the symmetric or asymmetric binding assertion to describe the token type and the algorithm to be used for message protection.
- Assemble your Web Services Security-enabled application by using an assembly tool.
- **Use the Web Services Security APIs (WSS API) to configure the SOAP message context (only for the client)**

WebSphere Application Server uses a new API programming model. In addition to the existing JAX-RPC programming model, a new programming model, Java API for XML Web Services (JAX-WS), has been added. The JAX-WS programming standard aligns with the document-centric messaging model and replaces the remote procedure call programming model defined by the Java API for XML-based RPC (JAX-RPC) specification.

For example, an application could create system policy sets and then use the WebSphere Application Server WSS API to acquire the security context token for programmatic API-based Web Services Secure Conversation (WS-SecureConversation).

You can also use the administrative console to perform the encryption, signing, and token configuration tasks that the WSS APIs perform to secure web services.

The following high-level steps describe how to configure WebSphere Application Server to use WS-Security and to secure the SOAP messages using the WSS APIs. The generator and consumer tasks that are discussed in the following steps use WS-Security Versions 1.0 and 1.1.

- Use the WSSSignature API to configure the signing information for the request generator (client side) binding.

Different message parts can be specified in the message protection for a request on the generator side. The default required parts are BODY, ADDRESSING_HEADERS and TIMESTAMP.

The WSSSignature API also specifies the different algorithm methods to be used with the signature for message protection. The default signature method is RSA_SHA1. The default canonicalization method is EXC_C14N.

- Use the WSSSignPart API if you want to change the digest method and the transform method.

The default signed parts are WSSSignature.BODY, WSSSignature.ADDRESSING_HEADERS and WSSSignature.TIMESTAMP.

The WSSSignPart API also specifies the different algorithm methods to be used if you added or changed the signed parts. The default digest method is SHA1. The default transform method is TRANSFORM_EXC_C14N. For example, use the WSSSignPart API if you want to generate the signature for the SOAP message using the SHA256 digest method instead of the default value of SHA1.

- Use the WSSEncryption API to configure the encryption information on the request generator side.

The encryption information on the generator side is used for encrypting an outgoing SOAP message for the request generator (client side) bindings. The default targets of encryption are BODY_CONTENT and SIGNATURE.

The WSSEncryption API also specifies the different algorithm methods to be used to protect message confidentiality. The default data encryption method is AES128. The default key encryption method is KW_RSA_OAEP.

- Use the WSSEncryptPart API if you want to set the transform method only.

For example, if you want to change the data encryption method from the default value of AES128 to TRIPLE_DES.

No algorithm methods are required for encrypted parts.

- Use the WSS API to configure the token on the generator side.

The requirements for the security token depend on the token type. The JAAS Login Module and the JAAS CallbackHandler are responsible for creating the security token on the generator side. Different stand-alone tokens can be sent in request and response. The default token is the X509Token. The other token that can be used for signing is the DerivedKeyToken, which is used only with Web Services Secure Conversation (WS-SecureConversation).

- Use the WSSVerification API to verify the signature for the response consumer (client side) binding.

Different message parts can be specified in the message protection for a response on the consumer side. The required targets for verification are BODY, ADDRESSING_HEADERS and TIMESTAMP.

The WSSVerification API also specifies the different algorithm methods to be used for verifying the signature and for message protection. The default signature method is RSA_SHA1. The default canonicalization method is EXC_C14N.

- Use the WSSVerifyPart API to change the digest method and the transform method. The required verify parts are WSSVerification.BODY, WSSVerification.ADDRESSING_HEADERS and WSSVerification.TIMESTAMP.

The WSSVerifyPart API also specifies the different algorithm methods to be used if you added or changed the verification parts. The default digest method is SHA1. The default transform method is TRANSFORM_EXC_C14N.

- Use the WSSDecryption API to configure the decryption information for the response consumer (client side) binding.

The decryption information on the consumer side is used for decrypting an incoming SOAP message. The targets of decryption are BODY_CONTENT and SIGNATURE. The default key encryption method is KW_RSA_OAEP.

No algorithm methods are required for decryption.

- Use the WSSDecryptPart API if you want to set the transform method only.

For example, if you want to change the data encryption method from the default value of AES128 to TRIPLE_DES.

No algorithm methods are required for decrypted parts.

- Use the WSS API to configure the token on the consumer side.

The requirements for the security token depend on the token type. The JAAS Login Module and the JAAS CallbackHandler are responsible for validating (authenticating) the security token on the consumer side. Different stand-alone tokens can be sent in request or response.

The WSS API adds the information for the candidate token that is used for decryption. The default token is X509Token.

- **Use the wsadmin administrative scripting tool to configure policy sets.**

This method allows you to create, manage, and delete policy sets from the command-line or to create scripts to automate your tasks. You can use the wsadmin tool and the PolicySetManagement command group to manage default policy sets, create custom policy sets, configure policies, and manage attachments and bindings. For more information, use the policy set scripting topics in the information center.

To secure web services with WebSphere Application Server, you must configure the generator and the consumer security constraints. You must specify several different configurations. Although there is no specific sequence to specify these different configurations, some configurations reference other configurations. For example, decryption configurations reference encryption configurations.

Results

After completing these high-level steps for WebSphere Application Server, you have secured web services by configuring policy sets and by using the WSS API to configure encryption and decryption, the signature and signature verification information, and the consumer and generator tokens.

Securing messages at the request generator using WSS APIs:

You can secure SOAP messages by configuring signing information, encryption, and generator tokens to protect message integrity, confidentiality, and authenticity, respectively. This request (client-side) generator configuration defines the Web Services Security requirements for the outgoing SOAP message request.

Before you begin

To secure web services with WebSphere Application Server, you must configure the generator and the consumer security constraints. Therefore, in addition to securing messages at the request generator level, you must also secure messages at the response consumer level.

About this task

The request (client-side) generator configuration requirements involve generating a SOAP message request that uses a digital signature, incorporates encryption, and attaches security tokens.

To secure web service applications, you must specify several different configurations. Although there is no specific sequence to specify these different configurations, some configurations reference other configurations. For example, decryption configurations reference encryption configurations.

You can use the following interfaces to configure Web Services Security and to define policy types to secure the SOAP messages:

- Use the administrative console to configure policy sets.
- Use the Web Services Security APIs (WSS API) to configure the SOAP message context (only for the client)

The following high-level steps use the WSS APIs:

Procedure

- Configure generator signing to protect message integrity.
- Configure encryption to protect message confidentiality.
- Attach generator tokens to protect message authenticity.
- Propagate self-issued SAML bearer tokens using WSS APIs.
- Propagate self-issued SAML sender-vouches tokens with message protection using WSS APIs.
- Propagate self-issued SAML sender-vouches tokens with transport protection using WSS APIs.
- “Sending self-issued SAML holder-of-key tokens with symmetric key using WSS APIs” on page 1392.
- “Sending self-issued SAML holder-of-key tokens with asymmetric key using WSS APIs” on page 1394.

Results

After completing these procedures, you have secured messages at the request generator level.

What to do next

Next, if not already configured, secure messages with signature verification, decryption, and consumer tokens at the response consumer (client-side) level.

Configuring encryption to protect message confidentiality using the WSS APIs:

You can configure encryption information for the client-side request generator (sender) bindings. Encryption information is used to specify how the generators (senders) encrypt outgoing SOAP messages. To configure encryption, specify which message parts to encrypt and specify which algorithm methods and security tokens are to be used for encryption.

Before you begin

Confidentiality refers to encryption while integrity refers to digital signing. Confidentiality reduces the risk of someone understanding the message flowing across the Internet. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the correct target. Prior to

configuring encryption, familiarize yourself with XML encryption.

About this task

For encryption, you must specify the following:

- Which parts of the message are to be encrypted.
- Which encryption algorithms to specify.

To configure encryption and encrypted parts on the client side, use the `WSSEncryption` and `WSSEncryptPart` APIs, or configure policy sets using the administrative console.

WebSphere Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment.

WebSphere Application Server uses encryption information for the default generator to encrypt parts of the SOAP message. The `WSSEncryption` API configures the following required parts as encrypted parts.

Table 123. Required encrypted parts. Use encrypted parts to increase the confidentiality of SOAP messages.

Encryption parts	Description
Keywords	Keywords are used to add the encrypted parts to the SOAP message.
XPath expression	An XPath expression is used to add the encrypted parts to the SOAP message.
<code>WSSEncryptPart</code> object	This object adds the encrypted parts to the SOAP message.
<code>WSSSignature</code> object	This object adds the signature component as an encrypted part.
Header	This part adds the header in the SOAP header, specified by QName, as an encryption part.
Security token object	This object adds the security token as an encryption part.

Web Services Security API (WSS API) supports symmetric encryption, by using a shared key, only when Web Services Secure Conversation (WS-SecureConversation) is used.

The WSS APIs allow the use of either keywords or an XPath expression to specify the parts of the message that are to be encrypted. WebSphere Application Server supports the use of the following keywords:

Table 124. Supported encryption keywords. Use keywords to specify encrypted parts.

Keyword	References
<code>BODY_CONTENT</code>	The keyword for the contents of the SOAP message body as an encryption target.
<code>SIGNATURE</code>	The keyword for the signature component as an encryption target.

If configuring using the WSS APIs, the `WSSEncryption` and `WSSEncryptPart` APIs complete these high-level steps:

Procedure

1. Use the `WSSEncryption` API to configure encryption. The `WSSEncryption` API performs these tasks by default:
 - a. Generates the callback handler.
 - b. Generates the generator security token object.
 - c. Adds the security token reference type.
 - d. Adds the signature component.
 - e. Adds the `WSSEncryptPart` object.
 - f. Adds the parts to be encrypted. Adds the default parts as targets of encryption by using keywords and XPath expressions.
 - g. Adds the header in the SOAP message, specified by QName.

- h. Sets the default data encryption method.
 - i. Specifies whether the key is to be encrypted using a Boolean value.
 - j. Sets the default key encryption method.
 - k. Selects a part reference.
 - l. Sets the MTOM optimization Boolean value.
2. Use the `WSSEncryptPart` API to configure encrypted parts or add a transform method. The `WSSEncryptPart` API performs these tasks by default:
 - a. Sets the encrypted parts specified by using keywords or an XPath expression.
 - b. Sets the encrypted parts specified by an XPath expression.
 - c. Sets the signature component object, `WSSSignature`.
 - d. Sets the header in the SOAP message, specified by `QName`.
 - e. Sets the generator security token.
 - f. Adds the transform method, if needed.
 3. Change from the default values for algorithm or message parts, as needed. For example: you could change one or more of the following items:
 - Change the data encryption algorithm from the default value of AES 128.
 - Change the key encryption algorithm from the default value of `KW_RSA_OAEP`.
 - Specify to not encrypt the key (`false`).
 - Change the security token type from default of X.509 token.
 - Change the security token reference type from the default value of `SecurityToken.REF_STR`.
 - Only use `BODY_CONTENT` as an encryption part and not use `SIGNATURE` also.
 - Turn MTOM optimization on (`true`).

Results

The encryption information is configured for the generator binding.

Example

The following is an example of the `WSSEncryption` API:

```
WSSFactory factory = WSSFactory.getInstance();
WSSGenerationContext gencont = factory.newWSSGenerationContext();

X509GenerateCallbackHandler callbackhandler = generateCallbackHandler();
SecurityToken token = factory.newSecurityToken(X509Token.class, callbackhandler);
WSSEncryption enc = factory.newWSSEncryption(token);

gencont.add(enc);
```

What to do next

You must configure similar decryption information for the client-side response consumer (receiver) bindings, if you have not already configured the information.

Next, review the `WSSEncryption` API process.

Encrypting the SOAP message using the `WSSEncryption` API:

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure the client for request encryption on the generator side, use the `WSSEncryption` API to encrypt the SOAP message. The `WSSEncryption` API specifies which request SOAP message parts to encrypt when configuring the client.

Before you begin

You can use the WSS API or use policy sets on the administrative console to enable encryption and generator security tokens in the SOAP message. To secure SOAP messages, use the WSS APIs to complete the following encryption tasks, as needed:

- Configure encryption and choose the encryption methods using the WSSecurity API.
- Configure the encrypted parts, as needed, using the WSSecurityPart API.

About this task

The encryption information on the generator side is used for encrypting an outgoing SOAP message for the request generator (client side) bindings. The client generator configuration must match the configuration for the provider consumer.

Confidentiality settings require that confidentiality constraints be applied to generated messages. These constraints include specifying which message parts within the generated message must be encrypted, and which message parts to attach encrypted Nonce and timestamp elements to.

The following encryption parts can be configured:

Table 125. Encryption parts. Use the encryption parts to enable encryption in messages.

Encryption parts	Description
part	Adds the WSSecurityPart object as a target of the encryption part.
keyword	Adds the encryption parts using keywords. WebSphere Application Server supports the following keywords: <ul style="list-style-type: none"> • BODY_CONTENT • SIGNATURE
xpath	Adds the encryption part using an XPath expression.
signature	Adds the WSSignature component as a target of the encrypted part.
header	Adds the SOAP header, specified by QName, as a target of the encrypted part.
securityToken	Adds the SecurityToken object as a target of the encrypted part.

For encryption, certain default behaviors occur. The simplest way to use the WSSecurity API is to use the default behavior (see the example code).

WSEncryption provides defaults for the key encryption algorithm, the data encryption algorithm, the security token reference method, and the encryption parts such as the SOAP body content and the signature. The encryption default behaviors include:

Table 126. Encryption decisions. Use encryption default behavior to secure the message body content and signature.

Encryption decisions	Default behavior
Which SOAP message parts to encrypt using keywords	Sets the encryption parts that you can add using keywords. The default encryption parts are the BODY_CONTENT and SIGNATURE. WebSphere Application Server supports using these keywords: <ul style="list-style-type: none"> WSEncryption.BODY_CONTENT WSEncryption.SIGNATURE
Which data encryption method to choose (algorithm)	Sets the data encryption method. Both data and key encryption methods can be specified. The default data encryption algorithm method is AES 128. WebSphere Application Server supports these data encryption methods: <ul style="list-style-type: none"> WSEncryption.AES128: http://www.w3.org/2001/04/xmlenc#aes128-cbc WSEncryption.AES192: http://www.w3.org/2001/04/xmlenc#aes192-cbc WSEncryption.AES256: http://www.w3.org/2001/04/xmlenc#aes256-cbc WSEncryption.TRIPLE_DES: http://www.w3.org.2001/04/xmlenc#tripleDES-cbc
Whether to encrypt the key (isEncrypt)	Specifies whether to encrypt the key. The values are true or false. The default value is to encrypt the key (true).
Which key encryption method to choose (algorithm)	Sets the key encryption method. Both data and key encryption methods can be specified. The default key encryption algorithm method is key wrap RSA OAEP. WebSphere Application Server supports these key encryption methods: <ul style="list-style-type: none"> WSEncryption.KW_AES128: http://www.w3.org/2001/04/xmlenc#kw-aes128 WSEncryption.KW_AES192: http://www.w3.org/2001/04/xmlenc#kw-aes192 WSEncryption.KW_AES256: http://www.w3.org/2001/04/xmlenc#kw-aes256 WSEncryption.KW_RSA_OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p WSEncryption.KW_RSA15: http://www.w3.org/2001/04/xmlenc#rsa-1_5 WSEncryption.KW_TRIPLE_DES: http://www.w3.org/2001/04/xmlenc#kw-tripleDES
Which security token to specify (securityToken)	Sets the SecurityToken. The default security token type is the X509Token. WebSphere Application Server provides the following pre-configured consumer token types: <ul style="list-style-type: none"> Derived key token X.509 tokens
Which token reference to use (refType)	Sets the type of the security token reference. The default token reference is SecurityToken.REF_KEYID. WebSphere Application Server supports the following token reference types: <ul style="list-style-type: none"> SecurityToken.REF_KEYID SecurityToken.REF_STR SecurityToken.REF_EMBEDDED SecurityToken.REF_THUMBPRINT
Whether to use MTOM (mtomOptimize)	Sets Message Transmission Optimization Mechanism (MTOM) optimization for the encrypted part.

Procedure

1. To encrypt the SOAP message using the WSEncryption API, first ensure that the application server is installed.
2. The WSS API process for encryption performs these process steps:
 - a. Uses WSSFactory.getInstance() to get the WSS API implementation instance
 - b. Creates the WSSGenerationContext instance from the WSSFactory instance.
 - c. Creates the SecurityToken from WSSFactory used for encryption.
 - d. Creates WSEncryption from the WSSFactory instance using the SecurityToken. The default behavior of WSEncryption is to encrypt the body content and the signature.
 - e. Adds a new part to be encrypted in WSEncryption if the existing part is not appropriate. After addEncryptPart(), addEncryptHeader(), or addEncryptPartByXPath() is called, the default part is cleared.
 - f. Calls the encryptKey(false) if the key is not to be encrypted.
 - g. Sets the data encryption method if the default method is not appropriate.

- h. Sets the key encryption method if the default method is not appropriate.
- i. Sets the token reference if the default token reference is not appropriate.
- j. Adds WSSEncryption to WSSConsumingContext.
- k. Calls WSSGenerationContext.process() with the SOAPMessageContext.

Results

If there is an error condition during encryption, a WSSException is provided. If successful, the API calls the WSSGenerationContext.process(), the WS-Security header is generated, and the SOAP message is now secured using Web Services Security.

Example

The following example provides sample code using methods that are defined in WSSEncryption:

```
// Get the message context
Object msgcontext = getMessageContext();

// Generate the WSSFactory instance (step: a)
WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSGenerationContext instance (step: b)
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate the callback handler
X509GenerateCallbackHandler callbackHandler = new
    X509GenerateCallbackHandler(
        "",
        "enc-sender.jceks",
        "jceks",
        "storepass".toCharArray(),
        "bob",
        null,
        "CN=Bob, O=IBM, C=US",
        null);

// Generate the security token used for encryption (step: c)
SecurityToken token = factory.newSecurityToken(X509Token.class, callbackHandler);

// Generate WSSEncryption instance (step: d)
WSSEncryption enc = factory.newWSSEncryption(token);

// Set the part to be encrypted (step: e)
// DEFAULT: WSSEncryption.BODY_CONTENT and WSSEncryption.SIGNATURE

// Set the part specified by the keyword (step: e)
enc.addEncryptPart(WSSEncryption.BODY_CONTENT);

// Set the part in the SOAP Header specified by QName (step: e)
enc.addEncryptHeader(new QName("http://www.w3.org/2005/08/addressing",
    "MessageID"));

// Set the part specified by WSSSignature (step: e)
SecurityToken sigToken = getSecurityToken();
WSSSignature sig = factory.newWSSSignature(sigToken);
enc.addEncryptPart(sig);

// Set the part specified by SecurityToken (step: e)
UNTGenerateCallbackHandler untCallbackHandler =
    new UNTGenerateCallbackHandler("Chris", "sirhC");
SecurityToken unt = factory.newSecurityToken(UsernameToken.class,
    untCallbackHandler);
enc.addEncryptPart(unt, false);

// sSt the part specified by XPath expression (step: e)
StringBuffer sb = new StringBuffer();
sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
    and local-name()='Envelope']");
sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
    and local-name()='Body']");
sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
    and local-name()='Ping']");
sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
    and local-name()='Text']");
enc.addEncryptPartByXPath(sb.toString());

// Set whether the key is encrypted (step: f)
// DEFAULT: true
enc.encryptKey(true);

// Set the data encryption method (step: g)
```

```

// DEFAULT: WSEncryption.AES128
enc.setEncryptionMethod(WSEncryption.TRIPLE_DES);

// Set the key encryption method (step: h)
// DEFAULT: WSEncryption.KW_RSA_OAEP
enc.setEncryptionMethod(WSEncryption.KW_RSA15);

// Set the token reference (step: i)
// DEFAULT: SecurityToken.REF_KEYID
enc.setTokenReference(SecurityToken.REF_STR);

// Add the WSEncryption to the WSSGenerationContext (step: j)
gencont.add(enc);

// Process the WS-Security header (step: k)
gencont.process(msgcontext);

```

Note: The X509GenerationCallbackHandler does not need the key password because the public key is used for encryption. You do not need a password to obtain the public key from the Java keystore.

What to do next

If you have not previously specified which encryption methods to choose, use the WSS API or configure the policy sets using the administrative console to choose the data and key encryption algorithm methods.

Choosing encryption methods for generator bindings:

To configure the client for request encryption for the generator binding, you must specify which encryption methods to use when the client encrypts the SOAP messages.

Before you begin

Prior to completing these steps, read the XML encryption information to become familiar with encrypting and decrypting SOAP messages.

To specify which algorithm methods are to be used when the client encrypts the SOAP messages, complete the following tasks:

- Use the WSEncryption API to configure the data encryption algorithm and the key encryption algorithm methods.
- Use the WSSEncryptPart API to configure a transform algorithm method, if needed. The default is no transform algorithm.

About this task

Some of the encryption-related definitions are based on the XML-Encryption specification. The following information defines some data encryption-related terms:

Data encryption method algorithm

Data encryption algorithms specify the algorithm uniform resource identifier (URI) of the data encryption method. This algorithm encrypts and decrypts data in fixed size, multiple octet blocks.

By default, the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files.

For the AES256-cbc and the AES192-cbc algorithms, you must download the unrestricted Java™ Cryptography Extension (JCE) policy files from the following website: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

Key encryption method algorithm

Key encryption algorithms specify the algorithm uniform resource identifier (URI) of the method to encrypt the key that is used to encrypt data. The algorithm represents public key encryption algorithms that are specified for encrypting and decrypting keys.

By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property.

The property name is: `com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod`. The property value is one of the following URIs of the digest method:

- <http://www.w3.org/2001/04/xmlenc#sha256>
- <http://www.w3.org/2001/04/xmlenc#sha512>

By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the `OAEPParams`. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPParams`. The property value is the base 64-encoded value of the octet string.

Important: You can set these digest method and `OAEPParams` properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.

For the KW-AES256 and the KW-AES192 key encryption algorithms, you must download the unrestricted JCE policy files from the following website: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

Important: Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

Table 127. Encryption usage types. The encryption usage types describe encryption methods.

Usage types	Description
Data encryption	Specifies the algorithm URI that is used for both encrypting and decrypting data. Encrypts and decrypts data in fixed size, multiple octet blocks.
Key encryption	Specifies the algorithm URI that is used for encrypting and decrypting the encryption key.

Data encryption

WebSphere Application Server supports the following pre-configured data encryption algorithms:

Table 128. Data encryption algorithms. These pre-configuring encryption algorithms are supported by WebSphere Application Server.

Data encryption name	Algorithm URI
<code>WSSSEncryption.AES128</code> (the default value)	A URI of data encryption algorithm, AES 128: http://www.w3.org/2001/04/xmlenc#aes128-cbc
<code>WSSSEncryption.AES192</code>	A URI of data encryption algorithm, AES 192: http://www.w3.org/2001/04/xmlenc#aes192-cbc
<code>WSSSEncryption.AES256</code>	A URI of data encryption algorithm, AES 256: http://www.w3.org/2001/04/xmlenc#aes256-cbc
<code>WSSSEncryption.TRIPLE_DES</code>	A URI of data encryption algorithm, 3DES: http://www.w3.org/2001/04/xmlenc#tripledes-cbc

Key encryption

WebSphere Application Server supports the following pre-configured key encryption algorithms:

Table 129. Key encryption algorithms. These pre-configured encryption algorithms are supported by WebSphere Application Server.

Key encryption name	Algorithm URI
<code>WSSSEncryption.KW_AES128</code>	A URI of key encryption algorithm, key wrap AES 128: http://www.w3.org/2001/04/xmlenc#kw-aes128

Table 129. Key encryption algorithms (continued). These pre-configured encryption algorithms are supported by WebSphere Application Server.

Key encryption name	Algorithm URI
WSSSEncryption.KW_AES192	A URI of key encryption algorithm, key wrap AES 192: http://www.w3.org/2001/04/xmlenc#kw-aes192 Restriction: Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).
WSSSEncryption.KW_AES256	A URI of key encryption algorithm, key wrap AES 256: http://www.w3.org/2001/04/xmlenc#kw-aes256
WSSSEncryption.KW_RSA_OAEP (the default value)	A URI of key encryption algorithm, key wrap RSA OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p
WSSSEncryption.KW_RSA15	A URI of key encryption algorithm, key wrap RSA 1.5: http://www.w3.org/2001/04/xmlenc#rsa-1_5
WSSSEncryption.KW_TRIPLE_DES	http://www.w3.org/2001/04/xmlenc#kw-tripledes

To configure the encryption and encrypted part algorithm methods, use the WSSSEncryption API, or configure policy sets using the administrative console.

Note: Policy sets do not support symmetric key encryption. If you are using the WSS API for symmetric key encryption, you will not be able to interoperate with web services endpoints that use policy sets.

The WSS API process completes the following high-level steps to specify which encryption methods to use when configuring the client for request encryption:

Procedure

1. Using the WSSSEncryption API, adds the required data encryption algorithm. The data encryption algorithm is used for encrypting or decrypting parts of a SOAP message. Data encryption algorithms specify the algorithm uniform resource identifier (URI) of the data encryption method.

The client generator configuration must match the configuration for the provider consumer.

The default data encryption algorithm is AES 128. The data encryption name is AES128, and the URI of the data encryption algorithm, is <http://www.w3.org/2001/04/xmlenc#aes128-cbc>. WebSphere Application Server supports the following pre-configured data encryption algorithms:

- AES 128: <http://www.w3.org/2001/04/xmlenc#aes128-cbc>
The AES 128 algorithm is the default data algorithm method.
- AES 192: <http://www.w3.org/2001/04/xmlenc#aes192-cbc>
Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).
To use this AES 192-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.
- AES 256: <http://www.w3.org/2001/04/xmlenc#aes256-cbc>
To use this AES 256-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.
- TRIPLEDES: <http://www.w3.org/2001/04/xmlenc#tripledes-cbc>

2. As needed, changes the WSSSEncryption API method to specify another data encryption algorithm. For example, you might add the following code to change from the default AES 128 algorithm to the Triple DES algorithm:

```
// Default data encryption algorithm: AES128
WSSSEncryption enc = factory.newWSSSEncryption(x509t);
enc.setEncryptionMethod(EncryptionMethod.TRIPLEDES_CBC);
gencont.add(enc);
```

3. Using the WSSSEncryption API, adds the required key encryption algorithm. The key encryption algorithm is used for encrypting the key that is used for encrypting the message parts within the SOAP

message. If the encryption key, which is the key that is used for encrypting the message parts, is not encrypted, then the decryption API selects false to match the encryption key.

The client generator configuration must match the configuration for the provider consumer.

The default key encryption algorithm value is key wrap RSA OAP. The key encryption name is KW_RSA_OAEP, and the URI of the key encryption algorithm is <http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p>. WebSphere Application Server supports the following pre-configured key encryption algorithms:

- KW AES128: <http://www.w3.org/2001/04/xmlenc#kw-aes128>
- KW AES192: <http://www.w3.org/2001/04/xmlenc#kw-aes192>

To use this key wrap AES 192 algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP). KW AES 256: <http://www.w3.org/2001/04/xmlenc#kw-aes256>

To use this key wrap AES 256-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

- KW RSA OAEP: <http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p>.

The KW RSA OAEP algorithm is the default key algorithm method.

When running with Software Development Kit (SDK) Version 1.4, the list of supported key transport algorithms does not include this algorithm. This algorithm appears in the list of supported key transport algorithms when running with SDK Version 1.5. See more information at <http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p>

- KW RSA15: http://www.w3.org/2001/04/xmlenc#rsa-1_5
- KW TRIPLE DES: <http://www.w3.org/2001/04/xmlenc#kw-tripledes>

Note: For Web Services Secure Conversation, the WSSEncryption API might specify addition key-related information, such as the:

- algorithmName
- keyLength

Results

If there is an error condition, a WSSException is provided. If successful, the API calls the WSSGenerationContext.process(), the WS-Security header is generated, and the SOAP message is now secured using Web Services Security.

Example

The following example provides sample WSS API code using WSSEncryption.setEncryptionMethod() and WSSEncryption.setKeyEncryptionMethod().

```
// Get the message context
Object msgcontext = getMessageContext();

// Generate the WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate callback handler
X509GenerateCallbackHandler callbackHandler = new
    X509GenerateCallbackHandler(
        "",
        "enc-sender.jceks",
        "jceks",
        "storepass".toCharArray(),
        "bob",
```

```

        null,
        "CN=Bob, O=IBM, C=US",
        null);

// Generate the security token used for encryption
SecurityToken token = factory.newSecurityToken(X509Token.class , callbackHandler);

// Generate WSEncryption instance
WSEncryption enc = factory.newWSEncryption(token);

// Set the data encryption method
// DEFAULT: WSEncryption.AES128
enc.setEncryptionMethod(WSEncryption.TRIPLE_DES);

// Set the key encryption method
// DEFAULT: WSEncryption.KW_RSA_OAEP
enc.setEncryptionMethod(WSEncryption.KW_RSA15);

// Add the WSEncryption to the WSSGenerationContext
gencont.add(enc);

// Generate the WS-Security header
gencont.process(msgcontext);

```

What to do next

Next, if you want to add a transform algorithm, review the `WSEncryptPart` API process task.

Encryption methods:

For request generator binding settings, the encryption methods include specifying the data and key encryption algorithms to use to encrypt the SOAP message. The WSS API for encryption (`WSEncryption`) specifies the algorithm name and the matching algorithm uniform resource identifier (URI) for the data and key encryption methods. If the data and key encryption algorithms are specified, only elements that are encrypted with those algorithms are accepted.

Data encryption algorithms

The data encryption algorithm is used to encrypt parts of the SOAP message, including the body and the signature. Data encryption algorithms specify the algorithm uniform resource identifier (URI) for each type of data encryption algorithms.

The following pre-configured data encryption algorithms are supported:

Table 130. Data encryption algorithms. The algorithms are used to encrypt SOAP messages.

Data encryption algorithm name	Algorithm URI
<code>WSEncryption.AES128</code> (the default value)	A URI of data encryption algorithm, AES 128: http://www.w3.org/2001/04/xmlenc#aes128-cbc
<code>WSEncryption.AES192</code>	A URI of data encryption algorithm, AES 192: http://www.w3.org/2001/04/xmlenc#aes192-cbc
<code>WSEncryption.AES256</code>	A URI of data encryption algorithm, AES 256: http://www.w3.org/2001/04/xmlenc#aes256-cbc
<code>WSEncryption.TRIPLE_DES</code>	A URI of data encryption algorithm, TRIPLE DES: http://www.w3.org/2001/04/xmlenc#tripleDES-cbc

By default, the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files.

Important: Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

For the AES256-cbc and the AES192-CBC algorithms, you must download the unrestricted Java™ Cryptography Extension (JCE) policy files from the following website: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

The data encryption algorithm configured for encryption for the generator side must match the data encryption algorithm that is configured for decryption for the consumer side.

Key encryption algorithms

This algorithm is used to encrypt and decrypt keys. This key information is used to specify the configuration that is needed to generate the key for digital signature and encryption. The signing information and encryption information configurations can share the key information. The key information on the consumer side is used for specifying the information about the key that is used for validating the digital signature in the received message or for decrypting the encrypted parts of the message. The request generator is configured for the client.

Note: Policy sets do not support symmetric key encryption. If you are using the WSS API for symmetric key encryption, you will not be able to interoperate with web services endpoints using the policy sets.

Key encryption algorithms specify the algorithm uniform resource identifier (URI) of the key encryption method. The following pre-configured key encryption algorithms are supported:

Table 131. Supported pre-configured key encryption algorithms. The algorithms are used to encrypt and decrypt keys.

WSS API	URI
WSSEncryption.KW_AES128	A URI of key encryption algorithm, key wrap AES 128: http://www.w3.org/2001/04/xmlenc#kw-aes128
WSSEncryption.KW_AES192	A URI of key encryption algorithm, key wrap AES 192: http://www.w3.org/2001/04/xmlenc#kw-aes192 Restriction: Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).
WSSEncryption.KW_AES256	A URI of key encryption algorithm, key wrap AES 256: http://www.w3.org/2001/04/xmlenc#kw-aes256
WSSEncryption.KW_RSA_OAEP (the default value)	A URI of key encryption algorithm, key wrap RSA OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p
WSSEncryption.KW_RSA15	A URI of key encryption algorithm, key wrap RSA 1.5: http://www.w3.org/2001/04/xmlenc#rsa-1_5
WSSEncryption.KW_TRIPLE_DES	A URI of key encryption algorithm, key wrap TRIPLE DES: http://www.w3.org/2001/04/xmlenc#kw-tripledes

For Secure Conversation, additional key-related information must be specified, such as:

- algorithmName
- keyLength

By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property. The property name is:

`com.ibm.wsspi.wssecurity.enc.rsaoep.DigestMethod`. The property value is one of the following URIs of the digest method:

- <http://www.w3.org/2001/04/xmlenc#sha256>
- <http://www.w3.org/2001/04/xmlenc#sha512>

By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoep.OAEPparams`. The property value is the base 64-encoded value of the octet string.

Important: You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.

For the KW-AES256 and the KW-AES192 key encryption algorithms, you must download the unrestricted JCE policy files from the following website: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

The key encryption algorithm for the generator must match the key decryption algorithm that is configured for the consumer.

This example provides sample code for encryption to use the Triple DES for the data encryption method and to use RSA1.5 for the key encryption method:

```
// get the message context
Object msgcontext = getMessageContext();

// generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

// generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// generate callback handler
X509GenerateCallbackHandler callbackHandler = new X509GenerateCallbackHandler(
    "",
    "enc-sender.jceks",
    "jceks",
    "storepass".toCharArray(),
    "bob",
    null,
    "CN=Bob, O=IBM, C=US",
    null);

// generate the security token used to the encryption
SecurityToken token = factory.newSecurityToken(X509Token.class,
    callbackHandler);

// generate WSEncryption instance to encrypt the SOAP body content
WSEncryption enc = factory.newWSEncryption(token);
enc.addEncryptPart(WSEncryption.BODY_CONTENT);

// set the data encryption method
// DEFAULT: WSEncryption.AES128
enc.setEncryptionMethod(WSEncryption.TRIPLE_DES);

// set the key encryption method
// DEFAULT: WSEncryption.KW_RSA_OAEP
enc.setEncryptionMethod(WSEncryption.KW_RSA15);

// add the WSEncryption to the WSSGenerationContext
gencont.add(enc);

// generate the WS-Security header
gencont.process(msgcontext);
```

Adding encrypted parts using the WSEncryptPart API:

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure encrypted parts for the request generator (client side) bindings, use the WSEncryptPart API to define and add to the listing of elements in the encrypted part. WSEncryptPart is an interface that is part of the `com.ibm.websphere.wssecurity.wssapi.encryption` package.

Before you begin

You can use the WSS APIs or configure policy sets using the administrative console to enable the encrypted parts. To secure SOAP messages, use the WSS APIs to complete the following encryption tasks, as needed:

- Configure encryption and choose the encryption methods using the WSEncryption API.
- Configure the encrypted parts using the WSEncryptpart API, as needed.

About this task

Confidentiality settings require that confidentiality constraints be applied to generated messages. These constraints include specifying which message parts within the generated message must be encrypted, and which message parts to attach encrypted elements to. The encryption information on the generator side is used for encrypting an outgoing SOAP message. The request generator is configured for the client.

The WSEncryptPart API specifies information related to encrypted parts and sets the encrypted parts that have been added for message confidentiality protection. Use the WSEncryptPart to set the transform method and to specify the part to which the transform method is to be applied. Sets the transform method only if using SOAP with Attachments. The WSEncryptPart is usually not needed except, in some case for tasks such as setting the transform method.

The encrypted parts and related information displayed in the following table are used to protect the confidentiality of messages.

Table 132. Encrypted parts. Use encrypted parts to secure messages.

Encrypted parts	Description
part	Adds the WSEncryptPart object as a target of the encryption part.
keyword	Adds the encrypted parts using keywords. The default encryption parts that you can add using keywords are the BODY_CONTENT and SIGNATURE. WebSphere Application Server supports using these keywords: <ul style="list-style-type: none">• BODY_CONTENT• SIGNATURE
xpath	Adds the encrypted part by using an XPath expression.
signature	Adds the WSSSignature component as a target of the encrypted part. WSSSignature is applicable only if the SOAP message contains a signature element.
header	Adds the SOAP header, specified by QName, as a target of the encrypted part.
securityToken	Adds the SecurityToken object as a target of the encrypted part.

For encrypted parts, certain default behaviors occur. The simplest way to use the WSEncryptPart API is to use the default behavior. The WSEncryptPart API provides defaults for specifying the transform algorithm, setting objects as targets, specifying the encrypted parts, such as: the SOAP body content and the signature.

The encryption default behaviors include:

Table 133. Encrypted part decisions. Several encrypted message parts are set by default.

Encrypted part decisions	Default behavior
Which SOAP message parts to encrypt using keywords	Specifies which keywords to use for the encrypted parts. WebSphere Application Server sets the following SOAP message parts by default for encryption: <ul style="list-style-type: none">• WSEncryption.BODY_CONTENT• WSEncryption.SIGNATURE
Which transform method to add	WebSphere Application Server does not specify any transform method by default. Specify a transform method only if using SOAP with Attachments.

Procedure

1. To encrypt the SOAP message parts using the WSEncryptPart API, first ensure that the application server is installed.
2. The WSS API process using WSEncryptPart follows these process steps:
 - a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
 - b. Creates the WSSGenerationContext instance from the WSSFactory instance.
 - c. Creates the SecurityToken from WSSFactory to configure the encryption.
 - d. Creates WSEncryption from the WSSFactory instance using SecurityToken.
 - e. Creates WSEncryptPart from WSSFactory.

- f. Adds the parts to be encrypted and to be applied with the transform in WSSEncryptPart. WebSphere Application Server sets these encrypted parts by default for WSSEncryptPart: the BODY_CONTENT and SIGNATURE. After you add other encrypted parts, the default values are no longer valid. For example, if you call addEncryptPart(securityToken, false), only the security token is encrypted, and not the signature and body content. So if you want to encrypt the security token, the signature, and the body content, you must call addEncryptPart(securityToken, false), addEncryptPart(WSSEncryption.SIGNATURE), and addEncryptPart(WSSEncryption.BODY_CONTENT).
- g. Sets the transform method.
- h. Adds WSSEncryptPart to WSSEncryption.
- i. Adds WSSEncryption to WSSGenerationContext.
- j. Calls WSSGenerationContext.process() with the SOAPMessageContext.

Results

If there is an error condition during encryption of the message parts, a WSSException is provided. If successful, the API calls the WSSGenerationContext.process(), the WS-Security header is generated, and the SOAP message is now secured using Web Services Security.

What to do next

After enabling encrypted parts for the request generator (client side) binding, you must specify the same parts to be decrypted for the response consumer (client side) bindings. Next, to configure decryption and decrypted parts, use the WSS APIs or configure policy sets using the administrative console.

Configuring generator signing information to protect message integrity using the WSS APIs:

You can configure the signing information to protect message integrity for the request (client side) generator binding. Signing information includes the signature and the signed parts. To keep the integrity of the message, digital signatures are typically applied.

Before you begin

In addition to using a digital signature and configuring the signing information, the following tasks should also be performed:

- Verify the signing information.
- Incorporate encryption.
- Attach security tokens.

About this task

Integrity refers to digital signature while confidentiality refers to encryption. Integrity is provided by applying a digital signature to a SOAP message. To configure the signing information to protect message integrity, you must first digitally sign and then verify the signature for the SOAP messages. Integrity decreases the risk of data modification when you transmit data across a network.

Also, message integrity is provided by digitally signing the body, time stamp, and WS-Addressing headers using the signature algorithm methods. The WSS APIs specify which algorithm is to be used to sign the certificate. The signature algorithms specify the Uniform Resource Identifiers (URI) of the signature method. WebSphere Application Server supports several pre-configured request signing algorithm methods.

You can use the following interfaces to configure Web Services Security and to protect SOAP message integrity:

- Use the administrative console to configure policy sets for the signing information.
- Use the Web Services Security APIs (WSS API) to configure the SOAP message context (only for the client).

Perform the following signing tasks, using the WSS APIs, to configure the signing information and to protect message integrity for the generator binding.

Procedure

- Configure the signing information using the WSSSignature API. Configure the signing information for the generator binding using the WSSSignature API. Signing information is used to sign parts of a message including the SOAP body, the time stamp, and the WS-Addressing headers. Both signing and encryption can be applied to the same message parts, such as the SOAP body.
- Add or change signed parts using the WSSSignPart API.
- Configure the client for request signing methods using the WSSSignature or WSSSignPart APIs. To configure the client for request signing, choose the signing methods. The request signing methods include the signature, the canonicalization, the digest, and the transform methods. Use the WSSSignature API to configure the signature and canonicalization methods. Use the WSSSignPart API to configure the digest and transform methods.

Results

The WSS APIs also specify the security token for the generator (client) binding and set the type of token reference to protect message authenticity. By completing the steps in these tasks, you have configured generator signing to protect the integrity of the SOAP message.

What to do next

Next, verify the consumer signing information by using the WSS APIs or by configuring policy sets using the administrative console.

Configuring signing information using the WSS APIs:

You can configure the signing information for the client-side request generator (sender) bindings. Signing information is used to sign and validate parts of a message including the SOAP body, the timestamp information, and the Username token. To configure the client for request signing, specify which message parts to digitally sign when configuring the client.

Before you begin

WebSphere Application Server uses XML digital signature with existing algorithms such as RSA, HMAC, and SHA1. XML signature defines many methods for describing key information and enables the definition of a new method. Prior to completing these steps, familiarize yourself with XML digital signature for signing and verifying digital signatures for digital content.

About this task

By including XML signature in SOAP messages, the following issues are realized: message integrity and authentication. *Integrity* refers to digital signature whereas confidentiality refers to encryption. Integrity decreases the risk of data modification while the data is transmitted across the Internet. WebSphere Application Server uses the signing information for the default generator to sign parts of the message, such as the body, time stamp, and Username token.

For the signing information, you must specify the following:

- Which parts of the message are to be signed.
- The key information that is referenced by the key information for the signing keys.

- The signing algorithms.

WebSphere Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment.

The WSSSignature API configures the following parts as signature parts:

Table 134. Pre-configured signature parts. Use the signing information to validate parts of a message.

Part	Description
Security token object	This object authenticates the client. If this option is specified, then the message is signed. You can digitally sign the message using a security token if a login configuration authentication method is selected.
WSSTimestamp object	This object adds a time stamp to a message. The time stamp determines if the message is valid based on the time that the message is sent and then received.
WSSSignature Part object	This object adds the signature parts to a message.
SOAP header and the QName as a target	This signature part adds the header, specified by QName, as a verification part.

The WSS APIs allow the use of keywords or an XPath expression to specify which parts of the message are to be signed. WebSphere Application Server supports the use of the following keywords:

Table 135. Supported signature keywords. Key information is used to specify which parts of a message are signed.

Keyword	References
ADDRESSING_HEADERS	The Web Services Addressing (WS-Addressing) headers.
BODY	The SOAP message body. The body is the user data portion of the message.
TIMESTAMP	The creation and expiration timestamp information.

The Web Services Security API (WSS API) are used to configure the signing information for the request generator (client side) section of the bindings file. To configure the signing information on the client side, use the WSS APIs or configure policy sets for signing using the administrative console.

If configuring using the WSS APIs, the WSSSignature and WSSSignPart APIs complete the following steps to specify which message parts to digitally sign when configuring the client for request generator signing:

Procedure

1. The WSSSignature API adds the required parts of the SOAP message to digitally sign. Either a keyword or an XPath expression can be used to specify the required encryption parts.
2. The WSSSignature API sets the signature method algorithm. The default signature method is RSA_SHA1. WebSphere Application Server supports the following pre-configured algorithms:

- RSA SHA1: <http://www.w3.org/2000/09/xmldsig#rsa-sha1>
- HMAC SHA1 <http://www.w3.org/2000/09/xmldsig#hmac-sha1>

WebSphere Application Server does not support the following algorithm for DSA-SHA1: <http://www.w3.org/2000/09/xmldsig#dsa-sha1>. You cannot use the DSA-SHA1 algorithm if you want to be compliant with the Basic Security Profile (BSP).

Any ds:SignatureMethod/@Algorithm element in a signature is based on a symmetric key and must have a value of RSA-SHA1 or HMAC-SHA1.

The algorithm that is specified for the request generator configuration must match the algorithm that is specified for the request consumer configuration.

3. The WSSSignature API sets the canonicalization method. The default signature method is EXC_C14N. WebSphere Application Server supports the following pre-configured algorithms:
 - The URI of the exclusive canonicalization algorithm, EXC_C14N: <http://www.w3.org/2001/10/xml-exc-c14n#>.
 - The URI of the inclusive canonicalization algorithm, C14N: <http://www.w3.org/2001/10/xml-c14n#>.

The canonicalization algorithm that you specify for the generator must match the algorithm for the consumer.

4. The WSSSignature API adds a security token. The API adds information about the security token that is to be used for the signature, such as:
 - The class for security token.
 - The callback handler
 - The name of the JAAS login configuration.
5. The WSSSignature API sets the type of security token and sets the type of token reference. WebSphere Application Server supports the following pre-configured token references:

- SecurityToken.REF_STR
Represents the security token reference as a token reference type.
- SecurityToken.REF_KEYID
Represents the key identifier reference as a token reference type.
- SecurityToken.REF_EMBEDDED
Represents the embedded reference as a token reference type.
- SecurityToken.REF_THUMBPRINT
Represents the thumbprint reference as a token reference type.

6. If SecurityToken.REF_KEYID is set as the type of token reference, the WSSSignature API sets the key information signature type and configures the key information that is referenced by the key information references. WebSphere Application Server supports the following:

- Specifying that the KeyInfo element is not signed.
- Specifying that the entire <KeyInfo> element is signed.
- Specifying that the child elements <Keyinfochildelements> of the <KeyInfo> element are signed.

If you do not specify one of the previous signature types, WebSphere Application Server specifies that the entire <KeyInfo> element is signed, by default.

If you select Keyinfo or Keyinfochildelements and you select <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform> as the transform algorithm in a subsequent step, WebSphere Application Server also signs the referenced token.

The key information signature type for the generator must match the signature type for the consumer.

7. The WSSSignature API specifies whether to require signature confirmation. The OASIS Web Services Security (WS-Security) Version 1.1 specification defines the use of signature confirmation. If you are using WS-Security Version 1.0, this function is not available.

The signature confirmation value is stored in order to validate the signature confirmation with it after the receiving message is returned. This method is called if the response message is expected to attach the signature confirmation into the SOAP message.

8. The WSSSignPart API specifies the part reference. The part reference specifies which parts of the message to digitally sign.

The part reference refers to the message part that is digitally signed. The part attribute refers to the name of the <Integrity> element when the <PartReference> element is specified for the signature. You can specify multiple <PartReference> elements within the <SigningInfo> element. The <PartReference> element has two child elements when it is specified for the signature verification: <DigestTransform> and <Transform>.

9. The WSSSignPart API specifies the digest method algorithm. The digest method algorithm specified within the <DigestMethod> element is used in the <SigningInfo> element.

WebSphere Application Server supports the following pre-configured digest algorithms:

- <http://www.w3.org/2000/09/xmldsig#sha1>
- <http://www.w3.org/2001/04/xmlenc#sha256>
- <http://www.w3.org/2001/04/xmlenc#sha512>

10. The WSSSignPart API specifies the transform algorithm. The transform algorithm is that is specified within the <Transform> element and specifies the transform algorithm for the signature. WebSphere Application Server supports the following pre-configured transform algorithms:

- <http://www.w3.org/2001/10/xml-exc-c14n#>
- <http://www.w3.org/TR/1999/REC-xpath-19991116>
Do not use this transform algorithm if you want to be compliant with the Basic Security Profile (BSP). Instead use <http://www.w3.org/2002/06/xmldsig-filter2> to ensure compliance.
- <http://www.w3.org/2002/06/xmldsig-filter2>
- <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform>
- <http://www.w3.org/2002/07/decrypt#XML>
- <http://www.w3.org/2000/09/xmldsig#enveloped-signature>

The transform algorithm that you select for the generator must match the transform algorithm that you select for the consumer.

Important: If both of the following conditions are true, WebSphere Application Server signs the referenced token:

- You previously selected the Keyinfo or the Keyinfochildelements option
- You select <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform> as the transform algorithm.

11. If you configure the client and server signing information correctly, but receive a Soap body not signed error when running the client, you might need to configure the actor. Configure policy sets using the administrative console to configure the same actor strings for the web service on the server, which processes the request and sends the response back.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The actor might be different when you have web services acting as a gateway to other web services. However, in all other cases, make sure that the actor information matches on the client and server. When web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, web services do not process the message from a client. Instead, these web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

Results

After the WSSSignature and WSSSignPart APIs complete these steps, the signing information is configured for the generator sections of the bindings files.

Example

The following example shows WSS API sample code to configure the signature, to generate the callback handler, and to specify the X.509 token type as the security token:

```
WSSFactory factory = WSSFactory.getInstance();
// Instantiate a generation context
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate the callback handler and specify the X.509 token
X509GenerateCallbackHandler callbackhandler = generateCallbackHandler();
SecurityToken token = factory.newSecurityToken(X509Token.class,
                                             callbackhandler);

// Set the signature information
WSSSignature sig = factory.newWSSSignature(token);
// Add the header using QName
sig.addSignHeader(new QName("http://www.w3.org/2005/08/addressing", "To"));
sig.addSignHeader(new QName("http://www.w3.org/2005/08/addressing", "MessageID"));
```

```
sig.addSignHeader(new QName("http://www.w3.org/2005/08/addressing", "Action"));
// Apply the signature
gencont.add(sig);

// Secure the message
gencont.process(msgctx);
```

What to do next

You must configure similar signature information for the client-side request consumer (receiver) bindings by completing the following verification tasks:

- Verify the signature
- Choose the signature algorithm methods.
- Change or add signed parts, as needed.

If signature verification is already configured, configure the encryption and decryption information, or configure the consumer and generator tokens.

Configuring signing information using the WSSSignature API:

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure the signing information for the generator binding sections for the client-side request, use the WSSSignature API. The WSSSignature API is part of the `com.ibm.websphere.wssecurity.wssapi.signature` package.

Before you begin

Either you can use the WSS API or you can configure the policy sets by using the administrative console to enable the signing information. To secure SOAP messages, you must complete the following signing tasks:

- Configure the signing information.
- Choose the signing methods.
- Add or change signed parts, as needed.

About this task

WebSphere Application Server uses the signing information for the default generator to sign parts of the message, and uses XML digital signature with existing algorithms such as RSA-SHA1 and HMAC-SHA1.

XML signature defines many methods for describing key information and enables the definition of a new method. XML canonicalization (C14N) is often needed when you use XML signature. Information can be represented in various ways within serialized XML documents. The C14N process is used to canonicalize XML information. Select an appropriate C14N algorithm because the information that is canonicalized depends on this algorithm.

The signing information specifies the integrity constraints that are applied to generated messages. The constraints include specifying which message parts within the generated message must be digitally signed, and the message parts to attach digitally signed Nonce and timestamp elements to. The following signature and related signature part information are configured:

Table 136. Signature parts information. Use the signature parts to secure messages.

signature parts	Description
keyword	Adds a signature part using keywords. Use the following keywords for the signature parts: <ul style="list-style-type: none"> • ADDRESSING_HEADERS • BODY • TIMESTAMP <p>The WS-Addressing headers are not encrypted but can be signed.</p>
xpath	Adds a signature part by using an XPath expression.
part	Adds a WSSSignPart object as a target of the signature part.
timestamp	Adds a WSSTimestamp object as a target of the signature part. When specified, the timestamp information also specifies when the message is generated and when it expires.
header	Adds the header, specified by QName, as a target of the signature part.
securityToken	Adds a SecurityToken object as a target of the signature part.

For signing information, certain default behaviors occur. The simplest way to use the WSSSignature API is to use the default behavior (see the example code). The default values are defined by the WSS API for the signing method, the canonicalization method, the security token references, and the signature parts.

Table 137. Signature default behaviors. Several signature behaviors are configured by default.

Signature decisions	Default behavior
Which keywords to use	Sets the keywords. WebSphere Application Server supports the following keywords by default: <ul style="list-style-type: none"> • ADDRESSING_HEADERS • BODY • TIMESTAMP
Which signature method to use	Sets the signature algorithm. The default signature method is RSA SHA1. WebSphere Application Server supports the following pre-configured signature methods: <ul style="list-style-type: none"> • WSSSignature.RSA_SHA1: http://www.w3.org/2000/09/xmldsig#rsa-sha1 • WSSSignature.HMAC_SHA1: http://www.w3.org/2000/09/xmldsig#hmac-sha1 <p>The DSA-SHA1 digital signature method (http://www.w3.org/2000/09/xmldsig#dsa-sha1) is not supported.</p>
Which canonicalization method to use	Sets the canonicalization algorithm. The default canonicalization method is EXC C14N. WebSphere Application Server supports the following pre-configured canonicalization methods: <ul style="list-style-type: none"> • WSSSignature.EXC_C14N; http://www.w3.org/2001/10/xml-exc-c14n# • WSSSignature.C14N: http://www.w3.org/2001/10/xml-c14n#
Whether signature confirmation is required	Sets whether to require signature confirmation. The default value is false . Signature confirmation is defined in the OASIS Web Services Security Version 1.1 specification. If required, the value of your signature confirmation is stored in order to use it to validate the signature confirmation after receiving back the message that generated the signature confirmation in the response message. This method is for the requestor side.
Which security token to use	Sets the SecurityToken. The token type specifies which type of token to use for signing and validating messages. The X.509 token is the default token type. <p>WebSphere Application Server provides the following pre-configured consumer token types:</p> <ul style="list-style-type: none"> • Derived Key Token • X509 tokens <p>You can also create custom token types, as needed.</p>
Which token reference to set	Sets the refType. SecurityToken.REF_STR is the default value for the type of token reference. WebSphere Application Server supports these pre-configured token references types: <ul style="list-style-type: none"> • SecurityToken.REF_STR • SecurityToken.REF_KEYID • SecurityToken.REF_EMBEDDED • SecurityToken.REF_THUMBPRINT

If WSSSignature.requireSignatureConfirmation() is called, then the WSSSignature API expects that the response message will include the signature confirmation.

Procedure

1. To configure the signing information in a SOAP message by using the WSS API, first ensure that the application server is installed.
2. Use the WSSSignature API to sign the message parts and specify the algorithms in a SOAP message. The WSS API process for signature follows these process steps:
 - a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
 - b. Creates the WSSGenerationContext instance from the WSSFactory instance. WSSGenerationContext must be called in a JAX-WS client application.
 - c. Creates the SecurityToken from WSSFactory to configure the key for signing.
 - d. Creates WSSSignature from the WSSFactory instance using the SecurityToken. The default behavior of WSSSignature is to sign these signature parts: BODY, ADDRESSING_HEADERS, and TIMESTAMP.
 - e. Adds the part to be signed, if the default part is not appropriate. If the digest method or transform method is changed, creates WSSSignPart and add it to WSSSignature.
 - f. Creates WSSSignaturePart to WSSSignature. Calls the requiredSignatureConfirmation() method, if the signature confirmation is to be applied.
 - g. Sets the canonicalization method, if the default is not appropriate.
 - h. Sets the signature method, if the default is not appropriate.
 - i. Sets the token reference, if the default is not appropriate.
 - j. Adds WSSSignature to WSSGenerationContext.
 - k. Calls WSSGenerationContext.process() with the SOAPMessageContext.

Results

You have completed the steps to configure the signature for the generator section of the bindings. If there is an error condition when signing the message parts, a WSSException is provided. If successful, the WSSGenerationContext.process() is called, and Web Services Security is applied to the SOAP message.

Example

The following example provides sample code that uses methods that are defined in the WSSignature API.

```
// Get the message context
Object msgcontext = getMessageContext();

// Generate the com.ibm.websphere.wssecurity.wssapi.WSSFactory instance (step: a)
WSSFactory factory = com.ibm.websphere.wssecurity.wssapi.WSSFactory.getInstance();

// Generate the WSSGenerationContext instance (step: b)
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate the callback handler
X509GenerateCallbackHandler callbackHandler = new
    X509GenerateCallbackHandler(
        "",
        "dsig-sender.ks",
        "jks",
        "client".toCharArray(),
        "soaprequester",
        "client".toCharArray(),
        "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP", null);

// Generate the security token to be used for the signature (step: c)
SecurityToken token = factory.newSecurityToken(X509Token.class,
    callbackHandler);

// Generate the WSSSignature instance (step: d)
WSSSignature sig = factory.newWSSSignature(token);

// Set the part to be signed (step: e)
// DEFAULT: WSSSignature.BODY, WSSSignature.ADDRESSING_HEADERS,
// and WSSSignature.TIMESTAMP.

// Set the part in the SOAP Header specified by QName (step: e)
sig.addSignHeader(new
    QName("http://www.w3.org/2005/08/addressing",
```

```

        "MessageID"));
// Set the part specified by the keyword (step: e)
sig.addSignPart(WSSSignature.BODY);
// Set the part specified by SecurityToken (step: e)
UNTGenerateCallbackHandler untCallbackHandler = new
UNTGenerateCallbackHandler("Chris", "sirhC");
SecurityToken unt = factory.newSecurityToken(UsernameToken.class,
untCallbackHandler);
sig.addSignPart(unt);
// Set the part specified by WSSSignPart (step: e)
WSSSignPart sigPart = factory.newWSSSignPart();
sigPart.setSignPart(WSSSignature.TIMESTAMP);
sigPart.setDigestMethod(WSSSignPart.SHA256);
sig.addSignPart(sigPart);
// Set the part specified by WSSTimestamp (step: e)
WSSTimestamp timestamp = factory.newWSSTimestamp();
sig.addSignPart(timestamp);
// Set the part specified by XPath expression (step: e)
StringBuffer sb = new StringBuffer();
sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
and local-name()='Envelope']");
sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
and local-name()='Body']");
sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
and local-name()='Ping']");
sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
and local-name()='Text']");
sig.addSignPartByXPath(sb.toString());
// Set to apply the signature confirmation (step: f)
sig.requireSignatureConfirmation();
// Set the canonicalization method (step: g)
// DEFAULT: WSSSignature.EXC_C14N
sig.setCanonicalizationMethod(WSSSignature.C14N);
// Set the signature method (step: h)
// DEFAULT: WSSSignature.RSA_SHA1
sig.setSignatureMethod(WSSSignature.HMAC_SHA1);
// Set the token reference (step: i)
// DEFAULT: SecurityToken.REF_STR
sig.setTokenReference(SecurityToken.REF_KEYID);
// Add the WSSSignature to WSSGenerationContext (step: j)
gencont.add(sig);
// Generate the WS-Security header (step: k)
gencont.process(msgctx);

```

Note: The X509GenerationCallbackHandler needs the key password because the private key is used for signing.

What to do next

Next, chose the algorithm methods if you want a method that is different from the default values. If the algorithm methods do not need to be changed, next use the WSSVerification API to verify the signature and specify the algorithm methods in the consumer section of the binding. Note that the WSSVerification API is only supported on the response consumer (client side).

Adding signed parts using the WSSSignPart API:

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure parts to be signed for the request generator (client side) bindings, use the WSSSignPart API to protect the integrity of messages and to configure the digest and transform algorithm methods. The WSSSignPart API is part of the com.ibm.websphere.wssecurity.wssapi.signature package.

Before you begin

Either you can use the WSS API or you can configure the policy sets by using the administrative console to configure the signing information. To secure SOAP messages using the signing information, you must complete one of the following tasks:

- Configure the signature information
- Configure signed parts, as needed.

About this task

WebSphere Application Server uses the signing information for the default generator to sign parts of the message, and uses XML digital signature with existing digest and transform algorithms (for example, SHA1 or TRANSFORM_EXC_C14N).

The signing information specifies the integrity constraints that are applied to generated messages. The signed parts are used to protect the integrity of messages. You can specify the signed parts to add for message integrity protection.

The following table shows the required signed parts when the digital signature security constraint (integrity) is defined:

Table 138. Signed parts information. Use the signed parts to secure messages.

Signed parts	Description
keyword	Adds signed parts using keywords. WebSphere Application Server supports the following keywords for signed parts: <ul style="list-style-type: none">• BODY• ADDRESSING_HEADERS• TIMESTAMP The WS-Addressing headers are not encrypted but can be signed.
xpath	Adds the required signed parts by using an XPath expression.
header	Adds the header, specified by QName, as a signed part.
timestamp	Adds a WSSTimestamp object as a signed part. If specified, the timestamp information specifies when the message is generated and when it expires.

Different message parts can be specified in the message protection for request on the generator side. WSSSignPart allows for adding a transform algorithm, setting a digest method, setting objects as targets, specifying whether an element, and the signed parts, such as: the SOAP body, the WS-Addressing header, and timestamp information.

For signing information, certain default behaviors occur. The simplest way to use the WSSSignPart API is to use the default behavior (see the example code). The signed parts default behaviors include:

Table 139. Default behavior of signed parts. Several signed part characteristics are configured by default.

Signature decisions	Default behavior
Which SOAP message parts to sign	WebSphere Application Server supports the following SOAP message parts to be signed and used for message protection: <ul style="list-style-type: none">• WSSSignature.BODY• WSSSignature.ADDRESSING_HEADERS• WSSSignature.TIMESTAMP
Which digest method to use	Sets the digest algorithm method. The digest method algorithm that is specified within the <DigestMethod> element is used in the <SigningInfo> element. WebSphere Application Server supports the following pre-configured digest methods: <ul style="list-style-type: none">• WSSSignPart.SHA1 (the default value): http://www.w3.org/2000/09/xmldsig#sha1• WSSSignPart.SHA256: http://www.w3.org/2001/04/xmlenc#sha256• WSSSignPart.SHA512: http://www.w3.org/2001/04/xmlenc#sha512

Table 139. Default behavior of signed parts (continued). Several signed part characteristics are configured by default.

Signature decisions	Default behavior
Which transform algorithms to use	<p>Adds the transform method. The transform algorithm is specified within the <Transform> element and specifies the transform algorithm for the signature.</p> <p>WebSphere Application Server supports the following pre-configured transform algorithms:</p> <ul style="list-style-type: none"> WSSSignPart.TRANSFORM_EXC_C14N (the default value): http://www.w3.org/2001/10/xml-exc-c14n# WSSSignPart.TRANSFORM_XPATH2_FILTER: http://www.w3.org/2002/06/xmldsig-filter2 Use this transform method to ensure compliance with the Basic Security Profile (BSP). WSSSignPart.TRANSFORM_STRT10: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform WSSSignPart.TRANSFORM_ENVELOPED_SIGNATURE: http://www.w3.org/2000/09/xmldsig#enveloped-signature

Procedure

1. To enable Web Services Security by using the WSS API (WSSSignPart), first ensure that the application server is installed.
2. Use the WSSSignPart API to sign the message parts and specify the algorithms in a SOAP message. The WSS API process for signed parts follows these process steps:
 - a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
 - b. Creates the WSSGenerationContext instance from the WSSFactory instance.
 - c. Creates the SecurityToken from WSSFactory to configure the key for signing.
 - d. Creates WSSSignature from the WSSFactory instance using the SecurityToken.
 - e. Creates WSSSignPart from the WSSFactory instance.
 - f. Sets the part to be signed and the digest method or transform method specified by step g or step h if the default is not appropriate.
 - g. Sets the digest method if the default is not appropriate.
 - h. Sets the transform method if the default is not appropriate.
 - i. Adds WSSSignPart to WSSSignature. After any WSSSignPart is set to WSSSignature, the default parts to be signed, which are specified in WSSSignature, are ignored.
 - j. Adds WSSSignature to WSSGenerationContext.
 - k. Calls WSSGenerationContext.process() with the SOAPMessageContext.

Results

You have completed the steps to configure the signed parts for the generator section of the bindings files. If there is an error condition, a WSSException is provided. If successful, the WSSGenerationContext.process() is called, and Web Services Security is applied to the SOAP message.

Example

The following example provides sample code that uses all of methods that are defined in the WSSSignPart API:

```
// Get the message context
Object msgcontext = getMessageContext();

// Generate the WSSFactory instance (step: a)
WSSFactory factory = WSSFactory.getInstance();

// Generate WSSGenerationContext instance (step: b)
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate callback handler
X509GenerateCallbackHandler callbackHandler = new
    X509GenerateCallbackHandler
    "";
```

```

        "dsig-sender.ks",
        "jks",
        "client".toCharArray(),
        "soaprequester",
        "client".toCharArray(),
        "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP", null);

// Generate the security token used to the signature (step: c)
SecurityToken token = factory.newSecurityToken(X509Token.class, callbackHandler);

// Generate WSSSignature instance (step: d)
WSSSignature sig = factory.newWSSSignature(token);

// Set the part specified by WSSSignPart (step: e)
WSSSignPart sigPart = factory.newWSSSignPart();

// Set the part specified by WSSSignPart (step: f)
sigPart.setSignPart(WSSSignature.BODY);

// Set the digest method specified by WSSSignPart (step: g)
sigPart.setDigestMethod(WSSSignPart.SHA256);

// Set the transform method specified by WSSSignPart (step: h)
sigPart.setTransformMethod(WSSSignPart.TRANSFORM_STRT10);

// Add the part specified by WSSSignPart (step: i)
sig.addSignPart(sigPart);

// Add the WSSSignature to the WSSGenerationContext (step: j)
gencont.add(sig);

// Generate the WS-Security header (step: k)
gencont.process(msgcontext);

```

Note: The X509GenerationCallbackHandler needs the key password because the private key is used for signing.

What to do next

Use the WSSVerifyPart API or configure policy sets using the administrative console to verify the signed parts on the consumer side.

Configuring request signing methods for the client:

Use the WSSSignature and WSSSignPart APIs to choose the signing methods. The request signing methods include the signature, canonicalization, digest, and transform methods.

Before you begin

First, you must have specified which parts of the message sent by the client must be digitally signed using the WSS APIs or configuring policy sets using the administrative console.

About this task

The following table describes the purpose of this information. Some of these definitions are based on the XML-Signature specification, which is located at the following website <http://www.w3.org/TR/xmlsig-core>.

Table 140. Signing methods. Use the signing methods to secure messages.

Name of method	Description
Canonicalization algorithm	Canonicalizes the <SignedInfo> element before the information is digested as part of the signature operation.
Signature algorithm	Calculates the signature value of the canonicalized <SignedInfo> element. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration.
Transform method	Transforms the parts to be signed before the information is digested as part of the signature operation.
Digest method	Calculates the digest value of the transformed parts. The algorithm selected for the client request sender configuration must match the algorithms selected in the server request receiver configuration.

You can use the WSS APIs or configure policy sets using the administrative console to configure the signing algorithm methods. If using the WSS APIs, use the WSSSignature and WSSSignPart APIs to specify which message parts to digitally sign when configuring the client for request signing.

The WSSSignature and WSSSignPart APIs complete the following steps to configure the signature and signed part algorithm methods:

Procedure

1. For the generator binding, the WSSSignature API specifies the signature method. WebSphere Application Server supports the following pre-configured signature methods:
 - WSSSignature.RSA_SHA1 (the default value): <http://www.w3.org/2000/09/xmlldsig#rsa-sha1>
 - WSSSignature.HMAC_SHA1: <http://www.w3.org/2000/09/xmlldsig#hmac-sha1>

For the WSS APIs, WebSphere Application Server does not support the DSA-SHA1 digital signature method, <http://www.w3.org/2000/09/xmlldsig#dsa-sha1>.
2. For the generator binding, the WSSSignature API specifies the canonicalization method. WebSphere Application Server supports the following pre-configured canonicalization algorithms:
 - WSSSignature.EXC_C14N (the default value): The exclusive canonicalization algorithm, <http://www.w3.org/2001/10/xml-exc-c14n#>
 - WSSSignature.C14N: The inclusive canonicalization algorithm, <http://www.w3.org/2001/10/xml-c14n#>
3. For the generator binding, the WSSSignPart API specifies the digest method. WebSphere Application Server supports the following pre-configured digest methods:
 - WSSSignPart.SHA1 (the default value): <http://www.w3.org/2000/09/xmlldsig#sha1>
 - WSSSignPart.SHA256: <http://www.w3.org/2001/04/xmlenc#sha256>
 - WSSSignPart.SHA512: <http://www.w3.org/2001/04/xmlenc#sha512>
4. For the generator binding, the WSSSignPart API specifies the transform method. WebSphere Application Server supports the following pre-configured transform algorithms:
 - WSSSignPart.TRANSFORM_EXC_C14N (the default value): <http://www.w3.org/2001/10/xml-exc-c14n#>
 - WSSSignPart.TRANSFORM_XPATH2_FILTER: <http://www.w3.org/2002/06/xmlldsig-filter2>
 - WSSSignPart.TRANSFORM_STRT10: <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform>
 - WSSSignPart.TRANSFORM_ENVELOPED_SIGNATURE: <http://www.w3.org/2000/09/xmlldsig#enveloped-signature>

For the WSS APIs, WebSphere Application Server does not support the following transform algorithms:

 - <http://www.w3.org/TR/1999/REC-xpath-19991116>
 - <http://www.w3.org/2002/07/decrypt#XML>

Results

Using the WSS APIs, you have specified which algorithm methods are used to digitally sign a message when the client sends a message to a server.

Example

The following example is sample code for specifying the signature information, HMAC_SHA1 as signature method, C14N as a canonicalizaion method, SHA256 as a digest method, and EXC_C14N and TRANSFORM_STRT10 as the transform methods:

```
//get the message context
Object msgcontext = getMessageContext();

//generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();
```

```

//generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

//generate callback handler
X509GenerateCallbackHandler callbackHandler = new X509GenerateCallbackHandler(
    "",
    "dsig-sender.ks",
    "jks",
    "client".toCharArray(),
    "soaprequester",
    "client".toCharArray(),
    "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP",
    null);

//generate the security token used to the signature
SecurityToken token = factory.newSecurityToken(X509Token.class, callbackHandler);

//generate WSSSignature instance
WSSSignature sig = factory.newWSSSignature(token);

//set the canonicalization method
// DEFAULT: WSSSignature.EXC_C14N
sig.setCanonicalizationMethod(WSSSignature.C14N);

//set the signature method
// DEFAULT: WSSSignature.RSA_SHA1
sig.setSignatureMethod(WSSSignature.HMAC_SHA1);

//set the part specified by WSSSignPart
WSSSignPart sigPart = factory.newWSSSignPart();

//set the digest method
// DEFAULT: WSSSignPart.SHA1
sigPart.setDigestMethod(WSSSignPart.SHA256);

//add the transform method
// DEFAULT: WSSSignPart.TRANSFORM_EXC_C14N
sigPart.addTransformMethod(WSSSignPart.TRANSFORM_EXC_C14N);
sigPart.addTransformMethod(WSSSignPart.TRANSFORM_STRT10);

// add the WSSSignPart to the WSSSignature
sig.addSignPart(sigPart);

//add the WSSSignature to the WSSGenerationContext
gencont.add(sig);

//generate the WS-Security header
gencont.process(msgcontext);

```

What to do next

After you configure the client to digitally sign the message and to choose the algorithm methods, you must configure the server to verify the digital signature for request signing and to choose the algorithm methods.

Configure policy sets using the administrative console to configure the signature verification information and methods on the server.

Digital signing methods using the WSSSignature API:

You can configure the signing information for the generator binding using the WSS API. To configure the client for request signing, choose the digital signing methods. The algorithm methods include the signing and canonicalization methods.

You must configure generator signing information to protect message integrity by digitally signing SOAP messages. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network.

After you have specified which message parts to digitally sign, you must specify which method is used to digitally sign the message.

Methods

Methods that are used for the signing information include the:

Signature method

Sets the signature algorithm method.

Canonicalization method

Sets the canonicalization algorithm method.

Signature algorithms

The signature algorithms specify the algorithm that is used to sign the certificate. The signature algorithms specify the Uniform Resource Identifiers (URI) of the signature method. WebSphere Application Server supports the following pre-configured algorithms:

Table 141. Signature algorithms. The algorithms include the signing methods.

Algorithm	Description
WSSSignature.HMAC_SHA1	A URI of the signature algorithm, HMAC: http://www.w3.org/2000/09/xmlsig#hmac-sha1
WSSSignature.RSA_SHA1 (the default value)	A URI of the signature algorithm, RSA: http://www.w3.org/2000/09/xmlsig#rsa-sha1

For the WSS APIs, WebSphere Application Server does not support the DSA-SHA1 algorithm, <http://www.w3.org/2000/09/xmlsig#dsa-sha1>

The signing algorithm that is specified for the request generator configuration must match the algorithm that is specified for the request consumer configuration.

Canonicalization algorithms

The canonicalization algorithms specify the Uniform Resource Identifiers (URI) of the canonicalization method. WebSphere Application Server supports the following pre-configured algorithms:

Table 142. Signature canonicalization algorithms. The algorithms include the canonicalization methods.

Algorithm	Description
WSSSignature.EXC_C14N (the default value)	A URI of the exclusive canonicalization algorithm EXC_C14N: http://www.w3.org/2001/10/xml-exc-c14n#
WSSSignature.C14N	A URI of the inclusive canonicalization algorithm, C14N: http://www.w3.org/2001/10/xml-c14n#

The canonicalization algorithm that is specified for the request generator configuration must match the algorithm that is specified for the request consumer configuration.

The following example provides sample WSS API code that specifies the HMAC_SHA1 as a signature method and C14n as a canonicalization method:

```
//generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

//generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

//generate callback handler
X509GenerateCallbackHandler callbackHandler = new
    X509GenerateCallbackHandler(
        "",
        "dsig-sender.ks",
        "jks",
        "client".toCharArray(),
        "soaprequester",
        "client".toCharArray(),
        "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP",
        null);

//generate the security token used to the signature
SecurityToken token = factory.newSecurityToken(X509Token.class,
    callbackHandler);

//generate WSSSignature instance
```

```

WSSSignature sig = factory.newWSSSignature(token);

//set the canonicalization method
// DEFAULT: WSSSignature.EXC_C14N
sig.setCanonicalizationMethod(WSSSignature.C14N);

//set the signature method
// DEFAULT: WSSSignature.RSA_SHA1
sig.setSignatureMethod(WSSSignature.HMAC_SHA1);

//add the WSSSignature to the WSSGenerationContext
gencont.add(sig);

//generate the WS-Security header
gencont.process(msgcontext);

```

Signed parts methods using the WSSSignPart API:

You can configure the signed parts information for the generator binding using the WSS API. The algorithms include the digest and transform methods.

You can protect message integrity by configuring signed parts and key information. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network.

Methods

Methods that are used for the signed parts include the:

Digest method

Sets the digest algorithm method.

Transform algorithm

Sets the transform algorithm method.

Digest algorithms

The digest method algorithm specified within the element is used in the element. WebSphere Application Server supports the following pre-configured algorithms:

Table 143. Signed parts digest methods. The methods are used for the signed parts.

Digest method	Description
WSSSignPart.SHA1 (the default value)	A URI of the digest algorithm, SHA1: http://www.w3.org/2000/09/xmlsig#sha1
WSSSignPart.SHA256	A URI of the digest algorithm, SHA256: http://www.w3.org/2001/04/xmlenc#sha256
WSSSignPart.SHA512	A URI of the digest algorithm, SHA256: http://www.w3.org/2001/04/xmlenc#sha512

Transform algorithms

The transform method algorithm specified within the element is used in the element. WebSphere Application Server supports the following pre-configured algorithms:

Table 144. Signed parts transform methods. The methods are used for the signed parts.

Digest method	Description
WSSSignPart.TRANSFORM_ENVELOPED_SIGNATURE	A URI of the transform algorithm, enveloped signature: http://www.w3.org/2000/09/xmlsig#enveloped-signature
WSSSignPart.TRANSFORM_STRT10	A URI of the transform algorithm, STR-Transform: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
WSSSignPart.TRANSFORM_EXC_C14N (the default value)	A URI of the transform algorithm, Exc-C14N: http://www.w3.org/2001/10/xml-exc-c14n#

Table 144. Signed parts transform methods (continued). The methods are used for the signed parts.

Digest method	Description
WSSSignPart.TRANSFORM_XPATH2_FILTER	A URI of the transform algorithm, XPath2 filter: http://www.w3.org/2002/06/xmldsig-filter2

The transform algorithm is specified within the <Transform> element and specifies the transform algorithm for the signed part.

For the WSS APIs, WebSphere Application Server does not support the following transform algorithms:

- <http://www.w3.org/TR/1999/REC-xpath-19991116>
- <http://www.w3.org/2002/07/decrypt#XML>

The following example provides sample WSS API code for specifying the signature and signed parts, setting the signing key and adding the STR-Transform transform algorithm as signed parts:

```
//get the message context
Object msgcontext = getMessageContext();

//generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

//generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

//generate callback handler
X509GenerateCallbackHandler callbackHandler = new
    X509GenerateCallbackHandler(
        "",
        "dsig-sender.ks",
        "jks",
        "client".toCharArray(),
        "soaprequester",
        "client".toCharArray(),
        "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP",
        null);

//generate the security token used to the signature
SecurityToken token = factory.newSecurityToken(X509Token.class,
    callbackHandler);

//generate WSSSignature instance
WSSSignature sig = factory.newWSSSignature(token);

//set the part specified by WSSSignPart
WSSSignPart sigPart = factory.newWSSSignPart();

//set the part specified by WSSSignPart
sigPart.setSignPart(WSSSignature.BODY);

//set the digest method specified by WSSSignPart
sigPart.setDigestMethod(WSSSignPart.SHA256);

//set the transform method specified by WSSSignPart
sigPart.addTransform(WSSSignPart.TRANSFORM_STRT10);

//set the part specified by WSSSignPart
sig.addSignPart(sigPart);

//add the WSSSignature to the WSSGenerationContext
gencont.add(sig);

//generate the WS-Security header
gencont.process(msgcontext);
```

Attaching the generator token using WSS APIs to protect message authenticity:

When you specify the token generator, the information is used on the generator side to generate the security token.

Before you begin

The token processing and pluggable token architecture in the Web Services Security run time reuses the same security token interface and Java Authentication and Authorization Service (JAAS) Login Module

from the Web Services Security APIs (WSS API). The same implementation of token creation and validation can be used in both the WSS API and the WSS SPI in the Web Services Security run time.

Restriction: The `com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent` interface is not used with JAX-WS web services. If you are using JAX-RPC web services, this interface is still valid.

Note that the key name (KeyName) element is not supported in the application server because there is no KeyName policy assertion defined in the current OASIS Web Services Security draft specification.

About this task

The JAAS callback handler (CallbackHandler) and the JAAS login module (LoginModule) are responsible for creating the security token on the generator side and validating (authenticating) the security token on the consumer side.

For example, on the generator side, the Username token is created by the JAAS LoginModule and using the JAAS CallbackHandler to pass the authentication data. The JAAS LoginModule creates the Username SecurityToken object and passes it to the Web Services Security run time.

Then, on the consumer side, the Username Token XML format is passed to the JAAS LoginModule for validation or authentication and the JAAS CallbackHandler is used to pass authentication data from the Web Services Security run time to the LoginModule. After the token is authenticated, a Username SecurityToken object is created and passed it to the Web Services Security run time.

Note: WebSphere Application Server does not support a stackable login module with the WebSphere Application Server default login module implementation, meaning adding the login module before or after the WebSphere Application Server login module implementation. If you want to stack the login module implementations, you must develop the required login modules because there is no default implementation.

The `com.ibm.websphere.wssecurity.wssapi.token` package provided by WebSphere Application Server includes support for these classes:

- Security token (SecurityTokenImpl)
- Binary security token (BinarySecurityTokenImpl)

In addition, WebSphere Application Server provides the following pre-configured sub-interfaces for security tokens:

- Derived key token
- Security context token (SCT)
- Username token
- LTPA token propagation
- LTPA token
- X509PKCS7 token
- X509PKIPath token
- X509v3 token
- Kerberos v5 token

The Username token, the X.509 tokens, and the LTPA tokens are used by default for message authenticity. The derived key token and the X.509 tokens are used by default for signing and encryption.

The WSS API and WSS SPI are only supported on the client. To specify the security token type on the generator side, you can also configure policy sets using the administrative console. You can also use the WSS APIs or policy sets for matching consumer security tokens.

The default Login Module and Callback implementations are designed to be used as a pair, meaning both a generator and a consumer part. To use the default implementations, select the appropriate generator and consumer security token in a pair. For example, select `system.wss.generate.x509` in the token generator and `system.wss.consume.x509` in the token consumer when the X.509 token is required.

To configure the generator-side security token, use the appropriate pre-configured token generator interface from the WSS APIs to complete the following token configuration process steps:

Procedure

1. Generate the `wssFactory` instance.
2. Generate the `wssGenerationContext` instance.
The `WSSGenerationContext` interface stores the components for generating Web Services Security (WS-Security), such as the signing and encryption information, the security token, and the time stamp. When the `generate()` method is called, all of these components are generated.
3. Create the generator-side components, such as the `WSSSignature` and the `WSSEncryption` objects.
4. Specify a JAAS configuration by specifying the name of the JAAS login configuration. The Java Authentication and Authorization Service (JAAS) configuration specifies the name of the JAAS configuration. The JAAS configuration specifies how the token logs in on the consumer side. Do not remove the predefined system or application login configurations. However, within these configurations, you can add module class names and specify the order in which WebSphere Application Server loads each module.
5. Specify a token generator class name. The token generator class name specifies the required information to generate the `SecurityToken`. The Username token, the X.509 tokens, and the LTPA tokens are used by default for message authenticity.
6. Specify the settings for the callback handler by specifying a callback handler class name and also specifies the callback handler keys. This class name is the name of the callback handler implementation class that is used for the plug-in to the security token framework.

The callback handler implementation obtains the required security token and passes it to the token generator. The token generator inserts the security token in the Web Services Security header within the SOAP message. Also, the token generator is a plug-in point for the pluggable security token framework. Service providers can provide their own implementation, but the implementation must use the `WSSGenerationContext` interface.

WebSphere Application Server provides the following default callback handler implementations for the generator side:

`com.ibm.websphere.wssecurity.callbackhandler.PropertyCallback`

This class is a callback for handling the name-value pair in elements in the Web Services Security (WS-Security) configuration XML files.

`com.ibm.websphere.wssecurity.callbackhandler.UNTGUIPromptCallbackHandler`

This class is a callback handler for the Username token with the GUI prompt on the generator side. This instance is used to set the `WSSGenerationContext` object to generate a Username token.

`com.ibm.websphere.wssecurity.callbackhandler.UNTGenerateCallbackHandler`

This class is a callback handler for the Username token on the generator side. This instance is used to set into `WSSGenerationContext` object to attach a Username token. Use this implementation for a Java Platform, Enterprise Edition (Java EE) application client only.

`com.ibm.websphere.wssecurity.callbackhandler.X509GenerateCallbackHandler`

This class is a callback handler that is used to generate the X.509 certificate that is inserted in the Web Services Security header within the SOAP message as a binary security token on the generator side. This instance is used to generate the `WSSSignature` and `WSSEncryption` objects, set the objects into the `WSSGenerationContext` object to generate the X.509 binary

security tokens. A keystore and a key definition are required for this callback handler. If you use this implementation, a key store password, path, and type must be provided on the generator side.

com.ibm.websphere.wssecurity.callbackhandler.LTPAGenerateCallbackHandler

This class is a callback handler for the Lightweight Third Party Authentication (LTPA) tokens on the generator side. This instance is used to generate WSSSignature object and WSEncryption object to generate a LTPA token.

This callback handler is used to validate the LTPA security token inserted in the Web Services Security header within the SOAP message as a binary security token. However, if the user name and password are specified, WebSphere Application Server authenticates the user name and password to obtain the LTPA security token rather than obtaining it from the Run As Subject. Use this callback handler only when the web service is acting as a client on the application server. It is recommended that you do not use this callback handler on a Java EE application client. If you use this implementation, a basic authentication user ID and password must have been provided on the generator side.

com.ibm.websphere.wssecurity.callbackhandler.KRBTokenConsumeCallbackHandler

This class is a callback handler for the Kerberos v5 token on the generator side. This instance is used to set the WSSGenerationContext object to generate the Kerberos v5 AP-REQ as a binary security token. The instance is also used to generate the WSSSignature and WSEncryption objects to use the Kerberos session key or derived key in the SOAP message signature and encryption.

7. If a X.509 token is specified, additional token information is also specified.

Table 145. Information for X.509 token. Use the X.509 token for signing and encryption.

Token Information	Description
storeRef	The reference name of the keystore.
storePath	The keystore file path from which the keystore is loaded, if needed. It is recommended that you use the <code>\${USER_INSTALL_ROOT}</code> in the path name as this variable expands to the WebSphere Application Server path on your machine. This path is required when you use the X.509 tokens callback handler implementations.
storePassword	The password that is used to check the integrity of the keystore, or the keystore password that is used to unlock the keystore and to access the keystore file. The keystore and its configuration are used for some of the default callback handler implementations that are provided by WebSphere Application Server.
storeType	The keystore type of keystore that is used for the key locator. This selection indicates the format that is used by the keystore file. The following values are available for selection: JKS Use this option if the keystore uses the Java Keystore (JKS) format. JCEKS Use this option if the Java Cryptography Extension is configured in the software development kit (SDK). The default IBM JCE is configured in WebSphere Application Server. This option provides stronger protection for stored private keys by using Triple DES encryption. JCERACFKS Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only). PKCS11KS (PKCS11) Use this format if your keystore uses the PKCS#11 file format. Keystores using this format might contain RSA keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection. PKCS12KS (PKCS12) Use this option if your keystore uses the PKCS#12 file format.
alias	The key alias name. The key alias is used by the key locator to find the key within the keystore file.
keyPassword	The key password that is used for recovering the key. This password is needed to access the key object within the keystore file.
keyName	The name of the key. For digital signatures, the key name is used by the request generator or response consumer signing information to determine which key is used to digitally sign the message. For encryption, the key name is used to determine the key used for encryption. The key name must be a fully qualified, distinguished name (DN). For example, CN=Bob,O=IBM,C=US.
certStores	A list of certificate stores. A collection certificate store includes a list of untrusted, intermediary certificates and certificate revocation lists (CRLs). This step configures a collection certificate store and certificate revocation lists for the generator bindings.

Table 145. Information for X.509 token (continued). Use the X.509 token for signing and encryption.

Token Information	Description
identityAssertion	Specifies whether identity assertion is used. Selects this item if identity assertion is defined. This option indicates that only the identity of the initial sender is required and inserted into the Web Services Security header within the SOAP message. For an X.509 token generator, the application server sends the original signer certification only.
requestorCertificate	Specifies whether the certificate of the requestor is used.

The following can be specified for a X.509 token:

- a. Without any keystore.
- b. With a trust anchor. A trust anchor specifies a list of keystore configurations that contain trusted root certificates. These configurations are used to validate the certificate path of incoming X.509-formatted security tokens. For example, when you select the trust anchor or the certificate store of a trusted certificate, you must configure the trust anchor and the certificate store before setting the certificate path.
- c. With a keystore that is used for the key locator.
First, you must have created the keystore file, by using a key tool utility, for example. The keystore is used to retrieve the X.509 certificate. This entry specifies the password that is used to access the keystore file. Keystore objects within trust anchors contain trusted root certificates that are used by the CertPath API to validate the trustworthiness of a certificate chain.
- d. With keystore that is used for the key locator and the trust anchor.
- e. With a map that includes key-value pairs. For example, you might specify the value type name and the value type Uniform Resource Identifier (URI). The value type specifies the namespace URI of the value type for the generated token, and represents the token type of this class:

ValueType: <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3>

Specifies an X.509 certificate token.

ValueType: <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1>

Specifies X.509 certificates in a public key infrastructure (PKI) path. This callback handler is used to create X.509 certificates encoded with the PkiPath format. The certificate is inserted in the Web Services Security header within the SOAP message as a binary security token. A keystore is required for this callback handler. A CRL is not supported by the callback handler; therefore, the collection certificate store is not required or used. If you use this implementation, you must provide a key store password, path, and type on this panel.

ValueType: <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7>

Specifies a list of X.509 certificates and certificate revocation lists in a PKCS#7 format. This callback handler is used to create X.509 certificates encoded with the PKCS#7 format. The certificate is inserted in the Web Services Security header in the SOAP message as a binary security token. A keystore is required for this callback handler. You can specify a certificate revocation list (CRL) in the collection certificate store. The CRL is encoded with the X.509 certificate in the PKCS#7 format. If you use this implementation, you must provide a key store password, path, and type.

For some tokens, WebSphere Application Server provides a predefined local name for the value type. When you specify the following local name, you do not need to specify a value type URI:

ValueType: <http://www.ibm.com/websphere/appserver/tokentype/5.0.2>

For an LTPA token, you can use LTPA for the value type local name. This local name causes <http://www.ibm.com/websphere/appserver/tokentype/5.0.2> to be specified for the value type Uniform Resource Identifier (URI).

ValueType: <http://www.ibm.com/websphere/appserver/tokentype/5.0.2>

For LTPA token propagation, you can use LTPA_PROPAGATION for the value type local name. This local name causes <http://www.ibm.com/websphere/appserver/tokentype> to be specified for the value type Uniform Resource Identifier (URI).

8. If the Username token is specified as the token generator class name, the following token information can be specified:
 - a. Whether to use IdentityAssertion option. This option is selected if identity assertion is defined. This option indicates that only the identity of the initial sender is required and inserted into the Web Services Security header within the SOAP message. For example, WebSphere Application Server sends only the user name of the original caller for a Username token generator.
 - b. Whether to use RunAsSubject identity option. This option is used if an identity assertion is defined and you want to use the Run As identity instead of the initial caller identity for identity assertion in a downstream call. This option is valid only if you have configured the Username token as the token generator.
 - c. Whether to use sendRealm.
 - d. Whether to specify the nonce.

This option indicates whether a Nonce is included for the token generator. Nonce is a unique, cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of Username tokens. Nonce is valid only when the generated token type is a Username token, and it is available only for the request generator binding.
 - e. Specifies the keyword of the time stamp. This option indicates whether to verify a time stamp in the Username token. The time stamp is valid only when the incorporated token type is a Username token.
 - f. Specifies a map that includes key-value pairs. For example, you might specify the value type name and the value type Uniform Resource Identifier (URI). The value type specifies the namespace URI of the value type for the generated token, and represents the token type of this class:

URI value type: <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken>

Specifies a Username token.

9. If the Kerberos v5 token is specified as the token generator class name, the following token information can be specified:

Token Information	Description	Default Value
name	Kerberos client principal name	
password	Kerberos client password	
realm	Kerberos realm associated with the Kerberos client	Default realm name in Kerberos configuration file. Specify null to use the default value.
targetService	Kerberos service name associated with the target web services.	
targetHost	Kerberos realm name associated with the Kerberos service name.	
tokenValueType	Kerberos token value type in QName defined by Oasis Kerberos Token Profile v1.1 specification.	http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ
targetRealm	Kerberos realm name associated with the Kerberos service name.	Default realm name in the Kerberos configuration file
prompt	A boolean value to enable the login prompt.	false

Token Information	Description	Default Value
supportTokenRequireSHA1	A boolean value to require a SHA1 key that is used in subsequent request messages when the Kerberos token is used as a supporting token.	false SHA1 key is consumed only if the supporting Kerberos token is protected. If set to true, the SHA1 key is always consumed.
alwaysAPREQ	A boolean value to indicate that the client should always send the Kerberos AP_REQ token in the request messages.	false The SHA1 key is used instead in the subsequent messages. If set to true, the Kerberos AP_REQ token is always used.
requireDKT	A boolean value to require a derived key for message protection.	false
clabel	The client label for the derived key.	WS-SecureConversation Specify null to use the default value.
slabel	The service label for the derived key.	WS-SecureConversation Specify null to use the default value.
keylen	The length of the derived key.	16 Specify zero to use the default value
noncelen	The length of the nonce.	16 Specify zero to use the default value
encComponent	An instance of WSEncryption.	Set encComponent and sigComponent to null to initialize this first for either the encryption or signature component. Then, use the initialized component only in the callback handler constructor for the second component.
sigComponent	An instance of WSSSignature.	Set encComponent and sigComponent to null to initialize this first for either the encryption or signature component. Then, use the initialized component only in the callback handler constructor for the second component.

Additional token value types are defined in the OASIS Kerberos Token Profile v1.1 specification. Specify the token value type as the local name. It is not necessary to specify the value type URI for the Kerberos v5 token.

- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ1510
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ1510
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ4120
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ4120

10. If Secure Conversation is used for message protection, the following information must be specified:

Information	Description
bootstrapWSSGenerationContext	The bootstrap configuration used to secure the RequestSecurityToken (RST) token.
bootstrapWSSConmingContext	The bootstrap configuration used for consuming a secured RequestSecurityTokenResponse (RSTR).
ENDPOINT_URL	The service end point URL.
EncryptionAlgorithm	This determines the key size.
cLabel	The client label used when creating the derived key.
sLabel	The server label used when creating the derived key.

11. Set the components into the wssGenerationContext object.

12. Invoke the wssGenerationContext.process() method.

Results

Using the Web Services Security API (WSS API) process, you can configured the token generator.

What to do next

Next, you must specify a similar token consumer configuration.

Configuring generator security tokens using the WSS API:

You can secure the SOAP messages, without using policy sets, by using the Web Services Security APIs. To configure the token on the generator side, use the Web Services Security APIs (WSS API). The generator security tokens are part of the `com.ibm.websphere.wssecurity.wssapi.token` interface package.

Before you begin

The pluggable token framework in WebSphere Application Server has been redesigned so that the same framework from the WSS API can be reused. The same implementation of creating and validating security token can be used both for the Web Services Security runtime and for the WSS API application code. The redesigned framework also simplifies the SPI programming model and will make it easier to add security token types.

You can use the WSS API or you can configure the tokens by using the administrative console. To configure tokens, you must complete the following token tasks:

- Configure the generator tokens.
- Configure the consumer tokens.

About this task

The JAAS CallbackHandler and JAAS LoginModule are responsible for creating the security token on the generator side.

On the generator side, the token is created by using the JAAS LoginModule and by using JAAS CallbackHandler to pass authentication data. Then, the JAAS LoginModule creates the securityToken object, such as the UsernameToken, and passes it to the Web Services Security run time.

On the consumer side, the XML format is passed to the JAAS LoginModule for validation or authentication. then the JAAS CallbackHandler is used to pass authentication data from the Web Services Security runtime to the LoginModule. After the token is authenticated, a security token object is created, and the token is passed it to the Web Services Security runtime.

When using the WSS API for generator token creation, certain default behaviors occur. The simplest way to use the WSS API is to use the default behavior (see the example code). The WSS API provide default values for the token type, the token value, and the JAAS confirmation name. The default token behaviors include:

Table 146. Token decisions and default behaviors. Several token characteristics are configured by default.

Generator token decisions	Default behavior
Which token type to use	<p>The token type specifies which type of token to use for message integrity, message confidentiality, or message authenticity.</p> <p>WebSphere Application Server provides the following pre-configured generator token types for message integrity and message confidentiality:</p> <ul style="list-style-type: none"> • Derived key token • X509 tokens <p>You can also create custom token types, as needed.</p> <p>WebSphere Application Server also provides the following pre-configured generator token types for the message authenticity:</p> <ul style="list-style-type: none"> • Username token • LTPA tokens • X509 tokens <p>You can also create custom token types, as needed.</p>
What JAAS login configuration name to specify	The JAAS login configuration name specifies which JAAS login configuration name to use.
Which configuration type to use	The JAAS login module specifies the configuration type. Only the pre-configured generator configuration types can be used for generator token types.

The SecurityToken class (com.ibm.websphere.wssecurity.wssapi.token.SecurityToken) is the generic token class and represents the security token that has methods to get the identity, the XML format, and the cryptographic keys. Using the SecurityToken class, you can apply both the signature and encryption to the SOAP message. However, to apply both, you must have two SecurityToken objects, one for the signature and one for encryption, respectively.

The following tokens types are subclasses of the generic security token class:

Table 147. Subclasses of the SecurityToken. Use the subclasses to represent the security token.

Token type	JAAS login configuration name
Username token	system.wss.generate.unt
Security context token	system.wss.generate.sct
Derived key token	system.wss.generate.dkt

The following tokens types are subclasses of the binary security token class:

Table 148. Subclasses of the BinarySecurityToken. Use the subclasses to represent the binary security token.

Token type	JAAS login configuration name
LTPA token	system.wss.generate.ltpa
LTPA propagation token	system.wss.generate.ltpaProp
X.509 token	system.wss.generate.x509
X.509 PKI Path token	system.wss.generate.pkiPath
X.509 PKCS7 token	system.wss.generate.pkcs7

Note:

- For each JAAS login token generator configuration name, there is a respective token consumer configuration name. For example, for the Username token, the respective token consumer configuration name is system.wss.consume.unt.

- The LTPA and LTPA propagation tokens are only available to a requester that is running as a server-based client. The LTPA and LTPA propagation tokens are not supported for the Java SE 6 or Java EE application client.

Procedure

1. To configure the securityToken package, `com.ibm.websphere.wssecurity.wssapi.token`, first ensure that the application server is installed.
2. Use the Web Services Security token generator process to configure the tokens. For each token type, the process is similar to the following process that demonstrates the UsernameToken token generator process:
 - a. Use `WSSFactory.getInstance()` to get the WSS API implementation instance.
 - b. Create the `WSSGenerationContext` instance from the `WSSFactory` instance.
 - c. Create a JAAS `CallbackHandler`. The authentication data, such as the user name and password are specified as part of the `CallbackHandler`. For example, the following code specifies Chris as the user name and sirhC as the password: `UNTGenerationCallbackHandler("Chris", "sirhC");`
 - d. Call any JAAS `CallbackHandler` parameters and review the token class information for which parameters are required or optional. For example, for the `UsernameToken`, the following parameters can be configured also:

Nonce

Indicates whether a nonce is included in the user name token for the token generator. Nonce is a unique, cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of user name tokens. The nonce value is valid only when the generated token type is a `UsernameToken` and only when it applies to the request generator binding.

Created timestamp

Indicates whether to insert a time stamp into the `UsernameToken`. The timestamp value is valid only when the generated token type is a `UsernameToken` and only when it applies to the request generator binding.

- e. Create the `SecurityToken` from `WSSFactory`.
By default, the `UsernameToken` API specifies the `ValueType` as: `"http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken"`
By default, the `UsernameToken` API provides the `QName` of this class and specifies the `NamespaceURI` as `http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd` and also specifies the `LocalPart` as `UsernameToken`.
- f. Optional: Specify the JAAS login module configuration name. On the generator side, the configuration type is always generate (for example, `system.wss.generate.unt`).
- g. Add the `SecurityToken` to the `WSSGenerationContext`.
- h. Call `WSSGenerationContext.process()` and generate the WS-Security header.

Results

If there is an error condition, a `WSSEException` is provided. If successful, the `WSSGenerationContext.process()` is called, and the security token for the generator binding is attached.

Example

The following example code shows how to use WSS APIs to create a Username security token, attach the Username token to the SOAP message, and configure the Username token in the generator binding.

```
// import the packages
import javax.xml.ws.BindingProvider;
import com.ibm.websphere.wssecurity.wssapi.*;
import com.ibm.websphere.wssecurity.callbackhandler.*;
...
// obtain the binding provider
```

```

BindingProvider bp = ... ;

// get the request context
Map<String, Object> reqContext = bp.getRequestContext();

// generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

// generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// generate callback handler
UNTGenerateCallbackHandler untCallbackHandler =
new UNTGenerateCallbackHandler("Chris", "sirhC");

// generate the username token
SecurityToken unt = factory.newSecurityToken(UsernameToken.class, untCallbackHandler);

// add the SecurityToken to the WSSGenerationContext
gencont.add(unt);

// generate the WS-Security header
gencont.process(reqContext);

```

The following example code shows how to modify the preceding Username token sample to create an LTPAv2 token from the runAs identity on the current thread. The two lines of code that instantiate the callback handler and create the security token are replaced with the following two lines of code:

```

// generate callback handler
LTPAGenerateCallbackHandler ltpaCallbackHandler = new LTPAGenerateCallbackHandler(null, null);

// generate the LTPAv2 token
SecurityToken ltpa = wssfactory.newSecurityToken(LTPAv2Token.class, ltpaCallbackHandler);

```

The instantiation of the LTPAGenerateCallbackHandler object with (null, null) indicates that the LTPA token should be generated from the current runAs identity. If the callback handler is instantiated with basicAuth information, ("userName", "password"), a new LTPA token is created using the specified basicAuth information.

The following example shows how to use secure conversation with the WSS APIs to configure the generator tokens, as well as the consumer tokens. In this example, the SecurityContextToken token is created using the WS-SecureConversation draft namespace: <http://schemas.xmlsoap.org/ws/2005/02/sc/sct>. To use the WS-SecureConversation version 1.3 namespace, <http://docs.oasis-open.org/ws-sx/ws-secureconversation/200512/sct>, specify SecurityContextToken13.class instead of SecurityContextToken.class.

```

// import the packages
import javax.xml.ws.BindingProvider;
import com.ibm.websphere.wssecurity.wssapi.*;
import com.ibm.websphere.wssecurity.callbackhandler.*;
...
// obtain the binding provider
BindingProvider bp = ... ;

// get the request context
Map<String, Object> reqContext = bp.getRequestContext();

// generate WSSFactory instance
WSSFactory wssFactory = WSSFactory.getInstance();

WSSGenerationContext bootstrapGenCon = wssFactory.newWSSGenerationContext();

// Create a Timestamp
...
// Add Timestamp
...

// Sign the SOAP Body, WS-Addressing headers, and Timestamp
X509GenerateCallbackHandler btspReqSigCbHandler = new X509GenerateCallbackHandler(...);
SecurityToken btspReqSigToken = wssFactory.newSecurityToken(X509Token.class,
btspReqSigCbHandler);
WSSSignature bootstrapReqSig = wssFactory.newWSSSignature(btspReqSigToken);
bootstrapReqSig.setCanonicalizationMethod(WSSSignature.EXC_C14N);

// Add Sign Parts
...
bootstrapGenCon.add(bootstrapReqSig);

// Encrypt the SOAP Body and the Signature
X509GenerateCallbackHandler btspReqEncCbHandler = new X509GenerateCallbackHandler(...);
SecurityToken btspReqEncToken = wssFactory.newSecurityToken(X509Token.class,

```

```

                                                    btspReqEncCbHandler);
WSEncryption bootstrapReqEnc = wssFactory.newWSEncryption(btspReqEncToken);
bootstrapReqEnc.setEncryptionMethod(WSEncryption.AES128);
bootstrapReqEnc.setKeyEncryptionMethod(WSEncryption.KW_RSA15);

// Add Encryption parts
...
bootstrapGenCon.add(bootstrapReqEnc);
WSSConsumingContext bootstrapConCon = wssFactory.newWSSConsumingContext();
X509ConsumeCallbackHandler btspRspVfyCbHandler = new X509ConsumeCallbackHandler(...);
WSSVerification bootstrapRspVfy = wssFactory.newWSSVerification(X509Token.class,
                                                                btspRspVfyCbHandler);
bootstrapRspVfy.addAllowedCanonicalizationMethod(WSSVerification.EXC_C14N);

// Add Verify parts
...
bootstrapConCon.add(bootstrapRspVfy);
X509ConsumeCallbackHandler btspRspDecCbHandler = new X509ConsumeCallbackHandler(...);
WSSDecryption bootstrapRspDec = wssFactory.newWSSDecryption(X509Token.class,
                                                            btspRspDecCbHandler);
bootstrapRspDec.addAllowedEncryptionMethod(WSSDecryption.AES128);
bootstrapRspDec.addAllowedKeyEncryptionMethod(WSSDecryption.KW_RSA15);

// Add Decryption parts
...
bootstrapConCon.add(bootstrapRspDec);
SCTGenerateCallbackHandler sctgch = new SCTGenerateCallbackHandler(bootstrapGenCon,
                                                                    bootstrapConCon,
                                                                    ENDPOINT_URL,
                                                                    WSEncryption.AES128);

SecurityToken[] scts = wssFactory.newSecurityTokens(new Class[] {SecurityContextToken.class},
                                                    sctgch);
SecurityContextToken sct = (SecurityContextToken)scts[0];

// Use the SCT to generate DKTs for Secure Conversation
// Signature algorithm and client and service labels
DerivedKeyToken dktSig = sct.getDerivedKeyToken(WSSSignature.HMAC_SHA1,
                                                "WS-SecureConversation",
                                                "WS-SecureConversation");

// Encryption algorithm and client and service labels
DerivedKeyToken dktEnc = sct.getDerivedKeyToken(WSEncryption.AES128,
                                                "WS-SecureConversation",
                                                "WS-SecureConversation");

// Create the application generation context for the request message
WSSGenerationContext applicationGenCon = wssFactory.newWSSGenerationContext();

// Create and add Timestamp
...

// Add the derived key token and Sign the SOAP Body and WS-Addressing headers
WSSSignature appReqSig = wssFactory.newWSSSignature(dktSig);
appReqSig.setSignatureMethod(WSSSignature.HMAC_SHA1);
appReqSig.setCanonicalizationMethod(WSSSignature.EXC_C14N);
...
applicationGenCon.add(appReqSig);

// Add the derived key token and Encrypt the SOAP Body and the Signature
WSEncryption appReqEnc = wssFactory.newWSEncryption(dktEnc);
appReqEnc.setEncryptionMethod(WSEncryption.AES128);
appReqEnc.setTokenReference(SecurityToken.REF_STR);
appReqEnc.encryptKey(false);
...
applicationGenCon.add(appReqEnc);

// Create the application consuming context for the response message
WSSConsumingContext applicationConCon = wssFactory.newWSSConsumingContext();

//client and service labels and decryption algorithm
SCTConsumeCallbackHandler sctCbHandler = new SCTConsumeCallbackHandler("WS-SecureConversation",
                                                                        "WS-SecureConversation",
                                                                        WSSDecryption.AES128);

// Derive the token from SCT and use it to Decrypt the SOAP Body and the Signature
WSSDecryption appRspDec = wssFactory.newWSSDecryption(SecurityContextToken.class,
                                                       sctCbHandler);
appRspDec.addAllowedEncryptionMethod(WSSDecryption.AES128);
appRspDec.encryptKey(false);
...
applicationConCon.add(appRspDec);

// Derive the token from SCT and use it to Verify the
// signature on the SOAP Body, WS-Addressing headers, and Timestamp
WSSVerification appRspVfy = wssFactory.newWSSVerification(SecurityContextToken.class,
                                                         sctCbHandler);
...

```

```
applicationConCon.add(appRspVfy);
...
applicationGenCon.process(reqContext);
applicationConCon.process(reqContext);
```

What to do next

For each token type, configure the token using the WSS APIs or using the administrative console. Next, specify the similar consumer tokens if you have not done so.

If both the generator and consumer tokens are configured, continue securing SOAP messages either by signing the SOAP message or by encrypting the message, as needed. You can use either the WSS APIs or the administrative console to secure the SOAP messages.

Securing messages at the request generator using WSS APIs:

You can secure SOAP messages by configuring signing information, encryption, and generator tokens to protect message integrity, confidentiality, and authenticity, respectively. This request (client-side) generator configuration defines the Web Services Security requirements for the outgoing SOAP message request.

Before you begin

To secure web services with WebSphere Application Server, you must configure the generator and the consumer security constraints. Therefore, in addition to securing messages at the request generator level, you must also secure messages at the response consumer level.

About this task

The request (client-side) generator configuration requirements involve generating a SOAP message request that uses a digital signature, incorporates encryption, and attaches security tokens.

To secure web service applications, you must specify several different configurations. Although there is no specific sequence to specify these different configurations, some configurations reference other configurations. For example, decryption configurations reference encryption configurations.

You can use the following interfaces to configure Web Services Security and to define policy types to secure the SOAP messages:

- Use the administrative console to configure policy sets.
- Use the Web Services Security APIs (WSS API) to configure the SOAP message context (only for the client)

The following high-level steps use the WSS APIs:

Procedure

- Configure generator signing to protect message integrity.
- Configure encryption to protect message confidentiality.
- Attach generator tokens to protect message authenticity.
- Propagate self-issued SAML bearer tokens using WSS APIs.
- Propagate self-issued SAML sender-vouches tokens with message protection using WSS APIs.
- Propagate self-issued SAML sender-vouches tokens with transport protection using WSS APIs.
- “Sending self-issued SAML holder-of-key tokens with symmetric key using WSS APIs” on page 1392.
- “Sending self-issued SAML holder-of-key tokens with asymmetric key using WSS APIs” on page 1394.

Results

After completing these procedures, you have secured messages at the request generator level.

What to do next

Next, if not already configured, secure messages with signature verification, decryption, and consumer tokens at the response consumer (client-side) level.

Configuring encryption to protect message confidentiality using the WSS APIs:

You can configure encryption information for the client-side request generator (sender) bindings. Encryption information is used to specify how the generators (senders) encrypt outgoing SOAP messages. To configure encryption, specify which message parts to encrypt and specify which algorithm methods and security tokens are to be used for encryption.

Before you begin

Confidentiality refers to encryption while integrity refers to digital signing. Confidentiality reduces the risk of someone understanding the message flowing across the Internet. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the correct target. Prior to configuring encryption, familiarize yourself with XML encryption.

About this task

For encryption, you must specify the following:

- Which parts of the message are to be encrypted.
- Which encryption algorithms to specify.

To configure encryption and encrypted parts on the client side, use the WSSEncryption and WSSEncryptPart APIs, or configure policy sets using the administrative console.

WebSphere Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment.

WebSphere Application Server uses encryption information for the default generator to encrypt parts of the SOAP message. The WSSEncryption API configures the following required parts as encrypted parts.

Table 149. Required encrypted parts. Use encrypted parts to increase the confidentiality of SOAP messages.

Encryption parts	Description
Keywords	Keywords are used to add the encrypted parts to the SOAP message.
XPath expression	An XPath expression is used to add the encrypted parts to the SOAP message.
WSSEncryptPart object	This object adds the encrypted parts to the SOAP message.
WSSSignature object	This object adds the signature component as an encrypted part.
Header	This part adds the header in the SOAP header, specified by QName, as an encryption part.
Security token object	This object adds the security token as an encryption part.

Web Services Security API (WSS API) supports symmetric encryption, by using a shared key, only when Web Services Secure Conversation (WS-SecureConversation) is used.

The WSS APIs allow the use of either keywords or an XPath expression to specify the parts of the message that are to be encrypted. WebSphere Application Server supports the use of the following keywords:

Table 150. Supported encryption keywords. Use keywords to specify encrypted parts.

Keyword	References
BODY_CONTENT	The keyword for the contents of the SOAP message body as an encryption target.
SIGNATURE	The keyword for the signature component as an encryption target.

If configuring using the WSS APIs, the WSEncryption and WSEncryptPart APIs complete these high-level steps:

Procedure

1. Use the WSEncryption API to configure encryption. The WSEncryption API performs these tasks by default:
 - a. Generates the callback handler.
 - b. Generates the generator security token object.
 - c. Adds the security token reference type.
 - d. Adds the signature component.
 - e. Adds the WSEncryptPart object.
 - f. Adds the parts to be encrypted. Adds the default parts as targets of encryption by using keywords and XPath expressions.
 - g. Adds the header in the SOAP message, specified by QName.
 - h. Sets the default data encryption method.
 - i. Specifies whether the key is to be encrypted using a Boolean value.
 - j. Sets the default key encryption method.
 - k. Selects a part reference.
 - l. Sets the MTOM optimization Boolean value.
2. Use the WSEncryptPart API to configure encrypted parts or add a transform method. The WSEncryptPart API performs these tasks by default:
 - a. Sets the encrypted parts specified by using keywords or an XPath expression.
 - b. Sets the encrypted parts specified by an XPath expression.
 - c. Sets the signature component object, WSSSignature.
 - d. Sets the header in the SOAP message, specified by QName.
 - e. Sets the generator security token.
 - f. Adds the transform method, if needed.
3. Change from the default values for algorithm or message parts, as needed. For example: you could change one or more of the following items:
 - Change the data encryption algorithm from the default value of AES 128.
 - Change the key encryption algorithm from the default value of KW_RSA_OAEP.
 - Specify to not encrypt the key (false).
 - Change the security token type from default of X.509 token.
 - Change the security token reference type from the default value of SecurityToken.REF_STR.
 - Only use BODY_CONTENT as an encryption part and not use SIGNATURE also.
 - Turn MTOM optimization on (true).

Results

The encryption information is configured for the generator binding.

Example

The following is an example of the WSEncryption API:

```
WSSFactory factory = WSSFactory.getInstance();
WSSGenerationContext gencont = factory.newWSSGenerationContext();

X509GenerateCallbackHandler callbackhandler = generateCallbackHandler();
SecurityToken token = factory.newSecurityToken(X509Token.class, callbackhandler);
WSEncryption enc = factory.newWSEncryption(token);

gencont.add(enc);
```

What to do next

You must configure similar decryption information for the client-side response consumer (receiver) bindings, if you have not already configured the information.

Next, review the WSEncryption API process.

Encrypting the SOAP message using the WSEncryption API:

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure the client for request encryption on the generator side, use the WSEncryption API to encrypt the SOAP message. The WSEncryption API specifies which request SOAP message parts to encrypt when configuring the client.

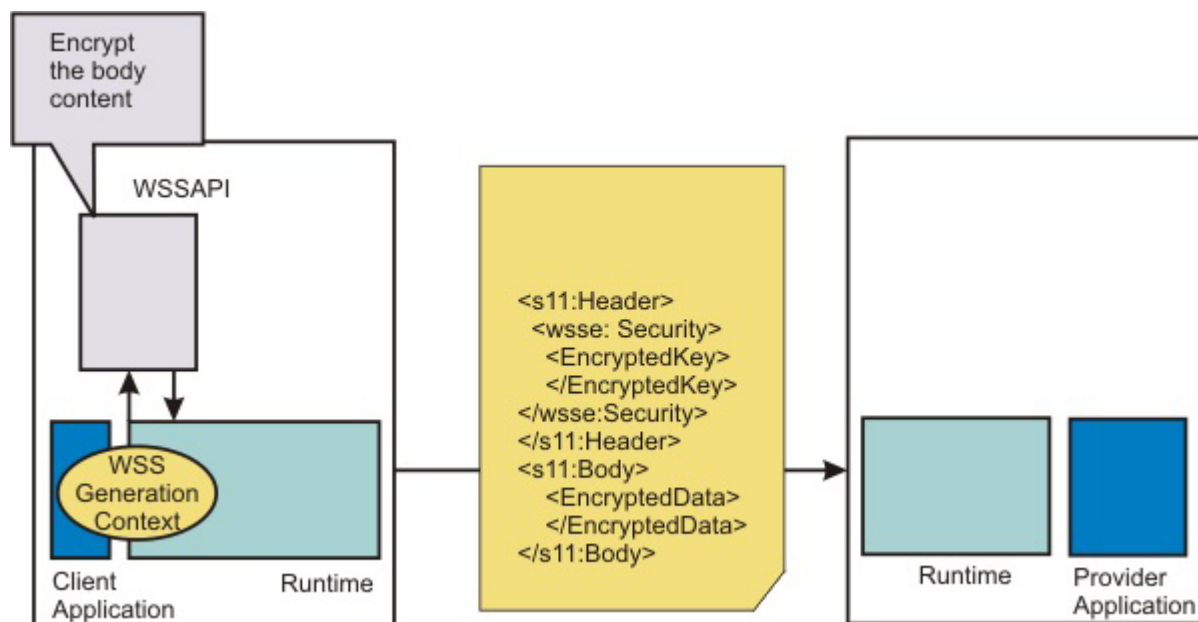

Before you begin

You can use the WSS API or use policy sets on the administrative console to enable encryption and add generator security tokens in the SOAP message. To secure SOAP messages, use the WSS APIs to complete the following encryption tasks, as needed:

- Configure encryption and choose the encryption methods using the WSEncryption API.
- Configure the encrypted parts, as needed, using the WSEncryptPart API.

About this task

The encryption information on the generator side is used for encrypting an outgoing SOAP message for the request generator (client side) bindings. The client generator configuration must match the configuration for the provider consumer.

Confidentiality settings require that confidentiality constraints be applied to generated messages. These constraints include specifying which message parts within the generated message must be encrypted, and which message parts to attach encrypted Nonce and timestamp elements to.

The following encryption parts can be configured:

Table 151. Encryption parts. Use the encryption parts to enable encryption in messages.

Encryption parts	Description
part	Adds the WSSEncryptPart object as a target of the encryption part.
keyword	Adds the encryption parts using keywords. WebSphere Application Server supports the following keywords: <ul style="list-style-type: none"> BODY_CONTENT SIGNATURE
xpath	Adds the encryption part using an XPath expression.
signature	Adds the WSSignature component as a target of the encrypted part.
header	Adds the SOAP header, specified by QName, as a target of the encrypted part.
securityToken	Adds the SecurityToken object as a target of the encrypted part.

For encryption, certain default behaviors occur. The simplest way to use the WSSEncryption API is to use the default behavior (see the example code).

WSSEncryption provides defaults for the key encryption algorithm, the data encryption algorithm, the security token reference method, and the encryption parts such as the SOAP body content and the signature. The encryption default behaviors include:

Table 152. Encryption decisions. Use encryption default behavior to secure the message body content and signature.

Encryption decisions	Default behavior
Which SOAP message parts to encrypt using keywords	Sets the encryption parts that you can add using keywords. The default encryption parts are the BODY_CONTENT and SIGNATURE. WebSphere Application Server supports using these keywords: <ul style="list-style-type: none"> WSSEncryption.BODY_CONTENT WSSEncryption.SIGNATURE

Table 152. Encryption decisions (continued). Use encryption default behavior to secure the message body content and signature.

Encryption decisions	Default behavior
Which data encryption method to choose (algorithm)	Sets the data encryption method. Both data and key encryption methods can be specified. The default data encryption algorithm method is AES 128. WebSphere Application Server supports these data encryption methods: <ul style="list-style-type: none"> • WSEncryption.AES128: http://www.w3.org/2001/04/xmlenc#aes128-cbc • WSEncryption.AES192: http://www.w3.org/2001/04/xmlenc#aes192-cbc • WSEncryption.AES256: http://www.w3.org/2001/04/xmlenc#aes256-cbc • WSEncryption.TRIPLE_DES: http://www.w3.org/2001/04/xmlenc#triple-des-cbc
Whether to encrypt the key (isEncrypt)	Specifies whether to encrypt the key. The values are true or false. The default value is to encrypt the key (true).
Which key encryption method to choose (algorithm)	Sets the key encryption method. Both data and key encryption methods can be specified. The default key encryption algorithm method is key wrap RSA OAEP. WebSphere Application Server supports these key encryption methods: <ul style="list-style-type: none"> • WSEncryption.KW_AES128: http://www.w3.org/2001/04/xmlenc#kw-aes128 • WSEncryption.KW_AES192: http://www.w3.org/2001/04/xmlenc#kw-aes192 • WSEncryption.KW_AES256: http://www.w3.org/2001/04/xmlenc#kw-aes256 • WSEncryption.KW_RSA_OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p • WSEncryption.KW_RSA15: http://www.w3.org/2001/04/xmlenc#rsa-1_5 • WSEncryption.KW_TRIPLE_DES: http://www.w3.org/2001/04/xmlenc#kw-triple-des
Which security token to specify (securityToken)	Sets the SecurityToken. The default security token type is the X509Token. WebSphere Application Server provides the following pre-configured consumer token types: <ul style="list-style-type: none"> • Derived key token • X.509 tokens
Which token reference to use (refType)	Sets the type of the security token reference. The default token reference is SecurityToken.REF_KEYID. WebSphere Application Server supports the following token reference types: <ul style="list-style-type: none"> • SecurityToken.REF_KEYID • SecurityToken.REF_STR • SecurityToken.REF_EMBEDDED • SecurityToken.REF_THUMBPRINT
Whether to use MTOM (mtomOptimize)	Sets Message Transmission Optimization Mechanism (MTOM) optimization for the encrypted part.

Procedure

1. To encrypt the SOAP message using the WSEncryption API, first ensure that the application server is installed.
2. The WSS API process for encryption performs these process steps:
 - a. Uses WSSFactory.getInstance() to get the WSS API implementation instance
 - b. Creates the WSSGenerationContext instance from the WSSFactory instance.
 - c. Creates the SecurityToken from WSSFactory used for encryption.
 - d. Creates WSEncryption from the WSSFactory instance using the SecurityToken. The default behavior of WSEncryption is to encrypt the body content and the signature.
 - e. Adds a new part to be encrypted in WSEncryption if the existing part is not appropriate. After addEncryptPart(), addEncryptHeader(), or addEncryptPartByXPath() is called, the default part is cleared.
 - f. Calls the encryptKey(false) if the key is not to be encrypted.
 - g. Sets the data encryption method if the default method is not appropriate.
 - h. Sets the key encryption method if the default method is not appropriate.
 - i. Sets the token reference if the default token reference is not appropriate.
 - j. Adds WSEncryption to WSSConsumingContext.
 - k. Calls WSSGenerationContext.process() with the SOAPMessageContext.

Results

If there is an error condition during encryption, a `WSSEException` is provided. If successful, the API calls the `WSSGenerationContext.process()`, the WS-Security header is generated, and the SOAP message is now secured using Web Services Security.

Example

The following example provides sample code using methods that are defined in `WSSEncryption`:

```
// Get the message context
Object msgcontext = getMessageContext();

// Generate the WSSFactory instance (step: a)
WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSGenerationContext instance (step: b)
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate the callback handler
X509GenerateCallbackHandler callbackHandler = new
    X509GenerateCallbackHandler(
        "",
        "enc-sender.jceks",
        "jceks",
        "storepass".toCharArray(),
        "bob",
        null,
        "CN=Bob, O=IBM, C=US",
        null);

// Generate the security token used for encryption (step: c)
SecurityToken token = factory.newSecurityToken(X509Token.class, callbackHandler);

// Generate WSSEncryption instance (step: d)
WSSEncryption enc = factory.newWSSEncryption(token);

// Set the part to be encrypted (step: e)
// DEFAULT: WSSEncryption.BODY_CONTENT and WSSEncryption.SIGNATURE

// Set the part specified by the keyword (step: e)
enc.addEncryptPart(WSSEncryption.BODY_CONTENT);

// Set the part in the SOAP Header specified by QName (step: e)
enc.addEncryptHeader(new QName("http://www.w3.org/2005/08/addressing",
    "MessageID"));

// Set the part specified by WSSSignature (step: e)
SecurityToken sigToken = getSecurityToken();
WSSSignature sig = factory.newWSSSignature(sigToken);
enc.addEncryptPart(sig);

// Set the part specified by SecurityToken (step: e)
UNTGenerateCallbackHandler untCallbackHandler =
    new UNTGenerateCallbackHandler("Chris", "sirhC");
SecurityToken unt = factory.newSecurityToken(UsernameToken.class,
    untCallbackHandler);
enc.addEncryptPart(unt, false);

// sSt the part specified by XPath expression (step: e)
StringBuffer sb = new StringBuffer();
sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
    and local-name()='Envelope']");
sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
    and local-name()='Body']");
sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
    and local-name()='Ping']");
sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
    and local-name()='Text']");
enc.addEncryptPartByXPath(sb.toString());

// Set whether the key is encrypted (step: f)
// DEFAULT: true
enc.encryptKey(true);

// Set the data encryption method (step: g)
// DEFAULT: WSSEncryption.AES128
enc.setEncryptionMethod(WSSEncryption.TRIPLE_DES);

// Set the key encryption method (step: h)
// DEFAULT: WSSEncryption.KW_RSA_OAEP
enc.setEncryptionMethod(WSSEncryption.KW_RSA15);

// Set the token reference (step: i)
// DEFAULT: SecurityToken.REF_KEYID
```

```
enc.setTokenReference(SecurityToken.REF_STR);  
  
// Add the WSEncryption to the WSSGenerationContext (step: j)  
gencont.add(enc);  
  
// Process the WS-Security header (step: k)  
gencont.process(msgcontext);
```

Note: The X509GenerationCallbackHandler does not need the key password because the public key is used for encryption. You do not need a password to obtain the public key from the Java keystore.

What to do next

If you have not previously specified which encryption methods to choose, use the WSS API or configure the policy sets using the administrative console to choose the data and key encryption algorithm methods.

Choosing encryption methods for generator bindings:

To configure the client for request encryption for the generator binding, you must specify which encryption methods to use when the client encrypts the SOAP messages.

Before you begin

Prior to completing these steps, read the XML encryption information to become familiar with encrypting and decrypting SOAP messages.

To specify which algorithm methods are to be used when the client encrypts the SOAP messages, complete the following tasks:

- Use the WSEncryption API to configure the data encryption algorithm and the key encryption algorithm methods.
- Use the WSEncryptPart API to configure a transform algorithm method, if needed. The default is no transform algorithm.

About this task

Some of the encryption-related definitions are based on the XML-Encryption specification. The following information defines some data encryption-related terms:

Data encryption method algorithm

Data encryption algorithms specify the algorithm uniform resource identifier (URI) of the data encryption method. This algorithm encrypts and decrypts data in fixed size, multiple octet blocks.

By default, the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files.

For the AES256-cbc and the AES192-cbc algorithms, you must download the unrestricted Java™ Cryptography Extension (JCE) policy files from the following website: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

Key encryption method algorithm

Key encryption algorithms specify the algorithm uniform resource identifier (URI) of the method to encrypt the key that is used to encrypt data. The algorithm represents public key encryption algorithms that are specified for encrypting and decrypting keys.

By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property.

The property name is: `com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod`. The property value is one of the following URIs of the digest method:

- <http://www.w3.org/2001/04/xmlenc#sha256>
- <http://www.w3.org/2001/04/xmlenc#sha512>

By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoep.OAEPparams`. The property value is the base 64-encoded value of the octet string.

Important: You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.
