How to send your comments	xxv
Chapter 1. Welcome to applications	1
Chapter 2. Using Web applications	11
Web applications	11
web.xml file	11
Migrating Web application components	13
Default Application	15
Servlets	16
Developing servlets with WebSphere Application Server extensions	16
Application lifecycle listeners and events	17
Listener classes for servlet context and session changes	17
Example: com.ibm.websphere.DBConnectionListener.java	18
Servlet filtering	18
Filter, FilterChain, FilterConfig classes for servlet filtering	19
Example: com.ibm.websphere.LoggingFilter.java	19
Configuring page list servlet client configurations	20
autoRequestEncoding and autoResponseEncoding	23
Examples: autoRequestEncoding and autoResponseEncoding encoding examples	23
JavaServer Pages files	24
Developing JavaServer Pages files with WebSphere extensions	24
Tag libraries	25
tsx:dbconnect tag JavaServer Pages syntax	25
dbquery tag JavaServer Pages syntax	26
dbmodify tag JavaServer Pages syntax	27
tsx:getProperty tag JavaServer Pages syntax and examples	27
tsx:userid and tsx:passwd tag JavaServer Pages syntax	28
tsx:repeat tag JavaServer Pages syntax	29
Example: Combining tsx:repeat and tsx:getProperty JavaServer Pages tags	29
Example: tsx:dbmodify tag syntax	29
Example: Using tsx:repeat JavaServer Pages tag to iterate over a results set	30
JspBatchCompiler tool	32
Bean Scripting Framework	33
Developing Web applications	33
Disabling JavaServer Pages run-time compilation	34
Example: Converting JavaScript source to the Bean Scripting Framework	35
Scenario: Creating a Bean Scripting Framework application	36
Example: Bean Scripting Framework code example	41
Web modules	44
Assembling Web applications	45
Context parameters	45
Security constraints	46
Servlet mappings	46
Invoker attributes	46
Error pages	46
File serving	46
Initialization parameters	46
Servlet caching	47
Web components	47
Web property extensions	47
Web resource collections	47
Welcome files	47

Troubleshooting tips for Web application deployment	47
Modifying the default Web container configuration	48
Web container	49
Web container settings	49
Web Module Deployment settings	49
Web container custom properties.	50
Web applications: Resources for learning.	51
Chapter 3. Managing HTTP sessions	53
Sessions	53
Migrating HTTP sessions	53
Developing session management in servlets	54
Example: SessionSample.java	55
Assembling so that session data can be shared	56
Session security support	56
Session management support	57
Configuring session management by level	58
Session tracking options	59
Session tracking with cookies	59
Session tracking with URL rewriting	59
Session tracking with SSL information	60
Configuring session tracking	61
Serializing access to session data	61
Session Management settings	61
Cookie settings	64
Configuring session tracking for Wireless Application Protocol (WAP) devices	65
Distributed sessions	65
Session recovery support	65
Distributed Environment settings	66
Configuring for database session persistence	66
Switching to a multirow schema	66
Configuring tablespace and page sizes for DB2 session databases	67
Database settings	67
Multirow schema considerations	68
Memory-to-memory replication.	69
Memory-to-memory topology: Peer-to-peer function with a local replicator	70
Memory-to-memory topology: Peer-to-peer function with remote/isolated replicators	71
Memory-to-memory topology: Client/server function with remote replicators	72
Memory-to-memory topology: Client/server function with isolated replicators	73
Memory-to-memory session partitions	74
Clustered session support	74
Configuring memory-to-memory replication for the peer-to-peer function with a local replicator (default memory-to-memory replication)	75
Memory-to-memory sessions settings	75
Configuring memory-to-memory replication for peer-to-peer functions with remote/isolated replicators	76
Configuring memory-to-memory replication for the client/server function using isolated replicators	77
Configuring memory-to-memory replication for the client/server function using remote replicators	79
Tuning session management	80
Configuring scheduled invalidation	80
Configuring write contents	81
Configuring write frequency	82
Base in-memory session pool size	82
Controlling write operations	83
Tuning parameter settings	83
Tuning parameter custom settings	84
Best practices for using HTTP Sessions	85

Managing HTTP sessions: Resources for learning:	88
Chapter 4. Using enterprise beans in applications	89
Enterprise beans.	89
Developing enterprise beans	90
Migrating enterprise bean code to the supported specification	91
WebSphere extensions to the Enterprise JavaBeans specification	93
Best practices for developing enterprise beans.	94
Unknown primary-key class.	98
Using access intent policies.	98
Access intent policies	98
Access intent service.	101
Access intent design considerations	102
Applying access intent policies to methods.	102
Using the AccessIntent API	103
Access intent exceptions	104
Access intent assembly settings	105
Access intent best practices	107
Frequently asked questions: Access intent	107
EJB modules	108
Assembling EJB modules	108
Container transactions	109
Method extensions	109
Method permissions	109
References	109
EJB containers	110
Container Managed Persistence over anything	110
Managing EJB containers	118
EJB container settings	118
EJB container system properties	119
EJB cache settings	119
Container interoperability	120
Deploying EJB modules	125
EJB module collection	125
EJB module settings	125
Enterprise beans: Resources for learning	126
EJB method Invocation Queuing	127
Chapter 5. Using extended messaging in applications	129
Extended messaging - overview	129
Extended messaging - receiving messages	130
Extended messaging - sending messages	131
Extended messaging - data mapping	132
Extended messaging - handling late responses	133
Extended messaging - transactional support	134
Extended messaging - exception handling	135
Extended messaging - application usage scenarios	136
Extended messaging - components	136
Designing an enterprise application to use extended messaging	138
Developing an enterprise application to use extended messaging	139
Deploying an enterprise application to use extended messaging	140
Configuring deployment attributes for a receiver bean.	140
Configuring deployment attributes for a sender bean	141
Configuring extended messaging service resources	143
Adding a new input port	143
Adding a new output port	143

Configuring an input port	144
Configuring an output port	144
Extended messaging service settings.	144
Extended messaging provider settings	147
Troubleshooting extended messaging	156
Extended Messaging: Resources for learning	156
Chapter 6. Using asynchronous messaging	159
Asynchronous messaging with WebSphere - an overview	159
Styles of messaging in applications	160
WebSphere Application Server cloning and WebSphere MQ clustering	160
Using JMS and messaging in applications	162
An overview of WebSphere asynchronous messaging using JMS	163
Administering WebSphere JMS support	166
Designing an enterprise application to use JMS	256
Developing a J2EE application to use JMS	259
Developing a JMS client	262
Deploying a J2EE application to use JMS	265
Tuning Java messaging service	266
Troubleshooting WebSphere Messaging.	268
Using message-driven beans in applications	272
Message-driven beans - an overview	272
Designing an enterprise application to use message-driven beans	275
Developing an enterprise application to use message-driven beans	276
Deploying an enterprise application to use message-driven beans	279
Configuring message listener resources for message-driven beans.	282
Important files for message-driven beans and extended messaging	291
Troubleshooting message-driven beans	292
Message-driven beans samples.	292
Chapter 7. Using application clients	295
Application clients	295
Application client functions.	296
ActiveX application clients	298
Applet clients	298
J2EE application clients.	299
Pluggable application clients	300
Thin application clients	302
Migration tips for application clients	303
Installing application clients	304
Best practices for installing application clients	306
Installing application clients silently	307
Developing application clients	308
Developing ActiveX application client code	308
Starting an ActiveX application	309
JClassProxy and JObjectProxy classes	311
Java virtual machine initialization tips.	314
Example: Developing an ActiveX application client to Enterprise Bean bridge using Java proxy objects	314
Example: Calling Java methods in the ActiveX to enterprise bean bridge.	315
Java field programming tips	316
ActiveX to Java primitive data type conversion values	317
Array tips for ActiveX application clients	318
Error handling codes for ActiveX application clients	319
Threading tips	319
Example: Viewing a System.out message	320

Example: Enabling logging and tracing for application clients	321
ActiveX client programming best practices	321
Developing applet client code	324
Accessing secure resources using SSL and applet clients	325
Applet client tag requirements	325
Applet client code requirements	326
Developing J2EE application client code	326
J2EE application client class loading	328
Developing pluggable application client code	330
Developing thin application client code	331
Developing thin application client code on a client machine	331
Developing thin application client code on a server machine	332
Assembling application clients	333
Deploying application clients on workstation platforms	334
Starting the Application Client Resource Configuration Tool and opening an EAR file	334
Data sources for application clients	334
Configuring new data source providers (JDBC providers) for application clients	335
Configuring new data sources for application clients	338
Configuring mail providers and sessions for application clients	338
Configuring new mail sessions for application clients	341
URLs for application clients	341
URL providers for the Application Client Resource Configuration Tool	342
Configuring new URL providers for application clients	342
Configuring new URLs with the Application Client Resource Configuration Tool	344
WebSphere asynchronous messaging using the Java Message Service API for the Application Client Resource Configuration Tool	345
Configuring Java messaging client resources	345
Configuring new connection factories for application clients	376
Configuring new Java Message Service destinations for application clients	376
Example: Configuring MQ Queue and Topic connection factories and destination factories for application clients	377
Example: Configuring WAS Queue and Topic connection factories and destination factories for application clients	378
Configuring new resource environment providers for application clients	379
Configuring new resource environment entries for application clients	380
Managing application clients	381
Updating data source and data source provider configurations with the Application Client Resource Configuration Tool	381
Updating URLs and URL provider configurations for application clients	382
Updating mail session configurations for application clients	382
Updating Java Message Service provider, connection factories, and destination configurations for application clients	382
Updating MQ Java Message Service provider, MQ connection factories, and MQ destination configurations for application clients	383
Updating resource environment entry and resource environment provider configurations for application clients	383
Removing application client resources	384
Running application clients	385
launchClient tool	386
Example: Using a Java 2 security manager with a J2EE application client	388
Example: Enabling Java 2 security prior to J2EE application client run time initialization	389
Application client troubleshooting tips	390
Chapter 8. Using Web services based on Web Services for J2EE	395
Web services	396
Web Services for J2EE	397

Java API for XML-based remote procedure call (JAX-RPC)	398
SOAP	398
SOAP with Attachments API for Java	399
Planning to use Web services based on Web Services for J2EE	399
Service-oriented architecture	400
Web services approach to a service-oriented architecture	400
Web services business models supported	403
Migrating Apache SOAP Web services to Web Services for J2EE	403
Developing Web services based on Web Services for J2EE	405
Example: Developing Web services based on Web Services for J2EE	406
Artifacts used to develop Web services based on Web Services for J2EE	408
Mapping between Java language, WSDL and XML	409
Java2WSDL command	429
WSDL2Java command	432
Setting up a development and unmanaged client execution environment for Web services based on Web Services for J2EE	435
Using the Java Messaging Service to transport Web services requests	435
Developing a Web service from a Java bean	437
Developing a Web service using a stateless session enterprise bean	448
Developing a new Web service with an existing WSDL file using a Java bean	451
Developing a new Web service from an existing WSDL file using a stateless session enterprise bean	452
Developing Web services clients based on Web Services for J2EE	454
Example: Developing Web services clients based on Web Services for J2EE	454
Developing client bindings from a WSDL file	455
Assembling a Web services-enabled client JAR file into an EAR file	456
Assembling a Web services-enabled client WAR file into an EAR file	457
Configuring the ibm-webservicesclient-bnd.xmi deployment descriptor	458
Configuring the webservicesclient.xml deployment descriptor	461
Configuring the webservicesclient.xml deployment descriptor for Handler classes	462
Testing Web services-enabled clients	466
Assembling Web services applications based on Web Services for J2EE	466
Assembling a Web services-enabled EJB JAR file	467
Assembling a Web services-enabled WAR file	469
Assembling a Web services-enabled EJB JAR into an EAR file	471
Assembling a Web services-enabled WAR into an EAR file	471
Enabling a Web services-enabled EAR file	472
Configuring the webservices.xml deployment descriptor	477
Configuring the ibm-webservices-bnd.xmi deployment descriptor	478
ibm-webservices-bnd.xmi assembly properties	479
Configuring the webservices.xml deployment descriptor for Handler classes	480
Deploying Web services based on Web Services for J2EE	481
wsdeploy command	481
Securing Web services based on WS-Security	483
Web services security specification- a chronology	484
Web services security support	485
Web services security and Java 2 Platform, Enterprise Edition security relationship	488
Web services security model in WebSphere Application Server	490
Web services security property collection	493
Web services security property configuration settings	493
Usage scenario for propagating security tokens	494
Configurations	495
Authentication method overview	509
XML digital signature	512
Securing Web services using XML digital signature	516
XML encryption	574

Securing Web services using XML encryption	577
Securing Web services using basicauth authentication	595
Identity assertion	602
Securing Web services using identity assertion authentication.	603
Securing Web services using signature authentication	608
Token type overview	613
Security token	619
Securing Web services using a pluggable token.	619
Tuning Web services based on Web Services for J2EE	629
Troubleshooting Web services based on Web Services for J2EE	629
Troubleshooting command-line tools for Web services based on Web Services for J2EE	630
Troubleshooting compiled bindings for Web services based on Web Services for J2EE	631
Troubleshooting the run time of Web services based on Web Services for J2EE	631
Troubleshooting the run time for a Web services client based on Web Services for J2EE	633
Troubleshooting serialization and deserialization in Web services based on Web Services for J2EE	633
Frequently asked questions about Web services based on Web Services for J2EE	635
Web services: Resources for learning	636
Chapter 9. Overview: Online garden retailer Web services scenarios	641
Web services scenario: Static inquiry on supplier	644
Web services scenario: Dynamic inquiry on supplier	646
Web services scenario: Cross supplier inquiry	648
Chapter 10. Web Services Invocation Framework (WSIF): Enabling Web services	651
Goals of WSIF	651
WSIF - Web services are more than just SOAP services	651
WSIF - Tying client code to a particular protocol implementation is restricting	652
WSIF - Incorporating new bindings into client code is hard	652
WSIF - Multiple bindings can be used in flexible ways	652
WSIF - Enabling a freer Web services environment promotes intermediaries	652
An overview of WSIF.	653
WSIF architecture	653
Using WSIF with Web services that offer multiple bindings	654
WSIF and WSDL	654
WSIF usage scenarios	654
Dynamic invocation	655
Using WSIF to invoke Web services	655
Using the WSIF providers	656
Developing a WSIF service	666
Using complex types.	675
Using the Java Naming and Directory Interface (JNDI)	676
Passing SOAP messages with attachments using WSIF.	678
Interacting with the J2EE container in WebSphere Application Server	680
Running WSIF as a client	680
WSIF system management and administration	681
Maintaining the WSIF properties file	681
Enabling security for WSIF	681
Troubleshooting the Web Services Invocation Framework	682
WSIF API	686
WSIF API reference: Creating a message for sending to a port	686
WSIF API reference: Finding a port factory or service.	687
WSIF API reference: Using ports	688
Chapter 11. Enabling the IBM WebSphere UDDI Registry	693
UDDI Registry terminology	693
UDDI Registry definitions	694

An overview of IBM UDDI Registries	694
Migrating from a previous version of IBM WebSphere UDDI Registry	695
Installing and setting up a UDDI Registry	698
Installing the UDDI Registry into a deployment manager cell	700
Installing the UDDI Registry into a single appserver	707
Reinstalling the UDDI Registry application	712
Applying Service updates to the UDDI Registry in a Network Deployment and single application server environment	713
Using a remote DB2 database for UDDI.	713
Removing the UDDI Registry application from a deployment manager cell	715
Removing the UDDI Registry application from a single application server	715
Configuring the UDDI Registry	716
Configuring global UDDI properties	716
Modifying the database userid and password	718
Configuring security roles	718
Configuring the UDDI User Console (GUI) for multiple language encoding support	719
Customizing the UDDI User Console (GUI)	719
Configuring SOAP interface properties	719
Configuring SOAP properties with the WebSphere Assembly Toolkit	720
Configuring SOAP properties in an application that is already deployed	720
Administering the UDDI Registry	720
Running the UDDI Registry	720
Backing up and restoring the UDDI Registry database	721
UDDI4J programming interface	721
UDDI user console	722
Displaying the user console	725
Custom Taxonomy Support in the UDDI Registry	726
UDDI Utility Tools	734
UDDI TestEntityExporter.java	745
UDDI TestEntityImporter.java	748
UDDI TestEntityPromoter.java	752
UDDI TestEntityFinder.java	754
UDDI TestEntityDeleter.java	758
UDDI TestUddiSerializer.java	761
UDDI TestUddiDeserializer.java	763
UDDI TestStubManager.java	765
UDDI TestCreateMinimalEntity.java	766
SOAP application programming interface for the UDDI Registry	768
Programming the SOAP API	768
SOAP API error handling tips in the UDDI Registry	769
UDDI Registry Application Programming Interface	769
Inquiry API for the UDDI Registry	769
Publish API for the UDDI Registry	771
UDDI EJB Interface for the UDDI Registry	772
Datatypes package in the UDDI Registry	777
EJB interface methods in the UDDI Registry	780
UDDI troubleshooting tips	781
Turning on UDDI trace	784
Messages	784
UDAI (Web Services UDDI) messages	785
UDCF (Web Services UDDI) messages	785
UDDA (Web Services UDDI) messages	786
UDDM (Web Services UDDI) messages	786
UDEJ (Web Services UDDI) messages	786
UDEX (Web Services UDDI) messages	786
UDIN (Web Services UDDI) messages	786

UDLC (Web Services UDDI) messages	805
UDPR (Web Services UDDI) messages	805
UDRS (Web Services UDDI) messages	805
UDSC (Web Services UDDI) messages	805
UDSP (Web Services UDDI) messages	805
UDUC (Web Services UDDI) messages	806
UDUT UDDI Utility Tools messages	808
UDUU (Web Services UDDI) messages	819
Running the UDDI samples	819
Installation Verification Program (IVP)	819
Reporting problems with the IBM WebSphere UDDI Registry	821
Feedback	821
Chapter 12. Web services gateway: Enabling Web services	823
Web services gateway - frequently asked questions	824
Web services gateway - What is new in this release	825
Web services gateway - Completing the installation	826
Web services gateway - prerequisites and constraints	827
Preserving an existing gateway configuration	828
Installing the gateway into an application server that is part of a deployment manager cell	829
Installing the gateway into a stand-alone application server	830
Testing the Web services gateway installation	832
Backing up and restoring a gateway configuration	833
Backing up and restoring UDDI publication links.	833
Backing up a gateway configuration	834
Restoring a gateway configuration	834
Administering the Web services gateway	835
Setting the namespace URI and WSDL URI for the Web services gateway	837
Working with channels	839
Working with filters	845
Working with JAX-RPC handlers	847
Working with UDDI references	851
Working with Web services	855
Running the Web services gateway Samples	866
Passing SOAP messages with attachments through the Web services gateway	866
SOAP messages with attachments - a definition.	867
Writing the WSDL extensions for SOAP messages with attachments	867
Developing Web services gateway extensions	868
Writing a filter for the Web services gateway	868
Using a filter to select a target service and port	877
Capturing Web service invocation information from the Web services gateway	878
Handling exceptions for the Web services gateway	879
Scaling the Web services gateway.	880
Scaling the Web services gateway using unlocked configuration deployment	881
Securing the Web services gateway	882
Enabling Web Services Security (WS-Security) for the gateway	882
Enabling basic authentication and authorization for the gateway	889
Invoking Web services over HTTPS	894
Enabling proxy authentication for the gateway	894
Tuning the Web services gateway	897
Selective SOAP parsing	899
Troubleshooting the Web services gateway	899
Web services gateway messages	904
Chapter 13. Class loading	923
Class loaders	923

Class loader collection	927
ClassLoader ID	927
ClassLoader Mode	927
Class loader settings	927
Migrating the class-loader Module Visibility Mode setting	927
Class loading: Resources for learning	928
Chapter 14. Using EJB query	929
EJB query language	929
Example: EJB queries	930
FROM clause	932
Inheritance in EJB query	933
Path expressions	933
WHERE clause	934
Scalar functions	941
Aggregation functions	944
SELECT clause	945
ORDER BY clause	946
Subqueries	946
EJB query restrictions	947
EJB Query: Reserved words	948
EJB query: BNF syntax	948
Comparison of EJB 2.0 specification and WebSphere query language	950
Using the dynamic query service	950
Example: Dynamic query remote client	952
Example: Dynamic query from local client	953
Dynamic query service performance considerations	953
Chapter 15. Using the internationalization service	955
Internationalization	955
Internationalization service: Overview	956
Internationalization challenges in distributed applications	957
Migrating internationalized applications	958
Assembling internationalized applications	959
Setting the internationalization type for servlets	959
Configuring container internationalization for servlets	960
Setting internationalization type for enterprise beans	961
Configuring container internationalization for enterprise beans	961
Using the internationalization context API	963
Gaining access to the internationalization context API	963
Accessing caller locales and time zone	964
Accessing invocation locales and time zone	965
Example: Internationalization context in an EJB client program	966
Example: Internationalization context in an EJB servlet	968
Example: Internationalization context in a session bean	970
Internationalization context API: Programming reference	971
Managing the internationalization service	980
Enabling the internationalization service for servlets and enterprise beans	981
Enabling the internationalization service for EJB clients	982
Troubleshooting the internationalization service	982
Internationalization service errors	983
Internationalization service exceptions	985
Internationalization: Resources for learning	986
Chapter 16. Application profiling	987
Application profiling: Overview	987

Application profiles	987
Application profiling performance considerations.	988
Application profiling tasks	990
Assembling applications for application profiling	991
Automatic configuration of application profiling	991
Applying profile-scoped access intent policies to entity beans	992
Creating a custom access intent policy	993
Creating an application profile	994
Configuring container managed tasks for application clients	995
Configuring container managed tasks for web components.	996
Configuring container managed tasks for Enterprise Java Beans	996
Configuring application managed tasks for application clients	997
Configuring application-managed tasks for web components	998
Configuring application managed tasks for Enterprise Java Beans	999
Specifying target servers for J2EE projects	999
Managing application profiles	1000
Using the TaskNameManager interface	1001
Application profiling exceptions	1002
Application profiling service settings.	1002
Application profile collection.	1003
Chapter 17. Using Business Rule Beans	1005
Advantages of externalizing business rules	1005
Overview of Business Rule Beans	1006
Externalized business rules	1007
Types of business rules	1007
Rule folders	1008
Rule attributes.	1008
Rule states	1010
Rule results.	1010
Dependent rules	1010
BRBeans run-time environment	1011
BRBeans run-time behavior	1011
BRBeans run-time exception handling	1012
Rule implementors	1012
Trigger point framework	1014
Trigger points	1015
As Of Date	1018
Predefined strategy objects	1018
Customized strategy objects	1020
Customized rule implementors.	1021
Rule management command	1022
Rule importer command	1022
Rule exporter command	1023
BRBeans properties file	1024
Database considerations for BRBeans	1025
Rule Management Application	1027
Rule management APIs	1027
BRBeans performance enhancements	1028
Developing BRBeans	1031
Determining where to place a trigger point	1031
Placing a trigger point in the application code	1032
Administering strategy objects to control triggers	1033
Implementing business rules	1034
Assembling applications for use with BRBeans.	1035
Managing rules	1036

Starting the Rule Management Application	1037
Copying or moving rules or rule folders	1037
Working with Quick Copy.	1037
Finding a rule	1038
Deleting rules	1038
Deleting rule folders	1038
Changing the properties of a rule	1039
Importing a rule	1039
Exporting a rule	1039
Renaming rules	1040
Renaming rule folders	1040
Specifying columns	1040
Changing the date and time format	1040
Rule Browser	1041
File menu	1041
Edit menu	1054
View menu	1057
Find Rules window	1058
Business rule beans: Resources for learning	1062
Chapter 18. Using asynchronous beans	1065
Asynchronous beans	1065
Example: Asynchronous bean connection management	1067
Configuring work managers	1068
Work managers	1069
Work manager collection	1070
Work manager service settings	1072
Assembling applications that use work managers	1073
Developing work objects to run code in parallel	1073
Work objects	1074
Example: Work object	1075
Developing event listeners	1076
Using the application notification service	1076
Example: Event listener	1077
Developing asynchronous scopes	1078
Asynchronous scopes	1079
Alarms	1080
Subsystem monitors	1081
Asynchronous scopes: Dynamic message bean scenario	1081
Interoperating with asynchronous beans	1082
Serialized Asynchronous beans interoperability.	1082
Java Management Extension MBean interoperability.	1084
Chapter 19. Using object pools	1085
Object pool managers	1086
Object pool manager collection	1087
Name	1087
JNDI Name.	1087
Description	1088
Category.	1088
Object pool manager settings	1088
Object pool service settings	1089
Startup	1089
Object pools: Resources for learning	1089
Object pool performance considerations	1090

Chapter 20. Using startup beans	1093
Chapter 21. Using the scheduler service	1095
Managing the scheduler service	1095
Creating the database for a scheduler	1095
Configuring a scheduler	1100
Enabling the scheduler service.	1104
Developing and scheduling tasks	1105
Developing a task that calls a session bean	1106
Developing a task that sends a JMS message	1106
Receiving scheduler notifications	1107
Submitting a task to a scheduler	1108
Managing tasks with a scheduler	1109
Scheduler interface	1110
Interoperating with the Scheduler service	1113
Recreating Scheduler tasks	1113
Deleting Scheduler tasks	1115
Recreating Scheduler tables.	1115
Chapter 22. Using shared work areas	1117
WorkArea service - Overview	1117
Work area property modes	1117
Nested work areas	1118
Distributed work areas.	1120
WorkArea service: Special considerations.	1121
Work area service performance considerations.	1121
Developing applications that use work areas	1122
UserWorkArea interface	1123
Example: WorkArea SimpleSample application.	1123
Accessing the WorkArea service	1124
Beginning a new work area	1124
Setting properties in a work area	1125
Using a work area to manage local work	1126
Completing a work area	1129
Managing the work area service	1131
Enabling the WorkArea service	1131
Managing the size of work areas	1132
Configuring work area partitions on the server	1133
Work area partition service	1133
WorkAreaPartitionManager interface.	1135
Example: Work area partition manager.	1136
Work area partition collection	1137
Bidirectional propagation	1139
Accessing a user defined work area partition	1140
Chapter 23. Working with the Event Programming Model in WebSphere.	1143
The Common Event Infrastructure in WebSphere	1143
Events and Common Base Events	1144
The structure of the Common Base Event	1144
Components you should know about	1149
Starting to use the Event Programming Model	1150
Planning to use the Event Programming Model.	1151
Installing the Event Programming Model	1153
Configuring the Event Programming Model using the Administration console	1154
Generating Common Base Events	1158
Obtain an emitter.	1159

Event creation from WebSphere applications	1159
Using the Java API	1159
Generating a Common Base Event in BPEL	1160
Populating events with event context data	1161
Send an event.	1163
Viewing events with the event browser	1163
Specifying the events to view	1164
Working with the events returned	1166
Working with WebSphere event infrastructure messages	1168
State observer plugin messages	1168
Business context data services messages	1171
Common Event Infrastructure Developer's Guide	1173
Introduction to the common event infrastructure	1173
Configuring the common event infrastructure	1175
Developing an event source.	1180
Developing an event consumer	1184
Working with events	1188

How to send your comments

Your feedback is important in helping to provide the most accurate and highest quality information.

- To send comments on articles in the WebSphere Application Server Information Center
 1. Display the article in your Web browser and scroll to the end of the article.
 2. Click on the **Feedback** link at the bottom of the article, and a separate window containing an e-mail form appears.
 3. Fill out the e-mail form as instructed, and click on **Submit feedback** .
- To send comments on PDF books, you can e-mail your comments to: **wasdoc@us.ibm.com** or fax them to 919-254-0206.

Be sure to include the document name and number, the WebSphere Application Server version you are using, and, if applicable, the specific page, table, or figure number on which you are commenting.

When you send information to IBM, you grant IBM a nonexclusive right to use or distribute the information in any way it believes appropriate without incurring any obligation to you.

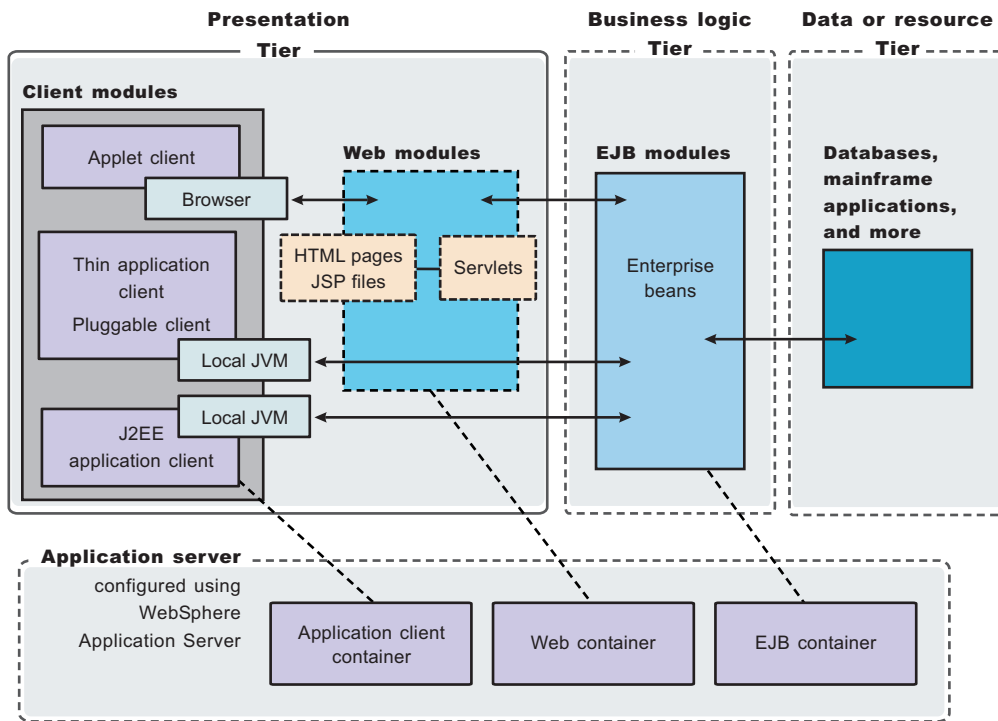

Chapter 1. Welcome to applications

In the WebSphere Application Server environment, the components making up a Java 2 Platform, Enterprise Edition (J2EE) application are referred to as *application modules*, specifically:

- Web modules
- Enterprise JavaBeans (EJB) modules
- Client modules

After you assemble modules into a main module called an application module or EAR file, you are ready to deploy the application module onto the application server.

You can deploy both Web and EJB modules as stand-alone applications. A J2EE application is generally comprised of all three application modules, each deployed in its own container that is provided by the application server that you have configured. The following diagram depicts how the application modules interact across the three-tier architecture of enterprise computing:

The diagram does not depict interaction between Web modules and the thin application, pluggable, or J2EE application client because it is a rare requirement. Applications that use these client types, however, can incorporate Web modules. The product provides different levels of support for the requirement, according to client type. Refer to articles specifically on your client type for more information.

Web modules

A Web module consists of the following components, in varying combinations (corresponding to the application client requirements, security requirements, and so on):

- HyperText Markup Language (HTML) pages and JavaServer Pages (JSP) supply the user interface and program logic.
- Servlets coordinate work between these components and business logic.

You create a Web module by assembling servlets, JSP files, and static content such as HTML pages into a single deployable unit. You can then deploy the Web module as a stand-alone Web application, or combine it with other modules to create J2EE applications.

Whichever application type you deploy, you have the option of activating **Session Manager** for your Web module. By using this service to manage HTTP sessions, you can personalize Web pages for individual users. A session is a series of requests to a servlet, originating from the same user at the same browser. Managing HTTP sessions allows servlets running in a Web container to keep track of individual users.

For example, a servlet might use sessions to provide "shopping carts" to on-line shoppers. Suppose the servlet is designed to record the items each shopper indicates he or she will purchase from the Web site. It is important that the servlet be able to associate incoming requests with particular shoppers. Otherwise, the servlet might mistakenly add choices of Shopper 1 to the cart of Shopper 2.

EJB modules

EJB modules are combinations of enterprise beans, which perform various roles in retrieving data from the Data and Resource tier and running business logic in a J2EE application. You also can deploy an EJB module as a stand-alone application (refer to Chapter 30, "Deploying and managing applications," on page 1409 for the necessary steps).

Version support

IBM WebSphere Application Server provides broad support for enterprise beans, including the Enterprise JavaBeans (EJB) 2.0 specification. The EJB 2.0 specification introduces a container-managed persistence (CMP) 2.0 component model, which provides a number of improvements to aid developer productivity and application performance. In addition, this product continues to fully support enterprise beans written to the CMP 1.1 programming model and deployed in previous versions of this product; applications can use CMP 1.1 beans, CMP 2.0 beans, or a mixture of both. CMP 1.1 beans can be directly carried forward in an EJB 1.1 ejb-jar module or may be repackaged and combined with CMP 2.0 beans in an EJB 2.0 module.

Several excellent trade books that cover the latest EJB specification and the CMP persistence model are already available. A good way to locate some of these is to visit your favorite online bookstore and search on the term *Enterprise JavaBeans*. For a more basic orientation, see "Enterprise beans: Resources for learning" on page 126.

Innovations for EJB development

For EJB 2.0 modules, a feature introduced in Version 5 of this product, called **access intent** policies, eases the management of interactions between CMP beans and their underlying data stores. Each policy sets such data access characteristics such as access type (read or update) and transaction isolation that affect the locking of resources, letting you choose the level of data integrity and performance for your application. The Integration Server product adds APIs to enable you to further customize IBM-provided access intent policies for your particular environment.

Your application development can also include **asynchronous messaging**, which the product supports as a method of communication based on the Java Message Service (JMS) programming interface. The base JMS support enables IBM WebSphere Application Server applications to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics). An application can explicitly poll for messages on a destination.

The product also provides a message listener service that applications can use to automatically retrieve messages from JMS destinations for processing by message-driven beans, without the application having to explicitly poll JMS destinations.

The Integration Server product provides **extended messaging**, which uses the EJB container to manage the messaging infrastructure, and provides more types of messaging beans. This enables application developers to concentrate on the business logic for enterprise beans and to leave the messaging usage to messaging objects and configuration of the EJB container.

Refer to:

- “Asynchronous messaging with WebSphere - an overview” on page 159 An overview of WebSphere asynchronous messaging.
- “Using JMS and messaging in applications” on page 162 Implementing WebSphere J2EE applications that use JMS.

For information about the types of enterprise beans, see the Enterprise beans article.

Client modules

WebSphere Application Server supports multiple models of a client module, each suitable for different types of applications. For example: the various dependencies of the models on Web modules for access to business logic can accommodate different client-side requirements for deployment. If a developer wants to create an application requiring no initial code deployment to client machines, an appropriate client module choice is the applet client. This client receives the necessary application code through download from HTML pages.

Most models of a client module are only available when you install the product. For a list of supported products and version information, see the Supported Prerequisites Web site.

ActiveX application client

WebSphere Application Server provides an ActiveX to EJB bridge that enables ActiveX programs to access WebSphere Enterprise JavaBeans through a set of ActiveX automation objects.

Applet client

The applet client provides a browser-based Java run time capable of interacting with enterprise beans directly, instead of indirectly through a servlet.

J2EE application client

The J2EE application client programming model provides the benefits of Java TM 2 Platform for WebSphere Application Server Enterprise (J2EE).

Pluggable application client (Windows platforms only)

The pluggable application client is a thin application client that uses the Sun Java run-time environment (JRE) instead of the IBM JRE environment.

Thin application client

This application client is a Java application client without the J2EE client container support. It uses a different programming model than the J2EE application client.

5.1 +

Integration Server client

The Integration Server client is a thin application client that provides additional run time support for the J2EE application client and the thin application client to access WebSphere Business Integration Server Foundation server features, such as business rule beans, internationalization services, and the activity session service.

Note: The Imaginary Buffer Line product provides a CD-ROM and installation program for installing application clients without installing the entire application server. This smaller footprint is useful if you want to run client applications on multiple client machines. For more information, see Installing application clients.

Web services

Web services are services that you use over the Internet. If you have an existing application, and you want to make the service that your application provides available to others - either within your own organization or beyond it - you can use Web services technologies to provide a standard Web interface for your service. Used in this manner, Web services can be defined as middleware. You can connect applications together no matter how each application is implemented or where it is located.

Middleware is not new, but what is new is Web services technology and its power to connect by using open standards. Web services operate at a level of abstraction that is similar to the Internet; they can work with any operating system, hardware platform or programming language that can be Web-enabled.

The core technologies on which Web services are developed and implemented include:

- XML (Extensible Markup Language). XML solves the problem of data independence. You use it to describe data, and also to map that data into and out of any application or programming language.
- Web services for Java 2 platform, Enterprise Edition (J2EE) specification defines the programming model and run-time architecture for implementing Web services based on the Java language. WebSphere Application Server Version 5.0.2 and 5.1 supports Web Services for J2EE Version 1.0. If you want to know how to implement a Web service interface to an existing application, then deploy your Web service within the application server, see Using Web services based on Web Services for J2EE.
- Java API for XML-Based RPC (JAX-RPC) enables you to develop SOAP-based interoperable and portable Web services and Web services clients. WebSphere Application Server Version 5.0.2 and 5.1 supports JAX-RPC Version 1.0.
- WSDL (Web Services Description Language). You use this XML-based language to create a description of an underlying application. It is this description that turns an application into a Web service, by acting as the interface between the underlying application and other Web-enabled applications. WebSphere Application Server Version 5.0.2 and 5.1 supports WSDL Version 1.1.
- SOAP (Simple Object Access Protocol). SOAP is the core communications protocol for the Web, and most Web services use this protocol to talk to each other. WebSphere Application Server Version 5.0.2 and 5.1 supports SOAP Version 1.1.
- SOAP with attachments API for Java (SAAJ) is used for SOAP messaging that works behind the scenes in the Java API for XML-based RPC (JAX-RPC) implementation. You can also use this API to directly write SOAP messaging applications rather than using JAX-RPC. SAAJ allows you to do XML messaging from the Java platform by making method calls by creating, sending and consuming XML messages over the Internet. WebSphere Application Server Version 5.0.2 and 5.1 supports SAAJ Version 1.1.

WebSphere Application Server also provides other mechanisms that can help you get the most out of your Web services:

A Web Services Invocation Framework (WSIF)

SOAP bindings for Web services are part of the WSDL specification. So when you think of using a Web service, you probably think of assembling a SOAP message and sending it across the network to the service endpoint, using some SOAP client API. The WSDL specification allows for extensibility points which can describe alternate ways of invoking a Web service. A WSIF client can make use of these non-SOAP descriptions to invoke a service in a more efficient way. For example, a Web service provider might offer a SOAP binding for the service and a local Java binding that allows you to treat the local service implementation (a Java class) as a Web service. If the client is deployed in the same environment as the service, then the local Java binding for the service can be used. This provides more efficient communication with the service by making direct Java calls rather than sending and receiving SOAP messages.

To deploy a Web service as a WSIF-enabled service, you first develop and deploy the Web service, then you develop the WSIF client based on the WSDL document for that Web service -

unless you are also using the Web services gateway, in which case the gateway automatically redeploys your Web service as a WSIF-enabled service.

A Web services gateway

You use the gateway to handle Web service invocations between Internet and Intranet environments. You use it to make your internal Web services available externally, and to make external Web services available to your internal systems. You also use it to specify:

- The transport mechanisms (or channels) on which messages can be carried to and from the service.
- The filters or handlers (if any) that act upon these incoming and outgoing messages.
- The UDDI registries (if any) to which you want the service to be published
- The levels of security that you want to apply to the service.

When you deploy a Web service to the gateway, the gateway creates a copy of the WSDL file for that service and stores it at a new Web address. Users of the service through the gateway then use the gateway copy of the WSDL file. You should therefore (if possible) decide whether or not you want to use the gateway before you make the Web addresses of your deployed services available to others.

CORBA applications 5.1 +

In addition to J2EE enterprise applications, you can also deploy CORBA client/server applications in your environment (if your environment includes the CORBA C++ SDK). You can use the CORBA C++ SDK to build a lightweight WebSphere CORBA server to use with new or existing C and C++ programs. You also can use the SDK to build a WebSphere CORBA C++ client to use with a WebSphere EJB server or WebSphere CORBA C++ server.

For more information, refer to CORBA applications documentation.

Note: **5.1 +** In future releases, IBM intends to remove the C++ Object Request Broker (ORB), the C++ library for IDL valuetypes and the WebSphere Application Server C++ security client. IBM will no longer ship or support the Common Object Request Broker Architecture (CORBA) C++ Developer Kit. The CORBA technology is a bridge for migration to a Java 2 Platform Enterprise Edition (J2EE) and WebSphere Application Server environment. It is recommended that customers migrate to the Object Request Broker (ORB) service for Java technology that ships with WebSphere Application Server. However, there is no equivalent J2EE functionality for the C++ security client or the C++ Valuetype library. Customers that require such functionality must provide or develop their own.

The deprecation of the CORBA C++ Developer Kit does not affect support for CORBA interoperability with vendor software for CORBA services. View the following links for additional information about interoperability:

- [CORBA Interoperability Samples documentation](#)
- [IBM WebSphere Application Servers CORBA Interoperability white paper](#)

Application services

IBM WebSphere Application Server provides essential services to ease the building of dynamic and flexible e-business applications. These services support and extend the open standards of J2EE and Web services, with a focus on application reuse and integration.

The Enterprise Extensions product takes application services to the next level, providing a broad range of dynamic API extensions that address functional gaps in the J2EE programming model.

- **Class loading**

The WebSphere Application Server product provides several class-loading modes, policies, and features to enable you to deploy and run your applications successfully. An application server provides an Application class-loader policy that enables you to control the isolation of applications in a server. If you want applications to share classes, choose the SINGLE policy; otherwise choose the MULTIPLE policy, which isolates the class loaders for each application.

Similarly, at the application level, you can choose a WAR class-loader policy that configures the isolation of Web modules within an application. If you choose the policy APPLICATION, then each Web module in your application can see the classes of other Web modules. A policy of MODULE creates a separate class loader for each Web module, resulting in isolation for each of the classes of each Web module.

The class-loader mode setting, which you can configure at the server, application, or Web module level depending on your class-loader policy, enables you to control whether application class loaders override classes contained in base run-time class loaders. By default, the WebSphere Application Server class loaders have a class-loader mode of PARENT_FIRST, which is the standard JDK mode and does not allow the application class loader to override classes. You must take care when using the PARENT_LAST class-loader mode to make all dependent classes available within the application or you might get LinkageErrors or other class-loader exceptions. For example, if you provide a newer version of the Xerces.jar file and your application is using XSLT, you must also provide a xalan.jar file within your application.

- **Shared library**

Version 5.0 of WebSphere Application Server introduces the concept of a shared library. A shared library is a CLASSPATH and a symbolic name for that classpath. You define shared libraries at the cell, node, or server level and then associate the shared libraries either with an application server (making the classes available to all applications in the server) or with individual applications (making the classes available only to the referencing application). This mechanism provides a convenient way to make libraries of classes available to your applications outside of a standard J2EE enterprise application (EAR) file for easier version management and space efficiency. (See "Managing shared libraries" in the Information center.)

- **EJB query**

The EJB query language is used to specify a query over container-managed entity beans. WebSphere's EJB query language is compliant with the EJB QL defined in Sun's EJB 2.0 specification, but adds additional support as described in the topic "Comparison of EJB 2.0 specification and WebSphere query language" on page 950.

EJB query can be used to define a finder or select method of an EJB entity bean. Finder and select queries are specified in the bean deployment descriptor using the <ejb-ql> tag. Queries specified in the deployment descriptor are compiled into SQL during deployment. See Chapter 14, "Using EJB query," on page 929.

The Enterprise Extensions product includes the dynamic query service, an additional API that enables you to dynamically specify a query in your application by adding the executeQuery() method. See "Using the dynamic query service" on page 950.

- **Internationalization support**

The internationalization service manages the distribution of locale and time zone information, or *internationalization context*, in applications that run on WebSphere Application Server Enterprise installations. The internationalization service solves the problem of mismatched locales and time zones by systematically managing the distribution of internationalization context across the various components of EJB applications.

The internationalization service transparently propagates internationalization context over requests that originate from J2EE-compliant Web service clients. The service creates a SOAP header block that contains the invocation context scoped to the current thread; this SOAP representation is then inserted into the outgoing Web services request. For incoming requests, the service scopes the propagated internationalization context, referred to as *caller context*, to the invocation of the stateless session bean that is enabled as a Web service. The service also scopes an *invocation context* as prescribed by the internationalization context management policies that were assigned to the enterprise bean's methods during application assembly.

For more information about the internationalization service, see Chapter 15, “Using the internationalization service,” on page 955

- **Workarea service**

The WorkArea service enables application developers to implicitly propagate information beyond the information passed in remote calls. Applications can create a work area, insert information into it, and make remote invocations. The work area is propagated with each remote method invocation, eliminating the need to explicitly include an appropriate argument in the definition of each method. The methods on the server side can use or ignore the information in the work area as appropriate. See Chapter 22, “Using shared work areas,” on page 1117

- **Application profiling**

Application profiling enables you to configure multiple access intent policies on the same method of an entity bean; and to configure multiple access intent policies for dynamic query on the same entity bean.

To use application profiling, application developers identify named units of work, or *tasks*. A task typically corresponds to the execution of a concrete and high-level job within the application. The IBM WebSphere Application Server run-time environment queries the task at the invocation of any entity bean, and establishes the appropriate access intent policy under which the bean should execute. An *application profile* is the set of access intent or query intent policies that should be selectively applied, as well as the list of tasks for which the policies should be applied. See Chapter 16, “Application profiling,” on page 987

- **Scheduler service**

The scheduler service enables J2EE work to be executed at a requested time or interval. The scheduler API supports different implementations of the TaskInfo interface, each of which can be used to schedule a particular type of work; for example, you can develop a task that calls a session bean or a task that sends a JMS message. You can set a notification sink on a task in order to receive the notification events that are generated by a scheduler when it performs an operation on the task. See Chapter 21, “Using the scheduler service,” on page 1095

- **Asynchronous beans**

An asynchronous bean is a Java object or enterprise bean that can be executed asynchronously by a J2EE application, using the J2EE context of the bean’s creator. These beans also can run with copies of other J2EE contexts. For example:

- Internationalization context
- Application profiles
- Work areas
- Access intent policies

Asynchronous beans enable the construction of stateful, “active” J2EE applications. These applications address a segment of the application space that J2EE has not previously addressed (that is, advanced applications that require application threading, active agents within a server application, or distributed monitoring capabilities). See Chapter 18, “Using asynchronous beans,” on page 1065.

- **Object pools**

Objects are frequently pooled by Java applications in order to avoid the cost of creating new Java objects and the associated garbage collection delays that result when these objects are reclaimed after use. An object pool keeps a number of pre-allocated objects on behalf of its users. Applications can get an object from the pool, use it, and later return it to the pool. This allows the individual object instances to be reused and effectively limits the amount of garbage generated by the application. Chapter 19, “Using object pools,” on page 1085

- **Startup beans**

Startup beans are stateful session beans that enable J2EE applications to execute business logic when an application starts or stops. The startup bean is loaded when the application starts. The start() method is then invoked on the bean’s remote interface. This method can execute any business logic needed by the application at start time. Similarly, the bean’s stop() method is called on the instance when the application is stopped and can execute any business logic needed by the application at stop time. See Chapter 20, “Using startup beans,” on page 1093

Startup beans are especially useful when used in combination with asynchronous beans to develop an active J2EE server application.

- **Business Rule Beans (BRBeans)**

Business Rule Beans are used to separate business rules from an application's core behavior, allowing the application code to remain intact and untouched even as business practices change. Each business rule is represented by an entity bean that persistently stores information related to that rule. Each business rule is assigned an appropriate rule name and stored in a rule folder. The application developer identifies "points of variability" within an application and codes trigger points at these locations. These trigger points invoke one or more business rules. See Chapter 17, "Using Business Rule Beans," on page 1005

- **Transactions**

IBM WebSphere Application Server applications can use transactions to coordinate multiple updates to resources as atomic units (as indivisible units of work) such that all or none of the updates are made permanent. The way that applications use transactions depends on the type of application component, as follows:

- A session bean can either use container-managed transactions (where the bean delegates management of transactions to the container) or bean-managed transactions (where the bean manages transactions itself)
- Entity beans use container-managed transactions
- Web components (servlets) use bean-managed transactions

The product is a transaction manager that supports the coordination of resource managers through their XAResource interface and participates in distributed global transactions with other OTS 1.2 compliant transaction managers (for example, J2EE 1.3 application servers). Applications can also be configured to interact with databases, JMS queues, and JCA connectors through their local transaction support when distributed transaction coordination is not required.

Resource managers that offer transaction support can be categorized into those that support two-phase coordination (by offering an XAResource interface) and those that support only one-phase coordination (for example through a LocalTransaction interface). The IBM WebSphere Application Server transaction support provides coordination, within a transaction, for any number of two-phase capable resource managers. It also enables a single one-phase capable resource manager to be used within a transaction in the absence of any other resource managers, although a WebSphere transaction is not necessary in this case. With the Last Participant Support of Enterprise Extensions, you can coordinate the use of a single one-phase commit (1PC) capable resource with any number of two-phase commit (2PC) capable resources in the same global transaction. At transaction commit, the two-phase commit resources are prepared first using the two-phase commit protocol, and if this is successful the one-phase commit-resource is then called to `commit(one_phase)`. The two-phase commit resources are then committed or rolled back depending on the response of the one-phase commit resource.

The ActivitySession service of Enterprise Extensions provides an alternative unit-of-work (UOW) scope to that provided by global transaction contexts. It is a distributed context that can be used to coordinate multiple one-phase resource managers. The product EJB container and deployment tooling support ActivitySessions as an extension to the J2EE programming model. Enterprise beans can be deployed with lifecycles that are influenced by ActivitySession context, as an alternative to transaction context. An application can then interact with a resource manager through its LocalTransaction interface for the period of a client-scoped ActivitySession rather than just the duration of an EJB method.

- **Naming**

Naming clients use **Naming Services** primarily to access objects, such as EJB homes, associated with applications installed on IBM WebSphere Application Server. Objects are made available to clients by being bound into a name space. A name space is under the control of a name server. In this product, there are potentially many name servers, and the name spaces controlled by the various name servers are federated together to form the view of a single name space. Each name server presents the same logical view of the federated name spaces.

Name servers provided by this product are a CORBA CosNaming implementation. IBM WebSphere Application Server provides a CosNaming JNDI plug-in which enables clients to access the name servers through the JNDI interface. Clients to EJB applications typically use JNDI to perform Naming operations. Clients may access the name servers directly through the CORBA programming model. The

CosNaming interface is part of the CORBA programming model. CORBA clients which need to access EJB homes or some other objects bound to the name space would typically use the CORBA CosNaming interface to perform Naming operations.

- **Dynamic cache**

Dynamic cache improves application performance by caching outputs and contents of outputs of servlets, JavaServer Pages (JSP) files, Web services, and commands. On subsequent client requests to the same applications, dynamic cache intercepts these calls and responds by serving the output or the contents of output from the cache.

Dynamic cache in this product version includes:

- **Servlet/JSP files caching**

This caches output of dynamic servlets and JSP files by working with the Java virtual machine of the application server by intercepting calls to service methods and serving Web pages from the cache. This improves server response time, throughput and scalability.

- **Command caching**

Commands that are written to the Command Architecture encapsulate business logic tasks and provide a standard way to invoke the business logic request. Command objects need to implement CacheableCommand interface instead of TargetableCommand interface to cache. Like in servlets and JSP caching, requests to execute business logic in the command is intercepted by the cache. If a command with the same request attributes are available in cache, output properties are copied from the cached instance to the requested instance and returned without executing the business logic again.

- **Web Services caching**

Web service responses can be cached just like servlet and JSP results. These requests are intercepted and the cache ID is computed based on how the cache ID rules are specified in the cache policy. A hash of the whole SOAPEnvelope can be used as a cache ID or it can be parsed and the service name, operation name and parameter names to these operations used as cache ID. If a cache entry is not found for the computed cache ID, the request is forwarded to the SOAP engine and the result is cached.

- **Edge Side Include caching**

This provides the ability to cache, assemble and deliver dynamic web pages at the edge of the enterprise network. Edge Side Includes (ESI) is a simple markup language which enables dynamic web pages (which by themselves are not so cache efficient) to be broken down into cacheable fragments. These fragments are then cached on the edge of the network and assembled into a single page upon user requests.

- **Distributed caching**

Cache contents can be shared and replicated among servers through dynamic caching by using an underlying JMS based message broker system, DRS (Data Replication Service). Sharing characteristics of individual cache entries are configured using the cache policy specification.

- **User profiles**

Managing **user profiles** allows a company to maintain database tables containing fields for demographic data of individual customers or other users on the company system. For example, when a user repeatedly logs onto a Web site that supports user profiles, the Web site can display headlines and advertising tailored to the shopping preferences of that user. The site can address the user by his or her logon name. User profile API is deprecated in the current release.

Process choreographer

Process choreographer is a powerful enterprise workflow tool that supports running Business Process Execution Language (BPEL) processes in a J2EE environment. These processes can be used to integrate J2EE resources, Web services, and activities that require human interaction.

For more information, refer to process choreographer documentation.

Assembly tools

Assembly is an activity in which you package code components into "modules" that comply with the J2EE specification. You define configurations for the modules, in the form of XML documents known as deployment descriptors. The modules can be assembled into an enterprise application (EAR) file and deployed on a server.

5.1 + The Application Server Toolkit provides a graphical interface tool, called *Assembly Toolkit*, for assembly processes. See "Chapter 29, "Assembling applications with the Assembly Toolkit," on page 1391." For a discussion of archives and Web components supported by the Assembly Toolkit, see "Archive support in Version 5" on page 1393."

Deployment

Deployment involves placing applications onto application servers and running the applications. The main tasks include:

1. Installing application files onto an application server.
2. Configuring the application for the particular operational environment.
3. Starting the newly deployed application.

Information on these tasks is available from "Chapter 30, "Deploying and managing applications," on page 1409." The information describes how to deploy applications using the WebSphere Application Server administrative console. You can also deploy applications using the wsadmin tool, which provides deployment capabilities identical to those available using the administrative console.

Packaging and class loading

You can package your business logic as a Java 2 Platform, Enterprise Edition (J2EE) application enterprise archive (EAR) file or as an enterprise bean (EJB) or Web module for deployment to WebSphere Application Server. You must also consider the class loading relationships among modules.

Uninstalling and redeploying applications

At some point, you will need to uninstall your deployed applications. Or you might need to update your applications and deploy them again. You might be able to use hot deployment and dynamic reloading, where you do not need to restart the application server (or the application in some cases) after deploying an updated application.

Chapter 2. Using Web applications

A developer creates the files comprising a Web application, and then assembles the Web application components into a Web module. Next, the deployer (typically the developer in a unit-testing environment or the administrator in a production environment) installs the Web application on the server.

1. **(Optional)** Migrate existing Web applications to run in the new version of WebSphere.
2. Design the Web application and develop its code artifacts: Servlets, JavaServer Pages (JSP) files, and static files, as for example, images and Hyper Text Markup Language (HTML) files. See the "Resources for learning" article for links to design documentation.
3. **(Optional)** Implement JavaScript within JSP tags using the Bean Scripting Framework (BSF).

5.1+ Support in the JSP Engine for the Bean Scripting Framework is deprecated with WebSphere Application Server 5.1.

4. Develop the Web application, using WebSphere Application Server extensions to enhance its functionality.
5. Assemble the Web application into a Web module using the Assembly Toolkit. Web module assembly properties might include the ability to:
 - Configure servlet page lists.
 - Configure servlet filters.
 - Serve servlets by class name.
 - Enable file serving.
6. Deploy the Web module or application module that contains the Web application.
Following deployment, you might find it handy to use the tool that enables batch compiling of the JSP files for quicker initial response times.
7. **(Optional)** Troubleshoot your Web application. (See "Web Container troubleshooting tips" in the Information center.)
8. **(Optional)** Modify the default Web container configuration in the application server in which you deployed the Web module or application module containing the Web application.
9. **(Optional)** Manage the deployed Web application.

Web applications

A Web application is comprised of one or more related servlets, JavaServer Pages technology (JSP files), and Hyper Text Markup Language (HTML) files that you can manage as a unit.

The files in a Web application are related in that they work together to perform a business logic function.

For example, one of the WebSphere Application Server samples is a *Simple Greeting* Web application. (See "Samples Gallery" in the Information Center.) This application, comprised of a servlet and Web pages, greets new users when the application is accessed.

The Web application is a concept supported by the Java Servlet Specification. Web applications are typically packaged as .war files.

web.xml file

The web.xml file provides configuration and deployment information for the Web components that comprise a Web application. Examples of Web components are servlet parameters, servlet and JavaServer Pages (JSP) definitions, and Uniform Resource Locators (URL) mappings.

The servlet 2.3 specification dictates the format of the web.xml file, which makes this file portable among Java Two Enterprise Edition (J2EE) compliant products.

Location

The `web.xml` file must reside in the `WEB-INF` directory under the context of the hierarchy of directories that exist for a Web application. For example, if the application is `client.war`, then the `web.xml` file is placed in the `install_root/client war/WEB-INF` directory.

Usage notes

- Is this file read-only?

No

- Is this file updated by a product component?

This file is updated by the Assembly Toolkit.

- If so, what triggers its update?

The Assembly Toolkit updates the `web.xml` file when you assemble Web components into a Web module, or when you modify the properties of the Web components or the Web module.

- How and when are the contents of this file used?

WebSphere Application Server functions use information in this file during the configuration and deployment phases of Web application development.

</web-app>

```

Migrating Web application components

Supported open specification levels in WebSphere Application Server Version 5 are documented in article, "Migrating," in the Information Center.

Migration of Web applications deployed in WebSphere Application Server Version 4.x is not necessary; version 2.2 of the servlet specification and version 1.1 of the JavaServerPages (JSP) specification are still supported. However, where there are behavioral differences between the Java Two Enterprise Edition (J2EE) 1.2 and J2EE 1.3 specifications, bear in mind that J2EE 1.3 specifications are implemented in WebSphere Application Server Version 5 and will override any J2EE 1.2 behaviors.

Servlet migration might be a concern if your application:

- implements a WebSphere internal servlet to bypass a WebSphere Application Server Version 4.x single application path restriction.
- extends a PageListServlet that relies on configuration information in the servlet configuration XML file.
- uses a servlet to generate Hyper Text Markup Language (HTML) output.
- calls the `response.sendRedirect()` method for a servlet using the `encodeRedirectURL` function or executing within a non-context root.

JSP migration might be a concern if your application references JSP page implementation classes in unnamed packages, or if you install WebSphere Application Server Version 4.x EAR files (deployed in Version 4.x with the JSP Precompile option), in Version 5.

Follow these steps if migration issues apply to your Web application:

1. Use WebSphere Application Server Version 5 package names for any WebSphere Application Server Version 4.x internal servlets, which are implemented in your application.

In WebSphere Application Server Version 4.x, Web modules with a context root setting of / are not supported. Accessing Web modules with this root context results in HTTP 404 - File not Found errors.

To bypass the errors, and to enable the serving of static files from the root context, WebSphere Application Server Version 4.x users are advised to add the servlet class, `com.ibm.servlet.engine.webapp.SimpleFileServlet`, to their Web module.

The Version 4.x single path limitation does not exist in Version 5. However, users who choose to use the `com.ibm.servlet.engine.webapp.SimpleFileServlet` in Version 5 must do one of the following:

- Rename `com.ibm.servlet.engine.webapp.SimpleFileServlet` to `com.ibm.ws.webcontainer.servlet.SimpleFileServlet`.
- Open a Web deployment descriptor editor in the Assembly Toolkit and select **File serving enabled** on the **Extensions** tab.

The following list identifies the other internal servlets affected by the Version 5 package name change:

- DefaultErrorReporter
- AutoInvoker

Use the Version 5 package name, `com.ibm.ws.webcontainer.servlet.servlet class name` for these servlets.

2. Use the WASPostUpgrade migration tool to migrate servlets that extend PageListServlet and rely on configuration information in the associated XML servlet configuration file. In Version 4.x, the XML servlet configuration file provides configuration data for page lists and augments servlet configuration

information. This file is named as either *servlet_class_name*.servlet or *servlet_name*.servlet, and is stored in the same directory as the servlet class file.

The XML servlet configuration file is not supported in WebSphere Application Server Version 5.

3. Set a content type if your servlet generates Hyper Text Markup Language (HTML) output.

The default behavior of the Web container changed in WebSphere Application Server Version 5. If the servlet developer does not specify a content type in the servlet then the container is forbidden to set one automatically. Without an explicit content type setting, the content type is set to null. The Netscape browser displays HTML source as plain text with a null content type setting.

To resolve this problem, do one of the following:

- Explicitly set a content type in your servlet.
- Open a Web deployment descriptor editor in the Assembly Toolkit and select **Automatic Response Encoding enabled** on the **Extensions** tab.

4. Set the Java environment variable, `com.ibm.websphere.sendredirect.compatibility`, to **true** if you want your URLs interpreted relative to the application root.

The default value of the Java environment variable `com.ibm.websphere.sendredirect.compatibility` changed in WebSphere Application Server Version 5. In Version 4, the default setting of this variable is true. In Version 5, the setting is false.

When this variable is set to false, if a URL has a leading slash, the URL is interpreted relative to the Web module/application root. However, if the URL does not have a leading slash, it is interpreted relative to the Web container root (also known as the Web server document root). Therefore, if an application has a WAR file that has a context root of `myPledge_app` and a servlet that has a servlet mapping of `/Intranet/`, a JSP file in the WAR file cannot access the servlet when its `encodeRedirectURL` is set to `/Intranet/myPledge`. The JSP file can access the servlet if the `encodeRedirectURL` is set to `myPledge_app/Intranet/myPledge`, or if the `com.ibm.websphere.sendredirect.compatibility` variable is set to true.

See "Configuring JVM sendRedirect calls to use context root" in the Information Center.

5. Use the WASPostUpgrade migration tool to migrate WebSphere Version 4.x enterprise applications to Version 5.

Note: The WebSphere Application Server Version 4.x JSP page implementation class files are not compatible with the WebSphere Application Server Version 5 JSP container.

The WASPostUpgrade tool automatically precompiles JSP files, which ensures the JSP page implementation class files are compatible with Version 5.

If you install Version 4.x EAR files, deployed with the JSP Precompile option, in Version 5, and you choose not to follow the migration path, do one of the following:

- Select the Pre-compile JSP option in the administrative console Install New Application window.
See article [Installing a new application](#) for more information.
- Specify the `-preCompileJSPs` option when using the `wsadmin` tool.

6. Import your classes if your application uses unnamed packages.

Section 8.2 of the JSP 1.2 specification states:

The JSP container creates a JSP page implementation class for each JSP page. The name of the JSP page implementation class is implementation dependent. The JSP page implementation object belongs to an implementation-dependent named package. The package used may vary between one JSP and another, so minimal assumptions should be made. The unnamed package should not be used without an explicit *import* of the class.

For example, if `myBeanClass` is in the unnamed package, and you reference it in a `jsp:useBean` tag, then you must explicitly import `myBeanClass` with the page directive `import` attribute, as shown in the following example:

```
<%@page import="myBeanClass" %>
.
.
.
<jsp:useBean id="myBean" class="myBeanClass" scope="session"/>
```

In WebSphere Application Server Version 5, the JSP engine creates JSP page implementation classes in the `org.apache.jsp` package. If a class in the unnamed package is not explicitly imported, then the `javac` compiler assumes the class is in package `org.apache.jsp`, and the compilation fails.

The *Incompatibilities* section of the version 1.4.Java 2 Platform, Standard Edition (J2SE) documentation states:

The compiler now rejects import statements that import a type from the unnamed namespace. Previous versions of the compiler would accept such import declarations, even though they were arguably not allowed by the language (because the type name appearing in the import clause is not in scope). The specification is being clarified to state clearly that you cannot have a simple name in an import statement, nor can you import from the unnamed namespace.

To summarize, the syntax:

```
import SimpleName;
```

is no longer legal. Nor is the syntax

```
import ClassInUnnamedNamespace.Nested;
```

which would import a nested class from the unnamed namespace.

To fix such problems in your code, move all of the classes from the unnamed namespace into a named namespace.

See "Resources for learning" for links to the J2SE, JSP, and Servlet specification documentation.

Default Application

The IBM WebSphere Application Server provides a default configuration that allows administrators to easily verify that the Application Server is running. When the product is installed, it includes an application server called *server1* and an enterprise application called *Default Application*.

Default Application contains a Web Module called *DefaultWebApplication* and an enterprise bean JAR file called *Increment*. The *Default Application* provides a number of servlets, described below. These servlets are available in the product.

For additional code examples, visit the Samples Gallery. Learn how to locate and install the Samples Gallery by viewing the Samples Gallery reference page in the Information Center.

The URL for accessing Samples is: `http://localhost:9080/WSamples/`

Snoop

Use the Snoop servlet to retrieve information about a servlet request. This servlet returns the following information:

- Servlet initialization parameters
- Servlet context initialization parameters
- URL invocation request parameters
- Preferred client locale
- Context path
- User principal
- Request headers and their values
- Request parameter names and their values
- HTTPS protocol information
- Servlet request attributes and their values
- HTTP session information
- Session attributes and their values

The Snoop servlet includes security configuration so that when WebSphere Security is enabled, clients must supply a user ID and password to execute the servlet.

The URL for the Snoop servlet is: `http://localhost:9080/snoop/`.

HelloHTML

Use the HelloHTML pervasive servlet to exercise the PageList support provided by the WebSphere Web container. This servlet extends the PageListServlet, which provides APIs that allow servlets to call other Web resources by name or, when using the *Client Type detection* support, by type.

You can invoke the Hello servlet from an HTML browser, speech client, or most Wireless Application Protocol (WAP) enabled browsers using the URL: `http://localhost:9080/HelloHTML.jsp`.

HitCount

Use the HitCount Demonstration application to demonstrate incrementing a counter using a variety of methods, including:

- A servlet instance variable
- An HTTP session
- An enterprise bean

You can instruct the servlet to execute any of these methods within a transaction that you can omit or roll back. If the transaction is committed, the counter is incremented. If the transaction is rolled back, the counter is not incremented.

The enterprise bean method uses a Container- Managed Persistence enterprise bean that persists the counter value to a Cloudscape database. This enterprise bean is configured to use the Default Datasource, which is set to the DefaultDB database.

When using the enterprise bean method, you can instruct the servlet to look up the enterprise bean, either in the WebSphere global namespace, or in the namespace local to the application.

The URL for the HitCount application is: `http://localhost:9080/HitCount.jsp`.

Servlets

Servlets are Java programs that use the Java Servlet Application Programming Interface (API). You must package servlets in a Web ARchive (WAR) file or Web module for deployment to the application server. *Servlets* run on a Java-enabled Web server and extend the capabilities of a Web server, similar to the way applets run on a browser and extend the capabilities of a browser.

Servlets can support dynamic Web page content, provide database access, serve multiple clients at one time, and filter data.

For the purposes of IBM WebSphere Application Server, discussions of servlets focus on Hyper Text Transfer Protocol (HTTP) servlets, which serve Web-based clients.

Developing servlets with WebSphere Application Server extensions

Several WebSphere Application Server extensions are provided for enhancing your servlets. This task provides a summary of the extensions that you can utilize.

1. Review the supported specifications.

Create Java components, referring to the Servlet specifications from Sun Microsystems.

See Resources for learning for links to coding specifications and examples.

The application server includes its own packages that extend and add to the Java Servlet Application Programming Interface (API). These extensions and additions make it easier to manage session states, create personalized Web pages, generate better servlet error reports, and access databases. Locate the Javadoc for the application server APIs in the product `install_root\web\apidocs` directory.

All the public WebSphere Application Server APIs are located in the `com.ibm.websphere...` packages.

2. Use your favorite integrated development environment (IDE), or a text editor, to develop or migrate code artifacts that meet the specifications.
3. Test the code artifacts.

Assemble your code artifacts into a Web module using the Assembly Toolkit as a prerequisite to deploying the code to the application server.

Application lifecycle listeners and events

Application lifecycle listeners and events, now part of the Servlet API, enable you to notify interested listeners when servlet contexts and sessions change. For example, you can notify users when attributes change and if sessions or servlet contexts are created or destroyed.

The lifecycle listeners give the application developer greater control over interactions with `ServletContext` and `HttpSession` objects. Servlet context listeners manage resources at an application level. Session listeners manage resources associated with a series of requests from a single client. Listeners are available for lifecycle events and for attribute modification events. The listener developer creates a class that implements the `javax.listener` interface, corresponding to the desired listener functionality.

At application startup time, the container uses introspection to create an instance of your listener class and registers it with the appropriate event generator.

When a servlet context is created, the `contextInitialized` method of your listener class is invoked, which creates the database connection for the servlets in your application to use, if this context is for your application.

When the servlet context is destroyed, your `contextDestroyed` method is invoked, which releases the database connection, if this context is for your application.

Listener classes for servlet context and session changes

The following methods are defined as part of the `javax.servlet.ServletContextListener` interface:

- `void contextInitialized(ServletContextEvent)` - Notification that the Web application is ready to process requests.

Place code in this method to see if the created context is for your Web application and if it is, allocate a database connection and store the connection in the servlet context.

- `void contextDestroyed(ServletContextEvent)` - Notification that the servlet context is about to shut down.

Place code in this method to see if the created context is for your Web application and if it is, close the database connection stored in the servlet context.

Two new listener interfaces are defined as part of the `javax.servlet` package:

- `ServletContextListener`
- `ServletContextAttributeListener`

One new filter interface is defined as part of the `javax.servlet` package:

- `FilterChain` interface - methods: `doFilter()`

Two new event classes are defined as part of the `javax.servlet` package:

- ServletContextEvent
- ServletContextAttributeEvent

Three new listener interfaces are defined as part of the javax.servlet.http package:

- HttpSessionListener
- HttpSessionAttributeListener
- HttpSessionActivationListener

One new event class is defined as part of the javax.servlet.http package:

- HttpSessionEvent

Example: com.ibm.websphere.DBConnectionListener.java

The following example shows how to create a servlet context listener:

```
package com.ibm.websphere;

import java.io.*;
import javax.servlet.*;

public class DBConnectionListener implements ServletContextListener
{
    // implement the required context init method
    void contextInitialized(ServletContextEvent sce)
    {
    }

    // implement the required context destroy method
    void contextDestroyed(ServletContextEvent sce)
    {
    }
}
```

Servlet filtering

Servlet filtering is an integral part of the Servlet 2.3 API. Servlet filtering provides a new type of object called a *filter* that can transform a request or modify a response.

You can chain filters together so that a group of filters can act on the input and output of a specified resource or group of resources.

Filters typically include logging filters, image conversion filters, encryption filters, and Multipurpose Internet Mail Extensions (MIME) type filters (functionally equivalent to the servlet chaining). Although filters are not servlets, their lifecycle is very similar.

Filters are handled in the following manner:

- The Web container determines whether it needs to construct a FilterChain containing the LoggingFilter for the requested resource.
The FilterChain begins with the invocation of the LoggingFilter and ends with the invocation of the requested resource.
- If other filters need to go in the chain, the Web container places them after the LoggingFilter and before the requested resource.
- The Web container then instantiates and initializes the LoggingFilter (if it was not done previously) and invokes its doFilter(FilterConfig) method to start the chain.
- The LoggingFilter preprocesses the request and response objects and then invokes the filter chain doFilter(ServletRequest, ServletResponse) method.

This method passes the processing to the next resource in the chain (in this case, the requested resource).

- Upon return from the filter chain `doFilter(ServletRequest, ServletResponse)` method, the `LoggingFilter` performs post-processing on the request and response object before sending the response back to the client.

Filter, FilterChain, FilterConfig classes for servlet filtering

The following interfaces are defined as part of the `javax.servlet` package:

- `Filter` interface - methods: `doFilter()`, `getFilterConfig()`, `setFilterConfig()`
- `FilterChain` interface - methods: `doFilter()`
- `FilterConfig` interface - methods: `getFilterName()`, `getInitParameter()`, `getInitParameterNames()`, `getServletContext()`

The following classes are defined as part of the `javax.servlet.http` package:

- `HttpServletRequestWrapper` - methods: See the Servlet 2.3 Specification
- `HttpServletResponseWrapper` - methods: See the Servlet 2.3 Specification

Example: `com.ibm.websphere.LoggingFilter.java`

The following example shows how to implement a filter:

```
package com.ibm.websphere;

import java.io.*;
import javax.servlet.*;

public class LoggingFilter implements Filter
{
    File _loggingFile = null;

    // implement the required init method
    public void init(FilterConfig fc)
    {
        // create the logging file
        xxx;
    }

    // implement the required doFilter method...this is where most of
    the work is done
    public void doFilter(ServletRequest request,
        ServletResponse response, FilterChain chain)
    {
        try
        {
            // add request info to the log file
            synchronized(_loggingFile)
            {
                xxx;
            }

            // pass the request on to the next resource in the chain
            chain.doFilter(request, response);
        }
        catch (Throwable t)
        {
            // handle problem...
        }
    }

    // implement the required destroy method
    public void destroy()
    {
        // make sure logging file is closed
        _loggingFile.close();
    }
}
```

Configuring page list servlet client configurations

You can define PageListServlet configuration information in the IBM Web Extensions file. The IBM Web Extensions file is created and stored in the Web Applications archive (WAR) file by the Assembly Toolkit.

To configure and implement page lists:

1. To configure page list information, use the Add Markup Language entry dialog of the Assembly Toolkit. On the **Servlets** tab of a Web deployment descriptor editor, select a servlet and click **Add** under **WebSphere Extensions**.
2. Add the `callPage()` method to your servlet to invoke a JavaServer Page (JSP) file in response to a client request.

The PageListServlet has a `callPage()` method that invokes a JSP file in response to the HTTP request for a page in a page list. The `callPage()` method can be invoked in one of the following ways:

- `callPage(String pageName, HttpServletRequest request, HttpServletResponse response)`

where the method arguments are:

pageName

A page name defined in the PageListServlet configuration

request

The HttpServletRequest object

response

The HttpServletResponse object

- `callPage(String mName, String pageName, HttpServletRequest request, HttpServletResponse response)`

where the method arguments are:

mName A markup language type

pageName

A page name defined in the PageListServlet configuration

request

The HttpServletRequest object

response

The HttpServletResponse object

3. Use the PageList Servlet client type detection support to determine the markup language type a calling client requires for the response.

Page lists

Page lists allow you to avoid hard-coding URLs in servlets and JSP files. A page list specifies the location where a request is to be forwarded, but automatically customizes that location depending on the MIME type of the servlet. Use these properties to specify a markup language and an associated MIME type. For the given MIME type, you also specify a set of pages to invoke.

WebSphere Application Server supplies the PageListServlet servlet, which you can use to call a JavaServer Pages (JSP) file by name based on the configuration data in the `client_types.xml` file. This file maps a JSP file to a Uniform Resource Identifier (URI). When the URI is invoked, it specifies another JSP file in a Web module. This support allows you to access multiple Uniform Resource Locators (URLs) without hard-coding them in your servlets.

You can also logically group page lists according to the markup language type, such as, Hypertext Markup Language (HTML) or Wireless Markup Language (WML). This allows applications that use servlets to extend the PageListServlet servlet, to call JSP files which return the proper markup-language type for the client request. For example, a request that originates from a PDA device requires WML data. The application server sends the request to a servlet that extends the PageListServlet servlet, and the servlet calls a JSP file that returns a WML response.

Client type detection support

In addition to providing the page list mapping capability, the `PageListServlet` also provides *Client Type Detection* support. A servlet determines the markup language type that a calling client needs in the response, using the configuration information in the `client_types.xml` file.

Client type detection support allows a servlet, extending the `PageListServlet`, to call an appropriate JavaServer Pages (JSP) file. The servlet invokes the `callPage()` method, which calls a JSP file based on the markup-language type of the request.

client_types.xml

The `client_types.xml` file provides client type detection support for servlets extending `PageListServlet`. Using the configuration data in the `client_types.xml` file, servlets can determine the language type that calling clients require for the response.

The client type detection support allows servlets to call appropriate JavaServer Pages (JSP) files with the `callPage()` method. Servlets select JSP files based on the markup-language type of the request.

Servlets must use the following version of the `callPage()` method to determine the markup language type required by the client:

```
callPage(String mlName, String pageName, HttpServletRequest request,
         HttpServletResponse response)
```

where the arguments are:

- `mlName` - a markup language type
- `pageName` - a page name defined in the `PageListServlet` configuration
- `request` - the `HttpServletRequest` object
- `response` - the `HttpServletResponse` object

Review the Extending `PageListServlet` code example to see how the `callPage()` method is invoked by a servlet.

In the example, the client type detection method, `getMLTypeFromRequest(HttpServletRequest request)`, provided by the `PageListServlet`, inspects the `HttpServletRequest` object request headers, and searches for a match in the `client_types.xml` file.

The client type detection method does the following:

- Uses the input `HttpServletRequest` and the `client_types.xml` file, to check for a matching HTTP request name and value.
- Returns the markup-language value configured for the `<client-type>` element, if a match is found. If multiple matches are found, this method returns the markup-language for the first `<client-type>` element for which a match is found.
- If no match is found, returns the value of the markup-language for the default page defined in the `PageListServlet` configuration.

Location

The `client_types.xml` file is located in the `install_root/properties` directory.

Usage notes

- Is this file read-only?
No
- Is this file updated by a product component?
No
- If so, what triggers its update?
This file is created and updated manually by users.

- How and when are the contents of this file used?

Servlets, extending `PageListServlet`, use this file to determine the language type that calling clients require for the response.

Sample file entry

```
<?xml version="1.0" >
<!DOCTYPE clients [
<!ELEMENT client-type (description, markup-language,request-header+)>
<!ELEMENT description (#PCDATA)>
<!ELEMENT markup-language (#PCDATA)>
<!ELEMENT request-header (name, value)>
<!ELEMENT clients (client-type+)>
<!ELEMENT name (#PCDATA)>
<!ELEMENT value (#PCDATA)>]>
<clients>
  <client-type>
    <description>IBM Speech Client</description>
    <markup-language>VXML</markup-language>
    <request-header>
      <name>user-agent</name>
      <value>IBM VoiceXML pre-release version 000303</value>
    </request-header>
    <request-header>
      <name>accept</name>
      <value>text/vxml</value>
    </request-header>
  </client-type>
  <client-type>
    <description>WML Browser</description>
    <markup-language>WML</markup-language>
    <request-header>
      <name>accept</name>
      <value>text/x-wap.wml</value>
    </request-header>
    <request-header>
      <name>accept</name>
      <value>text/vnd.wap.xml</value>
    </request-header>
  </client-type>
</clients>
```

Example: Extending PageListServlet

The following example shows how a servlet extends the `PageListServlet` class and determines the markup-language type required by the client. The servlet then uses the `callPage()` method to call an appropriate JavaServer Pages (JSP) file. In this example, the JSP file that provides the the correct markup-language for the response is *Hello.page*.

```
public class HelloPervasiveServlet extends PageListServlet implements Serializable
{
  /*
  * doGet -- Process incoming HTTP GET requests
  */
  public void doGet(HttpServletRequest request, HttpServletResponse response)
  throws IOException, ServletException
  {
    // This is the name of the page to be called:
    String pageName = "Hello.page";

    // First check if the servlet was invoked with a queryString that contains
    // a markup-language value.
    // For example, if this is how the servlet is invoked:
    // http://localhost/servlets/HelloPervasive?mlname=VXML
    // then use the following method:
    String mlname= getMLNameFromRequest(request);
```

```

// If no markup language type is provided in the queryString,
// then try to determine the client
// Type from the request, and use the markup-language name configured in
// the client_types.xml file.
if (mlName == null)
{
    mlName = getMLTypeFromRequest(request);
}
try
{
    // Serve the request page.
    callPage(mlName, pageName, request, response);
}
catch (Exception e)
{
    handleError(mlName, request, response, e);
}
}
}

```

autoRequestEncoding and autoResponseEncoding

Two new WebSphere Application Server extensions are available in Version 5, `autoRequestEncoding` and `autoResponseEncoding`.

In WebSphere Application Server Version 5, the Web container no longer automatically sets request and response encodings, and response content types. Programmers are expected to set these values using available methods in the Servlet 2.3 Specification. If programmers choose not to use the character encoding methods, they can specify the `autoRequestEncoding` and `autoResponseEncoding` extensions, which enable the application server to set the encoding values and content type.

The values of the `autoRequestEncoding` and `autoResponseEncoding` extensions are either `true` or `false`. The default value for both extensions is `false`. If the value is `false` for both `autoRequestEncoding` and `autoResponseEncoding`, then the request and response character encoding is set to the Servlet 2.3 Specification default, which is ISO-8859-1. Also, if the value is set to `false` for a response, the Web container cannot set a response content type.

Use the Assembly Toolkit to change the default values for the `autoRequestEncoding` and `autoResponseEncoding` extensions.

Review the `autoRequestEncoding` and `autoResponseEncoding` encoding examples for a description of Web container behavior when these values are set to `true`.

Examples: autoRequestEncoding and autoResponseEncoding encoding examples

The default value of the `autoRequestEncoding` and `autoResponseEncoding` extensions is `false`, which means that both the request and response character encoding is set to the Servlet 2.3 Specification default of ISO-8859-1. Different character encodings are possible if the client defines character encoding in the request header, or if the code includes the `setCharacterEncoding(String encoding)` method. Also, if the value is set to `false` for a response, the Web container cannot set a response content type.

If the `autoRequestEncoding` value is set to `true`, and the client did not specify character encoding in the request header, and the code does not include the `setCharacterEncoding(String encoding)` method, the Web container tries to determine the correct character encoding for the request parameters and data.

The Web container performs each step in the following list until a match is found:

- Looks at the character set (charset) in the *Content-Type* header.
- Attempts to map the servers locale to a character set using defined properties.
- Attempts to use the `DEFAULT_CLIENT_ENCODING` system property, if one is set.

- Uses the ISO-8859-1 character encoding as the default.

If the `autoResponseEncoding` value is set to `true`, and the client did not specify character encoding in the request header, and the code does not include the `setCharacterEncoding(String encoding)` method, the Web container does the following:

- Attempts to determine the response content type and character encoding from information in the request header.
- Uses the ISO-8859-1 character encoding as the default.

JavaServer Pages files

JavaServer Pages (JSP) files are application components coded to the Sun Microsystems JavaServer Pages (JSP) Specification. JSP files enable the separation of the Hypertext Markup Language (HTML) code from the business logic in Web pages so that HTML programmers and Java programmers can more easily collaborate in creating and maintaining pages.

The IBM extensions to the JSP Specification include JSP tags that resemble HTML tags. These JSP tags make it easy for HTML authors to add the power of Java technology to Web pages, without being experts in Java programming.

JSP files support a division of roles:

HTML authors

Develop JSP files that access databases and reusable Java components, such as servlets and beans.

Java programmers

Create the reusable Java components and provide the HTML authors with the component names and attributes.

Database administrators

Provide the HTML authors with the name of the database access and table information.

Developing JavaServer Pages files with WebSphere extensions

Several IBM WebSphere extensions are provided for enhancing your JavaServer Pages (JSP) files. This task provides a summary of the extensions that you can utilize.

1. Review the supported specifications.

Create Java components, referring to the JSP specifications from Sun Microsystems.

See [Resources for learning](#) for links to coding specifications and examples.

WebSphere Application Server Version 3.5 added IBM extensions to the base Application Programming Interfaces (APIs). Since the JavaServer Pages (JSP) 1.1 and JSP 1.2 Specifications are backward compatible to the JSP 1.0 Specifications, you can invoke the APIs with the IBM extensions without modification.

The extensions belong to these categories:

Syntax for variable data

Put variable fields in JSP files and have servlets and beans dynamically replace the variables with values from a database when the JSP output is returned to the browser.

Syntax for database access

Add a database connection to a Web page and then use that connection to query or update the database. You can provide the user ID and password for the database connection at request time, or you can hard code the user ID and password within the JSP file.

2. Use your favorite integrated development environment (IDE), or a text editor, to develop or migrate code artifacts that meet the specifications.
3. Test the code artifacts.
4. **(Optional)** Batch compile your JSP files if necessary.

Tag libraries

Java ServerPages (JSP) tag libraries contain classes for common tasks such as processing forms and accessing databases from JSP files.

Tag libraries encapsulate, as simple tags, core functionality common to many Web applications. The Java Standard Tag Library (JSTL) supports common programming tasks such as iteration and conditional processing, and provides tags for:

- manipulating XML documents
- supporting internationalization
- using Structured Query Language (SQL)

Tag libraries also introduce the concept of an expression language to simplify page development, and include a version of the JSP expression language.

A tag library has two parts - a Tag Library Descriptor (TLD) file and a JAR file.

tsx:dbconnect tag JavaServer Pages syntax

Use the <tsx:dbconnect> tag to specify information needed to make a connection to a Java Database Connectivity (JDBC) or an Open Database Connectivity (ODBC) database.

The <tsx:dbconnect> syntax does not establish the connection. Use the <tsx:dbquery> and <tsx:dbmodify> syntax instead to reference a <tsx:dbconnect> tag in the same JavaServer Pages (JSP) file to establish the connection.

When the JSP file compiles into a servlet, the Java processor adds the Java coding for the <tsx:dbconnect> syntax to the servlet service() method, which means a new database connection is created for each request for the JSP file.

This section describes the syntax of the <tsx:dbconnect> tag.

```
<tsx:dbconnect id="connection_id"
  userid="db_user" passwd="user_password"
  url="jdbc:subprotocol:database"
  driver="database_driver_name"
  jndiname="JNDI_context/logical_name">
</tsx:dbconnect>
```

where:

- **id**

Represents a required identifier. The scope is the JSP file. This identifier is referenced by the connection attribute of a <tsx:dbquery> tag.

- **userid**

Represents an optional attribute that specifies a valid user ID for the database that you want to access. Specify this attribute to add the attribute and its value to the request object.

Although the userid attribute is optional, you must provide the user ID. See <tsx:userid> and <tsx:passwd> for an alternative to hard coding this information in the JSP file.

- **passwd**

Represents an optional attribute that specifies the user password for the userid attribute. (This attribute is not optional if the userid attribute is specified.) If you specify this attribute, the attribute and its value are added to the request object.

Although the passwd attribute is optional, you must provide the password. See <tsx:userid> and <tsx:passwd> for an alternative to hard coding this attribute in the JSP file.

- **url** and **driver**

Represents a required attribute if you want to establish a database connection. You must provide the URL and driver.

The application server supports connection to JDBC databases and ODBC databases.

- For a JDBC database, the URL consists of the following colon-separated elements: jdbc, the subprotocol name, and the name of the database to access. An example for a connection to the Sample database included with IBM DB2 is:

```
url="jdbc:db2:sample"  
driver="COM.ibm.db2.jdbc.app.DB2Driver"
```

- For an ODBC database, use the Sun JDBC-to-ODBC bridge driver included in their Java2 Software Developers Kit (SDK) or another vendor's ODBC driver.

The url attribute specifies the location of the database. The driver attribute specifies the name of the driver to use in establishing the database connection.

If the database is an ODBC database, you can use an ODBC driver or the Sun JDBC-to-ODBC bridge. If you want to use an ODBC driver, refer to the driver documentation for instructions on specifying the database location with the url attribute and the driver name.

If you use the bridge, the url syntax is jdbc:odbc:database. An example follows:

```
url="jdbc:odbc:autos"  
driver="sun.jdbc.odbc.JdbcOdbcDriver"
```

Note: To enable the application server to access the ODBC database, use the ODBC Data Source Administrator to add the ODBC data source to the System DSN configuration. To access the ODBC Administrator, click the ODBC icon on the Windows NT Control Panel.

- **jdbcname**

Represents an optional attribute that identifies a valid context in the application server Java Naming and Directory Interface (JNDI) naming context and the logical name of the data source in that context. The Web administrator configures the context using an administrative client such as the WebSphere Administrative Console.

If you specify the jdbcname attribute, the JSP processor ignores the driver and url attributes on the <tsx:dbconnect> tag.

An empty element (such as <url></url>) is valid.

dbquery tag JavaServer Pages syntax

Use the <tsx:dbquery> tag to establish a connection to a database, submit database queries, and return the results set.

The <tsx:dbquery> tag does the following:

1. References a <tsx:dbconnect> tag in the same JavaServer Pages (JSP) file and uses the information the tag provides to determine the database URL and driver. You can also obtain the user ID and password from the <tsx:dbconnect> tag if those values are provided in the <tsx:dbconnect> tag.
2. Establishes a new connection
3. Retrieves and caches data in the results object.
4. Closes the connection and releases the connection resource.

This section describes the syntax of the <tsx:dbquery> tag.

```
<%-- SELECT commands and (optional) JSP syntax can be placed within the tsx:dbquery. --%>  
<%-- Any other syntax, including HTML comments, are not valid. --%>  
<tsx:dbquery id="query_id" connection="connection_id" limit="value" >  
</tsx:dbquery>
```

where:

- **id**

Represents the identifier of this query. The scope is the JSP file. Use id to reference the query. For example, from the <tsx:getProperty> tag, use id to display the query results.

The id is a tsx reference to the bean and can be used to retrieve the bean from the page context. For example, if id is named mySingleDBBean, instead of using:

- if (mySingleDBBean.getValue("UISEAM",0).startsWith("N"))

use:

- `com.ibm.ws.webcontainer.jsp.tsx.db.QueryResults bean = (com.ibm.ws.webcontainer.jsp.tsx.db.QueryResults)pageContext. findAttribute("mySingleDBBean"); if (bean.getValue("UISEAM",0).startsWith("N")). . .`

The bean properties are dynamic and the property names are the names of the columns in the results set. If you want different column names, use the SQL keyword for specifying an alias on the SELECT command. In the following example, the database table contains columns named FNAME and LNAME, but the SELECT statement uses the AS keyword to map those column names to FirstName and LastName in the results set:

```
Select FNAME, LNAME AS FirstName, LastName from Employee where FNAME='Jim'
```

- **connection**

Represents the identifier of a `<tsx:dbconnect>` tag in this JSP file. The `<tsx:dbconnect>` tag provides the database URL, driver name, and optionally, the user ID and password for the connection.

- **limit**

Represents an optional attribute that constrains the maximum number of records returned by a query. If this attribute is not specified, no limit is used. In such a case, the effective limit is determined by the number of records and the system caching capability.

- **SELECT command and JSP syntax**

Represents the only valid SQL command, SELECT. The `<tsx:dbquery>` tag must return a results set. Refer to your database documentation for information about the SELECT command. See other articles in this section for a description of JSP syntax for variable data and inline Java code.

dbmodify tag JavaServer Pages syntax

The `<tsx:dbmodify>` tag establishes a connection to a database and then adds records to a database table.

The `<tsx:dbmodify>` tag does the following:

1. References a `<tsx:dbconnect>` tag in the same JavaServer Pages (JSP) file and uses the information provided by that tag to determine the database URL and driver.
Note: You can also obtain the user ID and password from the `<tsx:dbconnect>` tag if those values are provided in the `<tsx:dbconnect>` tag.
2. Establishes a new connection.
3. Updates a table in the database.
4. Closes the connection and releases the connection resource.

This section describes the syntax of the `<tsx:dbmodify>` tag.

```
<%-- Any valid database update commands can be placed within the DBMODIFY tag. -->  
<%-- Any other syntax, including HTML comments, are not valid. -->  
<tsx:dbmodify connection="connection_id">  
</tsx:dbmodify>
```

where:

- **connection**

Represents the identifier of a `<tsx:dbconnect>` tag in this JSP file. The `<tsx:dbconnect>` tag provides the database URL, driver name, and (optionally) the user ID and password for the connection.

- **Database commands**

Represents valid database commands. Refer to your database documentation for details

tsx:getProperty tag JavaServer Pages syntax and examples

The `<tsx:getProperty>` tag gets the value of a bean to display in a JavaServer Pages (JSP) file.

This IBM extension of the Sun JSP `<jsp:getProperty>` tag implements all of the `<jsp:getProperty>` function and adds the ability to introspect a database bean created using the IBM extension `<tsx:dbquery>` or `<tsx:dbmodify>`.

Note: You cannot assign the value from this tag to a variable. The value, generated as output from this tag, displays in the browser window.

This section describes the syntax of the `<tsx:getProperty>` tag:

```
<tsx:getProperty name="bean_name"
  property="property_name" />
```

where:

- **name**
Represents the name of the bean declared by the `id` attribute of a `<tsx:dbquery>` syntax within the JSP file. See `<tsx:dbquery>` for an explanation. The value of this attribute is case-sensitive.
- **property**
Represents the property of the bean to access for substitution. The value of the attribute is case-sensitive and is the locale-independent name of the property.

Tag example:

```
<tsx:getProperty name="userProfile" property="username" />
<tsx:getProperty name="request" property=request.getParameter("corporation") />
```

In most cases, the value of the property attribute is just the property name. However, to access the request bean or to access a property of a property (sub property), specify the full form of the property attribute. The full form also gives you the option to specify an index for indexed properties. You can specify the optional index as a constant (such as 2), or an index like the one described in the `<tsx:repeat>` tag. Some examples using the full form of the property attribute follow:

```
<tsx:getProperty name="staffQuery" property=address(currentAddressIndex) />
<tsx:getProperty name="shoppingCart" property=items(4).price />
<tsx:getProperty name="fooBean" property=foo(2).bat(3).boo.far />
```

tsx:userid and tsx:passwd tag JavaServer Pages syntax

With the `<tsx:userid>` and `<tsx:passwd>` tags, you do not have to hard code a user ID and password in the `<tsx:dbconnect>` tag.

Use the `<tsx:userid>` and `<tsx:passwd>` tags to accept user input for the values and then add that data to the request object. You can access the request object with a JavaServer Pages (JSP) file, such as the *JSPEmployee.jsp* example that requests the database connection.

You must use `<tsx:userid>` and `<tsx:passwd>` tags within a `<tsx:dbconnect>` tag.

This section describes the syntax of the `<tsx:userid>` and `<tsx:passwd>` tags.

```
<tsx:dbconnect id="connection_id"
  <font color="red"><userid></font>
  <tsx:getProperty name="request" property=request.getParameter("userid") />
  <font color="red"></userid></font>
  <font color="red"><passwd></font>
  <tsx:getProperty name="request" property=request.getParameter("passwd") />
  <font color="red"></passwd></font>
  url="protocol:database_name:database_table"
  driver="JDBC_driver_name">
</tsx:dbconnect>
```

where:

- **<tsx:getProperty>**

Represents the syntax as a mechanism for embedding variable data.

- **userid**

Represents a reference to the request parameter that contains the user ID. You must add the parameter to the request object that passes to this JSP file. You can set the attribute and its value in the request object, using an HTML form or a URL query string to pass the user-specified request parameters.

- **passwd**

Represents a reference to the request parameter that contains the password. Add the parameter to the request object that passes to this JSP file. You can set the attribute and its value in the request object, using an HTML form or a URL query string, to pass user-specified values.

tsx:repeat tag JavaServer Pages syntax

The <tsx:getProperty> tag repeats a block of HTML tagging.

Use the <tsx:repeat> syntax to iterate over a database query results set. The <tsx:repeat> syntax iterates from the start value to the end value until one of the following conditions is met:

- The end value is reached.
- An exception is thrown.

The output of a <tsx:repeat> block is buffered until the block completes. If an exception is thrown before a block completes, no output is written for that block.

This section describes the syntax of the <tsx:repeat> tag:

```
<tsx:repeat index=name start="starting_index" end="ending_index">
</tsx:repeat>
```

where:

- **index**

Represents an optional name used to identify the index of this repeat block. The value is case-sensitive and its scope is the JSP file.

- **start**

Represents an optional starting index value for this repeat block. The default is 0.

- **end**

Represents an optional ending index value for this repeat block. The maximum value is 2,147,483,647.

If the value of the end attribute is less than the value of the start attribute, the end attribute is ignored.

Example: Combining tsx:repeat and tsx:getProperty JavaServer Pages tags

The following code snippet shows you how to code these tags:

```
<tsx:repeat>
<tr>
  <td><tsx:getProperty name="empqs" property="EMPNO" />
  <tsx:getProperty name="empqs" property="FIRSTNAME" />
  <tsx:getProperty name="empqs" property="WORKDEPT" />
  <tsx:getProperty name="empqs" property="EDLEVEL" />
</td>
</tr>
</tsx:repeat>
```

Example: tsx:dbmodify tag syntax

In the following example, a new employee record is added to a database. The values of the fields are based on user input from this JavaServer Pages (JSP) file and referenced in the database commands using the <tsx:getProperty> tag.

```

<tsx:dbmodify connection="conn" >
insert into EMPLOYEE
  (EMPNO,FIRSTNME,MIDINIT,LASTNAME,WORKDEPT,EDLEVEL)
values
('<tsx:getProperty name="request" property=request.getParameter("EMPNO") />',
'<tsx:getProperty name="request" property=request.getParameter("FIRSTNME") />',
'<tsx:getProperty name="request" property=request.getParameter("MIDINIT") />',
'<tsx:getProperty name="request" property=request.getParameter("LASTNAME") />',
'<tsx:getProperty name="request" property=request.getParameter("WORKDEPT") />',
'<tsx:getProperty name="request" property=request.getParameter("EDLEVEL") />')
</tsx:dbmodify>

```

Example: Using `tsx:repeat` JavaServer Pages tag to iterate over a results set

The `<tsx:repeat>` tag iterates over a results set. The results set is contained within a bean. The bean can be a static bean, for example, a bean created by using the IBM WebSphere Studio database wizard, or a dynamically generated bean, for example, a bean generated by the `<tsx:dbquery>` syntax. The following table is a graphic representation of the contents of a bean called, *myBean*:

	col1	col2	col3
row0	friends	Romans	countrymen
row1	bacon	lettuce	tomato
row2	May	June	July

Some observations about the bean:

- The column names in the database table become the property names of the bean. The `<tsx:dbquery>` section describes a technique for mapping the column names to different property names.
- The bean properties are indexed. For example, `myBean.get(Col1(row2))` returns May.
- The query results are in the rows. The `<tsx:repeat>` tag iterates over the rows, beginning at the start row.

The following table compares using the `<tsx:repeat>` tag to iterate over a static bean, versus a dynamically generated bean:

Static Bean Example	<tsx:repeat> Bean Example
<p>myBean.class</p> <pre>// Code to get a connection // Code to get the data Select * from myTable; // Code to close the connection</pre> <p>JSP file</p> <pre><tsx:repeat index=abc> <tsx:getProperty name="myBean" property="coll(abc)" /> </tsx:repeat></pre> <p>Notes:</p> <ul style="list-style-type: none"> • The bean (myBean.class) is a static bean. • The method to access the bean properties is myBean.get(<i>property(index)</i>). • You can omit the property index, in which case the index of the enclosing <tsx:repeat> tag is used. You can also omit the index on the <tsx:repeat> tag. • The <tsx:repeat> tag iterates over the bean properties row by row, beginning with the start row. 	<p>JSP file</p> <pre><tsx:dbconnect id="conn" userid="alice"passwd="test" url="jdbc:db2:sample" driver="COM.ibm.db2.jdbc.app.DB2Driver"> </tsx:dbconnect > <tsx:dbquery id="dynamic" connection="conn" > Select * from myTable; </tsx:dbquery> <tsx:repeat index=abc> <tsx:getProperty name="dynamic" property="coll(abc)" /> </tsx:repeat></pre> <p>Notes:</p> <ul style="list-style-type: none"> • The bean (dynamic) is generated by the <tsx:dbquery> tag and does not exist until the syntax executes. • The method to access the bean properties is dynamic.getValue(<i>"property", index</i>). • You can omit the property index, in which case the index of the enclosing <tsx:repeat> tag is used. You can also omit the index on the <tsx:repeat> tag. • The <tsx:repeat> tag syntax iterates over the bean properties row by row, beginning with the start row.

Implicit and explicit indexing

Examples 1, 2, and 3 show how to use the <tsx:repeat> tag. The examples produce the same output if all indexed properties have 300 or fewer elements. If there are more than 300 elements, Examples 1 and 2 display all elements, while Example 3 shows only the first 300 elements.

Example 1 shows *implicit indexing* with the default start and default end index. The bean with the smallest number of indexed properties restricts the number of times the loop repeats.

```
<table>
<tsx:repeat>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="city" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="address" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="telephone" />
  </tr></td>
</tsx:repeat>
</table>
```

Example 2 shows indexing, starting index, and ending index:

```
<table>
<tsx:repeat index=myIndex start=0 end=2147483647>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=city(myIndex) />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=address(myIndex) />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=telephone(myIndex) />
  </tr></td>
</tsx:repeat>
</table>
```

Example 3 shows *explicit indexing* and ending index with implicit starting index. Although the index attribute is specified, you can still implicitly index the indexed property city because the (myIndex) tag is not required.

```
<table>
<tsx:repeat index=myIndex end=299>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="city" /t>
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="address(myIndex)" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="telephone(myIndex)" />
  </tr></td>
</tsx:repeat>
</table>
```

Nesting <tsx:repeat> blocks

You can nest <tsx:repeat> blocks. Each block is separately indexed. This capability is useful for interleaving properties on two beans, or properties that have subproperties. In the example, two <tsx:repeat> blocks are nested to display the list of songs on each compact disc in the user's shopping cart.

```
<tsx:repeat index=cdindex>
  <h1><tsx:getProperty name="shoppingCart" property=cds.title /></h1>
  <table>
  <tsx:repeat>
    <tr><td><tsx:getProperty name="shoppingCart" property=cds(cdindex).playlist />
    </td></tr>
  </tsx:repeat>
  </table>
</tsx:repeat>
```

JspBatchCompiler tool

As an IBM enhancement to JavaServer Pages support, IBM WebSphere Application Server provides a batch JSP compiler. Use this function to batch compile your JSP files and thereby enable faster responses to the initial client requests for the JSP files on your production Web server.

Batch compiling makes the first request for a JSP file much faster because the JSP file is translated and compiled into a servlet. Batch compiling is also useful as a fast way to resynchronize all of the JSP files for an application.

To use the JSP batch compiler for JSP files, enter the following command on a single line at an operating system command prompt:

```
JspBatchCompiler -enterpriseapp.name <name>
[ -webmodule.name <name>]
[ -cell.name <name>]
[ -node.name <name>]
[ -server.name <name>]
[ -filename <jsp name>]
[ -keepgenerated <true|false>]
[ -verbose <true|false>]
[ -deprecation <true|false>]
```

If the names specified for these arguments are comprised of two or more words separated by spaces, you must add quotation marks around the names.

where:

- **enterpriseapp.name**
Represents the name of the enterprise application you want to compile.
- **webmodule.name**

Represents the name of the specific Web module that you want to compile. If this argument is not set, all Web modules in the enterprise application are compiled.

- **cell.name**

Represents the name of the cell in which the application is deployed. The default is `BaseApplicationServerCell`.

- **node.name**

Represents the name of the node in which the application is deployed. The default is `DefaultNode`.

- **server.name**

Represents the name of the server in which the application is deployed. The default is `server1`.

- **filename**

Represents the name of a single JSP file that you want to compile. If this argument is not set, all files in the Web module are compiled. Alternatively, if *filename* is set to the name of a directory, only the JSP files in that directory are compiled.

- **keepgenerated**

Represents the option to save or erase the generated files.

If set to yes, WebSphere Application Server saves the generated `.java` files used for compilation on your server. By default, this argument is set to no and the `.java` files are erased after the class files have compiled.

- **verbose**

Indicates the compiler should generate verbose output while compiling the generated sources.

- **deprecation**

Indicates the compiler should generate deprecation warnings while compiling the generated sources.

Bean Scripting Framework

The Bean Scripting Framework (BSF) enables you to use scripting language functions in your Java server-side applications. This framework also extends scripting languages so that you can use existing Java classes and Java beans in the JavaScript language. Support in the JSP Engine for the Bean Scripting Framework is deprecated with WebSphere Application Server 5.1.

With BSF, you can write scripts that create, manipulate and access values from Java objects, or you can write Java programs that evaluate and access results from scripts.

WebSphere Application Server provides the Bean Scripting Framework, which consists of a BSF manager, a BSF engine, and a scripting engine.

BSF provides an access mechanism to Java objects for the scripting languages it supports, so that both the scripting language and the Java code can access code exclusive functions. The access mechanism is implemented through a registry of objects maintained by BSF.

BSF in WebSphere Application Server supports the Rhino ECMAScript.

The "Resources for Learning" article provides external BSF links that document future supported languages.

Developing Web applications

Design a Web application and the components that it needs.

For general Web application design information, see "Resources for learning."

There are two basic approaches to selecting tools for developing Web applications:

- You can use one of the available integrated development environments (IDEs). IDE tools automatically generate significant parts of the servlet and JavaServer Pages (JSP) code, and Hypertext Markup Language (HTML) files. They also contain integrated tools for packaging and testing the Web application components. The IBM WebSphere Application Developer product is the recommended IDE. For more information, see the documentation for that product.
- If you decide to develop Web components without an IDE, you need at least an ASCII text editor. You can also use tools available in the Java Software Development Kit (SDK) and in this product to assemble, test, and deploy the Web application components.

The following steps support the second approach, development without an IDE.

1. If necessary, migrate any pre-existing code to the required version of the servlet and JSP specification.
2. Write and compile the components of the Web application. To access classes that were extended, compile your code using the `-classpath` option on the `javac` compiler. This option allows you to reference the `j2ee.jar` file in the product `<install_root>\lib` directory.

For example, to compile a servlet running on the Windows NT version of WebSphere Application Server, specify:

```
javac -classpath D:\Program Files\WebSphere\AppServer\lib\j2ee.jar MyServlet.java
```

To compile that same servlet on the Windows NT version of WebSphere Network Deployment, specify:

```
javac -classpath D:\Program Files\WebSphere\DeploymentManager\lib\j2ee.jar MyServlet.java
```

3. **(Optional)** Disable JavaServer Pages (JSP) runtime compilation, if necessary.

Assemble the application components in one or more Web modules.

Disabling JavaServer Pages run-time compilation

By default, the JavaServer Pages (JSP) engine translates a requested JSP file, compiles the `.java` file, and loads the compiled servlet into the run-time environment. In previous releases of WebSphere Application Server, if a `.class` file did not exist, the JSP engine always translated and compiled the JSP file. You had to turn off the Web applications reload capability to prevent additional translations and recompiles of the file.

With Version 5.0.1 of WebSphere Application Server, you can now change the JSP engine default behavior by indicating a JSP file should never be translated or compiled at run time, even when a `.class` file does not exist.

If run-time compilation is disabled, you must precompile the JSP files, which provides the following advantages:

- Reduces compilation related disk operations.
- Minimizes disk storage requirements necessary for handling temporary `.java` and `.class` files generated during a run-time compilation.
- Forces you to verify that a JSP file compiled successfully before deploying and installing the application in WebSphere Application Server.

You can disable run-time JSP file compilation on a global or an individual Web application basis:

- To disable the translation and compilation of JSP files for all Web applications, set the Web container Custom property `disableJspRuntimeCompilation` to `true`.

Set this property through the Web container Custom properties panel in the administrative console. To view this administrative console page, click:

```
Servers > Application Servers > server_name > Web Container >
  Custom Properties > property_name
```

Valid values for this setting are `true` or `false`. If this property is set to `true`, then translation and compilation of the JSP files is disabled at run time for all Web applications.

- To disable the translation and compilation of JSP files for a specific Web application, set the JSP engine initialization parameter `disableJspRuntimeCompilation` to `true`. This setting, if enabled, determines the run-time behavior of the JSP engine and overrides the Web container custom property setting.

Set this parameter through the JavaServer Pages attribute assembly settings panel in the Chapter 29, “Assembling applications with the Assembly Toolkit,” on page 1391.

Web Modules > *component_instance* > **Assembly Property Extensions**

Valid values for this setting are `true` or `false`. If this parameter is set to `true`, then, for that specific Web application, translation and compilation of the JSP files is disabled at run time, and the JSP engine only loads precompiled files.

- If neither the Web container custom property nor the JSP attribute assembly parameter is set, the first request for a JSP file results in the translation and compilation of the JSP file when the `.class` file does not exist. Subsequent requests for the file also result in compilations and translations, but only if the following conditions are met:
 - Compilations and translations are required.
 - Reloading is enabled for the Web module.
 - Reload interval is exceeded.

If you disable run-time compilation and a request arrives for a JSP file that does not have a matching `.class` file, the JSP engine returns HTTP error 501 (Not implemented) to the browser. If the JSP file does not exist, the JSP engine returns HTTP error 404 (File not found) to the browser. In both cases, an exception is written to the System Out (SYSOUT) and First Failure Data Capture (FFDC) logs. If a JSP file has a matching `.class` file but that file is out of date, the JSP engine still loads the `.class` file into memory.

Perform the following steps to determine whether the `disableJspRuntimeCompilation` option is enabled in WebSphere Application Server:

1. Enable the Diagnostic Trace Service and set the trace specification to `com.ibm.ws.webcontainer.jsp.servlet.*=all=enabled`.
2. Request a JSP file.
3. Locate the string, `disableJspRuntimeCompilation:true`, in the `trace.log` file.
4. Ensure the `jspUri`: entry matches the requested JSP file.

If both the `disableJspRuntimeCompilation:true` string and the matching `jspUri`: entry appear in the trace, the `disableJspRuntimeCompilation` setting is enabled for the Web application.

Example: Converting JavaScript source to the Bean Scripting Framework

JavaScript code is one of the most popular languages of Web developers. This language supports the following base objects, plus additional objects from the Document Object Model:

- array
- date
- math
- number
- string

Server-side JavaScript code supports the same base objects, and additional objects that support user access to databases, file systems and e-mail systems.

Like client-side JavaScript code, server-side JavaScript code is also platform, browser, and language independent.

You can convert server-side JavaScript applications to the Bean Scripting Framework. This article describes how to perform this conversion.

Server-side JavaScript source code

Suppose you have the following server-side JavaScript application:

```
<html>
<head>
<title>Hello World server-side JavaScript example</title>
</head>
<body>
<br><br>
</body>
</html>

<server>
function writePage()
  write("<center><font size='6'>Hello World</font></center>");
</server>
```

Converting server-side JavaScript source code to the Bean Scripting Framework (BSF)

Make the following changes to the JavaScript source code to enable BSF:

```
<%@ page language="javascript" %>
<html>
<head>
<title>Hello World server-side BSF/JavaScript example</title>
</head>
<body>
<br><br>
</body>
</html>

<%
  out.println("<center><font size='6'>Hello World</font></center>");
%>
```

Review the other BSF reference articles for deployment information and additional programming examples.

Scenario: Creating a Bean Scripting Framework application

Scenario description

Programming skills in JavaScript code are more prevalent than programming skills using JavaServer Pages (JSP) tags. Using the Bean Scripting Framework, JavaScript programmers can gradually introduce JSP tags in their JavaScript applications without completely rewriting the source code. The BSF method not only reduces the potential of programming errors, but also provides a painless way to learn a new technology.

The following scenario illustrates how to implement a BSF application using JavaScript within JSP tags.

Developing the BSF application

At ABC elementary school, John Doe teaches third grade mathematics. He wants to help his students memorize their multiplication tables, and thinks a small Web-based quiz could help meet his objective. However, John Doe only knows JavaScript.

Using the Bean Scripting Framework to help leverage his JavaScript skills, John Doe creates two JSP files, `multiplication_test.jsp` and `multiplication_scoring.jsp`.

In the `multiplication_test.jsp` file, John Doe uses both client-side and server-side JavaScript code to generate a test of 100 random multiplication questions, displayed using a three minute timer. He then writes the `multiplication_scoring.jsp` file to read the data submitted by the `multiplication_test.jsp` file and to generate the scoring results.

John Doe creates the following two files:

multiplication_test.jsp:

```
<html>
<head>
<title>Multiplication Practice Test</title>
<script language="javascript">
var countMin=3;
var countSec=0;
function updateDisplay (min, sec) {
    var disp;
    if (min <= 9) disp = " 0";
    else disp = " ";
    disp += (min + ":");
    if (sec <= 9) disp += ("0" + sec);
    else disp += sec;
    return(disp);
}
function countDown() {
    countSec--;
    if (countSec == -1) {
        countSec = 59;
        countMin--;
    }
    document.multtest.counter.value = updateDisplay(countMin, countSec);
    if((countMin == 0) &&(countSec == 0)) document.multtest.submit();
    else var down = setTimeout("countDown();", 1000);
}
</script>
</head>
<body bgcolor="#ffffff" onLoad="countDown();">
<%@ page language="javascript" %>
<h1>Three Minute Multiplication Drill</h1>
<hr>
<h2>Remember: this is an opportunity to excel!</h2>
<p>
<form method="POST" name="multtest" action="multiplication_scoring.jsp">
<div align="center">
<table>
<tr>
<td>
<h3>Time left:
<input type="text" name="counter" size="9" value="03:00" readonly>
</h3>
</td>
<td>
<input type="submit" value="Submit for scoring!">
</td>
</tr>
</table>
<table border="1">
<%
var newrow = 0;
var q_num = 0;
function addQuestion(num1, num2) {
    if (newrow == 0) out.println("<tr>");
    out.println("<td>");
    out.println(num1 + " x " + num2 + " = ");
    out.println("</td><td>");
    out.print("<input name=\"\" + q_num + \"|\" + num1 + \":\" + num2 + \"\");
    out.println("type=\"text\" size=\"10\">");
    out.println("</td>");

```

```

    if (newrow == 3) {
        out.println("</tr>");
        newrow = 0;
    }
    else newrow++;
    q_num++;
}
for (var i = 0; i < 100; i++) {
    var rand1 = Math.ceil(Math.random() * 12);
    var rand2 = Math.ceil(Math.random() * 12);
    addQuestion(rand1, rand2);
}
%>
</table>
</div>
</form>

```

multiplication_scoring.jsp:

```

<html>
<head>
<title>Multiplication Practice Test Results</title>
</head>
<body bgcolor="#ffffff">
<%@ page language="javascript" %>
<h1>Multiplication Drill Score</h1>
<hr>
<div align="center">
<table border="1">
<tr><th>Problem</th><th>Correct Answer</th><th>Your Answer</th></tr>
<%
var total_score = 0;
function score (current, pos1, pos2) {
    var multiplier = current.substring(pos1 + 1, pos2);
    var multiplicand = current.substring(pos2 + 1, current.length());
    var your_product = request.getParameterValues(current)[0];
    var true_product = multiplier * multiplicand;
    out.println("<tr>");
    out.println("<td>" + multiplier + " x " + multiplicand + " = </td>");
    out.println("<td>" + true_product + "</td>");
    if (your_product == true_product) {
        total_score++;
        out.print("<td bgcolor=\"\#00ff00\">");
    }
    else {
        out.print("<td bgcolor=\"\#ff0000\">");
    }
    out.println(your_product + "</td>");
    out.println("</tr>");
}
var equations = request.getParameterNames();
while(equations.hasMoreElements()) {
    var currElt = equations.nextElement();
    var splitPos1 = currElt.indexOf("|");
    var splitPos2 = currElt.indexOf(":");
    if (splitPos1 >=0 && splitPos2 >= 0) score(currElt, splitPos1, splitPos2);
}
%>
</table>
<h2>Total Score: <%= total_score %></h2>
<h3><a href="multiplication_test.jsp">Try again?</a></h3>
</div>
</body>
</html>

```

Follow these steps to see how John Doe uses BSF to implement JavaScript in a JSP application:

1. Give your files a .jsp extension.
2. Use server-side JavaScript code in your application.

The `multiplication_test.jsp` file incorporates both client-side and server-side JavaScript. Server-side JavaScript is similar to client-side JavaScript; the primary difference consists of using a different set of objects. Whereas client-side Javascript programmers invoke `document` and `window` objects, server-side JavaScript programmers, using the Bean Scripting Framework, invoke a set of objects provided by the JSP technology. Also, client-side scripts are enclosed in `<script>` tags, but server-side scripts use JSP scriptlet and expression tags.

3. Examine the following blocks of code:

```
<script language="javascript">
var countMin=3;
var countSec=0;
function updateDisplay (min, sec) {
    var disp;
    if (min <= 9) disp = " 0";
    else disp = " ";
    disp += (min + ":");
    if (sec <= 9) disp += ("0" + sec);
    else disp += sec;
    return(disp);
}
function countDown() {
    countSec--;
    if (countSec == -1) {
        countSec = 59;
        countMin--;
    }
    document.mulptest.counter.value = updateDisplay(countMin, countSec);
    if((countMin == 0) && (countSec == 0)) document.mulptest.submit();
    else var down = setTimeout("countDown();", 1000);
}
</script>
....
<body bgcolor="#ffffff" onLoad="countDown();">
...
<form method="POST" name="multtest" action="multiplication_scoring.jsp">
...
<input type="text" name="counter" size="9" value="03:00" readonly>
...
```

The JavaScript code contained in the `<script>` block implements a timer set within the `<input>` field named `counter`. The `onLoad` event handler in the `<body>` tag causes the browser to load and execute the code when the the page is loaded.

The `document.mulptest.submit()` statement causes the form named `multtest` to be submitted when the timer expires.

4. Identify the code to the BSF function.

The following code example, from the `multiplication_test.jsp` file, displays the use of a JSP directive. This directive tells the WebSphere Application Server BSF function that this file is using the JavaScript language, and that the JavaScript code is enclosed by the `<% ... %>` scriptlet tags. The out implicit JSP object in this code example, creates the body section of a table from 100 randomly generated questions.

```
...
<%@ page language="javascript" %>
...
<%
var newrow = 0;
var q_num = 0;

function addQuestion(num1, num2) {
    if (newrow == 0) out.println("<tr>");
```

```

        out.println("<td>");
        out.println(num1 + " x " + num2 + " = ");
        out.println("</td><td>");
        out.print("<input name=\"" + q_num + "\" |" + num1 + ":" + num2 + "\" ");
        out.println("type=\"text\" size=\"10\">");
        out.println("</td>");

        if (newrow == 3) {
            out.println("</tr>");
            newrow = 0;
        }
        else newrow++;

        q_num++;
    }

    for (var i = 0; i < 100; i++) {
        var rand1 = Math.ceil(Math.random() * 12);
        var rand2 = Math.ceil(Math.random() * 12);

        addQuestion(rand1, rand2);
    }

    %>
    ...

```

5. Read the results.

To score the results of the practice drill, John Doe uses the request implicit JSP object in the `multiplication_scoring.jsp` file to obtain the POST data created within the `<form>` tags in the `multiplication_test.jsp` file.

The `multiplication_scoring.jsp` file uses the POST data to build an output file containing the original question, the student's answer, and the correct answer, and then prints the text in a table format using the `out` implicit object.

The following code example from the `multiplication_scoring.jsp` file illustrates the use of the `request` and `out` JSP objects:

```

...
<%@ page language="javascript" %>
...
<%
var total_score = 0;
function score (current, pos1, pos2) {
    var multiplier = current.substring(pos1 + 1, pos2);
    var multiplicand = current.substring(pos2 + 1, current.length());
    var your_product = request.getParameterValues(current)[0];
    var true_product = multiplier * multiplicand;
    out.println("<tr>");
    out.println("<td>" + multiplier + " x " + multiplicand + " = </td>");
    out.println("<td>" + true_product + "</td>");
    if (your_product == true_product) {
        total_score++;
        out.print("<td bgcolor=\"\#00ff00\">");
    }
    else {
        out.print("<td bgcolor=\"\#ff0000\">");
    }
    out.println(your_product + "</td>");
    out.println("</tr>");
}
var equations = request.getParameterNames();
while(equations.hasMoreElements()) {
    var currElt = equations.nextElement();
    var splitPos1 = currElt.indexOf("|");
    var splitPos2 = currElt.indexOf(":");
    if (splitPos1 >=0 && splitPos2 >= 0) score(currElt, splitPos1, splitPos2);
}

```

```

%>
...
<h2>Total Score: <%= total_score %></h2>
...

```

Note: Although using separate scriptlet blocks of code for different portions of a conditional expression is common in JSP files implemented in Java, it is invalid for JSP files implemented using JavaScript through the Bean Scripting Framework. The JavaScript code must be entirely contained within the scriptlet tags.

The following code example illustrates invalid usage:

```

<% if (pass == 0) %>
    <i>pass is true</i>
<% else %>
    <i>pass is not true</i>

```

Deploying the BSF application

You assemble and deploy BSF applications in the same manner as JSP applications. Review the Chapter 29, “Assembling applications with the Assembly Toolkit,” on page 1391 article for more information.

Deploy the BSF code examples in WebSphere Application Server to view this applications processing and output. Use the following quick steps to deploy the application.

The intent of these “quick steps” is to provide you with instant application output. However, the supported method for deployment is the same as for standard JSP files.

1. Use the DefaultApplication to add your BSF files.

Copy your .jsp files to the DefaultApplication directory:

```

<app server install directory>/installedApps/<node
name>/DefaultApplication.ear/DefaultApplication.war

```

2. Start the application server.
3. Open a browser and request your BSF application.

Use the following URL to request your application:

```

http://hostName:9080/<jspFileName>.jsp

```

Example: Bean Scripting Framework code example

The following code examples show how to implement JavaScript using the Bean Scripting Framework (BSF).

For a quick demonstration of the BSF function, copy these code examples into 2 separate files, and deploy them in WebSphere Application Server using the instructions in the BSF scenario article.

Multiplication practice test

```

<html>
<head>
<title>Multiplication Practice Test</title>
<!--
This file and its companion, multiplication_score.jsp, illustrate the
use of ECMAScript within the BSF framework. The task is a simple
timed math quiz, which is 3 minutes in duration. When the quiz ends,
the score is computed and displayed.
Users are then asked if they wish to try
the quiz again.
-->
<!--

```

This code fragment displays and updates the quiz countdown in client side JavaScript code.

```
-->
<script language="javascript">
var countMin=3;
var countSec=0;

// This code computes the current countdown time.
function updateDisplay (min, sec) {
    var disp;

    if (min <= 9) disp = " 0";
    else disp = " ";

    disp += (min + ":");

    if (sec <= 9) disp += ("0" + sec);
    else disp += sec;

    return(disp);
}

//This code fragment displays the current countdown time in the user's
//browser window, and submits the results for scoring when the countdown
//ends.

function countDown() {
    countSec--;
    if (countSec == -1) {
        countSec = 59;
        countMin--;
    }
    document.mutttest.counter.value = updateDisplay(countMin, countSec);
    if((countMin == 0) && (countSec == 0)) document.mutttest.submit();
    else var down = setTimeout("countDown();", 1000);
}

</script>
</head>
<body bgcolor="#ffffff" onLoad="countDown();">

<!--
The body of the quiz runs as JavaServer Pages (JSP) code using BSF.
The code outputs the problems in table format using the POST method
and invokes the scoring module when the user chooses to end the quiz
or when the countdown ends.
-->
<%@ page language="javascript" %>

<h1>Three Minute Multiplication Drill</h1>
<hr>

<h2>Remember: this is an opportunity to excel!</h2>
<p>

<form method="POST" name="multttest" action="multiplication_scoring.jsp">
<div align="center">
<table>
<tr>
<td>
<h3>Time left:
<input type="text" name="counter" size="9" value="03:00" readonly>
</h3>
</td>
<td>
<input type="submit" value="Submit for scoring!">
</td>

```

```

var newrow = 0;
var q_num = 0;

// This code generates a new random multiplication problem up to the number
//twelve, and enters it into the table of problems.

function addQuestion(num1, num2) {
    if (newrow == 0) out.println("<tr>");

    out.println("<td>");
    out.println(num1 + " x " + num2 + " = ");
    out.println("</td><td>");
    out.print("<input name=\"" + q_num + "\"" + num1 + ":" + num2 + "\" ");
    out.println("type=\"text\" size=\"10\">");
    out.println("</td>");

    if (newrow == 3) {
        out.println("</tr>");
        newrow = 0;
    }
    else newrow++;

    q_num++;
}

//This code obtains two random operands and formats 100 quiz problems.

for (var i = 0; i < 100; i++) {
    var rand1 = Math.ceil(Math.random() * 12);
    var rand2 = Math.ceil(Math.random() * 12);

    addQuestion(rand1, rand2);
}

%>
</table>
</div>
</form>

</body>
</html>

```

Multiplication practice test results

```

<html>
<head>
<title>Multiplication Practice Test Results</title>
</head>
<body bgcolor="#ffffff">

<!--
This JSP code is invoked when the user submits a math quiz for scoring,
or when the quiz countdown expires. The JSP code tabulates the problem list,
the correct answer, the user's answer, and scores the test. It then offers
the user an opportunity to try the quiz again.
-->
<%@ page language="javascript" %>

<h1>Multiplication Drill Score</h1>
<hr>

<div align="center">

```

```

<table border="1">
<tr><th>Problem</th><th>Correct Answer</th><th>Your Answer</th></tr>
<%
var total_score = 0;

// This code parses the submitted form, extracts the a problem generated by the
// multiplication_test.jsp file, outputs it, computes the correct answer,
// and displays this information and the user answer. The code scores
// the quiz using a running sum of correct answers.

function score (current, pos1, pos2) {
    var multiplier = current.substring(pos1 + 1, pos2);
    var multiplicand = current.substring(pos2 + 1, current.length());
    var your_product = request.getParameterValues(current)[0];
    var true_product = multiplier * multiplicand;

    out.println("<tr>");
    out.println("<td>" + multiplier + " x " + multiplicand + " = </td>");
    out.println("<td>" + true_product + "</td>");

    if (your_product == true_product) {

<h3><a href="/multiplication_test.jsp">Try again?</a></h3>
</div>

</body>
</html>

```

Web modules

A Web module represents a Web application. A Web module is created by assembling servlets, JavaServer Pages (JSP) files, and static content such as HyperText Markup Language (HTML) pages into a single deployable unit. Web modules are stored in Web archive (WAR) files, which are standard Java archive files.

A Web module contains:

- One or more servlets, JSP files, and HTML files.
- A deployment descriptor, stored in an Extensible Markup Language (XML) file.

The file, named `web.xml`, declares the contents of the module. It contains information about the structure and external dependencies of Web components in the module and describes how the components are used at run time.

You can create Web modules as stand-alone applications, or you can combine Web modules with other modules to create J2EE applications. You install and run a Web module in the Web container of an application server.

Assembling Web applications

Assemble a Web module to contain servlets, JavaServer page (JSP) files, and related code artifacts. (Group enterprise beans, client code, and resource adapter code in separate modules). After assembling a Web module, you can install it as a stand-alone application or combine it with other modules into an enterprise application.

Use the Assembly Toolkit to assemble a Web module in any of the following ways:

- Import an existing Web module (WAR file).
- Create a new Web module.
- Copy code artifacts (such as servlets) from one Web module into a new Web module.

Although you can input various properties for Web archives, available properties are specific to the Servlet, JSP, and J2EE specification level.

1. Start the Assembly Toolkit.
2. Optional: Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. Optional: Open the J2EE Hierarchy view. Click **Window > Show View > J2EE Hierarchy**. Other helpful views include the Project Navigator view (**Window > Show View > Other > J2EE > Project Navigator**) and the Navigator view (**Window > Show View > Navigator**).
4. **5.1+** Optional: To use application assembly services of WebSphere Business Integration (WBI) Server Foundation such as Internationalization, ActivitySession or Application profiling, select the **Integration Server** target server.
 - a. Click **Project > Properties > J2EE**.
 - b. For **Target server**, select **Integration Server**. For this release, **Integration Server v5.1**.
 - c. Click **OK**.

You can set values for WBI Server Foundation services on the **Extended Services** tab of a deployment descriptor editor open on the module.

5. Migrate WAR files created with the Application Assembly Tool (AAT) or a different tool to the Assembly Toolkit. To migrate files, import your WAR files to the Assembly Toolkit.
6. Create a new Web module.
7. Copy code artifacts (such as servlets) from one Web module into a new Web module.
8. Verify the contents of the new Web module in either of the following ways:
 - In the J2EE Hierarchy view, expand **Web Modules** and view the new module.
 - Click **Window > Show View > Navigator** to see the associated files for the Web module in a Navigator view.

Context parameters

A servlet context defines a server's view of the Web application within which the servlet is running. The context also allows a servlet to access resources available to it.

Using the context, a servlet can log events, obtain URL references to resources, and set and store attributes that other servlets in the context can use. These properties declare a Web application's parameters for its context. They convey setup information, such as a webmaster's e-mail address or the name of a system that holds critical data.

Security constraints

Security constraints determine how Web content is to be protected.

These properties associate security constraints with one or more Web resource collections. A constraint consists of a Web resource collection, an authorization constraint and a user data constraint.

- A Web resource collection is a set of resources (URL patterns) and HTTP methods on those resources. All requests that contain a request path that matches the URL pattern described in the Web resource collection is subject to the constraint. If no HTTP methods are specified, then the security constraint applies to all HTTP methods.
- An authorization constraint is a set of roles that users must be granted in order to access the resources described by the Web resource collection. If a user who requests access to a specified URI is not granted at least one of the roles specified in the authorization constraint, the user is denied access to that resource.
- A user data constraint indicates that the transport layer of the client or server communications process must satisfy the requirement of either guaranteeing content integrity (preventing tampering in transit) or guaranteeing confidentiality (preventing reading while in transit).

Servlet mappings

A servlet mapping is a correspondence between a client request and a servlet.

Servlet containers use URL paths to map client requests to servlets, and follow the URL path-mapping rules as specified in the Java Servlet specification. The container uses the URI from the request, minus the context path, as the path to map to a servlet. The container chooses the longest matching available context path from the list of Web applications that it hosts.

Invoker attributes

Invoker attributes are used by the servlet that implements the invocation behavior.

Error pages

Error page locations allow a servlet to find and serve a URI to a client based on a specified error status code or exception type.

These properties are used if the error handler is another servlet or JSP file. The properties specify a mapping between an error code or exception type and the path of a resource in the Web application. The container examines the list in the order that it is defined, and attempts to match the error condition by status code or by exception class. On the first successful match of the error condition, the container serves back the resource defined in the Location property.

File serving

File serving allows a Web application to serve static file types, such as HTML. File-serving attributes are used by the servlet that implements file-serving behavior.

Initialization parameters

Initialization parameters are sent to a servlet in its `HttpConfig` object when the servlet is first started.

Servlet caching

Dynamic caching can be used to improve the performance of servlet and JavaServer Pages (JSP) files by serving requests from an in-memory cache. Cache entries contain the servlet's output, results of the servlet's execution, and metadata.

Web components

A web component is a servlet, Java Server Page (JSP), or HTML file. One or more web components make up a web module.

Web property extensions

Web property extensions are IBM extensions to the standard deployment descriptors for Web applications. These extensions include mime filtering and servlet caching.

Web resource collections

A Web resource collection defines a set of URL patterns (resources) and HTTP methods belonging to the resource.

HTTP methods handle HTTP-based requests, such as GET, POST, PUT, and DELETE. A URL pattern is a partial Uniform Resource Locator that acts as a template for matching the pattern with existing full URLs in an attempt to find a valid file.

Welcome files

A Welcome file is an entry point file (for example, `index.html`) for a group of related HTML files.

Welcome files are located by using a group of partial URIs. The Web container uses the partial URIs to find a valid file when the initial URI is not found.

Troubleshooting tips for Web application deployment

Deployment of a Web application is successful if you can access the application by typing a Uniform Resource Locator (URL) in a browser, or if you can access the application by following a link.

If you cannot access your application, follow these steps to eliminate some common errors that can occur during migration or deployment.

Web module does not run in WebSphere Application Server Version 5.

Symptom	Your Web module does not run when you migrate it to Version 5
Problem	In Version 4.x, the classpath setting that affected visibility was <i>Module Visibility Mode</i> . In Version 5, you must use class loader policies to set visibility.
Recommended response	Reassemble an existing module, or change the visibility settings in the class loader policies. in the class loader policies.
	See article Migration of module visibility modes from Version 4.x for more information and examples.

Welcome page is not visible.

Symptom	You cannot access an application with a Web path of: <code>/webapp/myapp</code>
Problem	The default welcome page for a Web application is assumed to be <i>index.html</i> . You cannot access the default page of the <i>myapp</i> application unless it is named <i>index.html</i> .

Recommended response To identify a different welcome page, modify the properties of the Web module during assembly.

HTML files are not found.

Symptom Your Web application ran successfully on prior versions, but now you encounter errors that the welcome page (typically *index.html*), or referenced HTML files are not found:
Error 404: File not found: Banner.html
Error 404: File not found: HomeContent.html

Problem For security and consistency reasons, Web application URLs are now case-sensitive on all operating systems.

Suppose the content of the index page is as follows:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 5.0 Frameset//EN">
<HTML>
<TITLE>
Insurance Home Page
</TITLE>
  <frameset rows="18,80">
    <frame src="Banner.html" name="BannerFrame" SCROLLING=NO>
    <frame src="HomeContent.html" name="HomeContentFrame">
  </frameset>
</HTML>
```

However the actual file names in the \WebSphere\AppServer\installedApps\... directory where the application is deployed are:

```
banner.html
homecontent.html
```

Recommended response To correct this problem, modify the *index.html* file to change the names *Banner.html* and *HomeContent.html* to *banner.html* and *homecontent.html* to match the names of the files in the deployed application.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.

Modifying the default Web container configuration

The Web container is created initially with default properties values suitable for simple Web applications. However, these values might not be appropriate for more complex Web applications.

Your application is considered complex if it requires any of the following features:

- virtual host
- servlet caching
- special client request loads
- persistent HTTP session support
- special HTTP transport settings
- transaction class mappings

Modify the following properties if you have a complex application:

1. If your Web application requires a virtual host, other than the default_host, or requires servlet caching, modify the Web container **General Properties**.
2. If your application handles special client request loads, modify the Web Container **Additional Properties > Thread Pool** setting.

3. If your application requires persistent HTTP session support, modify the Web Container **Additional Properties > Session Management** setting.
4. If your application requires one of the following HTTP transport settings:
 - Unique hostname and port for client access
 - SSL enablementmodify the Web Container **Additional Properties > HTTP transports** setting.
5. If your application requires global settings for internal servlets for WAR files packaged by third-party tools, modify the Web Container **Additional Properties > Custom Properties** setting.
6. If your application uses transaction class mappings to classify workload, modify the Web Container **Additional Properties > Advanced Settings**.

Web container

A Web container handles requests for servlets, JavaServer Pages (JSP) files, and other types of files that include server-side code. The Web container creates servlet instances, loads and unloads servlets, creates and manages request and response objects, and performs other servlet management tasks.

The Web server plug-ins, provided by the WebSphere Application Server, help supported Web servers pass servlet requests to Web containers.

Web container settings

Use this page to configure the web container settings.

To view this administrative console page, click **Servers > Application Servers > *server_instance* > Web container**.

Configuration - General Properties

Default virtual host

Specifies a virtual host that enables a single host machine to resemble multiple host machines. Resources associated with one virtual host cannot share data with resources associated with another virtual host, even if the virtual hosts share the same physical machine.

Select a virtual host option:

Default Host

The product provides a default virtual host with some common aliases, such as the machine IP address, short host name, and fully qualified host name. The alias comprises the first part of the path for accessing a resource such as a servlet. For example, it is `localhost:9080` in the request `http://localhost:9080/myServlet`.

Admin Host

This is another name for the application server; also known as *server1* in the base installation. This process supports the use of the administrative console.

Servlet caching

Specifies that if a servlet is invoked once and it generates output to be cached, a cache entry is created containing not only the output, but also side effects of the invocation. These side effects can include calls to other servlets or Java Server Pages (JSP) files, as well as metadata about the entry, including timeout and entry priority information.

Enable servlet caching

Check this box to enable servlet caching.

Web Module Deployment settings

Use this page to configure an instance of Web module deployment.

To view this administrative console page, click **Applications > Enterprise Application > application_instance > Web Modules > Web Module_instance**.

URI

Specifies a URI that, when resolved relative to the application URL, specifies the location of the module archive contents on a file system. The URI must match the ModuleRef URI in the deployment descriptor of an application if the module was packaged as part of a deployed application or enterprise archive (EAR) file.

Alternate DD

Specifies the file name for an alternative deployment descriptor file to use instead of the original deployment descriptor file in the module JAR file.

This file is the *post-assembly* version of the deployment descriptor file. You can edit the original deployment descriptor file to resolve dependencies and security information. Specifying the use of the alternative deployment descriptor keeps the original deployment descriptor file intact.

The value of the *Alternate DD* property must be the full path name of the deployment descriptor file, relative to the module root directory. By convention, the file is in the ALT-INF directory. If this property is not specified, the deployment descriptor file is read from the module JAR file.

Starting weight

Specifies the order in which modules are started. Lower weighted modules are started before higher weighted modules.

Classloader Mode

Specifies whether the class loader should search in the parent class loader or in the application class loader first to load a class. The standard for JDK class loaders and WebSphere class loaders is PARENT_FIRST. By specifying PARENT_LAST, your application can override classes contained in the parent class loader, but this action can potentially result in ClassCastException or LinkageErrors if you have mixed use of overridden classes and non-overridden classes.

The options are PARENT_FIRST and PARENT_LAST. The default is to search in the parent class loader before searching in the application class loader to load a class.

Data type	String
Default	PARENT_FIRST

Web container custom properties

Use this page to configure arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console.

To view this administrative console page, click **Servers > Application Servers > server_name > Web Container > Custom Properties**.

Name

Specifies the name (or key) for the property.

Data type	String
------------------	--------

Value

Specifies the value paired with the specified name.

Data type	String
------------------	--------

Description

Provides information about the name-value pair.

Data type String

Global settings for internal servlets

Web Archive (WAR) files packaged using third-party tools cannot specify behavior for the services exposed by the Web container internal servlets. You can globally enable/disable internal servlets for all Web applications at the Web container level by creating name-value pairs such as:

<u>Name</u>	<u>Value</u>
fileServingEnabled	true
directoryBrowsingEnabled	true
serveServletsByClassnameEnabled	true

Settings defined in an assembly tool take precedence over the global settings set through the custom properties at the Web container level.

Web application deployment extensions continue to hold configuration information for the services provided by the internal servlets, and take precedence over the global settings set through the custom properties at the Web container level.

UTF-8 encoded URLs

WebSphere Application Server Version 5.1, introduces support for UTF-8 encoded Uniform Resource Locators (URLs) to support the double-byte characters in URLs. The UTF-8 encoded URL feature is enabled by default. You can prevent the web container from explicitly decoding URLs in UTF-8 and have them use the ISO-8859 standard as per the current HTTP specification by using the following name-value pair:

<u>Name</u>	<u>Value</u>
DecodeUriAsUTF8	false

Chapter 3. Managing HTTP sessions

IBM WebSphere Application Server provides a service for managing HTTP sessions: Session Manager. The key activities for session management are summarized below.

Before you begin these steps, make sure you are familiar with the programming model for accessing HTTP session support in the applications following the Servlet 2.3 API.

1. Plan your approach to session management, which could include session tracking, session recovery, and session clustering.
2. Create or modify your own applications to use session support to maintain sessions on behalf of Web applications.
3. Assemble your application.
4. Deploy your application.
5. Ensure the administrator appropriately configures session management in the administrative domain.
6. Adjust configuration settings and perform other tuning activities for optimal use of sessions in your environment.

Sessions

A session is a series of requests to a servlet, originating from the same user at the same browser.

Sessions allow applications running in a Web container to keep track of individual users.

For example, a servlet might use sessions to provide "shopping carts" to online shoppers. Suppose the servlet is designed to record the items each shopper indicates he or she wants to purchase from the Web site. It is important that the servlet be able to associate incoming requests with particular shoppers. Otherwise, the servlet might mistakenly add Shopper_1's choices to the cart of Shopper_2.

A servlet distinguishes users by their unique session IDs. The session ID arrives with each request. If the user's browser is cookie-enabled, the session ID is stored as a cookie. As an alternative, the session ID can be conveyed to the servlet by URL rewriting, in which the session ID is appended to the URL of the servlet or JavaServer Pages (JSP) file from which the user is making requests. For requests over HTTPS or Secure Sockets Layer (SSL), Another alternative is to use SSL information to identify the session.

Migrating HTTP sessions

Note: In Version 5 default write frequency mode is `TIME_BASED_WRITES`, which is different from Version 4.0 and 3.5 default mode of `END_OF_SERVICE`.

Migrating from Version 4.0

No programmatic changes are required to migrate from version 4.0 to version 5.

Migrating from Version 3.5

If you have Version 3.5 applications running in Servlet 2.1 mode, some of the following Version 5 differences might influence how you choose to track and manage sessions.

1. During application development, modify session-related APIs as needed.
Some API changes are required in order to redeploy existing applications on Version 5. These include changes to the `HttpSession` API itself as well as issues associated with moving to support for the

Servlet 2.3 specification. Certain Servlet 2.1 API methods have been deprecated in Servlet 2.3 API . These deprecated APIs still work in Version 5.0, but they may be removed in a future version of the API. Changes are summarized in the following list:

- Replace instances of `getValue()` with `getAttribute()`
- Replace instances of `getValueNames()` with `getAttributeNames()`
- Replace instances of `removeValue()` with `removeAttribute()`
- Replace instances of `putValue()` with `setAttribute()`

2. During application development, modify Web application behavior as needed.

In accordance with the Servlet 2.3 specification, `HttpSession` objects must be scoped within a single Web application context; they may not be shared between contexts. This means that a session can no longer span Web applications. Objects added to a session by a servlet or JSP in one Web application cannot be accessed from another Web application. The same session ID may be shared (because the same cookie is in use), but each Web application will have a unique session associated with the session ID. Version 5 provides a feature that can be used to extend scope of a session to enterprise application.

3. Use administrative tools to configure Session Manager security settings as needed. Relative to session security, the default Session Manager setting for Integrate Security is now false. This is different from the default setting in some earlier releases.
4. Use administrative tools to configure the JSP enabler and application server as needed.

In Version 3.5 of the product, JSP files that contained the usebean tag with scope set to session did not always work properly when session persistence was enabled. Specifically, the JSP writer needed to write a scriptlet to explicitly set the attribute (that is, to call `setAttribute()`) if it was changed as part of JSP processing.

Two new features in Version 5.0 help address this problem:

- You can set `dosetattribute` to true on the JSP InitParameter.
- You can set the Write Contents option to Write all.

The differences between the two solutions are summarized in the following table:

	Applies to	Configured at	Action
<code>dosetattribute</code> set to <i>true</i>	JSP	JSP enabler	Assures that JSP session-scoped beans always call <code>setAttribute()</code>
Write Contents option set to <i>Write all</i>	servlet or JSP	application server	All session data (changed or unchanged) is written to the external location

If session persistence is enabled and a class reload for the Web application occurs, the sessions associated with the Web application are maintained in the persistent store and will be available after the reload.

Developing session management in servlets

This information, combined with the coding example `SessionSample.java`, provides a programming model for implementing sessions in your own servlets.

1. Get the `HttpSession` object.

To obtain a session, use the `getSession()` method of the `javax.servlet.http.HttpServletRequest` object in the Java Servlet 2.3 API.

When you first obtain the `HttpSession` object, the Session Management facility uses one of three ways to establish tracking of the session: cookies, URL rewriting, or Secure Sockets Layer (SSL) information.

Assume the Session Management facility uses cookies. In such a case, the Session Management facility creates a unique session ID and typically sends it back to the browser as a *cookie*. Each

subsequent request from this user (at the same browser) passes the cookie containing the session ID, and the Session Management facility uses this ID to find the user's existing HttpSession object.

In Step 1 of the code sample, the Boolean(create) is set to true so that the HttpSession object is created if it does not already exist. (With the Servlet 2.3 API, the javax.servlet.http.HttpServletRequest.getSession() method with no boolean defaults to true and creates a session if one does not already exist for this user.)

2. Store and retrieve user-defined data in the session.

After a session is established, you can add and retrieve user-defined data to the session. The HttpSession object has methods similar to those in java.util.Dictionary for adding, retrieving, and removing arbitrary Java objects.

In Step 2 of the code sample, the servlet reads an integer object from the HttpSession, increments it, and writes it back. You can use any name to identify values in the HttpSession object. The code sample uses the name sessiontest.counter.

Because the HttpSession object is shared among servlets that the user might access, consider adopting a site-wide naming convention to avoid conflicts.

3. (Optional) Output an HTML response page containing data from the HttpSession object.

4. Provide feedback to the user that an action has taken place during the session. You may want to pass HTML code to the client browser indicating that an action has occurred. For example, in step 3 of the code sample, the servlet generates a Web page that is returned to the user and displays the value of the sessiontest.counter each time the user visits that Web page during the session.

5. (Optional) Notify Listeners. Objects stored in a session that implement the javax.servlet.http.HttpSessionBindingListener interface are notified when the session is preparing to end and become invalidated. This notice enables you to perform post-session processing, including permanently saving the data changes made during the session to a database.

6. End the session. You can end a session:

- Automatically with the Session Management facility if a session is inactive for a specified time. The administrators provide a way to specify the amount of time after which to invalidate a session.
- By coding the servlet to call the invalidate() method on the session object.

Example: SessionSample.java

```
import java.io.*;
import java.util.*;
import javax.servlet.*;
import javax.servlet.http.*;

public class SessionSample extends HttpServlet {
    public void doGet (HttpServletRequest request, HttpServletResponse response)
        throws ServletException, IOException {

        // Step 1: Get the Session object

        boolean create = true;
        HttpSession session = request.getSession(create);

        // Step 2: Get the session data value

        Integer ival = (Integer)
            session.getAttribute ("sessiontest.counter");
        if (ival == null) ival = new Integer (1);
        else ival = new Integer (ival.intValue () + 1);
        session.setAttribute ("sessiontest.counter", ival);

        // Step 3: Output the page

        response.setContentType("text/html");
```

```

    PrintWriter out = response.getWriter();
    out.println("<html>");
    out.println("<head><title>Session Tracking Test</title></head>");
    out.println("<body>");
    out.println("<h1>Session Tracking Test</h1>");
    out.println("You have hit this page " + ival + " times" + "<br>");
    out.println("Your " + request.getHeader("Cookie"));
    out.println("</body></html>");
}
}

```

Assembling so that session data can be shared

In accordance with the Servlet 2.3 API specification, by default the Session Management facility supports session scoping by Web module. Only servlets in the same Web module can access the data associated with a particular session. WebSphere Application Server provides an option that you can use to extend the scope of the session attributes to an enterprise application. Therefore, you can share session attributes across all the Web modules in an enterprise application. This option is provided as an IBM extension.

Restriction: To use this option, you must install all the Web modules in the enterprise application on a given server. You cannot split up Web modules in the enterprise application by servers. For example, with an enterprise application containing two Web modules, you cannot use this option when one Web module is installed on one server and second Web module is installed on a different server. In such split installations, applications might share session attributes across Web modules using distributed sessions, but session data integrity is lost when concurrent access to a session is made in different Web modules. It also severely restricts use of some Session Management features, like TIME_BASED_WRITES. For enterprise applications on which this option is enabled, the Session Management configuration on the Web module inside the enterprise application is ignored. Then Session Management configuration defined on enterprise application is used if Session Management is overwritten at the enterprise application level. Otherwise, the Session Management configuration on the Web container is used.

Servlet API Behavior

Note: If shared HttpSession context is turned on in an enterprise application, HttpSession listeners defined in all the Web modules inside the enterprise application are invoked for session events. The order of listener invocation is not guaranteed.

Do the following to share session data across Web modules in an enterprise application:

1. Start the Assembly Toolkit.
2. In the Assembly Toolkit, right-click the application (EAR file) you want to share and click **Open With > Deployment Descriptor Editor**.
3. In the application deployment descriptor editor of the Assembly Toolkit, select **Shared session context** under **WebSphere Extensions**. Make sure the class definition of attributes put into session are available to all Web modules in the enterprise application. The shared session context does not fully meet the requirements of the Specifications.
4. Save the application (EAR) file. In the Assembly Toolkit, after you close the application deployment descriptor editor, confirm that you want to save changes made to the application.

Session security support

You can integrate HTTP sessions and security in IBM WebSphere Application Server. When security integration is enabled in the Session Management facility and a session is accessed in a protected resource, you can access that session only in protected resources from then on. You cannot mix secured and unsecured resources accessing sessions when security integration is turned on. Security integration in the Session Management facility is not supported in form-based login with SWAM.

Security integration rules for HTTP sessions

Only authenticated users can access sessions created in secured pages and are created under the identity of the authenticated user. Only this authenticated user can access these sessions in other secured pages. To protect these sessions from unauthorized users, you cannot access them from an unsecured page.

Programmatic details and scenarios

IBM WebSphere Application Server maintains the security of individual sessions.

An identity or user name, readable by the `com.ibm.websphere.servlet.session.IBMSession` interface, is associated with a session. An unauthenticated identity is denoted by the user name `anonymous`. IBM WebSphere Application Server includes the `com.ibm.websphere.servlet.session.UnauthorizedSessionRequestException` class, which is used when a session is requested without the necessary credentials.

The Session Management facility uses the WebSphere Application Server security infrastructure to determine the authenticated identity associated with a client HTTP request that either retrieves or creates a session. WebSphere Application Server security determines identity using certificates, LPTA, and other methods.

After obtaining the identity of the current request, the Session Management facility determines whether to return the session requested using a `getSession()` call or not.

The following table lists possible scenarios in which security integration is enabled with outcomes dependent on whether the HTTP request is authenticated and whether a valid session ID and user name was passed to the Session Management facility.

	Unauthenticated HTTP request is used to retrieve a session	HTTP request is authenticated, with an identity of "FRED" used to retrieve a session
No session ID was passed in for this request, or the ID is for a session that is no longer valid	A new session is created. The user name is <code>anonymous</code>	A new session is created. The user name is <code>FRED</code>
A session ID for a valid session is passed in. The current session user name is <code>"anonymous"</code>	The session is returned.	The session is returned. Session Management changes the user name to <code>FRED</code>
A session ID for a valid session is passed in. The current session user name is <code>FRED</code>	The session is not returned. An <code>UnauthorizedSessionRequestException</code> error is thrown*	The session is returned.
A session ID for a valid session is passed in. The current session user name is <code>BOB</code>	The session is not returned. An <code>UnauthorizedSessionRequestException</code> error is thrown*	The session is not returned. An <code>UnauthorizedSessionRequestException</code> error is thrown*

* A `com.ibm.websphere.servlet.session.UnauthorizedSessionRequestException` error is thrown to the servlet.

Session management support

WebSphere Application Server provides facilities, grouped under the heading *Session Management*, that support the `javax.servlet.http.HttpSession` interface described in the Servlet API specification.

In accordance with the Servlet 2.3 API specification, the Session Management facility supports session scoping by Web module. Only servlets in the same Web module can access the data associated with a

particular session. Multiple requests from the same browser, each specifying a unique Web application, result in multiple sessions with a shared session ID. You can invalidate any of the sessions that share a session ID without affecting the other sessions.

You can configure a session timeout for each Web application. A Web application timeout value of 0 (the default value) means that the invalidation timeout value from the Session Management facility is used.

When an HTTP client interacts with a servlet, the state information associated with a series of client requests is represented as an HTTP session and identified by a session ID. Session Management is responsible for managing HTTP sessions, providing storage for session data, allocating session IDs, and tracking the session ID associated with each client request through the use of cookies or URL rewriting techniques. Session Management can store session-related information in several ways:

- In application server memory (the default). This information cannot be shared with other application servers.
- In a database. This storage option is known as *database persistent sessions*.

The last two options are referred to as *distributed sessions*. Distributed sessions are essential for using HTTP sessions for failover facility. When an application server receives a request associated with a session ID that it currently does not have in memory, it can obtain the required session state by accessing the external store (database or memory-to-memory). If distributed session support is not enabled, an application server cannot access session information for HTTP requests that are sent to servers other than the one where the session was originally created. Session Management implements caching optimizations to minimize the overhead of accessing the external store, especially when consecutive requests are routed to the same application server.

Storing session states in an external store also provides a degree of fault tolerance. If an application server goes offline, the state of its current sessions is still available in the external store. This availability enables other application servers to continue processing subsequent client requests associated with that session.

Saving session states to an external location does not completely guarantee their preservation in case of a server failure. For example, if a server fails while it is modifying the state of a session, some information is lost and subsequent processing using that session can be affected. However, this situation represents a very small period of time when there is a risk of losing session information.

The drawback to saving session states in an external store is that accessing the session state in an external location can use valuable system resources. Session Management can improve system performance by caching the session data at the server level. Multiple consecutive requests that are directed to the same server can find the required state data in the cache, reducing the number of times that the actual session state is accessed in external store and consequently reducing the overhead associated with external location access.

Configuring session management by level

When you configure session management at the Web container level, all applications and the respective Web modules in the Web container normally inherit that configuration, setting up a basic default configuration for the applications and Web modules below it.

However, you can set up different configurations individually for specific applications and Web modules that vary from the Web container default. These different configurations override the default for these applications and Web modules only.

Note: When you overwrite the default session management settings on the application level, all the Web modules below that application inherit this new setting unless they too are set to overwrite these settings.

1. Open the Administrative console.
 2. Select the level that this configuration applies to:
 - For the web container level:
 - a. Click **Servers > Application Servers**.
 - b. Select a server from the list of application servers.
 - c. Under Additional Properties, click **Web Container**.
 - For the enterprise application level:
 - a. Click **Applications > Applications**.
 - b. Select an applications from the list of applications.
 - For the Web module level:
 - a. Click **Applications > Enterprise Applications**.
 - b. Select an applications from the list of applications.
 - c. Under Related Items, click **Web Modules**.
 - d. Select a Web module from the list of Web modules defined for this application.
 3. Under **Additional Properties**, click **Session Management**.
 4. Make whatever changes you need to manage sessions
 5. If you are working on the Web module or application level and want these settings to override the inherited Session Management settings, under **General Properties**, select **Override**.
 6. Click **Apply** and **Save**.
-

Session tracking options

There are several options for session tracking, depending on what sort of tracking method you want to use:

- Session tracking with cookies
- Session tracking with URL rewriting
- Session tracking with Secure Sockets Layer (SSL) information

Session tracking with cookies

Tracking sessions with cookies is the default. No special programming is required to track sessions with cookies.

Session tracking with URL rewriting

An application that uses URL rewriting to track sessions must adhere to certain programming guidelines. The application developer needs to do the following:

- Program servlets to encode URLs
- Supply a servlet or Java Server Pages (JSP) file as an entry point to the application

Using URL rewriting also requires that you enable URL rewriting in the Session Management facility.

Note: In certain cases, clients cannot accept cookies. Therefore, you cannot use cookies as a session tracking mechanism. Applications can use URL rewriting as a substitute.

Program session servlets to encode URLs

Depending on whether the servlet is returning URLs to the browser or redirecting them, include either `encodeURL()` or `encodeRedirectURL()` in the servlet code. Examples demonstrating what to replace in your current servlet code follow.

Rewrite URLs to return to the browser

Suppose you currently have this statement:

```
out.println("<a href=\"/store/catalog\">catalog<a>");
```

Change the servlet to call the `encodeURL` method before sending the URL to the output stream:

```
out.println("<a href=\"\"");  
out.println(response.encodeURL ("/store/catalog"));  
out.println(">catalog</a>");
```

Rewrite URLs to redirect

Suppose you currently have the following statement:

```
response.sendRedirect ("http://myhost/store/catalog");
```

Change the servlet to call the `encodeRedirectURL` method before sending the URL to the output stream:

```
response.sendRedirect (response.encodeRedirectURL ("http://myhost/store/catalog"));
```

The `encodeURL()` and `encodeRedirectURL()` methods are part of the `HttpServletResponse` object. These calls check to see if URL rewriting is configured before encoding the URL. If it is not configured, the calls return the original URL.

If both cookies and URL rewriting are enabled and `response.encodeURL()` or `encodeRedirectURL()` is called, the URL is encoded, even if the browser making the HTTP request processed the session cookie.

You can also configure session support to enable protocol switch rewriting. When this option is enabled, the product encodes the URL with the session ID for switching between HTTP and HTTPS protocols.

Supply a servlet or JSP file as an entry point

The entry point to an application (such as the initial screen presented) may not require the use of sessions. However, if the application in general requires session support (meaning some part of it, such as a servlet, requires session support), then after a session is created, all URLs are encoded to perpetuate the session ID for the servlet (or other application component) requiring the session support.

The following example shows how you can embed Java code within a JSP file:

```
<%  
response.encodeURL ("/store/catalog");  
%>
```

Session tracking with SSL information

No special programming is required to track sessions with Secure Sockets Layer (SSL) information.

To use SSL information, turn on **Enable SSL ID tracking** in the Session Management property page. Because the SSL session ID is negotiated between the Web browser and HTTP server, this ID cannot survive an HTTP server failure. However, the failure of an application server does not affect the SSL session ID if an external HTTP Server is present between WebSphere Application Server and the browser.

SSL tracking is supported for the IBM HTTP Server and iPlanet Web servers only. You can control the lifetime of an SSL session ID by configuring options in the Web server. For example, in the IBM HTTP Server, set the configuration variable `SSLV3TIMEOUT` to provide an adequate lifetime for the SSL session ID. An interval that is too short can cause a premature termination of a session. Also, some Web browsers might have their own timers that affect the lifetime of the SSL session ID. These Web browsers may not leave the SSL session ID active long enough to serve as a useful mechanism for session tracking. Internal Http Server of WebSphere also supports SSL Tracking.

When using the SSL session ID as the session tracking mechanism in a cloned environment, use either cookies or URL rewriting to maintain session affinity. The cookie or rewritten URL contains session affinity information that enables the Web server to properly route a session back to the same server for each request.

Configuring session tracking

To configure session tracking, complete the following:

1. Go to the appropriate level of Session Management.
2. Specify which session tracking mechanism you want to pass the session ID between the browser and the servlet:
 - To track sessions with cookies, click **Enable Cookies**.
To change the cookie settings, click **Modify**.
 - To track sessions with URL rewriting, click **Enable URL Rewriting**.
If you want to enable protocol switch rewriting, click **Enable protocol switch rewriting**.
 - To track sessions with SSL information, click **Enable SSL ID tracking**.
3. Click **Apply**.
4. Click **Save**.
5. Define the session recovery characteristics.

Serializing access to session data

The Servlet API supports concurrent access to a session in a given server instance. WebSphere Application Server provides an option to prevent the concurrent access to a session in a given server instance so that concurrent modification of a session does not occur in a given server instance. This prevention is achieved by synchronizing the requests based on session. When this feature is turned on, a session is obtained for the request before invoking the servlet and requests are synchronized by locking the session for the servlet execution time. Note that synchronization is based on the memory copy of session. So this feature cannot serialize requests across servers based on session when session affinity fails.

Restriction: Use this feature only when concurrent modification of the same session data is possible and is not desirable by the application. This feature has overhead of serializing the requests based on a session.

Do the following to synchronize session access:

1. Select the level of Session Management on which you want to serialize session access.
2. Under Serialize Session access, click **Allow serial access**.
3. In the Maximum wait time box, type the amount of time, in milliseconds, a servlet waits on a session before continuing execution. The default is 120000 milliseconds or two minutes.
4. Select **Allow access on timeout** if you want the servlet to gain access to the session and continue normal execution even if the session is still locked by another servlet. If you do not select this box, the servlet execution will abort when the session request times out.
5. Click **Apply**.
6. Click **Save**.

Session Management settings

Use this page to manage HTTP session support. This support includes specifying a session tracking mechanism, setting maximum in-memory session count, controlling overflow, and configuring session timeout.

To view this administrative console page, click **Servers > Application Servers > server_name > Web Container > Session Management**.

Overwrite Session Management

Specifies whether or not these session management settings take precedence over those normally inherited from a higher level for the current application or web module.

By default, web modules inherit session management settings from the application level above it, and applications inherit session management settings from the web container level above it.

Session tracking mechanism

Specifies a mechanism for HTTP session management.

Mechanism	Function	Default
Enable SSL ID Tracking	Specifies that session tracking uses Secure Sockets Layer (SSL) information as a session ID. Enabling SSL tracking takes precedence over cookie-based session tracking and URL rewriting.	9600 seconds

There are two parameters available if you enable SSL ID tracking: SSLV3Timeout and Secure Authentication Service (SAS). SSLV3Timeout specifies the time interval after which SSL sessions are renegotiated. This is a high setting and modification does not provide any significant impact on performance. The SAS parameter establishes an SSL connection only if it goes out of the Java Virtual Machine (JVM) to another JVM. If all the beans are co-located within the same JVM, the SSL used by SAS does not hinder performance.

These are set by editing the `sas.server.properties` and `sas.client.props` files located in the `product_installation_root\properties` directory, where `product_installation_root` is the directory where WebSphere Application Server is installed.

Enable Cookies

Specifies that session tracking uses cookies to carry session IDs. If cookies are enabled, session tracking recognizes session IDs that arrive as cookies and tries to use cookies for sending session IDs. If cookies are not enabled, session tracking uses Uniform Resource Identifier (URL) rewriting instead of cookies (if URL rewriting is enabled).

Enabling cookies takes precedence over URL rewriting. Do not disable cookies in the Session Management facility of the application server that is running the administrative application because this action causes the administrative application not to function after a restart of the server. As an alternative, run the administrative application in a separate process from your applications.

Enable URL Rewriting

Click **Modify** to change these settings. Specifies that the session management facility uses rewritten URLs to carry the session IDs. If URL rewriting is enabled, the session management facility recognizes session IDs that arrive in the URL if the `encodeURL` method is called in the servlet.

Enable Protocol Switch Rewriting

Specifies that the session ID is added to a URL when the URL requires a switch from HTTP to HTTPS or from HTTPS to HTTP. If rewriting is enabled, the session ID is required to go between HTTP and HTTPS.

Maximum in-memory session count

Specifies the maximum number of sessions to maintain in memory.

The meaning differs depending on whether you are using in-memory or distributed sessions. For in-memory sessions, this value specifies the number of sessions in the base session table. Use the `Allow Overflow` property to specify whether to limit sessions to this number for the entire Session Management facility or to allow additional sessions to be stored in secondary tables. For distributed sessions, this value specifies the size of the memory cache for sessions. When the session cache has reached its maximum size and a new session is requested, the Session Management facility removes the least recently used session from the cache to make room for the new one.

Note: Do not set this value to a number less than the maximum thread pool size for your server.

Overflow

Specifies that the number of sessions in memory can exceed the value specified by the `Max In Memory Session Count` property. This option is valid only in nondistributed sessions mode.

Session timeout

Specifies how long a session can go unused before it is no longer valid. Specify either Set timeout or No timeout. Specify the value in minutes greater than or equal to two.

The value specified in a web module deployment descriptor file takes precedence over the administrative console settings. However, the value of this setting is used as a default when the session timeout is not specified in a web module deployment descriptor. Note that to preserve performance, the invalidation timer is not accurate to the second. When the Write Frequency is time based, ensure that this value is least twice as large as the write interval.

Security integration

Specifies that when security integration is enabled, the session management facility associates the identity of users with their HTTP sessions

Serialize session access

Specifies that concurrent session access in a given server is not allowed.

Maximum wait time

Specifies the maximum amount of time a servlet request waits on an HTTP session before continuing execution. This parameter is optional and expressed in seconds. The default is 120, or 2 minutes. Under normal conditions, a servlet request waiting for access to an HTTP session gets notified by the request that currently owns the given HTTP session when the request finishes.

Allow access on timeout

Specifies whether the servlet is executed normally or aborted in the event of a timeout. If this box is checked, the servlet executes normally. If this box is not checked, the servlet execution aborts and error logs are generated.

Cookie settings

Use this page to configure cookie settings for session management.

To view this administrative console page, click **Servers > Application Servers > *server_name* > Web Container > Session Management > Enable Cookies.**

Cookie name

Specifies a unique name for the session management cookie. The servlet specification requires the name JSESSIONID. However, for flexibility this value can be configured.

Secure cookies

Specifies that the session cookies include the secure field. Enabling the feature restricts the exchange of cookies to HTTPS sessions only.

Cookie domain

Specifies the domain field of a session tracking cookie. This value controls whether or not a browser sends a cookie to particular servers. For example, if you specify a particular domain, session cookies are sent to hosts in that domain. The default domain is the server.

Cookie path

Specifies that a cookie is sent to the URL designated in the path. Specify any string representing a path on the server. "/" indicates root directory. Specify a value to restrict the paths to which the cookie will be sent. By restricting paths, you prevent the cookie from going to certain URLs on the server. If you specify the root directory, the cookie is sent no matter which path on the given server is accessed.

Cookie maximum age

Specifies the amount of time that the cookie lives on the client browser. Specify that the cookie lives only as long as the current browser session, or to a maximum age. If you choose the maximum age option, specify the age in seconds. This value corresponds to the Time to Live (TTL) value described in the Cookie specification.

Default is the current browser session which is equivalent to setting the value to -1.

Configuring session tracking for Wireless Application Protocol (WAP) devices

Most Wireless Application Protocol (WAP) devices do not support cookies. The preferred way to track sessions for WAP devices is to use URL rewriting. However on most WAP devices, the maximum allowed URL length is 128 characters. With URL rewriting, a session identifier is added to the URL itself, effectively decreasing the space available for the actual URL and the number of parameters that can be sent on a request.

To reduce the length of session identifier, you can configure key (jsessionid), session ID length and clone ID. To make these configuration changes, complete the following:

1. Open the Administrative console.
2. Click **Servers > Application Servers**.
3. Select a server from the list of application servers.
4. Under Additional Properties, click **Web Container**
5. Under Additional Properties, click **Custom Properties**.
6. Add the appropriate properties from the following list:
 - HttpSessionIdLength
 - SessionRewriteIdentifier
 - HttpSessionCloneId
 - CloneSeparatorChange
 - NoAdditionalSessionInfo
 - SessionIdentifierMaxLength
7. Click **Apply** and **Save**.

Distributed sessions

WebSphere Application Server provides the following session mechanisms in a distributed environment:

- **Database Session persistence**, where sessions are stored in the database specified.

When a session contains attributes that implement `HttpSessionActivationListener`, notification occurs anytime the session is activated (that is, session is read to the memory cache) or passivated (that is, session leaves the memory cache). Passivation can occur because of a server shutdown or when the session memory cache is full and an older session is removed from the memory cache to make room for a newer session. It is not guaranteed that a session is passivated in one application server prior to being activated in another.

Session recovery support

For session recovery support, WebSphere Application Server provides distributed session support in the form of database sessions. Use session recovery support under the following conditions:

- When the user's session data must be maintained across a server restart
- When the user's session data is too valuable to lose through an unexpected server failure

All the attributes set in a session must implement `java.io.Serializable` if the session requires external storage. In general, consider making all objects held by a session serialized, even if immediate plans do not call for session recovery support. If the Web site grows, and session recovery support becomes necessary, the transition occurs transparently to the application if the sessions only hold serialized objects. If not, a switch to session recovery support requires coding changes to make the session contents serialized.

Distributed Environment settings

Use this page to specify a type for saving a session in a distributed environment.

To view this administrative console page, click **Servers > Application Servers > *server_name* > Web Container > Session Management > Distributed Environment Settings**.

Distributed Sessions

Specifies the type of distributed environment to be used for saving sessions.

None	Specifies that the session management facility discards the session data when the server shuts down.
Database	Specifies that the session management facility stores session information in the data source specified by the data source connection settings. Click Database to change these data source settings.

Configuring for database session persistence

To configure the session management facility for database session persistence, complete the following:

1. Define a JDBC provider.
2. Create a data source pointing to an existing database, using the JDBC provider that you defined. The data source should be non-JTA, for example, non-XA enabled. Note the JNDI name of the data source. Under **Data Sources > *datasource_name* > Custom Properties**, make sure the correct database is entered for the value of the **databaseName** property. If necessary, contact your database administrator to verify the correct database name.
3. Go to the appropriate level of Session Management.
4. Click **Distributed Environment Settings**
5. Select and click **Database**.
6. Specify the Data Source JNDI name from step 2.
7. Specify the database user ID and password for accessing the database.
8. Retype the password for confirmation.
9. Configure a table space and page sizes for DB2 session databases.
10. Switch to a multirow schema.
11. Click **OK**.
12. If you want to change the tuning parameters, click **Custom Tuning Parameters** and select a setting or customize one.
13. Click **Apply**.
14. Click **Save**.

Switching to a multirow schema

By default, a single session maps to a single row in the database table used to hold sessions. With this setup, there are hard limits to the amount of user-defined, application-specific data that WebSphere Application Server can access.

1. Modify the Session Management facility properties to switch from single to multirow schema.
2. Manually drop the database table or delete all the rows in the database table that the product uses to maintain HttpSession objects.

To drop the table:

- a. Determine which data source configuration Session Management is using.
- b. In the data source configuration, look up the database name.
- c. Use the database facilities to connect to the database.
- d. Drop the SESSIONS table.

Configuring tablespace and page sizes for DB2 session databases

If you are using DB2 for session persistence, you can increase the page size to optimize performance for writing large amounts of data to the database. Page sizes of 8K, 16K, and 32K are supported.

To use a page size other than the default (4K), do the following:

1. If the SESSIONS table already exists, drop it from the DB2 database.
2. Create a new DB2 buffer pool and table space, specifying the same page size (8K, 16K or 32K) for both, and assign the new buffer pool to this table space.

```
DB2 Connect to session
DB2 CREATE BUFFERPOOL sessionBP SIZE 1000 PAGESIZE 8K
DB2 Connect reset
DB2 Connect to session
DB2 CREATE TABLESPACE sessionTS PAGESIZE 8K MANAGED BY SYSTEM
    USING ('D:\DB2\NODE0000\SQL00005\sessionTS.0') BUFFERPOOL sessionBP
DB2 Connect reset
```

Refer to DB2 product documentation for details.

3. Configure the correct table space name and page size in the Session Management facility. Page size is referred to as *row size* on the Session Management page.)

When the product is restarted, the Session Management facility creates the new SESSIONS table in the specified tablespace based on the indicated page size.

Database settings

Use this page to specify the settings for database session support.

To view this administrative console page, click **Servers > Application Servers > server_name > Web Container > Session Management > Distributed Environment Settings > Database.**

Datasource JNDI Name

Specifies the datasource description

The JNDI name of the non-XA enabled data source from which Session Management obtains database connections. For example, if the JNDI name of the datasource is "jdbc/sessions", specify "jdbc/sessions." The data source represents a pool of database connections and a configuration for that pool (such as the pool size). The data source must already exist as a configured resource in the environment.

User ID

Specifies the user ID for database access

Password

Specifies the password for database access

Confirm Password

Specifies the password a second time to ensure it recorded correctly.

DB2 Row Size

Specifies the tablespace page size configured for the sessions table, if using a DB2 database. Possible values are 4, 8, 16, and 32 kilobytes (K). The default row size is 4K.

The default row size is 4K. In DB2, it can be updated to a larger value. This can help database performance in some environments. When this value is other than 4, you must specify Table Space Name to use. For 4K pages, the Table Space Name is optional.

Table Space Name

Specifies that tablespace to be used for the sessions table.

This value is required when the DB2 Page Size is other than 4K.

Multi row schema

Specifies that each instance of application data be placed in a separate row in the database, allowing larger amounts of data to be stored for each session. This action can yield better performance in certain usage scenarios. If using multirow schema is not enabled, instances of application data can be placed in the same row.

Multirow schema considerations

IBM WebSphere Application Server supports the use of a multirow schema option in which each piece of application specific data is stored in a separate row of the database. With this setup, the total amount of data you can place in a session is now bound only by the database capacities. The only practical limit that remains is the size of the session attribute object.

The multirow schema potentially has performance benefits in certain usage scenarios, such as when larger amounts of data are stored in the session but only small amounts are specifically accessed during a given servlet processing of an HTTP request. In such a scenario, avoiding unneeded Java object serialization is beneficial to performance.

Understand that switching between multirow and single row is not a trivial proposition.

In addition to allowing larger session records, using multirow schema can yield performance benefits. However, it requires a little work to switch from single-row to multirow schema, as shown in the instructions below.

Coding considerations and test environment

Consider configuring direct single-row usage to one database and multirow usage to another database while you verify which option suits your application needs. (Do this in code by switching the data source used; then monitor performance.)

Programming issue	Application scenario
Reasons to use single-row	<ul style="list-style-type: none">You can read or write all values with just one record read and write.This takes up less space in a database because you are guaranteed that each session is only one record long.
Reasons not to use single-row	2-megabyte limit of stored data per session.

Programming issue	Application scenario
Reasons to use multirow	<ul style="list-style-type: none"> • The application can store an unlimited amount of data; that is, you are limited only by the size of the database and a 2-megabyte-per-record limit. • The application can read individual fields instead of the whole record. When large amounts of data are stored in the session but only small amounts are specifically accessed during servlet processing of an HTTP request, multirow sessions can improve performance by avoiding unneeded Java object serialization.
Reasons not to use multirow	If data is small in size, you probably do not want the extra overhead of multiple row reads when you can store everything in one row.

In the case of multirow usage, design your application data objects not to have references to each other, to prevent circular references. For example, suppose you are storing two objects A and B in the session using `HttpSession.put(..)` method, and A contains a reference to B. In the multirow case, because objects are stored in different rows of the database, when objects A and B are retrieved later, the object graph between A and B is different than stored. A and B behave as independent objects.

Memory-to-memory replication

WebSphere Application Server supports session replication to another WebSphere Application Server instance. This support is referred to as *memory-to-memory session replication*. In this mode, sessions can replicate to one or more WebSphere Application Server instances to address HTTP Session single point of failure (SPOF). This is a new alternative in IBM WebSphere Application Server, Version 5 to the existing saving of HTTP Session to a database.

The WebSphere Application Server instance in which the session is currently processed is referred to as the *owner of the session*. In a clustered environment, session affinity in the WebSphere Application Server plug-in routes the requests for a given session to the same server. If the current owner server instance of the session fails, then the WebSphere Application Server plug-in routes the requests to another appropriate server in the cluster. This server either retrieves the session from a server that has the backup copy of the session or it retrieves the session from its own backup copy table. The server now becomes the owner of the session and affinity is now maintained to this server.

When a session is created or updated in a WebSphere Application Server instance, the session is transferred (or replicated) through one of the replicator entries under the replication domain that is configured with the session management facility. This session potentially gets replicated to the WebSphere Application Server instances that are also connected to the same replicator domain. The mode and partitioning determine whether WebSphere Application Server instances in the same replication domain gets the session.

There are three possible modes. You can set up a WebSphere Application Server instance to run in:

- **Server mode:** Only store backup copies of other WebSphere Application Server sessions and not to send out copies of any session created in that particular server
- **Client mode:** Only broadcast or send out copies of the sessions it owns and not to receive backup copies of sessions from other servers
- **Both mode:** Simultaneously broadcast or send out copies of the sessions it owns and act as a backup table for sessions owned by other WebSphere Application Server instances

You can select the replication mode of server, client, or both when configuring the session management facility for memory-to-memory replication. The default is both. This storage option is controlled by the mode parameter.

With respect to mode, the following are the primary examples of memory-to-memory replication configuration:

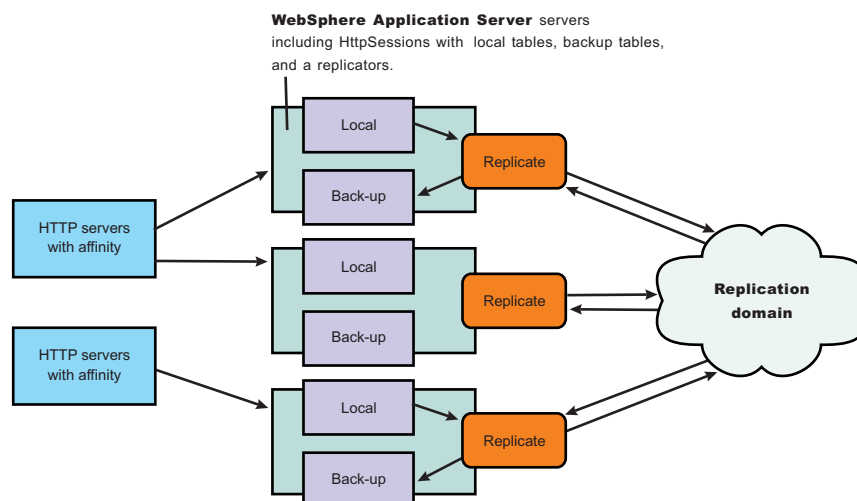

- Peer-to-peer with a local replicator
- Peer-to-peer with remote replicators
- Client/server with remote replicators
- Client/server with isolated replicators

In a cluster, by default, sessions are replicated in all the servers in the cluster that are connected to the same replicator domain. This replication can be redundant if a large number of servers exist in a cluster. The session management facility has an option to partition the servers into groups when storing sessions.

Memory-to-memory topology: Peer-to-peer function with a local replicator

The basic peer-to-peer (both client and server function, or both mode) topology is the default configuration. This configuration uses a local replicator (a replicator on the same server as the session manager) and no partitioning.

Memory to memory topology: Basic peer to peer or “both mode”

In this basic peer-to-peer topology, each server Java Virtual Machine (JVM):

- Host the Web application leveraging HTTP session
- Send out changes to the HTTP session that it owns
- Receive backup copies of the HTTP session from all of the other servers in the cluster
- House a replicator to which the session manager connects

This configuration represents the most consolidated topology, where the various system parts are collocated and requires the fewest server processes. When using this configuration, the most stable implementation is achieved when each node has equal capabilities (CPU, memory, and so on), and each handles the same amount of work.

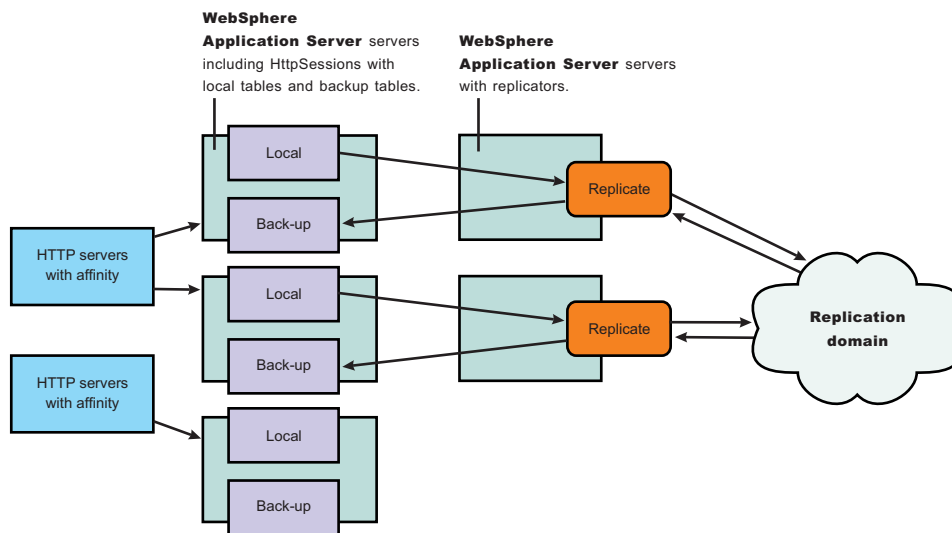

This topology is the most redundant because everyone replicates to everyone. On any failure recovery scenario, the server routed to already has a copy of the session. But as you add servers, more overhead (both CPU and memory) is needed to deal with replication. Without partitioning, scaling breaks down the

quickest with this configuration. When scaling breaks down because of the machine characteristics, the client hit rate, the network speed, and the size on average of the HTTP session. The remaining topologies: client/server with isolated replicators, client/server with remote replicators, and peer-to-peer with remote replicators help mitigate and manage the scaling characteristics of replication. Replication costs are also reduced through the use of partitioning and time based write (employed by default) in these topologies.

Memory-to-memory topology: Peer-to-peer function with remote/isolated replicators

In this topology, the replicators are separated from the clustered servers running the deployed application.

Memory to memory topology: Peer to peer with remote replicators

This method increases the number of servers used, which can be an increased cost for any installation. However, if containable, the separation of replicators produces several benefits:

- A replicator can handle the activity from session managers in multiple servers. A one-to-one correspondence between the replicators and servers can often be unnecessary; having a primary server (with a second server as a backup) is often sufficient.
- Not running the replicator in the Java Virtual Machine (JVM) running the application can free up some heap and central processing unit (CPU) for running the application.
- Putting components into separate processes means that if one of the component processes fails, this failure does not affect the other components.

Replicators can often handle multiple servers (six to seven). By using this topology, you have two configuration options:

- Use one replicator, and keep the other as a backup on standby (remember, if a replicator goes down, the session manager automatically switches to the next replicator domain).
- Split your session manager/application servers between the two replicators.

After selecting memory-to-memory replication on the session manager, you must select memory-to-memory replication to go to the detail configuration panel. You can select the replication domain and replicator for this session manager to use.

Memory-to-memory topology: Client/server function with remote replicators

The following figure depicts the client/server with remote replicators topology. There is a tier of applications servers that host web applications using HTTP Session, and these sessions are replicated out as they are created and updated. There is a second tier of servers without a web application installed, where the session manager receives updates from the replication clients. The replicators facilitating the transfer of data reside with the replication servers.

Memory to memory topology: Clients and servers with remote replicators

Benefits of the client/server with remote replicators configuration include:

- Isolation (for failure recovery): in this case we are isolating the handling of backup data from local data; aside from isolating the moving parts in case of a catastrophic failure in one of them, you again free up memory and processing in the servers processing the web application, much the same as the isolating of the replicators as showed in the topology for peer-to-peer function with remote replicators.
- Isolation (for stopping and starting): you can recycle a backup without affecting the servers running the application (when there are two or more backups, failure recovery is possible), and conversely recycle an application JVM without potentially losing that backup data for someone.
- Consolidation: there is most likely no need to have a one-to-one correspondence between servers handling backups and those processing the applications; hence, you are again reducing the number of places to which you transfer the data.
- Disparate hardware: while you run your web applications on cheaper hardware, you may have one or two more powerful computers in the back end of your enterprise that have the capacity to run a couple of session managers in replication server mode; allowing you to free up your cheaper web application hardware to process the web application.

You can define replicators on both the replication client and the server Java Virtual Machines (JVMs), however, replicators on both the clients and the servers is redundant. In the client/server topologies defining replicators only on the backup replication server JVMs is recommended.

It is good to spread out the replication clients as equally across the replicators as possible (by default they select the first replicator in the domain), because both replication servers are doing work and not acting as a hot standby.

Timing considerations: Start the replication servers first to avoid unexpected timing windows. The clients attempt to reconnect to the replication domain if you start the replication clients before the replications

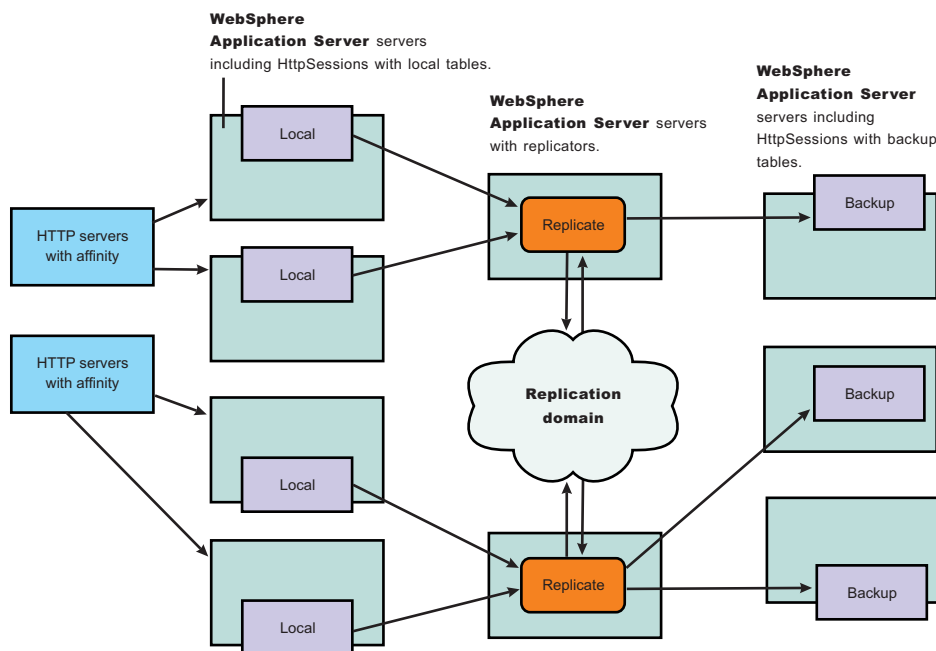

servers, even if the initial connection cannot be completed. However, if servers with the application come up, and requests on the applications occur before the replicators on the backup servers finish coming up, some expected client replication might not occur.

Memory-to-memory topology: Client/server function with isolated replicators

The following figure depicts the client/server with isolated replicators topology. In this topology, the replicators are separated from the backup servers and are on their own servers.

There is a tier of applications servers that host web applications using HTTP Session, and these sessions are replicated out as they are created and updated. There is a second tier of servers without a web application installed, where the session manager receives updates from the replication clients. The replicators facilitating the transfer of data reside with the replication servers

Memory to memory topology: Clients and servers with isolated replicators

Benefits of this topology include:

- The catastrophic failure of one server does not affect another server because of separate moving parts (the replicator and the backup server).
- You do not need a one-to-one correspondence between the replicators and the backup servers.

Although this topology is the most expensive from a Java Virtual Machine (JVM) perspective, and requires the most configuration through the administrative console, it provides the greatest degree of isolation from failure of a component, the most flexibility in starting/stopping the parts, and the most flexibility in mixing the right number of clients, servers, and replicators. Since both servers and clients need to connect to the replicators, starting the replicators removes the need for connection retries. Similarly, starting the clients after the servers, avoid timing windows where the clients send data before the servers are ready to receive them.

Memory-to-memory session partitions

In a replication domain, by default, sessions are replicated to all the servers that are connected to the same replication domain. This replication can be redundant if a large number of servers are located in a replication domain.

Group partitioning

The session management facility has an option to partition the servers into groups when storing sessions. From the session replication perspective, you can view the replicator as having n groups or partitions. The default is 10 groups (the recommended minimum for performance reasons). The number of groups is global for the entire replication domain and all the session managers connected into the replication domain through any of the replicators in that domain.

By default, the session management facility running in server mode listens to all the partitions on the replicator. When a session is created in this facility, it is written to one of the partitions on the replicator through a round-robin assignment performed by the session manager. At the session manager level, you can configure the session manager (when in either server or both mode) to listen to a subset of the group (by default, the session manager listens to all of them). Therefore, you can reduce or partition where the HTTP sessions get replicated. Also note that because a session manager listens to a subset of the groups, it does not mean that those are the only groups it replicates sessions on. The session manager round robins over all the groups being listened to by the complete set of session managers connected to the replication domain.

In a cluster environment with a large number of servers, some servers can be configured to listen on some partitions and others on a different partition. All the servers are still logically linked together through the replicator domain and you can retrieve a session in any server in the cluster. The number of groups of the replication domain is set under manage internal replication in the Environment tab. Configure which groups and partitions a specific Session Management facility listens to under session management.

Single replica partitioning

The alternative to group partitioning is to replicate the session to only one other server. When this option is chosen, a session manager dynamically picks another session manager that is connected to the same replication domain to replicate the HTTP session to during session creation. All updates to the session are only replicated to that single server. A round-robin algorithm is employed over the eligible session manager instances. The round robin will not include selection of other session managers in the same Java virtual machine (JVM), or other JVMs on the same node unless there is only 1 node connected to the replication domain. Because this is set at the replication domain level, every session manager connected to this replication domain uses single replica replication. The mode of the session manager has the same meaning, that is, clients only send out changes to one other session manager (albeit not in the same JVM or node), servers only receive, and session managers in both mode, send and receive changes.

Clustered session support

A clustered environment supports load balancing, where the workload is distributed among the application servers that compose the cluster. In a cluster environment, the same Web application must exist on each of the servers that can access the session. You can accomplish this setup by installing an application onto a cluster definition. Each of the servers in the group can then access the Web application

In a clustered environment, the Session Management facility requires an affinity mechanism so that all requests for a particular session are directed to the same application server instance in the cluster. This requirement conforms to the Servlet 2.3 specification in that multiple requests for a session cannot coexist in multiple application servers. One such solution provided by IBM WebSphere Application Server is *session affinity* in a cluster; this solution is available as part of the WebSphere Application Server plug-ins for Web servers. It also provides for better performance because the sessions are cached in memory. In clustered environments other than WebSphere Application Server clusters, you must use an affinity mechanism (for example, IBM WebSphere Edge Server affinity).

If one of the servers in the cluster fails, it is possible for the request to reroute to another server in the cluster. If distributed sessions support is enabled, the new server can access session data from the database or another WebSphere Application Server instance. You can retrieve the session data only if a new server has access to an external location from which it can retrieve the session.

Configuring memory-to-memory replication for the peer-to-peer function with a local replicator (default memory-to-memory replication)

To configure the session management facility for memory-to-memory session replication for peer-to-peer functions (both client and server function, or both mode) with a local replicator and no partitioning, complete the following steps:

1. Create an application cluster. This cluster is used to deploy the application.
 - a. Go to the Server Cluster page. Click **Servers> Clusters**.
 - b. Click **New**.
 - c. Type a cluster name for this application cluster.
 - d. Define a replication domain. Select the **Create Replication Domain for this cluster** check box.
 - e. Click **Next**.
 - f. Define each cluster member server. Type a cluster member name.
 - g. Select the **Create Replication Entry in this Server** check box. This step adds a replicator into this new server.
 - h. Click **Apply**. Repeat steps **f** through **h** for each server created in this cluster.
 - i. Click **Next** and review the summary of changes.
 - j. Click **Finish** to complete the configuration.

You have now created a cluster that contains the deployed application and the replication domain.

2. Enable memory-to-memory session replication for each server.
 - a. Go to the appropriate level of session management for the Web container level. Click **Application Servers> server_name> Web Container> Session Management**
 - b. Click **Distributed Environment Settings** under Additional Properties.
 - c. If a replicator has been created and is associated with this or another server, select **Memory to Memory Replication**. If no replicator is already created for any server, a note appears stating this. In this case, click **Memory to Memory Replication**. The Internal Replication Domain panels appear. These panels lead you through the process of creating a replication domain and a replicator. After you create a replication domain and a replicator, begin again with step **2a**.
 - d. Click **Apply**.
 - e. Repeat these steps for each server. Click **OK**.
3. If you want to change the tuning parameters, click **Custom Tuning Parameters** and select a setting or customize one.

Note: Using the default tuning parameter custom settings, which specifies time based write interval of 10 seconds, may result in data loss when an application server in your cluster fails. However, this is just a small opportunity for lost data when compared to the significant improvement in performance.

- a. Click **Apply**.
- b. Click **Save**.

Memory-to-memory sessions settings

Use this page to configure memory-to-memory sessions.

To view the Memory-to-memory Sessions page, click **Servers > Application Servers > *server_name* > Web Container > Session Management > Distributed Environment Settings > Memory to Memory Replication**.

Replication

Use one of these options to select the replicator for the session management facility to use for memory-to-memory replication.

Select replicator from the following domain

Specifies a replicator from a replication domain.

Click this option, and select a domain. Then click **Apply** to show all the replicators in that domain. Select the replicator in that domain.

Select replicator from another domain

Specifies a replicator in another domain that is not managed by this cell.

Click this option, and then type the IP address and the port number of the replicator.

Listen to partition groups

Specifies partitions on which the session management facility listens when running in Server mode for memory-to-memory session replication. The number of partitions is defined in the Manage Internal Replication pages. For Server mode and Both mode, the default is all partitions.

Runtime mode

Select the mode in which this server has to run: Both, Client and Server. The mode implies whether data is only sent (client), only received (server), or both. The default is both.

Configuring memory-to-memory replication for peer-to-peer functions with remote/isolated replicators

To configure the session management facility for memory-to-memory replication for peer-to-peer functions with remote replicators, complete the following steps:

1. Create an application cluster. This cluster is used to deploy the application.
 - a. Go to the Server Cluster page. Click **Servers> Clusters**.
 - b. Click **New**.
 - c. Type a cluster name for the application cluster.
 - d. Click **Next**.
 - e. Define each cluster member server. Type a cluster member name.
 - f. Click **Apply**. Complete steps **e** and **f** for each server created in this cluster.
 - g. Click **Next** and review the summary of changes.
 - h. Click **Finish** to complete the configuration.

You have now created a cluster that contains the deployed application.

2. Create a replicator cluster. The replication domain is defined in this replicator cluster.
 - a. Go to the Server Cluster page. Click **Servers> Clusters**.
 - b. Click **New**.
 - c. Type a cluster name for this replicator cluster.
 - d. Define a replication domain. Select the **Create Replication Domain for this cluster** check box.
 - e. Click **Next**.

- f. Associate replicators for each server. Select the **Create Replication Entry in this Server** check box.
- g. Click **Apply**. Complete steps **f** and **g** for each server created in this cluster.
- h. Click **Next** and review the summary of changes.
- i. Click **Finish** to complete the configuration.

You have now created a cluster that contains the replication domain. Do not deploy the application on this cluster.

3. Enable memory-to-memory session replication for each server.
 - a. Go to the appropriate level of Session Management for the Web container level. Click **Application Servers> Server_Name> Web Container> Session Management**
 - b. Click **Distributed Environment Settings** under Additional Properties.
 - c. If a replicator is already created and associated with this or another server, select **Memory to Memory Replication**. If no replicator has been created for any server, a note appears. In this case, click **Memory to Memory Replication**. The Internal Replication Domain panels appear. These panels lead you through the process of creating a replication domain and a replicator. After you create a replication domain and a replicator, begin again with step **3a**.
 - d. Click **Apply**.
 - e. Repeat these steps for each server. Click **OK**.
4. If you want to change the tuning parameters, click **Custom Tuning Parameters** and select a setting or customize one.

Note: Using the default tuning parameter custom settings, which specifies time based write interval of 10 seconds, may result in data loss when an application server in your cluster fails. However, this is just a small opportunity for lost data when compared to the significant improvement in performance.

- a. Click **Apply**.
- b. Click **Save**.

Configuring memory-to-memory replication for the client/server function using isolated replicators

To configure the session management facility for memory-to-memory session replication with replicators separated from the backup servers, complete the following steps:

1. Create an application cluster. This cluster is used to deploy the application.
 - a. Go to the Server Cluster page. Click **Servers> Clusters**.
 - b. Click **New**.
 - c. Type a cluster name for this application cluster.
 - d. Click **Next**.
 - e. Define each cluster member server. Type a cluster member name.
 - f. Click **Apply**. Complete steps **e** and **f** for each server created in this cluster.
 - g. Click **Next** and review the summary of changes.
 - h. Click **Finish** to complete the configuration.

Do not create a replication domain or replicators on the member server for the application cluster.

2. Create a cluster of session manager replication servers (backup cluster).
 - a. Go to the Server Cluster page. Click **Servers> Clusters**.
 - b. Click **New**.
 - c. Type a cluster name for the session manager of replication servers.

- d. Click **Next**.
- e. Define each cluster member server. Type a cluster member name.
- f. Define a replicator on each cluster member server. Select the **Create replication entry in this server** check box.
- g. Click **Apply**. Complete steps **e** through **g** for each server created in this cluster.
- h. Click **Next** and review the summary of changes.
- i. Click **Finish** to complete the configuration.

This step creates a cluster of session manager replication servers and creates a replicator on each cluster member server.

3. Create a replication cluster. The replication cluster defines the replication domain and each of the replicators.
 - a. Go to the Server Cluster page. Click **Servers> Clusters**.
 - b. Click **New**.
 - c. Type a replication cluster name.
 - d. Define a replication domain. Select the **Create Replication Domain for this cluster** check box.
 - e. Click **Next**.
 - f. Define each replicator. Type a cluster member name.
 - g. Select the **Create Replication Entry in this Server** check box.
 - h. Click **Apply**. Complete steps **f** through **h** for each server created in this cluster.
 - i. Click **Next** and review the summary of changes.
 - j. Click **Finish** to complete the configuration.
4. Enable memory-to-memory session replication for each cluster member server in the application cluster and the backup cluster. Memory-to-memory session replication does not need enablement in the replication cluster; these servers act as replicators only.
 - a. Go to the appropriate level of session management for the web container level. Click **Application Server > application_cluster_member_server** or **backup_cluster_member_server > Web Container > Session Management**.
 - b. Click **Distributed Environment Settings** under Additional Properties.
 - c. Click **Memory to Memory Replication** . Verify that each session manager (both the replication clients and the servers) point to a replicator from the replication cluster, distributing them as evenly as possible.
 - d. Click **Apply**.
 - e. Repeat these steps for each server. Click **OK**.

This step points the servers to the replicator of your choice.

5. If you want to change the tuning parameters, click **Custom Tuning Parameters** and select a setting or customize one.

Note: Using the default tuning parameter custom settings, which specifies time based write interval of 10 seconds, may result in data loss when an application server in your cluster fails. However, this is just a small opportunity for lost data when compared to the significant improvement in performance.

- a. Click **Apply**.
- b. Click **Save**.

Configuring memory-to-memory replication for the client/server function using remote replicators

To configure the session management facility for memory-to-memory replication for clients and servers with remote replicators, complete the following steps:

1. Create an application cluster. This cluster is used to deploy the application.
 - a. Go to the Server Cluster page. Click **Servers> Clusters**.
 - b. Click **New**.
 - c. Type a cluster name for this application cluster.
 - d. Click **Next**.
 - e. Define each cluster member server. Type a cluster member name.
 - f. Click **Apply**. Complete steps **e** and **f** for each server created in this cluster.
 - g. Click **Next** and review the summary of changes.
 - h. Click **Finish** to complete the configuration.

Do not create a replication domain or replicators on the member server for the application cluster. You have now created a cluster that contains the replication domain.

2. Create a cluster of session manager replication servers (backup cluster).
 - a. Go to the Server Cluster page. Click **Servers> Clusters**.
 - b. Click **New**.
 - c. Type a cluster name for the cluster of session manager replication servers.
 - d. Define a replication domain. Select the **Create Replication Domain for this cluster** check box.
 - e. Click **Next**.
 - f. Define each cluster member server. Type a cluster member name.
 - g. Define a replicator on each cluster member server. Select the **Create Replication Entry in this Server** check box.
 - h. Click **Apply**. Complete steps **f** through **h** for each server created in this cluster.
 - i. Click **Next** and review the summary of changes.
 - j. Click **Finish** to complete the configuration.

This step creates a cluster of session manager replication servers and associates a replication domain with that cluster. This step also creates a replicator on each cluster member server.

3. Enable memory-to-memory session replication for each cluster member server in the application cluster.
 - a. Go to the appropriate level of session management for the Web container level. Click **Application Server > application_cluster_member_server > Web Container > Session Management**.
 - b. Click **Distributed Environment Settings** under Additional Properties.
 - c. If a replicator is already created and is associated with this or another server, select **Memory to Memory Replication**. If no replicator has been created for any server, a note appears. In this case, click **Memory to Memory Replication**. The Internal Replication Domain panels appear. These panels lead you through the process of creating a replication domain and a replicator. After you create a replication domain and a replicator, begin again with step **2a**.
 - d. Click **Apply**.
 - e. Repeat these steps for each server. Click **OK**.

This step points the servers to the replicator of your choice.

4. If you want to change the tuning parameters, click **Custom Tuning Parameters** and select a setting or customize one.

Note: Using the default tuning parameter custom settings, which specifies time based write interval of 10 seconds, may result in data loss when an application server in your cluster fails. However, this is just a small opportunity for lost data when compared to the significant improvement in performance.

- a. Select the replication domain
- b. Select the replicator to which the member server connects.
- c. Ensure that the member server node is client-only. Verify that the remainder of the member servers are in client-only mode.
- d. Click **Apply**.
- e. Click **Save**.

Tuning session management

IBM WebSphere Application Server session support has features for tuning session performance and operating characteristics, particularly when sessions are configured in a distributed environment. These options support the administrator flexibility in determining the performance and failover characteristics for their environment.

The table summarizes the features, including whether they apply to sessions tracked in memory, in a database, with memory-to-memory replication, or all. Click a feature for details about the feature. Some features are easily manipulated using administrative settings; others require code or database changes.

Feature or option	Goal	Applies to sessions in memory, database, or memory-to-memory
Write frequency	Minimize database write operations.	Database and Memory-to-Memory
Session affinity	Access the session in the same application server instance.	All
Multirow schema	Fully utilize database capacities.	Database
Base in-memory session pool size	Fully utilize system capacity without overburdening system.	All
Write contents	Allow flexibility in determining what session data to write	Database and Memory-to-Memory
Scheduled invalidation	Minimize contention between session requests and invalidation of sessions by the Session Management facility. Minimize write operations to database for updates to last access time only.	Database and Memory-to-Memory
Tablespace and row size	Increase efficiency of write operations to database.	Database (DB2 only)

Configuring scheduled invalidation

Instead of relying on the periodic invalidation timer that runs on an interval based on the session timeout parameter, you can set specific times for the session management facility to scan for invalidated sessions in a distributed environment. When used with distributed sessions, this feature has the following benefits:

- You can schedule the scan for invalidated sessions for times of low application server activity, avoiding contention between invalidation scans of database or another WebSphere Application Server instance and read and write operations to service HTTP session requests.
- Significantly fewer external write operations can occur when running with the End of Service Method Write mode because the last access time of the session does not need to be written out on each HTTP request. (Manual Update options and Time Based Write options already minimize the writing of the last access time.)

Usage considerations

- With scheduled invalidation configured, HttpSession timeouts are not strictly enforced. Instead, all invalidation processing is handled at the configured invalidation times.
- HttpSessionBindingListener processing is handled at the configured invalidation times unless the HttpSession.invalidate() method is explicitly called.
- The HttpSession.invalidate() method immediately invalidates the session from both the session cache and the external store.
- The periodic invalidation thread still runs with scheduled invalidation. If the current hour of the day does not match one of the configured hours, sessions that have exceeded the invalidation interval are removed from cache, but not from the external store. Another request for that session results in returning that session back into the cache.
- When the periodic invalidation thread runs during one of the configured hours, all sessions that have exceeded the invalidation interval are invalidated by removal from both the cache and the external store.
- The periodic invalidation thread can run more than once during an hour and does not necessarily run exactly at the top of the hour.
- If you specify the interval for the periodic invalidation thread using the HttpSessionReaperPollInterval custom property, do not specify a value of more than 3600 seconds (1 hour) to ensure that invalidation processing happens at least once during each hour.

Configuring write contents

In Session Management, you can configure which session data is written to the database or to another WebSphere instance, depending on whether you are using database persistent sessions or memory to memory replication. This flexibility allows for fewer code changes for the JSP writer when the application will be operating in a clustered environment. The following options are available in Session Management for tuning what is to be written back:

- Write changed (the default) - Write only session data properties that have been updated through setAttribute() and removeAttribute() method calls.
- Write all - Write all session data properties.

The **Write all** setting might benefit servlet and JSP writers who change Java objects' states that reside as attributes in HttpSession and do not call HttpSession.setAttribute().

However, the use of **Write all** could result in more data being written back than is necessary. If this situation applies to you, consider combining the use of **Write all** with **Time-based write** to boost performance overall. As always, be sure to evaluate the advantages and disadvantages for your installation.

With either Write Contents setting, when a session is first created, complete session information is written, including all of the objects bound to the session. When using database session persistence, in subsequent session requests, what is written to the database depends on whether a single-row or multirow schema has been set for the session database, as follows:

Write Contents setting	Behavior with single-row schema	Behavior with multirow schema
Write changed	If any session attribute is updated, all objects bound to the session are written.	Only the session data modified through setAttribute() or removeAttribute() calls is written.
Write all	All bound session attributes are written.	All session attributes that currently reside in the cache are written. If the session has never left the cache, all session attributes are written.

1. Go to the appropriate level of Session Management.
2. Click Distributed Environment Settings

3. Click Custom Tuning Parameters.
4. Select Custom Settings, and click Modify.
5. Select the appropriate write contents setting.

Configuring write frequency

In the Session Management facility, you can configure the frequency for writing session data to the database or to a WebSphere instance, depending on whether you use database distributed sessions or memory-to-memory replication. This flexibility enables you to weigh session performance gains against varying degrees of failover support. The following options are available in the Session Management facility for tuning write frequency:

- **End of service servlet**- Write session data at the end of the servlet `service()` method call.
- **Manual update**- Write session data only when the servlet calls the `IBMSession.sync()` method.
- **Time based** (the default) - Write session data at periodic intervals, in seconds (called the *write interval*).

When a session is first created, session information is always written at the end of the `service()` call.

Using the time based write or manual update options can result in loss of data in failover scenarios since the backup copy of the session in the persistent store (for example, a database or another JVM) may not be in sync with the session in the session cache.

Base in-memory session pool size

The base in-memory session pool size number has different meanings, depending on session support configuration:

- With in-memory sessions, session access is optimized for up to this number of sessions.
- With distributed sessions (meaning, when sessions are stored in a database or in another WebSphere Application Server instance); it also specifies the cache size and the number of last access time updates saved in manual update mode.

For distributed sessions, when the session cache has reached its maximum size and a new session is requested, the Session Management facility removes the least recently used session from the cache to make room for the new one.

General memory requirements for the hardware system, and the usage characteristics of the e-business site, determines the optimum value.

Note that increasing the base in-memory session pool size can necessitate increasing the heap sizes of the Java processes for the corresponding WebSphere Application Servers.

Overflow in nondistributed sessions

By default, the number of sessions maintained in memory is specified by base in-memory session pool size. If you do not wish to place a limit on the number of sessions maintained in memory and allow overflow, set `overflow` to *true*.

Allowing an unlimited amount of sessions can potentially exhaust system memory and even allow for system sabotage. Someone could write a malicious program that continually hits your site and creates sessions, but ignores any cookies or encoded URLs and never utilizes the same session from one HTTP request to the next.

When overflow is disallowed, the Session Management facility still returns a session with the `HttpServletRequest.getSession(true)` method when the memory limit is reached, and this is an invalid session that is not saved.

With the WebSphere Application Server extension to HttpSession, com.ibm.websphere.servlet.session.IBMSession, an isOverflow() method returns *true* if the session is such an invalid session. An application can check this status and react accordingly.

Controlling write operations

You can manually control when modified session data is written out to the database or to another WebSphere Application Server instance by using the sync() method in the com.ibm.websphere.servlet.session.IBMSession interface, which extends the javax.servlet.http.HttpSession interface. By calling the sync() method from the service() method of a servlet, you send any changes in the session to the external location. When *manual update* is selected as the write frequency mode, session data changes are written to an external location only if the application calls the sync() method. If the sync() method is not called, session data changes are lost when a session object leaves the server cache. When *end of service servlet* or *time based* is the write frequency mode, the session data changes are written out whenever the sync() method is called. If the sync() method is not called, changes are written out at the end of service method or on a time interval basis based on the write frequency mode selected.

```
IBMSession iSession = (IBMSession) request.getSession();
iSession.setAttribute("name", "Bob");

//force write to external store
iSession.sync( )
```

Tuning parameter settings

Use this page to set tuning parameters for distributed sessions.

To view this administrative console page, click **Servers > Application Servers > server_name > Web Container > Session Management > Distributed Environment Settings > Custom Tuning Parameters**.

Tuning Level

Specifies that the session management facility provides certain predefined settings that affect performance.

Select one of these predefined settings or customize a setting. To customize a setting, select one of the predefined settings that comes closest to the setting desired, click **Custom settings**, make your changes, and then click **OK**.

Very high (optimize for performance)

Write frequency	Time based
Write interval	300 seconds
Write contents	Only updated attributes
Schedule sessions cleanup	true
First time of day default	0
Second time of day default	2

High

Write frequency	Time based
Write interval	300 seconds
Write Contents	All session attributes
Schedule sessions cleanup	false

Medium

Write frequency	End of servlet service
Write Contents	Only updated attributes
Schedule sessions cleanup	false

Low (optimize for failover)

Write frequency	End of servlet service
Write Contents	All session attributes
Schedule sessions cleanup	false

Custom settings

Write frequency default	Time based
Write interval default	10 seconds
Write contents default	All session attributes
Schedule sessions cleanup default	false

Tuning parameter custom settings

Use this page to customize tuning parameters for distributed sessions.

To view this administrative console page, click **Servers > Application Servers > *server_name* > Web Container > Session Management > Distributed Environment Settings > Custom Tuning Parameters > Custom settings**.

Write frequency

Specifies when the session is written to the persistent store.

End of servlet service	A session writes to a database or another WebSphere Application Server instance after the servlet completes execution.
Manual update	A programmatic sync on the IBMSession object is required to write the session data to the database or another WebSphere Application Server instance.
Time based	Session data writes to the database or another WebSphere Application Server instance based on the specified Write Interval value. Default: 10 seconds

Write contents

Specifies whether updated attributes are only written to the external location or all of the session attributes are written to the external location, regardless of whether or not they changed. The external location can be either a database or another application server instance.

Only updated attributes	Only updated attributes are written to the persistent store.
All session attribute	All attributes are written to the persistent store.

Schedule sessions cleanup

Specifies when to clean the invalid sessions from a database or another application server instance.

Specify distributed sessions cleanup schedule

Enables the scheduled invalidation process for cleaning up the invalidated HTTP sessions from the external location. Enable this option to reduce the number of updates to a database or another application server instance required to keep the HTTP sessions alive. When this option is not enabled, the invalidator process runs every few minutes to remove invalidated HTTP sessions.

When this option is enabled, specify the two hours of a day for the process to clean up the invalidated sessions in the external location. Specify the times when there is the least activity in the application servers. An external location can be either a database or another application server instance.

First Time of Day (0 - 23)

Indicates the first hour, in Greenwich Mean Time (GMT), during which the invalidated sessions are cleared from the external location. Specify this value as a positive integer between 0 and 23. This value is valid only when schedule invalidation is enabled.

Second Time of Day (0 - 23)

Indicates the second hour, in Greenwich Mean Time (GMT), during which the invalidated sessions are cleared from the external location. Specify this value as a positive integer between 0 and 23. This value is valid only when schedule invalidation is enabled.

Best practices for using HTTP Sessions

- **Enable Security integration for securing HTTP sessions**

HTTP sessions are identified by session IDs. A session ID is a pseudo-random number generated at the runtime. Session hijacking is a known attack HTTP sessions and can be prevented if all the requests going over the network are enforced to be over a secure connection (meaning, HTTPS). But not every configuration in a customer environment enforces this constraint because of the performance impact of SSL connections. Due to this relaxed mode, HTTP session is vulnerable to hijacking and because of this vulnerability, WebSphere Application Server has the option to tightly integrate HTTP sessions and WebSphere Application Server security. Enable security in WebSphere Application Server so that the sessions are protected in a manner that only users who created the sessions are allowed to access them.

- **Release HttpSession objects using `javax.servlet.http.HttpSession.invalidate()` when finished.**

HttpSession objects live inside the Web container until:

- The application explicitly and programmatically releases it using the `javax.servlet.http.HttpSession.invalidate()` method; quite often, programmatic invalidation is part of an application logout function.
- WebSphere Application Server destroys the allocated HttpSession when it expires (default = 1800 seconds or 30 minutes). The WebSphere Application Server can only maintain a certain number of HTTP sessions in memory based on Session Management settings. In case of distributed sessions, when maximum cache limit is reached in memory, the Session Management facility removes the least recently used (LRU) one from cache to make room for a session.

- **Avoid trying to save and reuse the HttpSession object outside of each servlet or JSP file.**

The HttpSession object is a function of the HttpServletRequest (you can get it only through the `req.getSession()` method), and a copy of it is valid only for the life of the `service()` method of the servlet or JSP file. You *cannot* cache the HttpSession object and refer to it outside the scope of a servlet or JSP file.

- **Implement the `java.io.Serializable` interface when developing new objects to be stored in the HTTP session.**

This action allows the object to properly serialize when using distributed sessions. Without this extension, the object cannot serialize correctly and throws an error. An example of this follows:

```
public class MyObject implements java.io.Serializable {...}
```

Make sure all instance variable objects that are not marked transient are serializable.

- **The HttpSession API does not dictate transactional behavior for sessions.**

Distributed HttpSession support does not guarantee transactional integrity of an attribute in a failover scenario or when session affinity is broken. Use transactionally aware resources like enterprise Java beans to guarantee the transaction integrity required by your application.

- **Ensure the Java objects you add to a session are in the correct class path.**

If you add Java objects to a session, place the class files for those objects in the correct classpath (the Application Classpath if utilizing sharing across Web modules in an enterprise application, or the WebModule Classpath if using the Servlet 2.2-complaint session sharing) or in the directory containing other servlets used in WebSphere Application Server. In the case of session clustering, this action applies to every node in the cluster.

Because the HttpSession object is shared among servlets that the user might access, consider adopting a site-wide naming convention to avoid conflicts.

- **Avoid storing large object graphs in the HttpSession object.**

In most applications each servlet only requires a fraction of the total session data. However, by storing the data in the HttpSession object as one large object, an application forces WebSphere Application Server to process all of it each time.

- **Utilize Session Affinity to help achieve higher cache hits in the WebSphere Application Server.**

WebSphere Application Server has functionality in the HTTP Server plug-in to help with session affinity. The plug-in will read the cookie data (or encoded URL) from the browser and helps direct the request to the appropriate application or clone based on the assigned session key. This functionality increases use of the in-memory cache and reduces hits to the database or another WebSphere Application Server instance

- **Maximize use of session affinity and avoid breaking affinity.**

Using session affinity properly can enhance the performance of the WebSphere Application Server. Session affinity in the WebSphere Application Server environment is a way to maximize the in-memory cache of session objects and reduce the amount of reads to the database or another WebSphere Application Server instance. Session affinity works by caching the session objects in the server instance of the application with which a user is interacting. If the application is deployed in multiple servers of a server group, the application can direct the user to any one of the servers. If the users starts on server1 and then comes in on server2 a little later, the server must write all of the session information to the external location so that the server instance in which server2 is running can read the database. You can avoid this database read using session affinity. With session affinity, the user starts on server1 for the first request; then for every successive request, the user is directed back to server1. Server1 has to look only at the cache to get the session information; server1 never has to make a call to the session database to get the information.

You can improve performance by not breaking session affinity. Some suggestions to help avoid breaking session affinity are:

- Combine all Web applications into a single application server instance, if possible, and use modeling or cloning to provide failover support.
- Create the session for the frame page, but do not create sessions for the pages within the frame when using multiframed JSP files. (See discussion later in this topic.)

- **When using multi-framed pages, follow these guidelines:**

- Create a session in only one frame or before accessing any frame sets. For example, assuming there is no session already associated with the browser and a user accesses a multi-framed JSP file, the browser issues concurrent requests for the JSP files. Because the requests are not part of any session, the JSP files end up creating multiple sessions and all of the cookies are sent back to the browser. The browser honors only the last cookie that arrives. Therefore, only the client can retrieve the session associated with the last cookie. Creating a session before accessing multi-framed pages that utilize JSP files is recommended.

- By default, JSPs get a HttpSession using request.getSession(true) method. So by default JSPs create a new session if none exists for the client. Each JSP page in the browser is requesting a new session, but only one session is used per browser instance. A developer can use `<% @ page session="false" %>` to turn off the automatic session creation from the JSP files that will not access the session. Then if the page needs access to the session information, the developer can use `<% HttpSession session = javax.servlet.http.HttpServletRequest.getSession(false); %>` to get the already existing session that was created by the original session creating JSP file. This action helps prevent breaking session affinity on the initial loading of the frame pages.
- Update session data using only one frame. When using framesets, requests come into the HTTP server concurrently. Modifying session data within only one frame so that session changes are not overwritten by session changes in concurrent frameset is recommended.
- Avoid using multi-framed JSP files where the frames point to different Web applications. This action results in losing the session created by another Web application because the JSESSIONID cookie from the first Web application gets overwritten by the JSESSIONID created by the second Web application.
- **Secure all of the pages (not just some) when applying security to servlets or JSP files that use sessions with security integration enabled, .**

When it comes to security and sessions, it is all or nothing. It does not make sense to protect access to session state only part of the time. When security integration is enabled in the Session Management facility, all resources from which a session is created or accessed must be either secured or unsecured. You cannot mix secured and unsecured resources.

The problem with securing only a couple of pages is that sessions created in secured pages are created under the identity of the authenticated user. Only the same user can access sessions in other secured pages. To protect these sessions from use by unauthorized users, you cannot access these sessions from an unsecure page. When a request from an unsecure page occurs, access is denied and an `UnauthorizedSessionRequestException` error is thrown. (`UnauthorizedSessionRequestException` is a runtime exception; it is logged for you.)

- **Use manual update and either the sync() method or time-based write in applications that read session data, and update infrequently.**

With `END_OF_SERVICE` as write frequency, when an application uses sessions and anytime data is read from or written to that session, the `LastAccess` time field updates. If database sessions are used, a new write to the database is produced. This activity is a performance hit that you can avoid using the Manual Update option and having the record written back to the database only when data values update, not on every read or write of the record.

To use manual update, turn it on in the Session Management Service. (See the tables above for location information.) Additionally, the application code must use the `com.ibm.websphere.servlet.session.IBMSession` class instead of the generic `HttpSession`. Within the `IBMSession` object there is a method called `sync()`. This method tells the WebSphere Application Server to write the data in the session object to the database. This activity helps the developer to improve overall performance by having the session information persist only when necessary.

Note: An alternative to using the manual updates is to utilize the timed updates to persist data at different time intervals. This action provides similar results as the manual update scheme.

- Implement the following suggestions to achieve high performance:
 - If your applications do not change the session data frequently, use Manual Update and the `sync()` function (or timed interval update) to efficiently persist session information.
 - Keep the amount of data stored in the session as small as possible. With the ease of using sessions to hold data, sometimes too much data is stored in the session objects. Determine a proper balance of data storage and performance to effectively use sessions.
 - If using database sessions, use a dedicated database for the session database. Avoid using the application database. This helps to avoid contention for JDBC connections and allows for better database performance.
 - If using memory to memory sessions, define replicators only on the servers and have the client attach to server replicator.

- If using memory to memory sessions, employ partitioning (either group or single replica) as your clusters grow in size and scaling decreases.
 - Verify that you have the latest fix packs for the WebSphere Application Server.
 - Utilize the following tools to help monitor session performance.
 - Run the `com.ibm.servlet.personalization.sessiontracking.IBMTrackerDebug` servlet. - To run this servlet, you must have the servlet invoker running in the Web application you want to run this from. Or, you can explicitly configure this servlet in the application you want to run.
 - Use the WebSphere Application Server Resource Analyzer which comes with WebSphere Application Server to monitor active sessions and statistics for the WebSphere Application Server environment.
 - Use database tracking tools such as "Monitoring" in DB2. (See the respective documentation for the database system used.)
-

Managing HTTP sessions: Resources for learning:

Use the following links to find relevant supplemental information about HTTP sessions. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Chapter 4. Using enterprise beans in applications

1. Design a J2EE application and the enterprise beans that it needs. See "Resources for learning" for links to design information that is specific to enterprise beans.
2. Develop any enterprise beans that your application will use.
3. Prepare for assembly. For your EJB 2.x-compliant entity beans, decide on an appropriate access intent policy.
4. Assemble the beans using the Assembly Toolkit into one or more EJB modules. This includes setting security. (See "Securing enterprise bean applications using the Assembly Toolkit" in the Information Center.)
5. Assemble the modules into a J2EE application using the Assembly Toolkit.
6. **5.1+** For a given application server, update the EJB container configuration if needed for the application to be deployed, and determine if you want to batch commands batch commands or defer commands for container managed persistence.
7. Deploy the application in an application server.
8. Test the modules.
 - As needed, debug problems with the container. See "Enterprise bean and EJB container troubleshooting tips" in the Information Center.
 - Debug access and deployment problems. See "Cannot access an enterprise bean from a servlet, a JSP file, a stand-alone program, or another client" and "Errors deploying enterprise beans" in the Information Center.
9. Assemble the production application using the Assembly Toolkit.
10. Deploy the application to a production environment.
11. Manage the application:
 - a. Manage installed EJB modules. After an application has been installed, you can manage its EJB modules individually through administrative console settings.
 - b. Manage other aspects of the J2EE application.
12. Update the module and redeploy it using the Assembly Toolkit.
13. Tune the performance of the application. See Best practices for developing enterprise beans.

Enterprise beans

An enterprise bean is a Java component that can be combined with other resources to create J2EE applications. There are three types of enterprise beans, *entity* beans, *session* beans, and *message-driven* beans.

All beans reside in EJB containers, which provide an interface between the beans and the application server on which they reside.

Entity beans store permanent data. Entity beans with container-managed persistence (CMP) require connections to a form of persistent storage. This storage might be a database, an existing legacy application, a file, or another type of persistent storage. Entity beans with bean-managed persistence manage permanent data in whichever manner is defined in the bean code. For example, they can write data to databases or XML files

Session beans do not require database access, although they can obtain it indirectly as needed through entity beans. Session beans can also obtain direct access to databases (and other resources) through the use of resource references. Session beans can be either *stateful* or *stateless*.

Message-driven beans are new in version 2.0 of the Enterprise JavaBeans (EJB) specification. They enable asynchronous message servicing. The EJB container and a Java Message Service (JMS) provider work together to process messages. When a message arrives from another application component through

JMS, the EJB container forwards it through an `onMessage()` call to a message-driven bean instance, which then processes the message. In other respects, message-driven beans are similar to stateless session beans.

Beans that require data access use *data sources*, which are administrative resources that define pools of connections to persistent storage mechanisms.

For more information about enterprise beans, see "Resources for learning."

Developing enterprise beans

Design a J2EE application and the enterprise beans that it needs.

- For general design information, see "Resources for learning."
- Before developing entity beans with container-managed persistence (CMP), read "Concurrency control."

There are two basic approaches to selecting tools for developing enterprise beans:

- You can use one of the available integrated development environments (IDEs). IDE tools automatically generate significant parts of the enterprise bean code and contain integrated tools for packaging and testing enterprise beans. The IBM WebSphere Application Developer product is the recommended IDE. For more information, see the documentation for that product.
- If you have decided to develop enterprise beans without an IDE, you need at least an ASCII text editor. You can also use a Java development tool that does not support enterprise bean development. You can then use tools available in the Java Software Development Kit (SDK) and in this product to assemble, test, and deploy the beans.

The following steps primarily support the second approach, development without an IDE.

1. If necessary, migrate any pre-existing code to the required version of the Enterprise JavaBeans (EJB) specification.
2. Write and compile the components of the enterprise bean.
 - At a minimum, an EJB 1.1 session bean requires a bean class, a home interface, and a remote interface. An EJB 1.1 entity bean requires a bean class, a primary-key class, a home interface, and a remote interface.
 - At a minimum, an EJB 2.0 session bean requires a bean class, a home or local home interface, and a remote or local interface. An EJB 2.0 entity bean requires a bean class, a primary-key class, a remote home or local home interface, and a remote or local interface. The types of interfaces go together: If you implement a local interface, you must define a local home interface as well.

Note: Optionally, the primary-key class can be *unknown*. See unknown primary-key class for more information.

- Available only through EJB 2.0, a message-driven bean requires only a bean class.
3. For each entity bean, complete work to handle persistence operations.
 - Create a database schema for the entity bean's persistent data.
 - For entity beans with container-managed persistence (CMP), you must store the bean's persistent data in one of the supported databases. WebSphere Application Server application assembly tools automatically generate SQL code for creating database tables for CMP entity beans. If your CMP beans require complex database mappings, it is recommended that you use the IBM WebSphere Studio Application Developer product to generate code for the database tables.
 - For entity beans with bean-managed persistence (BMP), you can create the database and database table by using the database tools or use an existing database and database table.

For more information on creating databases and database tables, consult your database documentation.

- **(CMP entity beans for EJB 2.0 only)** Define finder queries with EJB Query Language (EJB QL).

With EJB QL, you define finders in terms of CMP fields and container-managed relationships, as follows:

- *Public* finders are visible in the bean's home interface. Implemented in the bean class, they return only remote interfaces and collection types.
- *Private* finders, expressed as SELECT statements, are used only within the bean class. They can return both local and remote interfaces, dependent values, other CMP field types, and collection types.
- **(CMP entity beans for EJB 1.1 only: an IBM extension)** Create a finder helper interface for each CMP entity bean that contains specialized finder methods (other than the `findByPrimaryKey` method).

The following logic is required for each finder method (other than the `findByPrimaryKey` method) contained in the home interface of an entity bean with CMP:

- The logic must be defined in a public interface named *NameBeanFinderHelper*, where *Name* is the name of the enterprise bean (for example, `AccountBeanFinderHelper`).
- The logic must be contained in a String constant named *findMethodName* WhereClause, where *findMethodName* is the name of the finder method. The String constant can contain zero or more question marks (?) that are replaced from left to right with the value of the finder method's arguments when that method is called.

5.1+ Assemble the beans in one or more EJB modules.

Migrating enterprise bean code to the supported specification

Support for Version 2.0 of the Enterprise JavaBeans (EJB) specification is new for Version 5 of this product. Migration of enterprise beans deployed in Version 4.0.x of this product is not generally necessary; Version 1.1 of the EJB specification is still supported. Follow these steps as appropriate for your application deployment.

1. Modify enterprise bean code for changes in the specification.
 - For Version 1.0 beans, migrate at least to Version 1.1.
 - As stated previously, migration from Version 1.1 to Version 2.0 of the EJB specification is not required for redeployment on this version of the product. However, if your application requires the capabilities of Version 2.0, migrate your Version 1.1-compliant code.

Note: The EJB Version 2.0 specification mandates that prior to the EJB container's executing a `findByMethod` query, the state of all enterprise beans enlisted in the current transaction be synchronized with the persistent store. (This is so the query is performed against current data.) If Version 1.1 beans are reassembled into an EJB 2.0-compliant module, the EJB container synchronizes the state of Version 1.1 beans as well as that of Version 2.0 beans. As a result, you might notice some change in application behavior even though the application code for the Version 1.1 beans has not been changed.

2. Modify enterprise bean code for changes in deployment requirements. If the enterprise beans were previously deployed in Version 3.0.x of this product, modify import statements to match standard package names. In Version 3.0.2.x, the following standard packages were present under nonstandard names:

```
javax.sql.*  
javax.transaction.*
```

Any code using WebSphere data sources, including BMP entity beans and session beans that access databases, must be modified.

3. You might have to modify code for some EJB 1.1-compliant modules that were not migrated to Version 2.0. Use the following information to help you decide.
 - Some stub classes for deployed enterprise beans have changed in the Java 2 Software Development Kit, Version 1.4.1.
 - The task of generating deployment code for enterprise beans changed significantly for EJB 1.1-compliant modules relative to EJB 1.0-compliant modules.

- If the CMP beans write to databases with mixed-case table or column names and you used IBM VisualAge for Java, Version 3.5.x, to generate the original deployment code, you cannot simply reassemble the beans in this product. You must export the original EJB project from the VisualAge for Java product as an EJB 1.1 JAR. This preserves the metadata needed to generate the correct deployment code for mixed-case database tables and columns. For more information, see the documentation for the Deployment Tool for Enterprise JavaBeans.

For detailed information about source and binary compatibility between deployed versions, see "Resources for learning."

4. Reassemble and redeploy all modules to incorporate migrated code.

Migrating enterprise bean code from Version 1.0 to Version 1.1

The following information generally applies to any enterprise bean that currently complies with Version 1.0 of the Enterprise JavaBeans (EJB) specification. For more information about migrating code for beans produced with the IBM WebSphere Studio Application Developer tool, see the documentation for that product. For more information about migrating code in general, see "Resources for learning."

1. In session beans, replace all uses of `javax.jts.UserTransaction` with `javax.transaction.UserTransaction`. Entity beans may no longer use the `UserTransaction` interface at all.
2. In finder methods for entity beans, include `FinderException` in the `throws` clause.
3. Remove `throws` of `java.rmi.RemoteException`; throw `javax.ejb.EJBException` instead. However, continue to include `RemoteException` in the `throws` clause of `home` and `remote` interfaces as required by the use of Remote Method Invocation (RMI).
4. Remove uses of the `finalize()` method.
5. Replace calls to `getCallerIdentity()` with calls to `getCallerPrincipal()`. The use of `getCallerIdentity()` is deprecated.
6. Replace calls to `isCallerInRole(Identity)` with calls to `isCallerInRole(String)`. The use of `isCallerInRole(Identity)` and `java.security.Identity` is deprecated.
7. Replace calls to `getEnvironment()` in favor of JNDI lookup. As an example, change the following code:

```
String homeName =
    aLink.getEntityContext().getEnvironment().getProperty("TARGET_HOME_NAME");
if (homeName == null) homeName = "TARGET_HOME_NAME";
```

The updated code would look something like the following:

```
Context env = (Context)(new InitialContext()).lookup("java:comp/env");
String homeName = (String)env.lookup("ejb10-properties/TARGET_HOME_NAME");
```

8. In `ejbCreate` methods for an entity bean with container-managed persistence (CMP), return the bean's primary key class instead of `void`.
9. Add the `getHomeHandle()` method to `home` interfaces.

```
public javax.ejb.HomeHandle getHomeHandle() {return null;}
```

Consider enhancements to match the following changes in the specification:

- Primary keys for entity beans can be of type `java.lang.String`.
- Finder methods for entity beans return `java.util.Collection`.
- Check the format of any JNDI names being used. Local name spaces are also supported.
- Security is defined by role, and isolation levels are defined at the method level rather than at the bean level.

Migrating enterprise bean code from Version 1.1 to Version 2.0

Enterprise JavaBeans (EJB) Version 2.0-compliant beans may be assembled only in an EJB 2.0-compliant module, although an EJB 2.0-compliant module can contain a mixture of Version 1.x and Version 2.0 beans.

The EJB Version 2.0 specification mandates that prior to the EJB container's executing a *findByMethod* query, the state of all enterprise beans enlisted in the current transaction be synchronized with the persistent store. (This is so the query is performed against current data.) If Version 1.1 beans are reassembled into an EJB 2.0-compliant module, the EJB container synchronizes the state of Version 1.1 beans as well as that of Version 2.0 beans. As a result, you might notice some change in application behavior even though the application code for the Version 1.1 beans has not been changed.

The following information generally applies to any enterprise bean that currently complies with Version 1.1 of the EJB specification. For more information about migrating code for beans produced with the IBM WebSphere Studio Application Developer tool, see the documentation for that product. For more information about migrating code in general, see "Resources for learning."

1. In beans with container-managed persistence (CMP) version 1.x, replace each CMP field with abstract get and set methods. In doing so, you must make each bean class abstract.
2. In beans with CMP version 1.x, change all occurrences of *this.field = value* to *setField(value)*.
3. In each CMP bean, create abstract get and set methods for the primary key.
4. In beans with CMP version 1.x, create an EJB Query Language statement for each finder method.
5. In finder methods for beans with CMP version 1.x, return *java.util.Collection* instead of *java.util.Enumeration*.
6. Update handling of non-application exceptions.
 - To report non-application exceptions, throw *javax.ejb.EJBException* instead of *java.rmi.RemoteException*.
 - Modify rollback behavior as needed: In EJB versions 1.1 and 2.0, all non-application exceptions thrown by the bean instance result in the rollback of the transaction in which the instance is running; the instance is discarded. In EJB 1.0, the container does not roll back the transaction or discard the instance if it throws *java.rmi.RemoteException*.
7. Update rollback behavior as the result of application exceptions.
 - In EJB versions 1.1 and 2.0, an application exception does not cause the EJB container to automatically roll back a transaction.
 - In EJB Version 1.1, the container performs the rollback only if the instance has called *setRollbackOnly()* on its *EJBContext* object.
 - In EJB Version 1.0, the container is required to roll back a transaction when an application exception is passed through a transaction boundary started by the container.

WebSphere extensions to the Enterprise JavaBeans specification

This article outlines extensions to the Enterprise JavaBeans (EJB) specification that IBM provides with this product:

Inheritance in enterprise beans

In the Java language, *inheritance* is the creation of a new class from an existing class or a new interface from an existing interface. This product supports two forms of inheritance: standard class inheritance and EJB inheritance.

In standard class inheritance, the home interface, remote interface, or enterprise bean class inherits properties and methods from base classes that are not themselves enterprise bean classes or interfaces.

By contrast in enterprise bean inheritance, an enterprise bean inherits properties (such as container-managed persistence (CMP) fields and container-managed relationship (CMR) fields), methods, and method-level control descriptor attributes from another enterprise bean.

For more information, see the documentation for the IBM WebSphere Studio Application Developer product.

Optimistic concurrency control for container-managed persistence

This product supports optimistic concurrency control of data access.

Access intents for EJB persistence

This product supports the application of named data-access policies.

Performance enhancements

Through the lifetime-in-cache settings, this product provides a way for you to improve performance for beans that are only occasionally updated. For more information, see "Entity bean assembly settings."

Some enterprise beans created with the IBM WebSphere Studio Application Developer product can utilize *read-ahead* for loading a bean and its related beans in a single database operation. An entire object graph or any part of the graph can be preloaded by configuring a finder method to use read-ahead.

Assembly and deployment extensions

5.1+ This product supports IBM extensions of assembly and deployment options.

Best practices for developing enterprise beans

Use the following guidelines when designing and developing enterprise beans:

- Use a stateless session bean to act as the entry point for business logic. For more information about using session facades, see "Resources for learning."
- Entity beans should use container-managed persistence.
- In an Enterprise JavaBeans (EJB) Version 2.0 environment, use local interfaces to improve communication between enterprise beans in the same Java virtual machine.
Local calls avoid the overhead of RMI/IIOP and use pass-by-reference semantics instead of pass-by-value. For each call, the caller and callee beans share the state of arguments. EJB 2.0 beans can have both a local and remote interface but more typically have one or the other.
- For communicating with remote clients, provide remote and remote home interfaces. For communicating with local clients like servlets, entity beans, and message-driven beans, provide local and local home interfaces.

Batch commands for container managed persistence

From JDBC 2.0 on, *PreparedStatement* objects can maintain a list of commands that can be submitted together as a batch. Instead of multiple database round trips, there can be only one database round trip for all the batched persistence requests.

The WebSphere Application Server version 5.0.2 enables you to take advantage of this. You can turn this option on from the EJB CMP side. When you choose this option, the run time defers *ejbStore/ejbCreate/ejbRemove* or the equivalent database persistence requests (insert/update/delete) until they are needed. This can be at the end of the transaction, or when a flush is needed for finders related to this EJB type. When the persistence operation finally happens, run time accumulates the database requests and uses JDBC *PreparedStatement* batch operation to make a single JDBC call for multiple rows of the same operation.

Setting the run time for batched commands:

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.

5. In the Additional Properties area, select **Process Definition**.
6. In the Additional Properties area, select **Java Virtual Machine**.
7. Update the **Generic JVM arguments** with `Dcom.ibm.ws.pm.batch=true`.

Deferred Create for container managed persistence

The specification for Enterprise Java Beans (EJB) 2.x states that for Container Managed Persistence (CMP) during the `ejbCreate`, the container can create the representation of the entity in the database immediately, or defer it to a later time.

The WebSphere Application Server version 5.0.2 enables you to take advantage of this specification. You can turn this option on from the EJB CMP side. When you choose this option, the runtime defers `ejbCreate` (or the equivalent database persistence request) until it is needed. This can be at the end of the transaction, or when a flush is needed for finders related to this EJB type. By doing this you can reduce two round trips for the newly created entity (insert and update) to one (insert).

Setting the run time for deferred create:

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.
5. In the Additional Properties area, select **Process Definition**.
6. In the Additional Properties area, select **Java Virtual Machine**.
7. Update the **Generic JVM arguments** with `Dcom.ibm.ws.pm.deferredcreate=true`.

Explicit invalidation in the Persistence Manager cache

Container managed persistence (CMP) entity beans can be configured as *long-lifetime* beans. A long-lifetime bean is one that is configured with *Lifetime In Cache Usage* equal to a value other than the default **OFF**. A value other than **OFF** means that data for this bean is cached beyond the end of the transaction in which the bean was obtained by a finder or other method. The *Lifetime In Cache Usage* and *Lifetime In Cache* values control the basic length of time the cached data remains valid. When the specified time runs out, the cached data is no longer valid. See the *LifetimeInCache* help sections of the Assembly Toolkit (ATK) for more details.

However, there is also an API that lets the client application code explicitly invalidate the cached data of a bean on demand, superceding the basic lifetime of the cache data as controlled by the *Lifetime In Cache Usage* and *Lifetime In Cache* settings. This is useful where an application that does not use CMP beans modifies the data that underlies a CMP bean (for example, it updates a database table to which a CMP bean is mapped). Such an application can inform WebSphere Application Server that any cached version of this bean data is **stale** and no longer matches what is in the database. The data should be invalidated (in essence, discarded). For CMP beans that cannot tolerate stale data, this is an important feature.

Because the PM Cache Invalidation mechanism does consume resources in exchange for its benefits, it is not enabled by default. To enable it refer to Setting Persistence Manager Cache Invalidation .

Example: Explicit Invalidation in the Persistence Manager Cache: Usage Scenario

The scenario of use for this feature begins with configuring one or more bean types to be long-lifetime beans (see Explicit Invalidation in the Persistence Manager Cache, and configuring the necessary Java Message Service (JMS) resources (described below). Once this is done, the server is started. The scenario continues as follows:

1. Assume that a CMP entity bean of type *Department* has been configured to be a long-lifetime bean.

2. Transaction 1 begins. Application code looks up *Department's* home and calls a finder method (such as *findByPrimaryKey("dept01")*). As this is the first finder to return *Department dept01*, a trip is made to the database to obtain the data. Transaction 1 ends.
3. Transaction 2 begins. Application code calls *findByPrimaryKey("dept01")* again. Because this is not the first finder to return *Department dept01*, we get a cache hit and no database trip is made. So far this is current WebSphere Application Server behavior for long-lifetime beans. Transaction 2 ends.
4. Another application, which does not use the *Department* CMP bean, is executed. This application might or might not be run on the WebSphere Application Server; it could be a legacy application. The application updates the database table that is mapped to the *Department* bean, altering the row for *dept01*. For example, the *budget* column in the table (mapped to a Java double CMP attribute in the *Department* bean) is changed from \$10,000.00 to \$50,000.00. This application was designed to cooperate with WebSphere Application Server. After performing the update, the application sends an invalidate request message to invalidate the *Department* bean *dept01*.
5. Transaction 3 begins. Application code looks up *Department's* home and calls a finder method (such as *findByPrimaryKey("dept01")*). Because this is the first finder after *Department dept01* is invalidated, a new database trip is made to obtain the data. Transaction 3 ends.

Persistence Manager cache invalidation API

The PM cache invalidation API is in the form of a JMS message that the client sends to a specially-named JMS topic using a connection from a specifically named JMS *TopicConnectionFactory*. The JMS message must be an *ObjectMessage* created by the client. The client code creates a *PMCacheInvalidationRequest* object that describes the bean data to invalidate. Client code places the *PMCacheInvalidationRequest* object in the *ObjectMessage* and publishes the *ObjectMessage* (for further details on the JMS objects and terms used here, please see the Java Message Service documentation).

The public class *PMCacheInvalidationRequest* is central to the API, so we include a portion of its code here for illustration purposes (if you see any differences between this illustration and the actual class, the class is to be considered correct):

```
package com.ibm.websphere.ejbpersistence;

/**
 *An instance of this class represents a request to invalidate one or more
 *CMP beans in the PMcache. When an invalidate occurs, cached data for this
 *bean is removed from the cache; the next time an application tries to find
 *this bean, a fresh copy of the bean data is obtained from the data store.
 *
 *The ability to invalidate a bean means that a CMP bean may be configured
 *as a long-lifetime bean and thus be cached across transactions for much
 *greater performance on future attempts to find this bean. Yet when some
 *outside mechanism updates the bean data, sending an invalidation request
 *will remove stale data from the PMcache so applications do not behave falsely
 *based on stale data.
 */
public class PMCacheInvalidationRequest implements Serializable {
    . . .

    /**
     * Constructor used to invalidate a single bean
     * @param beanHomeJNDIName the JNDI name of the bean home. This is the same value
     * used to look up the bean home prior to calling findByPrimaryKey, for example.
     * @param beanKey the primary key of the bean to be invalidated. The actual
     * object type must be the primary key type for this bean type.
     */
    public PMCacheInvalidationRequest(String beanHomeJNDIName, Object beanKey)
        throws IOException {
        . . .
    }

    /**
     * Constructor used to invalidate a Collection of beans
```

```

* @param beanHomeJNDIName java.lang.String the JNDI name of the bean home.
* This is the same value used to look up the bean home prior to calling
* findByPrimaryKey, for example.
* @param beanKeys a Collection of the primary keys of the beans to be
* invalidated. The actual type of each object in the Collection must be the
* primary key type for this bean type.
*/
public PMCacheInvalidationRequest(String beanHomeJNDIName, Collection beanKeys)
throws IOException {
    . . .
}
/**
* Constructor used to invalidate all beans of a given type
* @param beanHomeJNDIName java.lang.String the JNDI name of the bean home.
* This is the same value used to look up the bean home prior to calling
* findByPrimaryKey, for example.
*/
public PMCacheInvalidationRequest(String beanHomeJNDIName) {
    . . .
}
}

```

If the client wants to perform the invalidation in a synchronous way, it can opt to receive an acknowledgement JMS message when the invalidation is complete. To ask for an acknowledgement (ACK) message, the client sets a *Topic* of its own choosing in the *JMSReplyTo* field of the *ObjectMessage* for the invalidation request (see JMS documentation for further details). The client then waits (using the *receive()* method of JMS) on receipt of the acknowledgement message before continuing execution.

An ACK message enables the caller to insure there is not even a brief (seconds or less) window during which PM cache data is stale. The sending of an acknowledgement for each request does, of course, take a bit more time and so is recommended to be used only when needed.

The JMS resources used to make an invalidation request (*TopicConnectionFactory*, *TopicDestination*, and so forth) must be configured by the user (using the Administration console or other method) if they want to use PM Cache Invalidation. In this way the user can choose whichever JMS provider they prefer (as long as it supports pub-sub). The names that must be used for these resources are defined as part of the API, and use names unique to the WebSphere Application Server namespace to avoid name conflict with customer JMS resources.

The following are the names that must be used when the user configures the JMS resources (shown as Java constants for clarity):

```

// The JNDI name of the TopicConnectionFactory
private static final String topicConnectionFactoryJNDIName =
    "com.ibm.websphere.ejbpersistence.InvalidatetCF";
// The JNDI name of the TopicDestination
private static final String topicDestinationJNDIName = "com.ibm.websphere.ejbpersistence.invalidate";
// The Topic name (part of the TopicDestination)
private static final String topicString = "com.ibm.websphere.ejbpersistence.invalidate";

```

Here are examples of how these constants can be used in client code:

```

// Look up the TopicConnectionFactory...
InitialContext ic = new InitialContext();
TopicConnectionFactory topicConnectionFactory =
    (TopicConnectionFactory) ic.lookup(topicConnectionFactoryJNDIName);
...
// Look up the Topic
Topic topic = (Topic) ic.lookup(topicDestinationJNDIName);

```

Note that JMS messages can be sent not only from J2EE application code (for example, a *SessionBean* or *BMP* entity bean method) but also from non-J2EE applications if your chosen JMS provider allows for

this. For example, the IBM MQ provider, available in WebSphere Application Server as the **Embedded Messaging** feature (selectable during installation), supports the use of MQ classes (or structures in other languages) to create a topic connection and topic that are compatible with the *TopicConnectionFactory* and *TopicDestination* you configure using WebSphere Application Server Application Console.

Setting Persistence Manager Cache Invalidation:

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.
5. In the Additional Properties area, select **Process Definition**.
6. In the Additional Properties area, select **Java Virtual Machine**.
7. Update the **Generic JVM arguments** with `-Dcom.ibm.ws.ejbpersistence.cacheinvalidation=true`.

Unknown primary-key class

When writing an entity bean for Enterprise Java Bean Version 2.0, the minimum requirements usually include a primary-key class. However, in some cases you might choose not to specify the primary-key class for an entity bean with container managed persistence (CMP). Perhaps there is no obvious primary key, or you want to allow the deployer to select the primary key fields at deployment time. The primary key type is usually derived from the type used by the database system that stores the entity objects, and you might not know what this key is.

So, the *unknown key type* is actually a type chosen at deployment time, making it changeable each time the bean is deployed. Your client code must deal with this key as type *Object*.

Currently, WebSphere Application Server supports top-down mapping and enables the deployer to choose *String* keys generated at the application server. For an example of how to use this function, see the Samples library.

Using access intent policies

You can use access intent policies to help the product run-time environment manage various aspects of Enterprise JavaBeans (EJB) persistence. You apply access intent policies to EJB Version 2.0 entity beans and their methods by using an application assembly tool. A set of default access intent policies comes with the Assembly Toolkit. You can also create your own custom policies.

1. Apply default access intent to CMP entity beans. For more information, see the online help available with the Assembly Toolkit.
2. Apply access intent policies to methods of CMP entity beans.
3. Create a custom access intent policy.
4. Apply access intent policies to BMP entity bean methods by using the *AccessIntent* API.
5. Apply multiple access intent policies to methods by using application profiling.

Access intent policies

An access intent policy is a named set of properties (access intents) that governs data access for Enterprise JavaBeans (EJB) persistence. You can assign policies to an entity bean and to individual methods on an entity bean's home, remote, or local interfaces during assembly. If you have the Integration Server product installed, you can assign these during development as well. You can set access intents only within EJB Version 2.x-compliant modules for entity beans with bean-managed persistence or with CMP Version 2.x.

This product supplies a number of access intent policies that specify permutations of read intent and concurrency control; the pessimistic/update policy can be qualified further. The selected policy determines the appropriate isolation level and locking strategy used by the run time environment.

Access intent policies are specifically designed to supplant the use of isolation level and access intent method-level modifiers found in the extended deployment descriptor for EJB version 1.1 enterprise beans. You cannot specify isolation level and read-only modifiers for EJB version 2.0 enterprise beans.

Access intent policies configured on an entity basis define the default access intent for that entity. The default access intent controls the entity unless you specify a different access intent policy based on either method-level configuration or application profiling

You can use application profiling or method level access intent policies to control access intent more precisely. Application profiling is only available in the Integration Server product. Method-level access intent policies are named and defined at the module level. A module can have one or many such policies. Policies are assigned, and apply, to individual methods of the declared interfaces of entity beans and their associated home interfaces. A policy is acted upon by either the combination of the EJB container and persistence manager (for entity beans with container-managed persistence) or directly by entity beans with bean-managed persistence.

For entity beans that are backed by tables with nullable columns, use an optimistic policy with caution. Nullable columns are automatically excluded from overqualified updates at deployment time; concurrent changes to a nullable field might result in lost updates. When used with the IBM WebSphere Studio Application Developer product, this product provides support for selecting a subset of the non-nullable columns that are to be reflected in the overqualified update statement that is generated in the deployment code to support optimistic policies.

An entity that is configured with a read-only policy that causes a bean to be activated can cause problems if updates are attempted within the same transaction. Those changes are not committed, and the process throws an exception because data integrity might be compromised.

Concurrency control

Concurrency control is the management of contention for data resources. A concurrency control scheme is considered *pessimistic* when it locks a given resource early in the data-access transaction and does not release it until the transaction is closed. A concurrency control scheme is considered *optimistic* when locks are acquired and released over a very short period of time at the end of a transaction.

The objective of optimistic concurrency is to minimize the time over which a given resource would be unavailable for use by other transactions. This is especially important with long-running transactions, which under a pessimistic scheme would lock up a resource for unacceptably long periods of time.

Under an optimistic scheme, locks are obtained immediately before a read operation and released immediately afterwards. Update locks are obtained immediately before an update operation and held until the end of the transaction.

To enable optimistic concurrency, this product uses an *overqualified update scheme* to test whether the underlying data source has been updated by another transaction since the beginning of the current transaction. With this scheme, the columns marked for update and their original values are added explicitly through a WHERE clause in the UPDATE statement so that the statement fails if the underlying column values have been changed. As a result, this scheme can provide column-level concurrency control; pessimistic schemes can control concurrency at the row level only.

Optimistic schemes typically perform this type of test only at the end of a transaction. If the underlying columns have not been updated since the beginning of the transaction, pending updates to container-managed persistence fields are committed and the locks are released. If locks cannot be

acquired or if some other transaction has updated the columns since the beginning of the current transaction, the transaction is rolled back: All work performed within the transaction is lost.

Pessimistic and optimistic concurrency schemes require different transaction isolation levels. Enterprise beans that participate in the same transaction and require different concurrency control schemes cannot operate on the same underlying data connection.

Whether or not to use optimistic concurrency depends on the type of transaction. Transactions with a high penalty for failure might be better managed with a pessimistic scheme. (A high-penalty transaction is one for which recovery would be risky or resource-intensive.) For low-penalty transactions, it is often worth the risk of failure to gain efficiency through the use of an optimistic scheme. In general, optimistic concurrency is more efficient when update collisions are expected to be infrequent; pessimistic concurrency is more efficient when update collisions are expected to occur often.

Read-ahead hints

Read-ahead schemes enable applications to minimize the number of database roundtrips by retrieving a working set of container-managed persistence (CMP) beans for the transaction within one query.

Read-ahead involves activating the requested CMP beans and caching the data for their related beans, which ensures that data is present for the beans that are most likely to be needed next by an application.

A *read-ahead hint* is a canonical representation of the related beans that are to be read. It is associated with the *findByPrimaryKey* method for the requested bean type, which must be an EJB 2.x-compliant CMP entity bean.

Read-ahead hints can be set only using the WebSphere Business Integration Server Foundation assembly tool or through the Add Access Intent wizard of the IBM WebSphere Studio Application Developer product.

Read-ahead is only supported for access intent policies that can be applied by the backend against which the application is deployed. Otherwise, the read-ahead hint is disregarded.

Currently, only *findByPrimaryKey* methods can have read-ahead hints. Only beans related to the requested beans by a container-managed relationship (CMR), either directly or indirectly through other beans, can be read ahead. Beans that use EJB inheritance should not be used in a read-ahead hint.

A read-ahead hint takes the form of a character string. You do not have to provide the string; the wizard generates it for you based on CMRs defined for the bean. The following example is provided as supplemental information only.

Suppose a CMP bean type A has a finder method that returns instances of bean A. A read-ahead hint for this method is specified using the following notation: *RelB.RelC; RelD*

Interpret the preceding notation as follows:

- Bean type A has a CMR with bean types B and D.
- Bean type B has a CMR with bean type C.

For each bean of type A that is retrieved from the database, its directly-related B and D beans and its indirectly-related C beans are also retrieved. The order of the retrieved bean data columns in each row of the result set is the same as their order in the read-ahead hint: an A bean, a B bean (or null), a C bean (or null), a D bean (or null). For hints in which the same relationship is mentioned more than once (for example, *RelB.RelC;RelB.RelE*), a bean's data columns appear only once, at the position it first appears in the hint.

The tokens shown in the notation (*RelB* and so on) must be CMR field names for the relationships as defined in the deployment descriptor for the bean. In indirect relationships such as *RelB.RelC*, *RelC* is a CMR field name defined in the deployment descriptor for bean type B.

A single read-ahead hint cannot refer to the same bean type in more than one relationship. For example, if a Department bean has a relationship *employees* with the Employee bean and also has a relationship *manager* with the Employee bean, the read-ahead hint cannot specify both *employees* and *manager*.

For more information about how to set read-ahead hints, see the documentation for the Websphere Studio Application Developer product.

Access intent service

Access intent is a WebSphere Application Server run-time service that enables you to more precisely manage an application's persistence. The access intent service defines a set of declarative annotations used by the Enterprise JavaBeans (EJB) container and its agents to make performance optimizations for entity bean access. These annotations are organized into sets called *access intent policies*.

Access intent policies contain a set of annotations considered as hints by the EJB container and its agents. Most access intent policies are hints representing high-level abstractions that can be mapped to a specific backend resource manager. It is the responsibility of the EJB persistence machinery to ensure the necessary concurrency control, connection, and cache management when carrying out the persistence details. The EJB persistence manager can use access intent hints to make better performance decisions when carrying out its assigned task. A smaller number of access intents are hints to the EJB container, influencing the management of EJB collections.

Although it is recommended that you always configure bean level access intent for your applications, if you find it necessary you can apply access intent policies to methods within the scope of an EJB module. In such cases the policy becomes the default access intent for all requests upon the configured methods.

You can also apply access intent policies to beans within the scope of application profiles. Consequently, you can configure beans with multiple and opposing access intent policies. The application profiling documentation explains in more detail how to configure an application to apply a particular access intent policy to a bean for one request, then apply another access intent policy to the same bean for a different request.

Access intent with BMP entity beans

Access intent's declarative functionality provides great power to you as a CMP entity bean developer. You can provide hints on how WebSphere Application Server is to manage the details of persistence without having to explicitly manage any of the persistence logic from within the application.

There are situations, however, in which you might need to develop BMP entity beans. Because the only meaningful difference between BMP and CMP components is who provides the persistence logic, BMP entity beans should be able to leverage access intent hints just as WebSphere Application Server does on behalf of CMP entity beans. BMP entity beans that use the access intent service participate in application profiling; that is, the value of the access intent attributes can differ from request to request, allowing the BMP entity bean to seamlessly modify its persistence strategy.

You can apply access intent policies to BMP entity bean methods as well as CMP entity bean methods. Because access intent hints are not contractual in nature, there is no obligation for a BMP entity bean to exploit them. BMP entity beans are expected to use only those access intent attributes that are important to that particular bean.

The current access intent policy is bound into the `java:comp` namespace for a particular BMP entity bean. That policy is current only for the duration of the method call during which the access intent policy was retrieved. In a typical scenario, you would cache the access type during invocation of the `ejbLoad()` method so that appropriate actions can be taken during invocation of the `ejbStore()` method.

Access intent design considerations

Use the access intent service to solve clear performance problems. Identify usage patterns that lead to poor application performance and apply appropriate access intent policies.

Refrain from over-tuning an application. You can introduce errors by incorrectly using the access intent service. For example, misuse of the `wsPessimisticUpdate-NoCollision` policy can result in lost updates; inappropriately setting the collection increment value can introduce performance issues; and problem determination is more difficult when an application is confusingly configured with multiple access intent policies. Clarity and simplicity should be your guiding principles when using the access intent service. This is even more important when applying access intent policies within the scope of application profiles (a feature of WebSphere Business Integration Server Foundation).

Even though access intent policies can be configured on any method of an entity bean, some attributes of a policy can only be leveraged by the run-time environment under certain conditions. For example, concurrency and access intent are only used for CMP entity beans when the `ejbLoad()` method is driven to open a connection to, and read data from, a given resource; that data is cached and used to drive the proper queries during invocation of the `ejbStore()` method. Read-ahead hints are only used during the execution of a finder for a bean. Finally, the collection increment and resource manager prefetch increment are only used on multi-object finders. Configuring policies on methods that will not use the policy is not an error (only certain attributes of any policy are used, even when the policy is appropriately applied to a method). However, configuring policies unnecessarily throughout an application obscures the design of the application and complicates the maintenance of the application.

Applying access intent policies to methods

You apply an access intent policy to a method, or set of methods, in an application's entity beans through the Assembly Toolkit.

1. Start the Assembly Toolkit.
2. Optional: Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. Optional: Open the J2EE Hierarchy view. Click **Window > Show View > J2EE Hierarchy**. Other helpful views include the Project Navigator view (**Window > Show View > Other > J2EE > Project Navigator**) and the Navigator view (**Window > Show View > Navigator**).
4. Select the **Access** tab.
5. On the right side of the **Access Intent for Entities 2.x (Method Level)** panel, select **Add**. The **Add Access Intent** panel displays.
6. Specify the **Name** for your new intent policy.
7. Select the **Access intent name** from the drop-down list.
8. Enter a **Description** to help you remember what this policy does.
9. Optional: Select **Read Ahead Hint**.
10. Click **Next**. The next **Add Access Intent** panel displays, with optional attributes.
11. Optional: Decide whether or not to overwrite these optional access intent attributes. Click on those you want to change.
12. Click **Next**. The next **Add Access Intent** panel, with a list of Enterprise Beans, displays.
13. Select one or more Enterprise Beans from the list.

Note: If you selected **Read Ahead Hint** in an earlier step, you can only select **ONE** bean at this step.

14. Click **Next**. The next **Add Access Intent** panel, with a list of methods, displays.
15. Select the methods you want to use.

16. If you *DID NOT* select **Read Ahead Hint** in an earlier step, click **Finish**. If you *DID* select the Read Ahead Hint option, you can click **Next** to specify your Read Ahead Hint for the specified bean. The next **Add Access Intent** panel, with a list of EJB preload paths, displays.
17. Edit the EJB preload path by selecting relationship roles from the **Relationship roles:** window.
18. Click **Finish**. A new entry is created in the **Access Intent for Entities 2.x (Method Level)** panel

Using the AccessIntent API

This task describes how to programmatically retrieve and call the AccessIntent API during the execution of BMP entity bean methods.

1. Look up the current access intent in the namespace. For example:

```
InitialContext ic = new InitialContext();
AccessIntent ai = ic.lookup("java:comp/websphere/AppProfile/AccessIntent");
```

2. Call the necessary get() methods. For example:

```
int concurrency = ai.getConcurrencyControl();
int accessType = ai.getAccessType();
if ( (concurrency == AccessIntent.CONCURRENCY_CONTROL_PESSIMISTIC)
    && (accessType == AccessIntent.ACCESS_TYPE_UPDATE) ) {
    boolean exclusive = ai.getPessimisticUpdateHintExclusive();
    // . . .
}
// . . .
```

Note: The access intent object reference retrieved from the java:comp lookup is current for the duration of the method in which the reference was looked up. Depending on how you configured the application profile, subsequent calls of the same method might not retrieve the same access intent reference. You can only look up the object reference during the call of a BMP entity bean's method; the reference does not exist during a request on a CMP entity bean. Therefore, access intent object references should not be cached beyond, or used outside of, the scope of the execution of any given BMP method.

AccessIntent interface

The AccessIntent interface is available to BMP entity beans by the following JNDI lookup:

```
java:comp/websphere/AppProfile/AccessIntent
```

AccessIntent interface

```
package com.ibm.websphere.appprofile.accessintent;

/**
 * This interface defines the essential access intents
 * available at runtime.
 */
public interface AccessIntent {

    /**
     * Returns the concurrency control intent, which indicates
     * the application prefers either pessimistic or optimistic
     * concurrency control when accessing the current component
     * in the context of the current transaction.
     */
    public int getConcurrencyControl();
    public final int CONCURRENCY_CONTROL_PESSIMISTIC = 1;
    public final int CONCURRENCY_CONTROL_OPTIMISTIC = 2;

    /**
     * Returns access type intent, which indicates the application
     * intends either update or read access of the current component
     * in the context of the current transaction.
     */
}
```

```

public int getAccessType();
public final int ACCESS_TYPE_UPDATE= 1;
public final int ACCESS_TYPE_READ = 2;

/**
 * Returns a boolean where true indicates that the runtime should
 * assume that there will be no collision on retrieved rows.
 */
public boolean getPessimisticUpdateHintNoCollision();

/*
 * Returns a boolean where true indicates that the runtime should
 * assume that there will be collisions on retrieved rows.
 */
public boolean getPessimisticUpdateHintExclusive();

/**
 * Returns the collection access intent, which indicates the
 * application intends to access the objects returned by the
 * currently executing finder in either serial or random fashion.
 */
public int getCollectionAccess();
public final int COLLECTION_ACCESS_RANDOM = 1;
public final int COLLECTION_ACCESS_SERIAL = 2;

/**
 * Returns the collection scope, which indicates the maximum
 * lifespan of a lazy collection.
 */
public int getCollectionScope();
public final int COLLECTION_SCOPE_TRANSACTION = 1;
public final int COLLECTION_SCOPE_ACTIVITYSESSION = 2;
public final int COLLECTION_SCOPE_TIMEOUT = 3;

/**
 * Returns the timeout value in seconds when collectionScope is Timeout.
 */
public int getCollectionTimeout();

/**
 * Returns the number of elements the application requests be contained
 * in each segment of the element collection returned by the currently
 * executing finder.
 */
public int getCollectionIncrement();

/**
 * Returns the ReadAheadHint requested by the application for the currently
 * executing finder.
 */
public ReadAheadHint getReadAheadHint();

/**
 * Returns the number of elements the application requests be contained in
 * each segment of a a query made on a database.
 */
public int getResourceManagerPreFetchIncrement();
}

```

Access intent exceptions

The following exceptions are thrown in response to the application of access intent policies:

com.ibm.ws.ejbpersistence.utilpm.PersistenceManagerException

If the method that drives the `ejbLoad()` method is configured to be read-only but updates are then made within the transaction that loaded the bean's state, an exception is thrown during invocation

of the `ejbStore()` method, and the transaction is rolled back. Likewise, the `ejbRemove()` method cannot succeed in a transaction that is set as read-only. If an update hint is applied to methods of entity beans with bean-managed persistence, the same behavior and exception results. The forwarded exception object contains the message string `PMGR1103E: update instance level read only bean beanName`

This exception is also thrown if the applied access intent policy cannot be honored because a finder, `ejbSelect`, or container-managed relationship (CMR) accessor method returns an inherently read-only result. The forwarded exception object contains the message string `PMGR1001: No such DataAccessSpec - methodName`

The most common occurrence of this error is when a custom finder that contains a read-only EJB Query Language (EJB QL) statement is called with an applied access intent of `wsPessimisticUpdate` or `wsPessimisticUpdate-Exclusive`. These policies require the use of a FOR UPDATE clause on the SQL SELECT statement to be executed, but a read-only query cannot support FOR UPDATE. Other examples of read-only queries include joins; the use of ORDER BY, GROUP BY, and DISTINCT keywords.

To eliminate the exception, edit the EJB query so that it does not return an inherently read-only result or change the access intent policy being applied.

- If an update access is required, change the applied access intent setting to `wsPessimisticUpdate-WeakestLockAtLoad` or `wsOptimisticUpdate`.
- If update access is not truly required, use `wsPessimisticRead` or `wsOptimisticRead`.
- If connection sharing between entity beans is required, use `wsPessimisticUpdate-WeakestLockAtLoad` or `wsPessimisticRead`.

com.ibm.websphere.ejb.container.CollectionCannotBeFurtherAccessed

If a lazy collection is driven after it is no longer in scope, and beyond what has already been locally buffered, a `CollectionCannotBeFurtherAccessed` exception is thrown.

com.ibm.ws.exception.RuntimeWarning

If an application is configured incorrectly, a run-time warning exception is thrown as the application starts; startup is ended. You can validate an application's configuration by choosing the `verify` function. Some examples of misconfiguration include:

- A method configured with two different access intent policies
- A method configured with an undefined access intent policy

javax.ejb.NoSuchEntityException

If an update fails under optimistic concurrency because fields changed within another transaction between load and store requests, a `NoSuchEntityException` is raised and the commit fails.

Access intent assembly settings

Access intent policies contain data-access settings for use by the persistence manager. Default access intent policies are configured on the entity bean. Optionally, you can associate access intent policies with one or more methods.

These settings are applicable only for EJB 2.x-compliant entity beans that are packaged in EJB 2.x-compliant modules. Connection sharing between beans with bean-managed persistence and those with container-managed persistence is possible if they all use the same access intent policy.

Name

Specifies a name for a mapping between an access intent policy and one or more methods.

Description

Contains text that describes the mapping.

Methods - Name

Specifies the name of an enterprise bean method, or the asterisk character (*). The asterisk is used to denote all of the methods of an enterprise bean's remote and home interfaces.

Methods - Enterprise bean

Specifies which enterprise bean contains the methods indicated in the Name setting.

Methods - Type

Used to distinguish between a method with the same signature that is defined in both the home and remote interface. Use `Unspecified` if an access intent policy applies to all methods of the bean.

Data type	String
Range	Valid values are Home, Remote, Local, LocalHome or Unspecified

Methods - Parameters

Contains a list of fully qualified Java type names of the method parameters. This setting is used to identify a single method among multiple methods with an overloaded method name.

Applied access intent

Specifies how the container must manage data access for persistence. Configurable both as a default access intent for an entity and as part of a method-level access intent policy.

Data type	String
Default	<code>wsPessimisticUpdate-WeakestLockAtLoad</code> . With Oracle, this is the same as <code>wsPessimisticUpdate</code> .
Range	Valid settings are <code>wsPessimisticUpdate</code> , <code>wsPessimisticUpdate-NoCollision</code> , <code>wsPessimisticUpdate-Exclusive</code> , <code>wsPessimisticUpdate-WeakestLockAtLoad</code> , <code>wsPessimisticRead</code> , <code>wsOptimisticUpdate</code> , or <code>wsOptimisticRead</code> . Only <code>wsPessimisticRead</code> and <code>wsOptimisticRead</code> are valid when class-level caching is enabled in the EJB container.

This product supports lazy collections. For each segment of a collection, iterating through the collection (`next()`) does not trigger a remote method call to retrieve the next remote reference. Two policies (`wsPessimisticUpdate` and `wsPessimisticUpdate-Exclusive`) are extremely lazy; the collection increment size is set to 1 to avoid overlocking the application. The other policies have a collection increment size of 25.

If an entity is not configured with an access intent policy, the run-time environment typically uses `wsPessimisticUpdate-WeakestLockAtLoad` by default. If, however, the **Lifetime in cache** property is set on the bean, the default value of **Applied access intent** is `wsOptimisticRead`; updates are not permitted.

Additional information about valid settings follows:

Profile name	Concurrency control	Access type	Transaction isolation
<code>wsPessimisticRead</code> (Note 1)	pessimistic	read	For Oracle, read committed. Otherwise, repeatable read
<code>wsPessimisticUpdate</code> (Note 2)	pessimistic	update	For Oracle, read committed. Otherwise, repeatable read
<code>wsPessimisticUpdate-Exclusive</code> (Note 3)	pessimistic	update	serializable
<code>wsPessimisticUpdate-NoCollision</code> (Note 4)	pessimistic	update	read committed
<code>wsPessimisticUpdate-WeakestLockAtLoad</code> (Note 5)	pessimistic	update	Repeatable read

Profile name	Concurrency control	Access type	Transaction isolation
wsOptimisticRead	optimistic	read	read committed
wsOptimisticUpdate (Note 6)	optimistic	update	read committed

Notes:

1. Read locks are held for the duration of the transaction.
2. The generated SELECT FOR UPDATE query grabs locks at the beginning of the transaction.
3. SELECT FOR UPDATE is generated; locks are held for the duration of the transaction.
4. A plain SELECT query is generated. No locks are held, but updates are permitted. Use cautiously. This intent enables execution without concurrency control.
5. Where supported by the backend, the generated SELECT query does not include FOR UPDATE; locks are escalated by the persistent store at storage time if updates were made. Otherwise, the same as wsPessimisticUpdate.
6. Generated overqualified-update query forces failure if CMP column values have changed since the beginning of the transaction.

Be sure to review the rules for forming overqualified-update query predicates. Certain column types (for example, BLOB) are ineligible for inclusion in the overqualified-update query predicate and might affect your design.

Access intent best practices

This topic outlines issues to consider when applying access intent policies to Enterprise JavaBeans (EJB) methods.

- **Start by configuring the default access intent policy for an entity.** After your application is built and running, you can more finely tune certain access paths in your application using application profiling or method-level access intent.
- **Don't mix access types.** Avoid using both pessimistic and optimistic policies in the same transaction. For most databases, pessimistic and optimistic policies use different isolation levels. This can result in multiple database connections, which prevents you from taking advantage of the performance benefits possible through connection sharing.
- **Take care when applying wsPessimisticUpdate-NoCollision.** This policy does not ensure data integrity. No database locks are held, so concurrent transactions can overwrite each other's updates. Use this policy only if you can be sure that only one transaction will attempt to update persistent store at any given time.

Frequently asked questions: Access intent

I have not applied any access intent policies at all. My application runs just fine with a DB2 database, but it fails with an Oracle database with the following message:

```
com.ibm.ws.ejbpersistence.utilpm.PersistenceManagerException: PMGR1001E: No such DataAccessSpec:FindAllCustomers. The backend datastore does not support the SQLStatement needed by this AccessIntent: (pessimistic update-weakestLockAtLoad)(collections: transaction/25) (resource manager prefetch: 0) (AccessIntentImpl@d23690a). Why?
```

If you have not configured access intent, all of your data is accessed under the default access intent policy (wsPessimisticUpdate-WeakestLockAtLoad). On DB2 databases, the weakest lock is a shared one, and the query runs without a FOR UPDATE clause. On Oracle databases, however, the weakest lock is an update lock; this means that the SQL query must contain a FOR UPDATE clause. However, not every SQL statement necessarily supports FOR UPDATE; for example, if the query is being run against multiple tables in a join, FOR UPDATE is not supported.

To avoid this problem, try either of the following:

- Modify your SQL query or reconfigure your application so that an update lock is supported
- Apply an access intent policy that supports optimistic concurrency

I am calling a finder method and I get an InconsistentAccessIntentException at run time. Why?

This can occur when you use method-level access intent policies to apply more control over how a bean instance is loaded. This exception indicates that the entity bean was previously loaded in the same transaction. This could happen if you called a multifinder method that returned the bean

instance with access intent policy X applied; you are now trying to load the second bean again by calling its `findByPrimaryKey` method with access intent Y applied. Both methods must have the same access intent policy applied.

Likewise, if the entity was loaded once in the transaction using an access intent policy configured on a finder, you might have called a container-managed relationship (CMR) accessor method that returned the entity bean configured to load using that entity's default access intent.

To avoid this problem, ensure that your code does not load the same bean instance twice within the same transaction with different access intent policies applied. Avoid the use of method-level access intent unless absolutely necessary.

I have two beans in a container-managed relationship. I call `findByPrimaryKey()` on the first bean and then call `getBean2()`, a CMR accessor method, on the returned instance. At that point, I get an `InconsistentAccessIntentException`. Why?

You are probably using read-ahead. When you loaded the first bean, you caused the second bean to be loaded under the access intent policy applied to the finder method for the first bean.

However, you have configured your CMR accessor method from the first bean to the second with a different access intent policy. CMR accessor methods are really finder methods in disguise; the run-time environment behaves as if you were trying to change the access intent for an instance you have already read from persistent store.

To avoid this problem, beans configured in a read-ahead hint are all driven to load with the same access intent policy as the bean to which the read-ahead hint is applied.

I have a bean with a one-to-many relationship to a second bean. The first bean has a pessimistic-update intent policy applied. When I try to add an instance of the second bean to the first bean's collection, I get an `UpdateCannotProceedWithIntegrityException`. Why?

The second bean probably has a read intent policy applied. When you add the second bean to the first bean's collection, you are not updating the first bean's state, you are implicitly modifying the second bean's state. (The second bean contains a foreign key to the first bean, which is modified.)

To avoid this problem, ensure that both ends of the relationship have an update intent policy applied if you expect to change the relationship at run time.

EJB modules

An EJB module is used to assemble one or more enterprise beans into a single deployable unit. An EJB module is stored in a standard Java archive (JAR) file.

An EJB module contains the following:

- One or more deployable enterprise beans.
- A deployment descriptor, stored in an Extensible Markup Language (XML) file. This file declares the contents of the module, defines the structure and external dependencies of the beans in the module, and describes how the beans are to be used at run time.

You can deploy an EJB module as a stand alone application, or combine it with other EJB modules or with Web modules to create a J2EE application. An EJB module is installed and run in an enterprise bean container.

For more information about EJB modules, see "Resources for learning."

Assembling EJB modules

Assemble an Enterprise JavaBeans (EJB) module to contain enterprise beans and related code artifacts. Group Web components, client code, and resource adapter code in separate modules. After assembling an EJB module, you can install it as a stand-alone application or combine it with other modules into an enterprise application.

To increase performance, break container-managed persistence (CMP) enterprise beans into several enterprise bean modules during assembly. The load time for hundreds of beans is improved by distributing the beans across several JAR files and packaging them to an EAR file. Load time is faster when the administrative server attempts to start the beans, for example, 8-10 minutes versus more than one hour when one JAR file is used.

Use the Assembly Toolkit to assemble an EJB module in any of the following ways:

- Import an existing EJB module (EJB JAR file).
 - Create a new EJB module.
 - Copy code artifacts (such as entity beans) from one EJB module into a new EJB module.
1. Start the Assembly Toolkit.
 2. Optional: Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
 3. Optional: Open the J2EE Hierarchy view. Click **Window > Show View > J2EE Hierarchy**. Other helpful views include the Project Navigator view (**Window > Show View > Other > J2EE > Project Navigator**) and the Navigator view (**Window > Show View > Navigator**).
 4. **5.1+** Optional: To use an application assembly service of WebSphere Business Integration (WBI) Server Foundation, select the **Integration Server** target server. Available WBI assembly services include ActivitySession, Application profiling, Extended access, Extended messaging, Internationalization, Last participant support, and Pushdown.
 - a. Click **Project > Properties > J2EE**.
 - b. For **Target server**, select **Integration Server**. For this release, **Integration Server v5.1**.
 - c. Click **OK**.
 5. Migrate enterprise bean (JAR) files created with the Application Assembly Tool (AAT) or a different tool to the Assembly Toolkit. To migrate files, import your enterprise bean files to the Assembly Toolkit.
 6. Create a new EJB module.
 7. Copy code artifacts (such as entity beans) from one EJB module into a new EJB module.
 8. Verify the contents of the new EJB module in either of the following ways:
 - In the J2EE Hierarchy view, expand **EJB Modules** and view the new module.
 - Click **Window > Show View > Navigator** to see the associated files for the EJB module in a Navigator view.

Container transactions

Container transaction properties specify how an EJB container is to manage transaction scopes for the enterprise bean's method invocations. A transaction attribute is mapped to one or more methods.

Method extensions

Method extensions are IBM extensions to the standard deployment descriptors for enterprise beans.

Method extension properties are used to define transaction isolation levels for methods, to control the delegation of a principal's credentials, and to define custom finder methods.

Method permissions

A method permission is a mapping between one or more security roles and one or more methods that a member of the role can call.

References

References are logical names used to locate external resources for enterprise applications. References are defined in the application's deployment descriptor file. At deployment, the references are bound to the physical location (global JNDI name) of the resource in the target operational environment.

This product supports the following types of references:

- An EJB reference is a logical name used to locate the home interface of an enterprise bean.
- A resource reference is a logical name used to locate a connection factory object.

These objects define connections to external resources such as databases and messaging systems. The container makes references available in a JNDI naming subcontext. By convention, references are organized as follows:

- EJB references are made available in the `java:comp/env/ejb` subcontext.
- Resource references are made available as follows:
 - JDBC DataSource references are declared in the `java:comp/env/jdbc` subcontext.
 - JMS connection factories are declared in the `java:comp/env/jms` subcontext.
 - JavaMail connection factories are declared in the `java:comp/env/mail` subcontext.
 - URL connection factories are declared in the `java:comp/env/url` subcontext.

EJB containers

An Enterprise JavaBeans (EJB) container provides a run-time environment for enterprise beans within the application server. The container handles all aspects of an enterprise bean's operation within the application server and acts as an intermediary between the user-written business logic within the bean and the rest of the application server environment.

One or more EJB modules, each containing one or more enterprise beans, can be installed in a single container.

The EJB container provides many services to the enterprise bean, including the following:

- Beginning, committing, and rolling back transactions as necessary.
- Maintaining pools of enterprise bean instances ready for incoming requests and moving these instances between the inactive pools and an active state, ensuring that threading conditions within the bean are satisfied.
- Most importantly, automatically synchronizing data in an entity bean's instance variables with corresponding data items stored in persistent storage.

By dynamically maintaining a set of active bean instances and synchronizing bean state with persistent storage when beans are moved into and out of active state, the container makes it possible for an application to manage many more bean instances than could otherwise simultaneously be held in the application server's memory. In this respect, an EJB container provides services similar to virtual memory within an operating system.

Between transactions, the state of an entity bean can be cached. The EJB container supports option A, B, and C caching.

For more information about EJB containers, see "Resources for learning."

Container Managed Persistence over anything

Before the release of WebSphere Business Integration Server Foundation Version 5.1, Container Managed Persistence (CMP) supported a number of *relational* backend systems. Users wanting to use WebSphere Application Server Enterprise Edition to host stateful and live business models needed a way to represent all the entities that exist in the business model, including *non-relational* backend systems. Version 5.1 addresses this need.

The CMP infrastructure is designed to work with the J2EE Connector Architecture (JCA), through an interface called *EJBToRAAdapter*. In addition to the current implementation of this interface (which connects to *relational* backend systems), Version 5.1 provides a new implementation that connects to *procedural* backend systems. The EJB Deployment tool can be used to return either of these

implementations. The new procedural implementation contains generic logic for adapting between JCA and the WebSphere Application Server persistence manager. Note that all of the actual connection logic is contained down in the *FunctionSet* of the bean.

However, the CMP over anything (CMP/A) function is not limited to JCA connectors. There are other approaches to backend data store connectivity that you can use. CMP over the web services, which enable communication with backend systems indirectly through a web service using JAX-RPC, or WSIF are available. You can also use a composed EJB model, where a CMP bean delegates its persistence logic to another EJB.

So now you can develop a simple CMP bean that works with whatever backend system you need, rather than having to go the cumbersome Bean Managed Persistence (BMP) bean development route, where all of the connection logic must go directly in the bean implementation class.

Version 5.1 introduces support for *pushdown* methods, which can be thought of as *container managed business methods*. In the CMP framework, you can use the class called *UserDefinedPushDownMethodImpl*, to place connectivity logic with a non-relational backend data store. The Java source code for this class is generated by the WebSphere Application Server deployment tools and contains methods corresponding to each CRUD method and each pushdown data-logic method defined in the PME EJB deployment descriptor.

This means that methods can be defined on a CMP bean that, rather than being implemented by the developer (in a BMP style of putting connection logic directly in the EJB's method implementation), are instead handled by the container and deployment tools. This is accomplished by defining the method as **abstract**, and then marking new PME extended deployment descriptor settings for these *PushDownMethodElements*. The new command-line code generation tool reads these extensions and generates appropriate entries.

WebSphere Business Integration Server Foundation Version 5.1 also includes a generic *UserDefinedPushDownMethods* interface (unrelated to the backend) and a *UserDefinedPushDownMethodImpl* class that implements the interface and that is specific to a given backend. When a method has been marked **userDefined**, the *FunctionSet* is delegated to the corresponding method of the *UserDefinedPushDownMethodImpl*. The implementer of the *UserDefinedPushDownMethodImpl* does not need to worry about processing CCI Records - it can simply do its work and let the *FunctionSet* code take care of that.

See Example: Container Managed Persistence over anything -- CCI and Example: Container Managed Persistence over anything -- EJB for examples.

Version 5.1 provides tooling that you can invoke from the command line or from the Assembly Toolkit. The tool generates the bean's *UserDefinedPushDownMethods* interface, and generates skeleton Java source code for the bean's *UserDefinedPushDownMethodImpl* class. You must fill this class in with the appropriate logic, compile it, and package it into the appropriate EJB JAR file. See Applying Container Managed Persistence services over anything for complete information.

The following links provide additional information concerning the procedural functions that use a CMP EJB. For relational stored procedure information, refer to "Stored procedure support for CMP EJB" in the Information Center.

Applying Container Managed Persistence services over anything

1. Develop your Container Managed Persistence (CMP) bean as usual. See Developing enterprise beans for more information. Optionally, you can also define abstract methods that are treated as pushdown methods.
2. Assemble the Enterprise JavaBean (EJB) Java Archive (JAR) file. In addition to standard packaging steps, make sure to set the proper deployment descriptor settings.

- a. Use the Assembly Toolkit to make your settings.
- b. There is a *PushDownContainerManagedEntityExtension* method associated with your CMP bean, and its *procedural* attribute is set to **True**. Set its *backEndType* attribute to one of the following:

CCI Creates skeleton for the *UserDefinedPushDownMethodsImpl* java file with some boiler-plate CCI code generated.

EJB Creates skeleton for the *UserDefinedPushDownMethodsImpl* java file with some boiler-plate EJB code generated.

JAX-RPC

Creates skeleton for the *UserDefinedPushDownMethodsImpl* java file with some boiler-plate JAX-RPC code generated.

WSIF Creates skeleton for the *UserDefinedPushDownMethodsImpl* java file with some boiler-plate WSIF code generated.

Custom

Creates empty skeleton for the *UserDefinedPushDownMethodsImpl* java file.

- c. Set additional attributes required for each *backEndType*. You are prompted for attributes according to which *backEndType* you specified.

CCI Set your bean's *connectionSpecClassName* attribute to the appropriate fully-qualified J2EE Connector Architecture (JCA) *ConnectionSpec* class name. For example, the class name for use with CICS ECI is *com.ibm.connector2.cics.ECIConnectionSpec*.

Set the *interactionSpecClassName* attribute to the appropriate fully-qualified J2EE Connector Architecture (JCA) *InteractionSpec* class name. For example, the class name for use with CICS ECI is *com.ibm.connector2.cics.ECIInteractionSpec*.

EJB Set the *ejbRefName* value that specifies the *java:comp* name for a reference to another EJB. For example, *ejb/AccountBackend*.

JAX-RPC

Set the *wSDLServiceFileName* attribute to the fully-qualified path (inside a JAR file) to a WSDL file that defines the web service being used.

WSIF Set the *wSDLServiceFileName* attribute to the fully-qualified path (inside a JAR file) to a WSDL file that defines the web service being used.

Custom

No special attributes.

All backend types

All backend types have an *ejbToRAAdapterClassName* entry, which enables you to specify a fully-qualified class name of a custom *EJBToRAAdapter* implementation.

- d. If you defined any abstract methods for pushdown, define a *PushDownMethodElement* for each of them, and set the *backEndMethodName* attribute to the name of the corresponding method.

3. Deploy the EJB JAR.

- a. Run the code generation tool *CMPDeploy* against the assembled EJB JAR file. You can do this from within the IDE or from the command line. The command syntax is:

```
CMPDeploy <ejb.jar | application.ear> <-dir directory> <-overwrite> <-verbose>
```

ejb.jar | application.ear

The name of the JAR or EAR file you want to deploy.

-dir Optional. The name of the directory into which you want the output files placed.

If you do not specify *-dir* the tool outputs its files into a package-based directory structure rooted at the current directory.

-overwrite

Optional. Causes any existing *UserDefinedPushDownMethodsImpl* class to be overwritten by the one you are creating.

If you do not specify `-overwrite` the tool will abort the process with a warning message if the *UserDefinedPushDownMethodsImpl* class already exists.

-verbose

Optional. Causes tracing messages to display during processing.

If you do not specify the `-verbose` option the tool does not display tracing messages, but only displays a message at the end of the process specifying either what was emitted or else what problems were encountered.

This command accepts either an EAR or JAR file, and generates the *UserDefinedPushDownMethods* interface, and skeleton Java source code for the bean's *UserDefinedPushDownMethodsImpl* class. For example, if the EJB JAR contains a *procedural* CMP bean called *Account*, then **CMPDeploy Account.jar** emits a generic *AccountUserDefinedPushDownMethods* interface, and a backend specific *AccountUserDefinedPushDownMethodsImpl.java* class that implements the interface.

4. Edit the emitted implementation class. Enter the appropriate connectivity logic for your specified backend data store.
5. Compile the emitted files.
6. Zip/jar the compiled files into the EJB JAR file.
7. Run the EJB deployment tool against the EJB JAR file. For more information, see documentation on the EJB deployment tool in the WebSphere Business Integration Server Foundation InfoCenter..
8. Package the deployed EJB JAR file into an EAR file.
9. Install the application containing this EJB EAR file. During installation, when asked for the resource binding for the CMP bean, specify the JNDI name of a *J2CConnectionFactory* (instead of the usual case of specifying the JNDI name of a *JDBC DataSource*), In the case of a non-CCI-based CMP bean (one that does NOT use JCA connectors), you must install the sample relational adapter provided by WebSphere Business Integration Server Foundation Version 5.1, and specify a binding to it.

Example: Container Managed Persistence over anything -- CCI Usage Scenario

For a CMP bean whose fully-qualified name is *com.ibm.test.BeCashAcctBean* (whose bean implementation class is named *BeCashAcctBean*), the *BeCashAcctBeanUserDefinedPushDownMethods* interface would be in the **com.ibm.test.websphere_deploy** package, and the *BeCashAcctBeanUserDefinedPushDownMethodsImpl* for a *backEndType* of CCI would be in the **com.ibm.test.websphere_deploy.cci** package.

Example

```
/**
 * User-defined push-down method ejbCreate.
 *
 * @param bean Reference to the bean implementation class
 * @param connection The CCI connection to the back-end system. This
 * connection was previously obtained (by the EJBTORAAAdapter implementation)
 * via connectionFactory.getConnection(connectionSpec). For non-CCI based
 * beans, this will be null and the user will have to manually connect to
 * the back-end system.
 *
 * @exception javax.ejb.CreateException Thrown if an exception occurs creating bean data
 * @exception ResourceException Any other exceptions are wrapped in a
 * ResourceException.
 */
public void ejbCreate(BeCashAcctBean bean, Object connection)
    throws javax.ejb.CreateException, ResourceException {
```

```

if (tc.isEntryEnabled())
    Tr.entry(
        tc,
        "ejbCreate(BeCashAcctBean, Object)",
        new Object[] { bean, connection });

```

Example: Container Managed Persistence over anything -- EJB Usage Scenario

For a CMP bean whose fully-qualified name is `com.ibm.test.Account` (whose bean implementation class is named `AccountBean`), the `AccountBeanUserDefinedPushDownMethods` interface would be in the `com.ibm.test.websphere_deploy` package, and the `AccountBeanUserDefinedPushDownMethodsImpl` for a `backEndType` of EJB would be in the `com.ibm.test.websphere_deploy.ejb` package.

Example

```

public float computeAverageDailyBalance(Date arg1, Date arg2, AccountBean bean,
Object connection) throws AccountAccessException, ResourceException
{
AccountBackendLocalHome home = helper.getEJBHome("ejb/AccountBackend",
AccountBackendLocalHome.class);
//throws ResourceException on error

AccountBackend bean = null;
float returnValue = 0.0;
int id = bean.getId();
try {
bean = home.create();
returnValue = bean.computeAverageDailyBalance(id, arg1, arg2);
} catch (Exception e) {
throw helper.createResourceException(e, this.getClass());
}

if (returnValue == -1) throw new AccountAccessException();

return returnValue;
}

```

Managing EJB containers

Each application server can have a single EJB container; one is created automatically for you when the application server is created. The following steps are to be performed only as needed to improve performance after the EJB application has been deployed.

1. Adjust EJB container settings.
2. Adjust EJB cache settings.

If adjustments do not improve performance, consider adjusting access intent policies for entity beans, reassembling the module, and redeploying the module in the application.

EJB container settings

Use this page to configure and manage a specific EJB container.

To view this administrative console page, click **Servers > Application Servers > *serverName* > EJB Container**.

Passivation directory

Specifies the directory into which the container saves the persistent state of passivated stateful session beans.

Beans are passivated when the number of active bean instances becomes greater than the cache size specified in the container configuration. When a stateful bean is passivated, the container serializes the bean instance to a file in the passivation directory and discards the instance from the bean cache. If, at a later time, a request arrives for the passivated bean instance, the container retrieves it from the passivation directory, deserializes it, returns it to the cache, and dispatches the request to it. If any step fails (for example, if the bean instance is no longer in the passivation directory), the method invocation fails.

For a cluster of servers that span multiple systems in a sysplex and have stateful session beans with an activation policy of *Transaction* deployed in them, the passivation directory must reside on a hierarchical file system (HFS) that is shared across the multiple systems.

Inactive pool cleanup interval

Specifies the interval at which the container examines the pools of available bean instances to determine if some instances can be deleted to reduce memory usage.

Data type	Integer
Units	Milliseconds
Range	0 to 2 147 483 674

Default datasource JNDI name

Specifies the JNDI name of a data source to use if no data source is specified during application deployment. This setting is not applicable for EJB 2.x-compliant CMP beans.

Servlets and enterprise beans use *data sources* to obtain these connections. When configuring a container, you can specify a default data source for the container. This data source becomes the default data source used by any entity beans installed in the container that use container-managed persistence (CMP).

The default data source for a container is *secure*. When specifying it, you must provide a user ID and password for accessing the data source.

Specifying a default data source is optional if each CMP entity bean in the container has a data source specified in its configuration. If a default data source is not specified and a CMP entity bean is installed in the container without specifying a data source for that bean, applications cannot use that CMP entity bean.

Initial state

Specifies the execution state requested when the server first starts.

Data type	String
Default	Started
Range	Valid values are Started and Stopped

EJB container system properties

In addition to the settings accessible from the administrative console, you can set the following system property by command-line scripting:

com.ibm.websphere.ejbcontainer.poolSize

Specifies the size of the pool for the specified bean type. This property applies to stateless, message-driven and entity beans. If you do not specify a default value, the container defaults of 50 and 500 are used.

Set the pool size for a given entity bean as follows:

```
beantype=min,max[:beantype=min,max...]
```

beantype is the J2EE name of the bean, formed by concatenating the application name, the # character, the module name, the # character, and the name of the bean (that is, the string assigned to the <ejb-name> field in the bean's deployment descriptor). *min* and *max* are the minimum and maximum pool sizes, respectively, for that bean type. Do not specify the square brackets shown in the previous prototype; they denote optional additional bean types that you can specify after the first. Each bean-type specification is delimited by a colon (:).

Use an asterisk (*) as the value of *beantype* to indicate that all bean types are to use those values unless overridden by an exact bean-type specification somewhere else in the string, as follows:

```
*=30,100
```

To specify that a default value be used, omit either *min* or *max* but retain the comma (,) between the two values, as follows (split for publication):

```
SMAApp#PerfModule#TunerBean=54,  
:SMAApp#SModule#TypeBean=100,200
```

You can specify the bean types in any order within the string.

EJB cache settings

Use this page to configure and manage the cache for a specific EJB container. To determine the cache absolute limit, multiply the number of enterprise beans active in any given transaction by the total number of concurrent transactions expected. Then, add the number of active session bean instances. You can use the Tivoli Performance Viewer to view bean performance information.

To view this administrative console page, click **Servers > Application Servers > *serverName* > EJB Container > EJB Cache Settings**.

Cleanup interval

Specifies the interval at which the container attempts to remove unused items from the cache in order to reduce the total number of items to the value of the cache size.

The cache manager tries to maintain some unallocated entries that can be allocated quickly as needed. A background thread attempts to free some entries while maintaining some unallocated entries. If the thread

runs while the application server is idle, when the application server needs to allocate new cache entries, it does not pay the performance cost of removing entries from the cache. In general, increase this parameter as the cache size increases.

Data type	Integer
Units	Milliseconds
Range	0 to 2 147 483 674
Default	3000

Cache size

Specifies the number of buckets in the active instance list within the EJB container.

A bucket can contain more than one active enterprise bean instance, but performance is maximized if each bucket in the table has a minimum number of instances assigned to it. When the number of active instances within the container exceeds the number of buckets, that is, the cache size, the container periodically attempts to reduce the number of active instances in the table by passivating some of the active instances. For the best balance of performance and memory, set this value to the maximum number of active instances expected during a typical workload.

Data type	Integer
Units	Buckets in the hash table
Range	Greater than 0. The container selects the next largest prime number equal to or greater than the specified value.
Default	2053

Container interoperability

Container interoperability describes the ability of WebSphere Application Server clients and servers at different versions to successfully negotiate differences in native Enterprise JavaBeans (EJB) Version 1.1 finder methods support and Java 2 Platform, Enterprise Edition (J2EE) Version 1.3 compliance.

At one time, there were significant interoperability problems among WebSphere Application Server, versions 4.0.x and 3.5.x distributed, and Version 4.0.x for zSeries. The introduction of interoperable versions of some class types solved these problems for distributed versions 3.5.6, 4.0.3, and 5 as well as for zSeries Version 4.0.x.

Older 4.0.x and 3.5.x client and application server versions do not support the interoperability classes, which makes them uninteroperable with versions that use the classes. The system property *com.ibm.websphere.container.portable* remedies this situation by enabling newer versions of the application server to turn off the interoperability classes. This lets a more recent application server return class types that are interoperable with an older client.

Depending on the value of *com.ibm.websphere.container.portable*, application servers at versions 5 and later, 4.0.3 and later, and 3.5.6 and later, return different classes for the following:

- Enumerations and collections returned by EJB 1.1 finder methods
- EJBMetaData
- Handles to:
 - Entity beans
 - Session beans
 - Home interfaces

If the property is set to *false*, application servers return the old class types, to enable interoperability with versions 3.5.5 and earlier, and 4.0.2 and earlier. If the property is set to *true*, application servers return the new classes.

Instructions for setting the `com.ibm.websphere.container.portable` property are in the release notes for versions 3.5.6 and later, and 4.0.3 and later. The following tables show interoperability characteristics for various version combinations of application servers and clients as well as default property values for each combination.

Interoperability of Version 3.5.x client with Version 5 (and later) application server

Clients at Version 3.5.5 and earlier are not interoperable with Version 5 and later servers when using:

- EJBMetaData
- Enumerations returned by EJB 1.x finder methods
- Handles to entity beans

If you would like to use updated Handle classes in EJB 2.x-compliant beans but have one of the older clients (versions 3.5.5 and earlier) installed, set the system property `com.ibm.websphere.container.portable.finder` to `false`. With this setting in place, the Version 5 application server uses the updated handles but returns the enumerations and collections that were used in the earlier clients.

To interoperate with Version 5 application servers, you must upgrade all Version 3.5.x clients to Version 3.5.6 or later.

Interoperability of Version 5 (and later) client with Version 3.5.x application server

Client at Version 5 and later, using this function	Application server at Version 3.5.6, property true	Application server at Version 3.5.6, property false (default)	Application server at Version 3.5.5 and earlier
EJBMetaData	Does not work across domains	Works	Does not work
Handle to session bean	Works	Works	Does not work
Handle to entity bean	Does not work across domains	Does not work across domains	Does not work across domains
Enumeration returned by EJB 1.x finder method	Works	Works	Works

Interoperability of Version 4.0.x client with Version 5 (and later) application server

Ideally, all 4.0.x clients that use Version 5 application servers should be at Version 4.0.3 or later.

Version 5 and later application servers return the interoperability class types by default (`true`). This can cause interoperability problems for distributed clients at versions 4.0.1 or 4.0.2. In particular, problems can occur with collections and enumerations returned by EJB 1.1 finder methods.

Although it is strongly discouraged, you can set `com.ibm.websphere.container.portable` to `false` on a Version 5 and later application server. This causes the application server to return the old class types, providing interoperability with clients at Version 4.0.2 and earlier. This is discouraged because:

- The Version 5 application server instance would become non-J2EE 1.3 compliant with regard to handles, home interface handles, and EJBMetaData.
- EJB 1.x finder methods return collection and enumeration objects that do not originate from `ejbportable.jar`.
- Interoperability restrictions still exist with the property set to `false`.
- Version 5 and later client handles to entity beans and home interfaces do not work across domains for the server you set to `false`.

If you would like to use updated Handle classes in EJB 2.x-compliant beans but have one of the older clients (versions 4.0.2 and earlier) installed, set the system property

com.ibm.websphere.container.portable.finder to false. With this setting in place, the Version 5 and later application server uses the updated handles but returns the enumerations and collections that were used in the earlier clients.

Interoperability of client at Version 4.0.2 and earlier with Version 5 (and later) application server

Client at Version 4.0.2 and earlier, using this function	Application server at Version 5 and later, property true (default)	Application server at Version 5 and later, property false
EJBMetaData	Does not work	Works for 4.0.2 client
Handle to session bean	Does not work	Works
Handle to entity bean	Does not work	Does not work across cells
Enumeration returned by EJB 1.x finder method	Does not work	Works
Collection returned by EJB 1.x finder method	Does not work	Works
Handle to home interface	Does not work	Does not work across cells

If you would like to use updated Handle classes in EJB 2.x-compliant beans but have one of the older clients (versions 3.5.5 and earlier, and 4.0.2 and earlier) installed, set the system property com.ibm.websphere.container.portable.finder to false. With this setting in place, the Version 5 and later server uses the new Handle classes but returns the older enumeration and collection classes.

Interoperability of client at Version 4.0.3 and later with Version 5 and later application server

Clients at Version 4.0.3 and later work well with Version 5 and later application servers. However, if you set the com.ibm.websphere.container.portable to false, client handles to entity beans and home interfaces do not work across domains for the server you set to false.

Client at Version 4.0.3 and later, using this function	Application server at Version 5 and later, property true (default)	Application server at Version 5 and later, property false
EJBMetaData	Works	Works
Handle to session bean	Works	Works
Handle to entity bean	Works	Does not work across cells
Enumeration returned by EJB 1.x finder method	Works	Works
Collection returned by EJB 1.x finder method	Works	Works
Handle to home interface	Works	Does not work across cells

Interoperability of Version 5 and later client with Version 4.0.x application server

Clients at Version 5 and later work well with Version 4.0.3 application servers if you set com.ibm.websphere.container.portable to true. Client handles to entity beans and home interfaces do not work across domains for any Version 4.0.3 server with com.ibm.websphere.container.portable at the default value, false. Version 5 client handles to application servers at Version 4.0.2 and earlier also have restrictions.

Client at Version 5 and later, using this function	Application server at Version 4.0.3, property true	Application server at Version 4.0.3, property false (default)	Application server at Version 4.0.2 or earlier
EJBMetaData	Works	Works	Works for 4.0.2 server only

Client at Version 5 and later, using this function	Application server at Version 4.0.3, property true	Application server at Version 4.0.3, property false (default)	Application server at Version 4.0.2 or earlier
Handle to session bean	Works	Works	Works
Handle to entity bean	Works	Does not work across domains	Does not work across domains
Enumeration returned by EJB 1.x finder method	Works	Works	Works
Collection returned by EJB 1.x finder method	Works	Works	Works
Handle to home interface	Works	Does not work across domains	Does not work across domains

Interoperability of zSeries Version 4.0.x client with Version 5 and later application server

The only valid configuration for container interoperability with zSeries Version 4.0.x clients is the default configuration for the Version 5 application server.

Interoperability of Version 5 and later client with zSeries Version 4.0.x application server

Version 5 clients should work with a zSeries Version 4.0.x application server with the correct interoperability fixes described in the zSeries documentation. The interoperability characteristics should be the same as for a Version 4.0.3 distributed application server with the property set to true.

Client at Version 5 and later, using this function	zSeries application server at Version 4.0.x
EJBMetaData	Works
Handle to session bean	Works
Handle to entity bean	Works
Enumeration returned by EJB 1.x finder method	Works
Collection returned by EJB 1.x finder method	Works
Handle to home interface	Works

Interoperability of the handle formats in WebSphere Application Server, Version 5 and Version 5.0.1

Applications that attempt to persist handles to enterprise beans and **EJBHome** needed to subclass **ObjectInputStream** in WebSphere Application Server, Version 5. This action was required so that the subclass **ObjectInputStream** could utilize the context class loader to resolve the classes for enterprise beans and **EJBHome** stubs.

In addition, handles created and persisted in WebSphere Application Server, Version 5 only work with objects that have an unchanged remote interface. If the remote interface is changed, the handle is no longer valid because the stub is serialized inside the handle and its serial Version UID changes if the remote interface changes.

This release introduces a new handle persistence mechanism that avoids the implementation drawbacks of the previous version. However, if handles are used for this WebSphere Application Server deployment, you should consider the following issues when applying this update, future WebSphere Application Server Fix Packs and EJB Container cumulative fixes for WebSphere Application Server, Version 5.

If a WebSphere Application Server, Version 5 persisted handle or home handle is encountered by a WebSphere Application Server, Version 5.0.1 system, it can be read and utilized. In addition, it will be

converted to WebSphere Application Server, Version 5.0.1 format if it is re-persisted. The WebSphere Application Server, Version 5.0.1 format cannot be read by a WebSphere Application Server, Version 5 system unless PQ72184 is applied.

Problems arise when handles are persisted and shared across systems that are not at the WebSphere Application Server, Version 5.0.1 level or later. However, a Version 5 system can receive a handle from Version 5.0.1 remotely through a call to get a handle on an enterprise bean or a getHomeHandle on an **EJBHome**. The remote call will succeed, however, any attempt to persist it on the Version 5 system will have the same limitations regarding the use of ObjectInputStream and changes in remote interface invalidating the persisted handle.

When your application stores handles persistently and shares this persistence with multiple clients or application servers, apply WebSphere Application Server, Version 5.0.1 or PQ72184 to both the client and server systems at the same time. Failure to do so can result in the inability of these systems to read the handle data stored by upgraded systems. Also, handles stored by the WebSphere Application Server, Version 5 can force the applications of the updated system to still subclass ObjectInputStream. Applications using the WebSphere Application Server Enterprise, Version 5 scheduler and process choreographer, are affected by these changes. These users should update their Version 5 systems at the same time with either Version 5.0.1 or PQ72184.

If the applications store handles in the session context, or locally in a file on the same system, that is not shared by other applications, on different systems, they might be able to update their systems individually, rather than all at once. If Client Container and thin client applications do not share persisted handle data, they can be updated as needed as well. However, handles created and persisted in WebSphere Application Server, Version 5, Version 4.0.3 and later (with the property flag set), or Version 3.5.7 and later (with the property flag set) are not usable if either the home or the remote interface changes.

If any WebSphere Application Server, Version 3.5.7 or Version 4.0.3 and later enables the system property `com.ibm.websphere.container.portable` to **true**, any handles to objects on that server have the same interoperability limitations. In addition, if any WebSphere Application Server, Version 3.5.7 and later or Version 4.0.3 applications store a handle obtained from a WebSphere Application Server, Version 5 or Version 5.0.1, the same restrictions apply, regarding the need to subclass ObjectInputStream and the usability of handles after a change to the remote interface is made.

Replication of the Http Session and Handles

This note applies to you if you place Handles to Homes or EJBs, or EJB or EJBHome references in the Http Session in your application and you use Http Session Replication. If you intend to replicate a mixed environment of Version 5.0.0 and Version 5.0.1 or 5.0.2 machines you should first apply the latest Version 5.0.0 container cumulative e-fix to the Version 5.0.0 machines before allowing the Version 5.0.1 or 5.0.2 server into the typology. The reason for this is that Version 5.0.0 servers are not able to understand the persisted Handle format used on the Version 5.0.1 and 5.0.2 server. This is similar to the case of Version 5.0.0 and Version 5.0.1 or 5.0.2 systems trying to use a shared database, mentioned above. But in this case, it is the Http Session object and not the database providing the persistence.

Top Down Deployment Mapping

The size of the Handle objects has grown due to the fix put in to allow serialization and deserialization to occur without the previous requirements of subclassing the ObjectInputStream and so on. Top down deployment of an object that contains EJB and EJBHome references create a database table ddl that has a field of 1000 bytes of VARCHAR for BITDATA which will contain the Handle. It might be that your object's Handle does not fit in the 1000 byte default field, and you might need to adjust this to a higher value. You might try increments of 250 bytes, that is, 1250, 1500, and so on.

Deploying EJB modules

Assemble one or more EJB modules, assemble one or more Web modules, and assemble them into a J2EE application.

1. Prepare the deployment environment. (See "Preparing to host applications" in the Information Center.)
2. Deploy the application.
3. **5.1+** Update the configuration for each EJB module as needed for the deployment environment.
4. For information about the EJB deployment tool, see the WebSphere Business Integration Server Foundation InfoCenter.

The next step is to test and debug the module. (See "Diagnosing and fixing problems" in the Information Center.)

EJB module collection

Use this page to manage the EJB modules deployed in a specific application.

To view this administrative console page, click **Applications > Enterprise Applications > *applicationName* > EJB modules**. Click the check boxes to select one or more of the EJB modules in your collection.

URI

When resolved relative to the application URL, this specifies the location of the module's archive contents on a file system. The URI matches the <ejb> or <web> tag in the <module> tag of the application deployment descriptor.

EJB module settings

Use this page to configure and manage a specific deployed EJB module.

Note: You cannot start or stop an individual EJB module for modification. You must start or stop the appropriate application entirely.

To view this administrative console page, click **Applications > Enterprise Applications > *applicationName* > EJB modules > *moduleName***.

URI

When resolved relative to the application URL, this specifies the location of the module archive contents on a file system. The URI must match the URI of a ModuleRef URI in the deployment descriptor of the deployed application (EAR).

Alternate DD

Specifies a deployment descriptor to be used at run time instead of the one installed in the module.

Starting weight

Specifies the order in which modules are started when the server starts. The module with the lowest starting weight is started first.

Data type	Integer
Default	5000
Range	Greater than 0

Enterprise beans: Resources for learning

Use the following links to find relevant supplemental information about enterprise beans. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to this product but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

EJB method Invocation Queuing

Method invocations to enterprise beans are only queued for remote clients, making the method call. An example of a remote client is an enterprise Java bean (EJB) client running in a separate Java virtual machine (JVM) (another address space) from the enterprise bean. In contrast, no queuing occurs if the EJB client, either a servlet or another enterprise bean, is installed in the same JVM on which the EJB method runs and on the same thread of execution as the EJB client.

Remote enterprise beans communicate by using the Remote Method Invocation over an Internet Inter-Orb Protocol (RMI-IIOP). Method invocations initiated over RMI-IIOP are processed by a server-side object request broker (ORB). The thread pool acts as a queue for incoming requests. However, if a remote method request is issued and there are no more available threads in the thread pool, a new thread is created. After the method request completes the thread is destroyed. Therefore, when the ORB is used to process remote method requests, the EJB container is an open queue, due to the use of unbounded threads. The following illustration depicts the two queuing options of enterprise beans.

EJB Queuing

The following are two tips for queueing enterprise beans:

- **Analyze the calling patterns of the EJB client.**

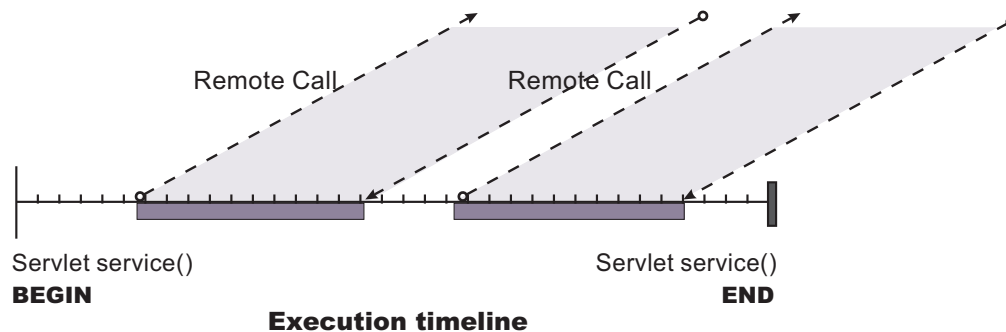

When configuring the thread pool, it is important to understand the calling patterns of the EJB client. If a servlet is making a small number of calls to remote enterprise beans and each method call is relatively quick, consider setting the number of threads in the ORB thread pool to a value lower than the Web

container thread pool size value.

Short-lived EJB calls

Longer-lived EJB calls

The degree to which the ORB thread pool value needs increasing is a function of the number of simultaneous servlets, that is, clients, calling enterprise beans and the duration of each method call. If the method calls are longer or the applications spend a lot of time in the ORB, consider making the ORB thread pool size equal to the Web container size. If the servlet makes only short-lived or quick calls to the ORB, servlets can potentially reuse the same ORB thread. In this case, the ORB thread pool can be small, perhaps even one-half of the thread pool size setting of the Web container.

- **Monitor the percentage of configured threads in use.**

Tivoli Performance Viewer shows a metric called *percent maxed*, which is used to determine how often the configured threads are used. A value that is consistently in the double-digits, indicates a possible bottleneck at the ORB. Increase the number of threads.

Chapter 5. Using extended messaging in applications

These topics provide information about implementing WebSphere enterprise applications that use extended messaging.

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface. Extended messaging extends the base JMS support, support for EJB 2.0 message-driven beans, and the Enterprise Java Bean (EJB) component model, to use the existing container-managed persistence and transactional behavior.

Using extended messaging, you can build enterprise beans that can provide messaging services along with methods that implement business logic. The enterprise beans can use the standard JMS styles of messaging (point-to-point and publish/subscribe). However, with extended messaging, the JMS usage is simplified, because JMS support is managed by the extended messaging service. This helps to effectively separate business logic from the messaging infrastructure. The use of data mapping enables messages to drive existing or new enterprise beans as though they were invoked from any EJB client.

You can use WebSphere Studio Application Developer Integration Edition to develop applications that use extended messaging. You can use the WebSphere Application Server runtime tools, like the administrative console, to deploy and administer applications that use extended messaging.

For more information about implementing WebSphere enterprise applications that use extended messaging, see the following topics:

- Extended messaging - application usage scenarios
- Extended messaging - components
- Designing an enterprise application to use a message-driven bean
- Developing an enterprise application to use a message-driven bean
- Deploying an enterprise application to use a message-driven bean
- Configuring extended messaging service resources
- Troubleshooting extended messaging

Extended messaging - overview

Extended messaging extends the base JMS support, support for EJB 2.0 message-driven beans, and the Enterprise Java Bean (EJB) component model, to use the existing container-managed persistence and transactional behavior.

In addition to providing such *container-managed messaging*, extended messaging provides new types of enterprise beans and administrative objects for messaging, and new functionality like data mapping and late response handling. (The abbreviation, CMM, for the term *container-managed messaging* is sometimes used to represent extended messaging.)

Extended messaging uses the bean-managed messaging implementation to provide the JMS interfaces, which ensures that both bean-managed and extended messaging use consistent JMS support.

An application that uses extended messaging can receive messages by using a receiver bean, either by the `onMessage()` method of a message-driven bean or by a stateless session bean that polls for a message from a named destination. With extended messaging and a message-driven bean, code within the bean can use the message to invoke business logic, as either a method within the same bean or another enterprise bean. Both the incoming message and the invocation of the receiver bean can be included within the scope of a transaction. For outbound messages, an application calls a sender bean that turns a method call into a JMS message that is then sent asynchronously. These message beans are implemented as enterprise beans by WebSphere Application Server. Application developers can create

these message beans by using WebSphere Studio Application Developer Integration Edition, although they can be created without the help of WebSphere Studio.

With extended messaging, the JMS usage is simplified, because JMS support is managed by the extended messaging service. This helps to effectively separate business logic from the messaging infrastructure. Also, the use of data mapping enables messages to drive existing or new enterprise beans as though they are invoked from any EJB client. WebSphere Studio enables the types of message beans that support extended messaging to be developed easily and hides the messaging infrastructure from developers.

For more conceptual information about extended messaging, see the following topics:

- Extended messaging - application usage scenarios
- Extended messaging - components
- Receiving messages with extended messaging
- Sending messages with extended messaging
- Data mapping with extended messaging
- Handling late responses with extended messaging
- Transactional support with extended messaging
- Exception handling with extended messaging

Extended messaging - receiving messages

To receive messages, applications that use extended messaging use a receiver bean, which can be a message-driven bean or a session bean:

- A receiver bean (deployed as a message-driven bean) is invoked when a message arrives at a JMS destination for which a listener is active.
- An application-callable receiver bean (deployed as a session bean) polls a JMS destination until a message arrives, gets the parsed message as an object, and can use getter methods to retrieve the message data.

Figure 1. Receiving messages with extended messaging. This figure shows an application calling a receiver bean (as a session bean) to receive messages from the JMS destination defined on an input port. The application also calls the `ReplySender()` method of the receiver bean to send a reply to the original message received. For more information about what is shown in this figure, see the text that accompanies this figure.

When a receiver bean gets a message, it can invoke another method passing either the JMS Message, or a set of parameters extracted from the message content. The invoked method can be contained in the receiver bean or in another enterprise bean (which is the preferred application structure). If data mapping is used, the method invoked by a receiver bean is unaware of the original JMS message.

In addition to receiving messages, extended messaging enables applications to reply to received messages in either of the following ways:

- **Sending a synchronous reply.** In this mode, which can be used by only receiver beans deployed as message-driven beans, the reply from the method invoked by the receiver bean is mapped to a JMS message and sent as a reply to the original message, using the replyTo field in the JMS header as the target destination.
- **Sending an asynchronous reply.** In this mode, which cannot be used receiver beans deployed as message-driven beans, the application calls the ReplySender() method to send the reply message. If the reply is passed as a set of parameters to the ReplySender() method, the reply is mapped to a JMS message before being sent.

If a receiver bean gets a JMS message, then depending upon the programming model (associated with the receiver bean by WebSphere Studio), one of the following interactions occurs:

- **Receive a request and send no reply.**

The receiver bean provides an anonymous invocation in the form of a method call. The data passed to the method is either the JMS message (if no data mapping is invoked) or a set of parameters mapped from the JMS message. The receiver bean cannot return a reply to this invocation. This mode of interaction can be used with point-to-point or publish/subscribe messaging.

- **Receive a request and send a synchronous reply.**

If the receiver bean gets a message, it invokes another method either in the same bean or another enterprise bean. When the method returns, the data returned from that call is mapped to a JMS message and sent to the reply destination specified in the original request message. The type of reply destination (queue or topic) must be the same as the type used by the original request received.

- **Receive a request and send an asynchronous reply.**

For a receiver bean deployed as a message-driven bean, the reply is returned (using the bean's ReplySender method) to the replyTo destination specified in the original request message.

For a receiver bean deployed as a session bean, the reply is returned to the destination defined in the input port for the receiver bean.

In addition to the asynchronous model of this interaction, this mode of interaction enables a method to send multiple replies to a single invocation.

Extended messaging - sending messages

To send messages, applications that use extended messaging call a method on a sender bean. A sender bean turns its method invocation into a JMS message, then passes that message to JMS. If needed, the sender bean can retrieve a response message, then translate that message into a result value and return it to the caller. If data mapping is used, the method that invokes a sender bean is unaware of the original JMS message. The sender bean methods can use data mapping to build JMS messages from data passed on the method call.

Figure 2. Sending messages with extended messaging. This figure shows an application calling a sender bean to send messages to the JMS destination defined on an output port. The application also calls the `receiveResponse()` method of the sender bean to receive a reply to the original message sent. For more information about what is shown in this figure, see the text that accompanies this figure.

A sender bean is an enterprise bean (stateless session bean) that can be built by WebSphere Studio Application Developer. A sender bean should not contain any application logic, to help preserve the separation between the messaging and business logic.

Each method defined on a class that implements a sender bean has one of the following modes of interaction (which is defined when the sender bean is built). The interaction extends the sender interface to address the issue of synchronizing anonymous invocations.

- **Send a request and receive no response.**

To send a JMS message, an application invokes the sender bean's method. The caller of the sender bean's method cannot receive a response to the message sent. This mode of interaction can be used with point-to-point or publish/subscribe messaging.

- **Send a request and receive a synchronous response.**

To send a JMS message and wait for a synchronous response, an application invokes the sender bean's method. The sender bean uses the message sender (an interface to JMS provided by extended messaging) to send the message and, when the response is received, to return the response message to the caller of the sender bean. This mode of interaction can be used with point-to-point messaging only.

- **Send a request and receive a deferred response.**

To send a JMS message and wait for a deferred response, an application invokes the sender bean's method. The sender bean uses the message sender to send the message, then returns to the caller without waiting for the response. The response is returned by a generated `receiveResponse()` method. This mode of interaction enables an application to receive more than one response message, as the application is responsible for retrieving the responses. This mode of interaction can be used with point-to-point messaging only.

Extended messaging - data mapping

A message bean can use data mapping to map between a JMS message and data as arguments:

- With data mapping, the target method of a receiver bean for an anonymous invocation receives the contents of an asynchronous message as arguments. The extended messaging service parses the JMS message and maps from the JMS message to the method arguments. Similarly, to send a message, an application invokes a method on a sender bean with appropriate arguments. The extended messaging service packs appropriate arguments into a JMS message then sends the asynchronous request.
- Without data mapping, the target method of a receiver bean for an anonymous invocation receives a JMS message; no data mapping is performed by extended messaging. Similarly, to send a message, an application invokes a method of a sender bean with a JMS message.

If a developer selects data mapping when creating a sender or receiver bean, extended messaging uses the parameter properties specified on the sender or receiver bean method signatures to perform the data mapping.

Extended messaging - handling late responses

If an application uses a sender bean to send a message, it can optionally retrieve a response to the message. The sender bean can either wait for the response or defer retrieval of the response. Sometimes a response is delayed within the messaging infrastructure, and therefore the application cannot receive the response. Extended messaging can retrieve such a response message (referred to as a late-response message) when it does arrive and pass it to a message-driven bean provided by the application to handle late responses. The message-driven bean used to handle the late response is a standard EJB 2.0 message-driven bean or a receiver bean deployed as a message-driven bean. The deployed message-driven bean can then perform its processing on the message.

Late responses should not be considered normal application behaviour.

For extended messaging to handle late responses for an application, the sender bean must be deployed with the **Handle late responses** option enabled.

Definition of a late response

A late response occurs when the application is no longer able to retrieve responses to messages that it has sent, as follows:

- **Send with deferred response.**

The application (enterprise bean) repeatedly tries to retrieve a response until it ends. When the application no longer wants to retry to get a response, it can register a request for extended messaging to handle the late response, by calling a `registerLateResponse()` method on the sender bean.

- **Send with synchronous response handling.**

When the sender bean sends a message, it waits for the response. The result of this is that either the sender bean retrieves the response message or a timeout error occurs. If the system raises a timeout error, the application can no longer retrieve a response to the message. At this time the extended messaging service registers the the message for a late response.

Handling responses

Extended messaging handles responses in the following stages:

1. Registering an interest in having a late response retrieved when it is available.

To request the system to handle late responses for a sender bean, you deploy the sender bean with the **Handle late responses** extension to the deployment Descriptor.

If selected, the **Handle late responses** option defines that extended messaging should pass the response, when it becomes available, to the message-driven bean provided by the application to handle late responses. When the sender bean is deployed a specialized listener port is associated with the bean. This listener port is known as a handle late response listener port.

If the option is not selected, then the system does not handle late responses, and it is the application's responsibility to handle any late responses.

2. Starting a JMS listener to retrieve the message when it is available, which then drives the message bean to handle the JMS message.

The listener port must be defined with the following properties:

- The same JMS destination as specified as the JMS response destination on the output port used by the sender bean.
- A listener port extension with Handle Late Responses enabled.

You cannot use a temporary destination for late responses.

3. If a request is made to handle a late response, the extended messaging service immediately registers a `LateResponse` message request with the extended message consumer for the given listener port.

The message request is registered independently of any transaction context that the sender bean has. A request record (containing the MessageID of the late response) is added to the AsyncMessageLog log. When the message is eventually received, it is passed to the message-driven bean deployed against the specified late response ListenerPort.

Extended messaging - transactional support

The global transaction context is not flowed on asynchronous (messaging) requests, so the receipt of an asynchronous message cannot be part of some existing remotely-established transaction. Reliability in an asynchronous environment is built on the message provider's ability to guarantee a once-and-once-only message delivery.

Transactional support with extended messaging builds on, and extends, the transactional support provided with bean-managed messaging, as follows:

- Transactional support for receiving messages
- Transactional support for sending messages

Transactional support for receiving messages (receiver beans)

The extended messaging transactional behaviour for receiver beans depends upon whether the bean is a receiver bean or an application-callable receiver bean.

- For a receiver bean (deployed as a message-driven bean), incoming message receipts are defined by the Transaction attribute of the onMessage() bean method. Message-driven beans can use bean-managed transactions (BMT) or container-managed transactions (CMT). For message-driven beans using CMT there are only two supported transaction options: Not supported and Required. If a message is to be received within a transaction, the message-driven bean must be using CMT with the Transaction attribute set to Required.
- For a receiver bean as a session bean, the bean only supports container-managed transactions, and the behaviour is defined by the Transaction attribute of the receiver bean method.

Dealing with retries

Note: In the asynchronous environment of transaction processing, rolling back a message receipt means that the message is not removed from the source destination. Although this behaviour is desirable and correct, it causes the message retained on the source queue to be reprocessed until the transaction commits. For receiver beans, you can control this behaviour as follows:

- **Receiver bean.**

To limit the number of times that a transaction is retried, you can either rely on the facilities of the JMS provider or use the retry limit facility of the Message Listener:

- WebSphere MQ JMS support provides the ability to move the message to a backout queue and uses two queue attributes, the backout threshold and the backout-requeue queue, to perform this.
- The Message Listener retry count can be used to stop the listener processing the queue if the threshold is reached. The listener behaviour can be disabled by setting the retry count value higher than the JMS provider threshold value.

- **Application-callable receiver bean.**

To limit the number of times that a transaction is retried depends on the facilities of the JMS provider to move the message to a backout queue.

Transactional support for sending messages (sender beans)

The transactional behaviour for sending messages is defined by the Transaction attribute on the send method within the sender bean.

If the `send()` method is part of a transaction, then the sending of an outgoing message occurs within any currently active transaction. This means that the message is not transmitted until the transaction is committed. If no transaction is active when the request to send the message occurs, then the message is transmitted immediately.

The transactional behaviour where the mode of interaction for a sender bean method specifies a response (that is, either *Send message and receive synchronous response* or *Send message and receive deferred response*) depends upon the type of response, as follows:

Transactional behaviour for a synchronous response

The sending of the request message and the receipt of the response message cannot be performed inside a transaction, because they are both performed within the same method. Therefore, the `send` is always non-transactional, regardless of the transactional setting for the method. The `receive` is either transactional or not, depending upon the Transaction setting of the method.

Transactional behaviour for a deferred response

The response message is received by a `receiveResponse()` method, which can have a different transactional behaviour to the sender method inside the sender bean. The transaction containing the `send` command must commit before the response can be received. The transactional behaviour is specified on the `send` and `receive` methods of the Sender bean.

Extended messaging - exception handling

Extended messaging provides the following exception handling for receiver beans and sender beans:

- Error handling for receiver beans
- Error handling for sender beans

Error handling for receiver beans

The following error conditions can lead to extended messaging exceptions

- Formatting error parsing the message, when performing data mapping
- Exception thrown by the application method
- `CMMException` when sending the reply

Errors are always logged. If the application does not catch the exception, the default behavior is to roll back any active transaction. If the received message is rolled back, then it can be processed again. This can occur a number of times until the message causing the error is removed from the queue by the JMS provider. (For more information, see *Dealing with retries* in Transactional support with extended messaging.)

With data mapping, if a receiver bean is deployed as a message-driven bean and a `replyTo` destination is configured, then error messages are sent as replies to that destination.

Application enterprise beans that call receiver beans deployed as session beans need to handle the `CMMException` exception. `CMMException` is an application exception which is declared in the `throws` clause of the methods in the generated receiver bean.

Error handling for sender beans

The following error conditions can lead to extended messaging exceptions

- Constructing the JMS message when data mapping from the parameters to the message
- Creating a message sender and sending the message
- Getting the response and parsing the message content

Errors are always logged. If the application does not catch the exception, the default behavior is to roll back any active transaction.

Application enterprise beans that call sender beans need to handle the `CMMException` exception, which is declared in the `throws` clause of the methods in the generated sender bean.

Extended messaging - application usage scenarios

Applications can use extended messaging to receive and send messages in a variety of ways:

- To receive messages, applications that use extended messaging use a receiver bean (deployed as a message-driven bean) or an application-callable receiver bean (deployed as a session bean):
 - A receiver bean is invoked when a message arrives at a destination for which a listener is active.
 - An application-callable receiver bean polls a destination (defined by an input port) until a message arrives or a timeout occurs.

In addition to receiving messages, extended messaging enables applications to send replies in response to the received messages.

For more conceptual information about receiving messages, see [Receiving messages with extended messaging](#).

- To send messages, applications that use extended messaging call sender bean methods. The sender bean sends messages to the target destination defined by an output port. The sender bean methods can be passed either a JMS message or a number of parameters that are mapped by extended messaging into a JMS message. Whether or not data mapping is used is specified when the application is developed.

In addition to sending messages, applications can choose to receive a response to the message, and can handle any responses either synchronously or asynchronously. If a response is not received in time, then the system can handle the late response by directing the message to a message-driven bean.

For more conceptual information about sending messages, see [Sending messages with extended messaging](#).

- Applications can combine receiving and sending messages in a variety of different ways. For example, a receiver bean deployed as a message-driven bean can forward the message by calling a sender bean. The receiver bean can give message data to sender bean in either of the following ways:
 - The receiver bean can pass the JMS message to the sender bean, which forwards that message.
 - The receiver bean can extract data from the initial message and send that data to the sender bean. The sender bean can then map the data values to a new JMS message, which it forwards.

The application can receive a response to the message that it sent, and then can send the message received or a new message built from data in the message received, as a response to the original message.

Also, data mapping can be used to hide the JMS message structure from the application logic. For more information about data mapping, see [Extended messaging - data mapping](#)

Extended messaging - components

Extended messaging builds on the base support for JMS messaging and message-driven beans provided by WebSphere Application Server. The new messaging components for extended messaging are referred to as the Message Bean package.

Components for receiving messages

The following components, shown in the figure [Components for receiving messages](#), are used to receive messages:

Receiver bean

An application that uses extended messaging can receive messages by using a receiver bean (using the `onMessage()` method of a message-driven bean) or an application-callable receiver bean (a stateless session bean that polls for a message from a named destination). Both receiver beans and application-callable receiver beans can receive and process asynchronous messages, and optionally return selected data as a response message.

Input port

An input port specifies the properties needed by receiver beans as session beans, by defining the following information:

- Information about the source destination for the message to be received
- Information about how to select and handle the message received
- Optional information about a reply destination, which is used if a reply is expected and replyTo information is not present in the JMSHeader of the message received.

A receiver bean as a deployed message-driven bean uses the associated listener port, so does not need an input port. For more information about message-driven beans and listener ports, see Message-driven beans - components.

For more conceptual information about receiving messages, see Receiving messages with extended messaging.

Figure 3. Components for receiving messages. This figure shows an application calling a receiver bean (as a session bean) to receive messages from the JMS destination defined on an input port. The application also calls the ReplySender() method of the receiver bean to send a reply to the original message received. For more information about what is shown in this figure, see the text that accompanies this figure.

Components for sending messages

The following components, shown in the figure Components for sending messages, are used to send messages:

Sender bean

Bean instances of a sender bean (also known as a message sender bean) can send asynchronous messages. The sender bean methods can be passed either a JMS message or a number of parameters that are mapped by extended messaging into a JMS message, which is then passed to JMS.

Output port

An output port specifies the properties needed by sender beans, to define the destination for the message being sent, and other optional properties if a response is expected. It is associated with the Sender Bean at deployment time and contains the following information:

- Information about the target destination for the message to be sent
- Information about how to select and handle the message to be sent
- Information about the destination used for the response.

For more conceptual information about sending messages, see [Sending messages with extended messaging](#).

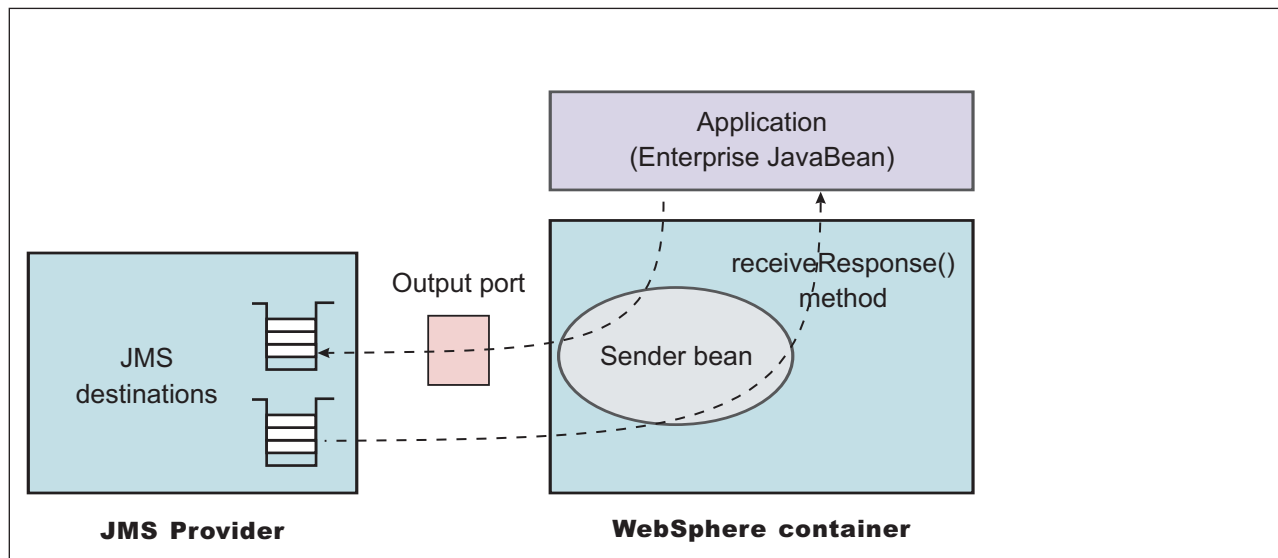

Figure 4. Components for sending messages. This figure shows an application calling a sender bean to send messages to the JMS destination defined on an output port. The application also calls the `receiveResponse()` method of the sender bean to receive a reply to the original message sent. For more information about what is shown in this figure, see the text that accompanies this figure.

Designing an enterprise application to use extended messaging

This topic describes things to consider when designing an enterprise application to use extended messaging.

The design of JMS-usage for applications that use extended messaging is the same as the design for JMS and message-driven beans, except that the JMS-usage is simplified because JMS support is managed by the extended messaging service. For design considerations related to JMS and message-driven beans, see the following topics:

-
-

The extra design consideration for applications that use extended messaging are as follows. For more detail, see the related topics.

1. For a receiver bean, decide whether to use a message-driven bean or stateless session bean.

Message-driven bean

You can use a deployed message-driven bean as a receiver bean, to automatically handle messages received at the associated listener port. As with any message-driven bean, when a message is received on the JMS destination monitored by the listener port, the message is passed to the `onMessage()` method of the message-driven bean.

You need to develop and deploy the message-driven bean, and configure its associated listener port, separately from the extended messaging tasks.

Stateless session bean

You can use a stateless session bean as a receiver bean, to poll for messages on a named destination associated with an input port.

You need to develop and deploy the session bean separately from the extended messaging tasks, but configure the associated input port as part of the extended messaging tasks.

2. Decide whether or not you want to use data mapping. If you call the methods of sender and receiver beans with data arguments, you need to use data mapping to construct the JMS messages needed. For data mapping, you need to decide what data arguments need to be specified as properties on the sender or receiver bean method signatures.

For a receiver bean deployed as a message-driven bean, you can define the mapping behavior if a data exception is caught by extended messaging. That is, you define whether a message should be flowed back if a ReplyTo destination is defined in the JMS message header.

3. Decide whether or not you want to handle late responses.

A sender bean can optionally retrieve a response to messages sent. If a response is delayed within the messaging infrastructure, the bean cannot receive the response. Extended messaging can retrieve such a response message (referred to as a late-response message) when it does arrive and pass it to a message-driven bean provided by the application to handle late responses. To handle late responses, you need to develop and deploy a standard EJB 2.0 message-driven bean that contains a registerLateResponse() method, and associate it with a listener port to be used to receive late responses.

Developing an enterprise application to use extended messaging

This topic describes how to develop an enterprise application to use extended messaging.

This task description assumes that developers are using the WebSphere Studio Application Developer to develop the application code (receiver and sender beans).

To develop an enterprise application to use extended messaging, complete the following steps:

1. Creating the Enterprise Application project. Because the sender and receiver beans used for extended messaging are EJB 2.0 enterprise beans, you must first have created a J2EE 1.3 Enterprise Application project for which extended messaging beans will be created.
 - a. Ensure that you have selected 1.3 as the highest J2EE version that is to be used in WebSphere Studio. For example: **Window-> Preferences... J2EE preferences-> Select the highest J2EE version that is to be used-> 1.3**
 - b. Create a J2EE 1.3 Enterprise Application project, as described in the WebSphere Studio article "Creating an Enterprise Application project."

2. Creating the application code.

To create the application code, use WebSphere Studio to generate the sender and receiver beans needed by the application, by completing one or more of the following subtasks as described in the WebSphere Studio Extended Messaging documentation:

- "Creating a sender bean"
- "Creating a receiver bean"
- "Creating an application-callable receiver bean"
- "Creating a sender bean and receiver bean"
- "Creating a sender bean and application-callable receiver bean"

The result of this stage is an enterprise bean, containing code automatically generated for extended messaging, that can be assembled into an .EAR file for deployment.

3. Assembling and packaging the application for deployment.

You can use WebSphere Studio to assemble and package the application for deployment.

The following aspects are specific to extended messaging:

- a. Configure a message selector for a receiver bean.
- b. Associate the JNDI names for sender and receiver beans with output and input ports.
- c. Specify the timeout for a sender bean response.
- d. Configure that a sender bean is to handle late responses and identify the listener port to be used for late responses.

The result of this task is an .EAR file, containing an application enterprise bean with code for extended messaging, that can be deployed in WebSphere Application Server.

For information about deploying an application to use extended messaging, see [Deploying an enterprise application to use extended messaging](#)

Deploying an enterprise application to use extended messaging

This topic describes how to deploy an enterprise application to use extended messaging.

This task description assumes that you have an .EAR file, which contains an application enterprise bean with code for extended messaging, that can be deployed in WebSphere Application Server.

The Application Install task is also a standard WebSphere Application Server task. As part of the install procedure you need to associate the Input and Output ports defined in System Management with the installed .EAR.

To deploy an enterprise application to use extended messaging, complete the following steps:

1. Use the administrative console to define and configure the extended messaging resources to be used by the application, as described in [Configuring extended messaging service resources](#). You should define the input ports for receiver beans, the output ports for sender beans, and listener port extensions for any sender beans that are to handle late responses.
2. Ensure that the deployment descriptor attributes for the sender and receiver beans match those of the extended messaging resources that you configured using the administrative console. The deployment descriptor values can be set when you generate the deployment code for the application, using WebSphere Studio Application Developer.
 - **5.1+** You can change the deployment descriptor values by using the Assembly Toolkit, as described in the following topics:
 - [Configuring deployment attributes for a receiver bean](#)
 - [Configuring deployment attributes for a sender bean](#).
3. If a sender bean is to handle late responses, deploy the message-driven bean to be used for late responses. For more information about deploying message-driven beans, see [Deploying an enterprise application to use message-driven beans](#).
4. Install the application into WebSphere Application Server.

This stage is a standard WebSphere Application Server task, as described in [Installing a new application](#).

When you install the application, you are prompted to specify the name of the listener port that the application is to use for late responses. Select the listener port, then click **OK**.

Configuring deployment attributes for a receiver bean

Use this task to configure the deployment attributes for a receiver bean for use with the extended messaging service.

You can specify these deployment attributes on each EJB method, as part of the deployment of the receiver bean. Changes to the deployment attributes override the values defined when the receiver bean was developed and deployment code was generated for the application.

You can configure the deployment attributes of an application by using the Deployment Descriptor Editor of WebSphere Studio Application Developer or the Assembly Toolkit.

This task description assumes that you have an EAR file for an application component, that can be deployed in WebSphere Application Server. For more details about using the Assembly Toolkit, see [Assembling applications with the Assembly Toolkit](#).

To configure the deployment attributes for a receiver bean, you can use the Assembly Toolkit to complete the following steps:

1. Start the Assembly Toolkit.
2. Create or edit the application EAR file. For example, to change attributes of an existing application, use the import wizard to import the EAR file into the Assembly Toolkit. To start the import wizard:
 - a. Click **File-> Import-> EAR file**
 - b. Click **Next**, then select the EAR file.
 - c. Click **Finish**
3. In the J2EE Hierarchy view, right-click the component instance, then click **Open With > Deployment Descriptor Editor**. A property dialog notebook for the component is displayed in the property pane.
4. In the property pane, click the Extended Messaging tab.
5. Specify appropriate deployment attributes: For example:
 - Method policies**
Add or remove method policies. To add a new method policy, complete the **Method policy name** and **Method policy description** fields, then click **Add**. To remove a method policy, select its name in the list displayed, then click **Remove**.
 - Input port**
For an application-callable receiver bean, this is the name of the input port to be used to receive messages.
 - Message selector**
For an application-callable receiver bean, this is a string used to select messages to be received.
6. Save your changes to the deployment descriptor.
 - a. Close the deployment descriptor editor.
 - b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.
7. Verify the archive files.
8. Generate code for deployment for EJB modules or for enterprise applications that use EJB modules.
9. Optional: Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard. Note that **Run on Server** works on the Windows, Linux/Intel, and AIX operating systems only; you cannot deploy remotely from the Assembly Toolkit to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

Important

Important: Use **Run On Server** for unit testing only. The Assembly Toolkit controls the WebSphere Application Server installation and, when an application is published remotely, the Toolkit overwrites the server configuration file for that server. Do not use on production servers. For instructions on remote testing, see the article “Setting Up a Remote WebSphere Application Server in WebSphere Studio V5” at http://www7b.boulder.ibm.com/wsdd/techjournal/0303_yuen/yuen.html.

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that is to run the application; for example, using the administrative console as described in Deploying and managing applications.

Configuring deployment attributes for a sender bean

Use this task to configure the deployment attributes for a sender bean.

You can specify deployment attributes on each EJB method.

Changes to the deployment attributes override the values defined when the sender bean was developed and deployment code was generated for the application.

You can configure the deployment attributes of an application by using the Deployment Descriptor Editor of WebSphere Studio Application Developer or the Assembly Toolkit.

This task description assumes that you have an EAR file for an application component, that can be deployed in WebSphere Application Server. For more details about using the Assembly Toolkit, see *Assembling applications with the Assembly Toolkit*.

To change the deployment attributes for a sender bean, you can use the Assembly Toolkit to complete the following steps:

1. Start the Assembly Toolkit.
2. Create or edit the application EAR file. For example, to change attributes of an existing application, use the import wizard to import the EAR file into the Assembly Toolkit. To start the import wizard:
 - a. Click **File-> Import-> EAR file**
 - b. Click **Next**, then select the EAR file.
 - c. Click **Finish**
3. In the J2EE Hierarchy view, right-click the component instance, then click **Open With > Deployment Descriptor Editor**. For example, expand **EJB Modules-> ejb_module_instance-> Session Beans** then select the bean instance. A property dialog notebook for the component is displayed in the property pane.
4. In the property pane, click the Extended Messaging tab.
5. In the property pane, specify appropriate deployment attributes:
 - Output port**
This is the name of the output port to be used to send messages.
 - Enable handle late responses**
Select this checkbox if the sender bean is to handle late responses. If you select this checkbox, also specify the following properties: **ReplyTimeout** and **Late response handler listener port name**.
 - Late response handler listener port name**
For a sender bean that has been developed to handle late responses, this is the name of the listener port to be used for late responses.
 - Reply Timeout**
For a sender bean that has been developed to handle late responses, this is the time after which responses are considered late. This property is used if a response timeout is not specified on a sender method call.
6. Save your changes to the deployment descriptor.
 - a. Close the deployment descriptor editor.
 - b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.
7. Verify the archive files.
8. Generate code for deployment for EJB modules or for enterprise applications that use EJB modules.
9. Optional: Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard. Note that **Run on Server** works on the Windows, Linux/Intel, and AIX operating systems only; you cannot deploy remotely from the Assembly Toolkit to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

Important

Important: Use **Run On Server** for unit testing only. Assembly Server Toolkit controls the WebSphere Application Server installation and, when an application is published remotely, the Toolkit overwrites the server configuration file for that server. Do not use on production servers.

For instructions on remote testing, see the article "Setting Up a Remote WebSphere Application Server in WebSphere Studio V5" at http://www7b.boulder.ibm.com/wsdd/techjournal/0303_yuen/yuen.html.

Configuring extended messaging service resources

Use these tasks with the WebSphere Administrative console to configure resources needed by the extended messaging service and applications that use extended messaging.

You can use WebSphere Application Server system management to configure resources needed by the extended messaging service and applications that use extended messaging.

For more information about the tasks involved, see the following topics:

- Adding a new input port
- Adding a new output port
- Configuring an input port
- Configuring an output port
- Configuring a listener port to handle late responses

Adding a new input port

Use this task to add a new input port to WebSphere Application Server.

An input port is for use by an application that uses extended messaging.

During this task you configure the initial properties of the input port. You can later change the properties of the port, as described in [Configuring an input port](#).

To add a new input port, complete the following steps:

1. Start the WebSphere Administrative console.
2. In the navigation pane, select **Resources-> Extended messaging provider** This displays resources for extended messaging in the content pane.
3. In the Additional Properties table of the content pane, select **Input ports** This displays a list of the input ports in the content pane.
4. Click **New**.
5. Specify appropriate properties of the input port.
6. Click **OK**.
7. To save your configuration, click **Save** on the task bar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

Adding a new output port

Use this task to add a new output port to WebSphere Application Server, and configure its properties, for use by an application that uses extended messaging.

During this task you configure the initial properties of the output port. You can later change the properties of the port, as described in [Configuring an output port](#).

To add a new output port, complete the following steps:

1. Start the WebSphere Administrative console.
2. In the navigation pane, select **Resources-> Extended messaging provider** This displays resources for extended messaging in the content pane.
3. In the Additional Properties table of the content pane, select **Output ports** This displays a list of the output ports in the content pane.
4. Click **New**.
5. Specify appropriate properties of the output port.
6. Click **OK**.

7. To save your configuration, click **Save** on the task bar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

Configuring an input port

Use this task to change the properties of an input port for use by an application that uses extended messaging.

To change the properties of an input port, complete the following steps:

1. Start the WebSphere Administrative console.
2. In the navigation pane, select **Resources-> Extended messaging provider** This displays resources for extended messaging in the content pane.
3. In the Additional Properties table of the content pane, select **Input ports** This displays a list of the input ports in the content pane.
4. Select the input port that you want to change.
5. Specify appropriate properties of the input port.
6. Click **OK**.
7. To save your configuration, click **Save** on the task bar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

Configuring an output port

Use this task to change the properties of an output port for use by an application that uses extended messaging.

To change the properties of an output port, complete the following steps:

1. Start the WebSphere Administrative console.
2. In the navigation pane, select **Resources-> Extended messaging provider** This displays resources for extended messaging in the content pane.
3. In the Additional Properties table of the content pane, select **Output ports** This displays a list of the output ports in the content pane.
4. Select the output port that you want to change.
5. Specify appropriate properties of the output port.
6. Click **OK**.
7. To save your configuration, click **Save** on the task bar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

Extended messaging service settings

Use this page to enable or disable the extended messaging service.

The Extended Messaging Service provides run-time service for the support of extended messaging.

To view this administrative console page, click **Servers > Application Servers > *server_name* > Extended Messaging Service** .

Startup

Specifies whether the server will attempt to start the extended messaging service.

Default

Selected

Range**Selected**

When the application server starts, it attempts to start the extended messaging service automatically.

Cleared

The server does not try to start the extended messaging service. If extended messaging is to be used in applications that run on this server, the system administrator must start the extended messaging service manually or select this property then restart the server.

Late response handling extension collection

Use this page to view the configuration properties of late response handling extensions.

Late response handling extensions enable the handling of late responses with extended messaging

To view this administrative console page, click **Application Servers > server_name > Extended Messaging Service > Listener Port Extensions** .

Enabled:

Specifies whether the handling of late responses is enabled.

Range**Selected**

Handling of late responses is enabled.

Cleared

Handling of late responses is not enabled.

Request Interval:

Specifies the interval that elapses between checking for late responses.

Data type

Integer

Units

milliseconds

Default

5

Range

An integer number of milliseconds, greater than or equal to 0:

- 0 indicates that the late response handler continually checks for requests
- Other values are an integer number of milliseconds between checks for requests.

Request Timeout:

Specifies the duration of time after which to give up waiting for a response.

Data type

Integer

Units

seconds

Default

0

Range

An integer number of milliseconds, greater than or equal to -1:

- -1 indicates that requests to handle late responses are never discarded.
- Other values are an integer number of milliseconds after which requests are discarded.

Listener Ports:

Specifies the name of the listener port to be used to handle late responses.

Late response handling extension settings:

Use this page to configure late response handling extensions.

To view this administrative console page, click **Application Servers** > *server_name* > **Extended Messaging Service** > **Listener Port Extensions** > *extension_name* .

Enabled:

Specifies whether the handling of late responses is enabled.

Range

Selected

Handling of late responses is enabled.

Cleared

Handling of late responses is not enabled.

Request Interval:

Specifies the interval that elapses between checking for late responses.

Data type

Integer

Units

milliseconds

Default

5

Range

An integer number of milliseconds, greater than or equal to -1:

- -1 indicates that requests to handle late responses are never discarded.
- Other values are an integer number of milliseconds after which requests are discarded.

Request Timeout:

Specifies the duration of time after which to give up waiting for a response.

Data type

Integer

Units

seconds

Default

0

Range

An integer number of milliseconds, greater than or equal to -1:

- -1 indicates that requests to handle late responses are never discarded.
- Other values are an integer number of milliseconds after which requests are discarded.

Listener Ports:

Specifies the name of the listener port to be used to handle late responses.

Extended messaging provider settings

Use this page to manage extended messaging providers.

The extended messaging provider manages resources defined for use with extended messaging.

To view this administrative console page, click **Resources > Extended Messaging Providers** .

Name

The name of the resource provider.

Data type	String
Range	1 through 30 ASCII characters

Description

An optional description for the resource factory.

Data type	String
------------------	--------

Input port collection

Use this page to view the configuration properties of input ports..

An input port specifies the properties needed by receiver beans as session beans. Receiver beans as message-driven beans do not need an input port, because the properties needed are associated with the deployed message-driven bean and the Message Listener service.

To view this administrative console page, click **Resources > Extended Messaging Providers > Input Port** .

Name:

The name by which the input port is known for administrative purposes.

Data type	String
Units	En_US ASCII characters

JNDI Name:

The JNDI name for the resource.

Data type	String
------------------	--------

Description:

A description of the input port, for administrative purposes.

Data type	String
------------------	--------

Category:

A string that can be used to classify or group the resource.

Data type	String
Range	1 through 30 ASCII characters

JMS Connection Factory JNDI Name:

The JNDI name for the JMS connection factory to be used by the input port; for example, jms/connFactory1.

Data type String

JMS Destination JNDI Name:

The JNDI name for the destination to be used by the input port; for example, jms/destn1.

Data type String

JMS Acknowledgement Mode:

JMS acknowledgment mode to be used for acknowledging messages.

This property applies only to message-driven beans that use bean-managed transaction demarcation (**Transaction type** is set to Bean).

Default Range

Auto Acknowledge

Auto Acknowledge

The session automatically acknowledges a message in either of the following cases:

- When the session has successfully returned from a call to receive a message.
- When the session has called a message listener to process the message and received a successful response from that listener.

Dups OK Acknowledge

The session acknowledges only the delivery of messages. This is likely to result in the delivery of some duplicate messages if JMS fails, so it should be used only by consumers that are tolerant of duplicate messages.

Destination Type:

The type of the JMS resource.

Default Range

Queue

Queue The receiver bean receives messages from a queue destination.

Topic The receiver bean receives messages from a topic destination.

Subscription durability:

[Topic destinations only.] Specifies whether a JMS topic subscription is durable or non-durable.

Default Durable

Range**Durable**

A subscriber registers a durable subscription with a unique identity that is retained by JMS. Subsequent subscriber objects with the same identity resume the subscription in the state it was left in by the earlier subscriber. If there is no active subscriber for a durable subscription, JMS retains the subscription's messages until they are received by the subscription or until they expire.

Nondurable

Nondurable subscriptions last for the lifetime of their subscriber object. This means that a client sees the messages published on a topic only while its subscriber is active. If the subscriber is not active, the client is missing messages published on its topic.

Reply JMS Connection Factory JNDI Name:

JNDI name of the JMS Connection Factory to be used for replies.

Data type String

Reply JMS Destination JNDI Name:

JNDI name of the JMS Destination to be used for replies.

Data type String

Input port settings:

Use this page to configure an input port.

To view this administrative console page, click **Resources > Extended Messaging Providers > Input Port > *inputport_name*** .

Name:

The name by which the input port is known for administrative purposes.

Data type String
Units En_US ASCII characters

JNDI Name:

The JNDI name for the resource.

Data type String

Description:

A description of the input port, for administrative purposes.

Data type String

Category:

A string that can be used to classify or group the resource.

Data type String
Range 1 through 30 ASCII characters

JMS Connection Factory JNDI Name:

The JNDI name for the JMS connection factory to be used by the input port; for example, jms/connFactory1.

Data type String

JMS Destination JNDI Name:

The JNDI name for the destination to be used by the input port; for example, jms/destn1.

Data type String

JMS Acknowledgement Mode:

JMS acknowledgment mode to be used for acknowledging messages.

This property applies only to message-driven beans that use bean-managed transaction demarcation (**Transaction type** is set to Bean).

Default Auto Acknowledge
Range **Auto Acknowledge**
The session automatically acknowledges a message in either of the following cases:

- When the session has successfully returned from a call to receive a message.
- When the session has called a message listener to process the message and received a successful response from that listener.

Dups OK Acknowledge
The session acknowledges only the delivery of messages. This is likely to result in the delivery of some duplicate messages if JMS fails, so it should be used only by consumers that are tolerant of duplicate messages.

Destination Type:

The type of the JMS resource.

Default Queue
Range **Queue** The receiver bean receives messages from a queue destination.
Topic The receiver bean receives messages from a topic destination.

Subscription durability:

[Topic destinations only.] Specifies whether a JMS topic subscription is durable or non-durable.

**Default
Range**

Durable
Durable

A subscriber registers a durable subscription with a unique identity that is retained by JMS. Subsequent subscriber objects with the same identity resume the subscription in the state it was left in by the earlier subscriber. If there is no active subscriber for a durable subscription, JMS retains the subscription's messages until they are received by the subscription or until they expire.

Nondurable

Nondurable subscriptions last for the lifetime of their subscriber object. This means that a client sees the messages published on a topic only while its subscriber is active. If the subscriber is not active, the client is missing messages published on its topic.

Reply JMS Connection Factory JNDI Name:

JNDI name of the JMS Connection Factory to be used for replies.

Data type String

Reply JMS Destination JNDI Name:

JNDI name of the JMS Destination to be used for replies.

Data type String

Output port collection

Use this page to view the configuration properties of output ports.

The Output port defines the parameters required by the extended messaging sender bean. These properties define the destination for the message being sent, together with optional details if a response is expected.

To view this administrative console page, click **Resources > Extended Messaging Providers > Output Port** .

Name:

The name by which the output port is known for administrative purposes.

Data type String

JNDI Name:

The JNDI name for the output port.

Data type String

Description:

A description of the output port, for administrative purposes.

Data type String

Category:

A string that can be used to classify or group the resource.

Data type String

JMS Connection factory JNDI name:

The JNDI name for the JMS connection factory to be used by the output port; for example, jms/connFactory1.

Data type String
Units En_US ASCII characters
Range 1 through 30 ASCII characters

JMS Destination JNDI name:

The JNDI name for the destination to be used by the output port; for example, jms/destn1.

Data type String

JMS Delivery Mode:

Specifies whether all messages sent to the destination are persistent or non-persistent.

Default Persistent
Range **Persistent**
Messages put onto the destination are persistent.
Nonpersistent
Messages put onto the destination are not persistent.

JMS Priority:

The message priority for this queue destination.

Data type Integer
Default 4
Range 0 to 9.

JMS Time To Live:

The time in milliseconds after which messages on this queue expire.

Data type Integer
Units Milliseconds
Default 0

Range	0 to <i>n</i>
	0 messages never time out.
	<i>n</i> messages time out in <i>n</i> milliseconds.

JMS Disable Message I.D.:

Specifies that the system should not generate a JMS message ID.

Default	Cleared
Range	Selected The system does not generate message IDs.
	Cleared The system generates message IDs automatically.

JMS Disabled Message Time Stamp:

Specifies that the system should not generate a JMS message timestamp.

Default	Cleared
Range	Selected Message time stamps are added automatically to messages sent.
	Cleared Message time stamps are not added automatically to messages sent.

Response JMS Connection Factory JNDI name:

The JNDI name for the JMS connection factory to be used for response messages handled by the output port; for example, `jms/connFactory1`.

Data type	String
Units	En_US ASCII characters
Range	1 through 30 ASCII characters

Response JMS Destination JNDI name:

The JNDI name for the destination to be used for response messages handled by the output port; for example, `jms/destn1`.

Data type	String
------------------	--------

Output port settings:

Use this page to configure an output port.

An output port specifies the properties needed by sender beans to define the destination for the message being sent, and other optional properties if a response is expected. The output port is associated with the sender bean at deployment time.

To view this administrative console page, click **Resources > Extended Messaging Providers > Output Port > `outputport_name`** .

Name:

The name by which the output port is known for administrative purposes.

Data type String

JNDI Name:

The JNDI name for the output port.

Data type String

Description:

A description of the output port, for administrative purposes.

Data type String

Category:

A string that can be used to classify or group the resource.

Data type String

JMS Connection factory JNDI name:

The JNDI name for the JMS connection factory to be used by the output port; for example, jms/connFactory1.

Data type String
Units En_US ASCII characters
Range 1 through 30 ASCII characters

JMS Destination JNDI name:

The JNDI name for the destination to be used by the output port; for example, jms/destn1.

Data type String

JMS Delivery Mode:

Specifies whether all messages sent to the destination are persistent or non-persistent.

Default Persistent
Range **Persistent**
Messages put onto the destination are persistent.
Nonpersistent
Messages put onto the destination are not persistent.

JMS Priority:

The message priority for this queue destination.

Data type	Integer
Default	4
Range	0 to 9.

JMS Time To Live:

The time in milliseconds after which messages on this queue expire.

Data type	Integer
Units	Milliseconds
Default	0
Range	0 to <i>n</i> 0 messages never time out. <i>n</i> messages time out in <i>n</i> milliseconds.

JMS Disable Message I.D.:

Specifies that the system should not generate a JMS message ID.

Default	Cleared
Range	Selected The system does not generate message IDs. Cleared The system generates message IDs automatically.

JMS Disabled Message Time Stamp:

Specifies that the system should not generate a JMS message timestamp.

Default	Cleared
Range	Selected Message time stamps are added automatically to messages sent. Cleared Message time stamps are not added automatically to messages sent.

Response JMS Connection Factory JNDI name:

The JNDI name for the JMS connection factory to be used for response messages handled by the output port; for example, jms/connFactory1.

Data type	String
Units	En_US ASCII characters
Range	1 through 30 ASCII characters

Response JMS Destination JNDI name:

The JNDI name for the destination to be used for response messages handled by the output port; for example, jms/destn1.

Data type	String
------------------	--------

Troubleshooting extended messaging

Use this overview task to help resolve a problem that you think is related to the extended messaging service.

The extended messaging service uses the standard WebSphere Application Server RAS facilities. If you encounter a problem that you think might be related to the extended messaging service, complete the following stages:

1. Check for extended messaging service messages in the application server's SystemOut log at `was_home\logs\server_name\SystemOut`. Any error messages associated with the extended messaging service are labelled with EMSG. The error message indicates the nature of the problem and provides some detail. The extended messaging service issues EMSG error messages if it fails to initialize, parse its configuration file, or encounters some runtime error.
2. Check for more messages in the application server's SystemOut log. If the JMS server is running, but you have problems accessing JMS resources, check the SystemOut log file, which should contain more error messages and extra details about the problem.
3. Check the Release Notes for specific problems and workarounds. The section *Possible Problems and Suggested Fixes* of the Release Notes, available from the WebSphere Application Server library web site, is updated regularly to contain information about known defects and their workarounds. Check the latest version of the Release Notes for any information about your problem. If the Release Notes does not contain any information about your problem, you can also search the Technotes database on the WebSphere Application Server web site.
4. Check for problems with the WebSphere Messaging functions or message-driven beans. For more information about troubleshooting WebSphere Messaging, see the related topics listed at the bottom of this file.
5. Get a detailed exception dump for extended messaging. If the information obtained in the preceding steps is still inconclusive, you can enable the application server debug trace for the "Messaging" group to provide a detailed exception dump.

Extended Messaging: Resources for learning

Use the following links to find relevant supplemental information about Extended Messaging. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Chapter 6. Using asynchronous messaging

Use these topics to use asynchronous messaging with WebSphere Application Server, to enable enterprise applications to use JMS resources, message-driven beans, and extended messaging.

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface.

The base JMS support enables WebSphere enterprise applications to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics). An enterprise application can explicitly poll for messages on a destination.

WebSphere Application Server also provides a message listener service that enterprise applications can use to automatically retrieve messages from JMS destinations for processing by message-driven beans, without the application having to explicitly poll JMS destinations.

5.1 + With WBI Server Foundation, enterprise applications can use another level of functionality for asynchronous messaging, called extended messaging. The application server manages the messaging infrastructure, and extra standard types of messaging beans are provided to add functionality to that provided by message-driven beans. This level of functionality enables application developers to concentrate on the business logic to be implemented by the enterprise beans and to leave the messaging usage to standard messaging objects and configuration of the extended messaging service.

You can use the WebSphere administrative console to administer the WebSphere Application Server support for asynchronous messaging. For example, you can configure JMS providers and their resources, and can control the activity of the JMS server and the messaging services.

For more information about implementing WebSphere enterprise applications that use asynchronous messaging, see the following topics:

- An overview of WebSphere asynchronous messaging
- Implementing WebSphere enterprise applications that use JMS
- Implementing WebSphere enterprise applications that use message-driven beans
- Implementing WebSphere enterprise applications that use extended messaging

For more information about JMS, see the JMS documentation at <http://java.sun.com/products/jms/docs.html>.

Asynchronous messaging with WebSphere - an overview

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface.

The base JMS support enables WebSphere J2EE applications to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics). An J2EE application can explicitly poll for messages on a destination.

WebSphere Application Server also provides a message listener service that J2EE applications can use to automatically retrieve messages from JMS destinations for processing by message-driven beans, without the application having to explicitly poll JMS destinations.

5.1 + With WBI Server Foundation, J2EE applications can use another level of functionality for asynchronous messaging, called extended messaging. The application server manages the messaging infrastructure, and extra standard types of messaging beans are provided to add functionality to that provided by message-driven beans. This level of functionality enables application developers to

concentrate on the business logic to be implemented by the enterprise beans and to leave the messaging usage to standard messaging objects and configuration of the extended messaging service.

You can use the WebSphere administrative console to administer the WebSphere Application Server support for asynchronous messaging. For example, you can configure JMS providers and their resources, and can control the activity of the JMS server and the messaging services.

Styles of messaging in applications

Applications can use the following styles of asynchronous messaging:

Point-to-Point

Point-to-point applications use queues to pass messages between each other. The applications are called point-to-point, because a client sends a message to a specific queue and the message is picked up and processed by a server listening to that queue. It is common for a client to have all its messages delivered to one queue. Like any generic mailbox, a queue can contain a mixture of messages of different types.

Publish/subscribe

Publish/subscribe systems provide named collection points for messages, called topics. To send messages, applications publish messages to topics. To receive messages, applications subscribe to topics; when a message is published to a topic, it is automatically sent to all the applications that are subscribers of that topic. By using a topic as an intermediary, message publishers are kept independent of subscribers.

Both styles of messaging can be used in the same application.

Applications can use asynchronous messaging in the following ways:

One-way

An application sends a message, and does not want a response. This pattern of use is often referred to as a datagram.

Request / response

An application sends a request to another application and expects to receive a response in return.

One-way and forward

An application sends a request to another application, which sends a message to yet another application.

These messaging techniques can be combined to produce a variety of asynchronous messaging scenarios.

For more information about how such messaging scenarios are used by WebSphere enterprise applications, see the following topics:

- An overview of asynchronous messaging with JMS
- An overview of asynchronous messaging with message-driven beans
- An overview of extended messaging

For more information about these messaging techniques and the Java Messaging Service (JMS), see Sun's Java Message Service (JMS) specification documentation.

WebSphere Application Server cloning and WebSphere MQ clustering

This topic provides a summary of information about using WebSphere Application Server horizontal cloning with WebSphere MQ server clustering support. It describes a scenario that shows how the message listener service can be configured to take advantage of WebSphere MQ server clustering and provides some information about how to resolve potential runtime failures in the clustering scenario. The information in this topic is based on the scenario shown in the figure WebSphere Application Server horizontal cloning with WebSphere MQ clustered queues.

Note: WebSphere MQ server clustering is only available with the full WebSphere MQ product installed as the JMS provider.

For a WebSphere application server configured to use the extended messaging service, each JMS listener is used to retrieve messages from destinations defined to the server. In the following information the listener configurations are the same for each WebSphere application server. Each application server host contains a WebSphere application server and an WebSphere MQ server. If a host is only used to distribute messages, it only contains an WebSphere MQ server. There can be many servers defined in the configuration, although for simplicity the information in this topic is based on a scenario containing only three servers as shown in “WebSphere Application Server cloning and WebSphere MQ clustering” on page 160.

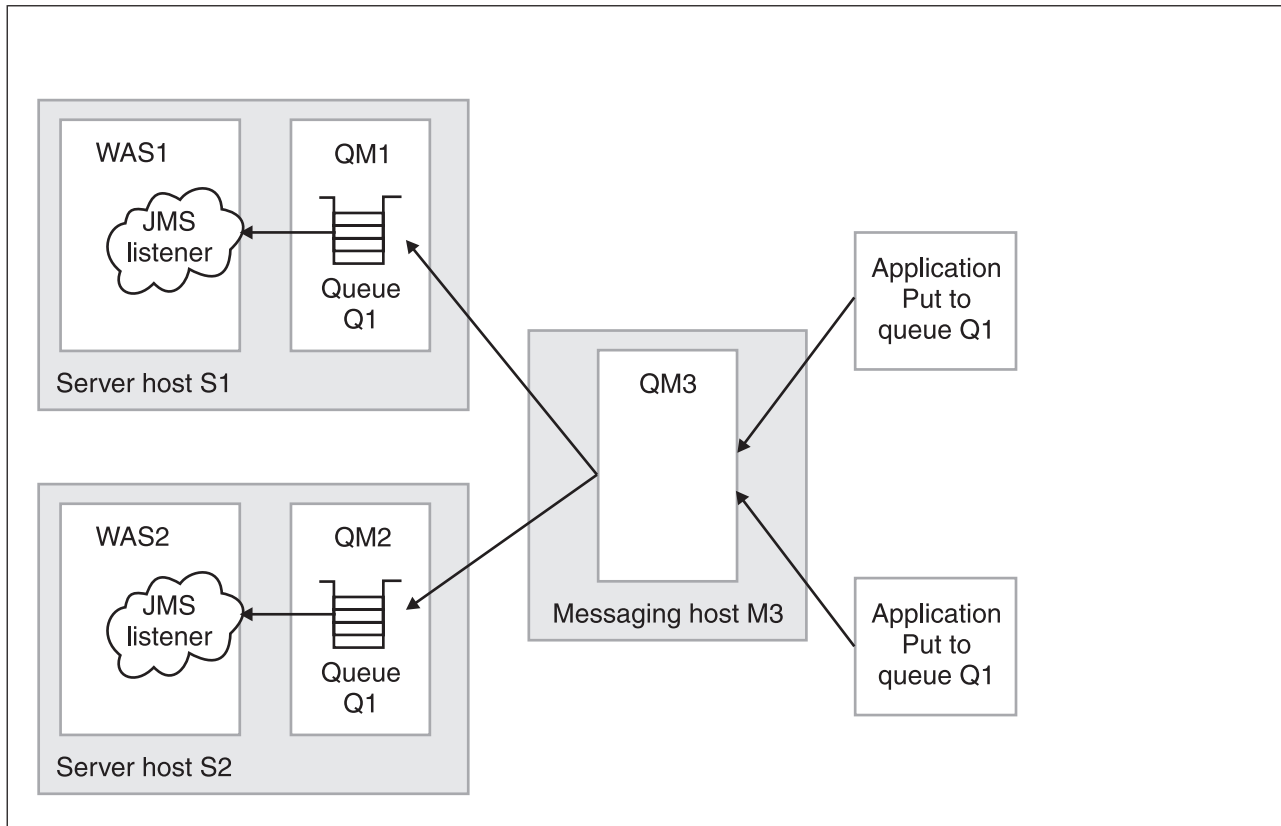

Figure 5. WebSphere Application Server horizontal cloning with WebSphere MQ clustered queues. This figure shows two WebSphere Application Server hosts, with horizontal clustering, and a messaging host used to distribute messages for WebSphere MQ server clustering. For more information, see the text that accompanies this figure.

The scenario shown in “WebSphere Application Server cloning and WebSphere MQ clustering” on page 160 comprises the following three hosts:

- Server host S1 contains the following servers:

WebSphere MQ server.

The server is defined to have a queue manager, QM1, and a local queue, Q1. The queue manager belongs to a cluster. The queue is populated by the WebSphere MQ server located on host M3. Applications can add messages directly to the queue, Q1, but would not be subjected to the control of the WebSphere MQ cluster.

WebSphere Application Server

This contains a cloned application server, WAS1, which is configured with a JMS listener. The listener is configured to retrieve messages from JMS destination Q1.

- Server host S2 contains the following servers:

WebSphere MQ server.

The server is defined to have a queue manager, QM2, and a local queue, Q1. The queue

manager belongs to the same cluster as QM1 on host S1. As with QM1, the queue is populated by the WebSphere MQ server located on host M3. Applications can add messages directly to the queue, Q1, but would not be subjected to the control of the MQ cluster.

WebSphere Application Server

This contains a cloned application server, WAS2 (identical to WAS1 on host S1), which is configured with a JMS listener. The listener is configured to retrieve messages from JMS destination Q1.

- Messaging host M3 contains the following servers:

WebSphere MQ server.

The server is defined to have a queue manager, QM3, which also belongs to the same cluster as QM1 and QM2. Applications add messages to the queue manager and queue Q1. The cluster to which this queue manager belongs causes messages to be distributed to all other queue managers in the cluster which have queue Q1 defined.

Note: Queue Q1 is not defined as a local queue on this host. If the queue was defined locally, then messages would remain on the server for local processing; messages would not be distributed by the queue manager cluster control to the other queue managers in the cluster that do have the queue defined.

This host does not have a WebSphere application server defined. All message retrieval processing is performed by the other two application servers on hosts S1 and S2.

Recovery scenarios

There are several failure scenarios that could occur with the clustering configuration; for example:

- WAS server failures.

In this scenario the failure of any single WebSphere application server results in the messages for the specified destination remaining on the queue, until the server is restarted.

- WebSphere MQ Queue Manager failures.

There are two different failures to consider:

1. Failure of a queue manager on the same host as a WebSphere application server (for example, failure of QM2 on host S2). In this case messages are delivered to the other available application servers, until the WebSphere MQ server is back online, when messages are processed as expected.
2. Failure of the messaging host M3 and its queue manager, QM3. In this case, the result of an outage is more significant because no messages are delivered to the other queue managers in the cluster. In a fully-deployed and scaled production system, host M3 would not be designed to be a single point of failure, and additional messaging servers would be added to the cluster configuration.

Using JMS and messaging in applications

Use these tasks to implement WebSphere J2EE applications that use JMS.

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface.

The base JMS support enables WebSphere enterprise applications to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics). An enterprise application can explicitly poll for messages on a destination.

Using the base support for JMS, you can build enterprise beans that use the JMS API directly to provide messaging services along with methods that implement business logic.

You can use the WebSphere administrative console to administer the JMS support of WebSphere Application Server. For example, you can configure JMS providers and their resources, and can control the activity of the JMS server.

For more information about implementing WebSphere enterprise applications that use JMS, see the following topics:

- An overview of WebSphere asynchronous messaging using JMS
- Administering WebSphere messaging
- Developing a J2EE application to use JMS
- Developing a JMS client
- Deploying a J2EE application to use JMS
- Tuning Java messaging service
- Troubleshooting WebSphere messaging

For more information about JMS, see the JMS documentation at <http://java.sun.com/products/jms/docs.html>.

An overview of WebSphere asynchronous messaging using JMS

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface. JMS provides a common way for Java programs (clients and J2EE applications) to create, send, receive, and read asynchronous requests, as JMS messages.

This topic provides an overview of asynchronous messaging using JMS support provided by WebSphere Application Server. For more details about JMS, see Sun's Java Message Service (JMS) specification documentation.

The base support for asynchronous messaging using JMS, shown in the following figure, provides the common set of JMS interfaces and associated semantics that define how a JMS client can access the facilities of a JMS provider. This enables WebSphere J2EE applications, as JMS clients, to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics). An J2EE application can use JMS queue destinations for point-to-point messaging and JMS topic destinations for publish/subscribe messaging. An J2EE application can explicitly poll for messages on a destination then retrieve messages for processing by business logic beans (enterprise beans).

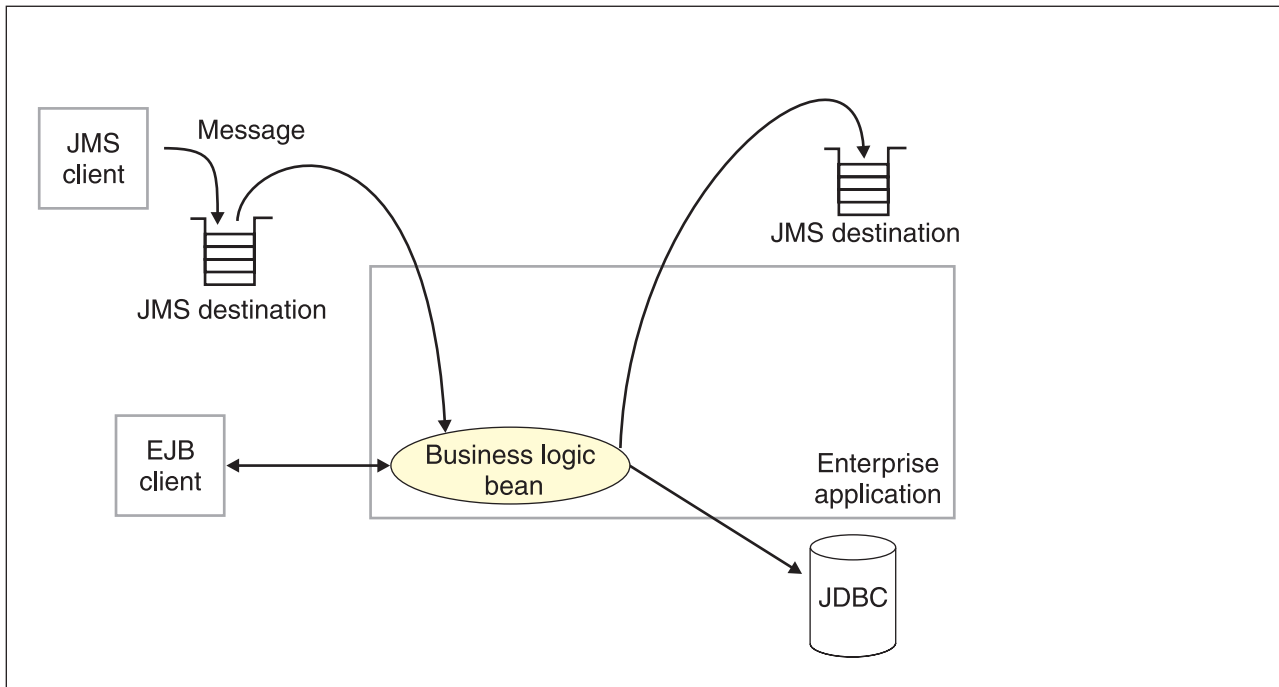

Figure 6. Asynchronous messaging using JMS. This figure shows an enterprise application polling a JMS destination to retrieve an incoming message, which it processes with a business logic bean. The business logic bean uses standard JMS calls to process the message; for example, to extract data or to send the message on to another JMS destination. For more information, see the text that accompanies this figure.

With the base JMS/XA support, the J2EE application uses standard JMS calls to process messages, including any responses or outbound messaging. Responses can be handled by an enterprise bean acting as a sender bean, or handled in the enterprise bean that receives the incoming messages. Optionally, this process can use two-phase commit within the scope of a transaction. This level of functionality for asynchronous messaging is called bean-managed messaging, and gives an enterprise bean complete control over the messaging infrastructure; for example, for connection and session pool management. The application server has no role in bean-managed messaging.

WebSphere Application Server also supports automatic asynchronous messaging using message-driven beans (a type of enterprise bean defined in the EJB 2.0 specification) and JMS listeners (part of the JMS application server facilities). Messages are automatically retrieved from JMS destinations, optionally within a transaction, then sent to the message-driven bean in an J2EE application, without the application having to explicitly poll JMS destinations. For more information about asynchronous messaging with message-driven beans, see An overview of asynchronous messaging with message-driven beans

5.1+ With WBI Server Foundation, J2EE applications can use another level of functionality for asynchronous messaging, called extended messaging. The application server manages the messaging infrastructure, and extra standard types of messaging beans are provided to add functionality to that provided by message-driven beans. This level of functionality enables application developers to concentrate on the business logic to be implemented by the enterprise beans and to leave the messaging usage to standard messaging objects and configuration of the extended messaging service.

WebSphere JMS support - components

The main components of WebSphere JMS support are shown in the following figure and described after the figure:

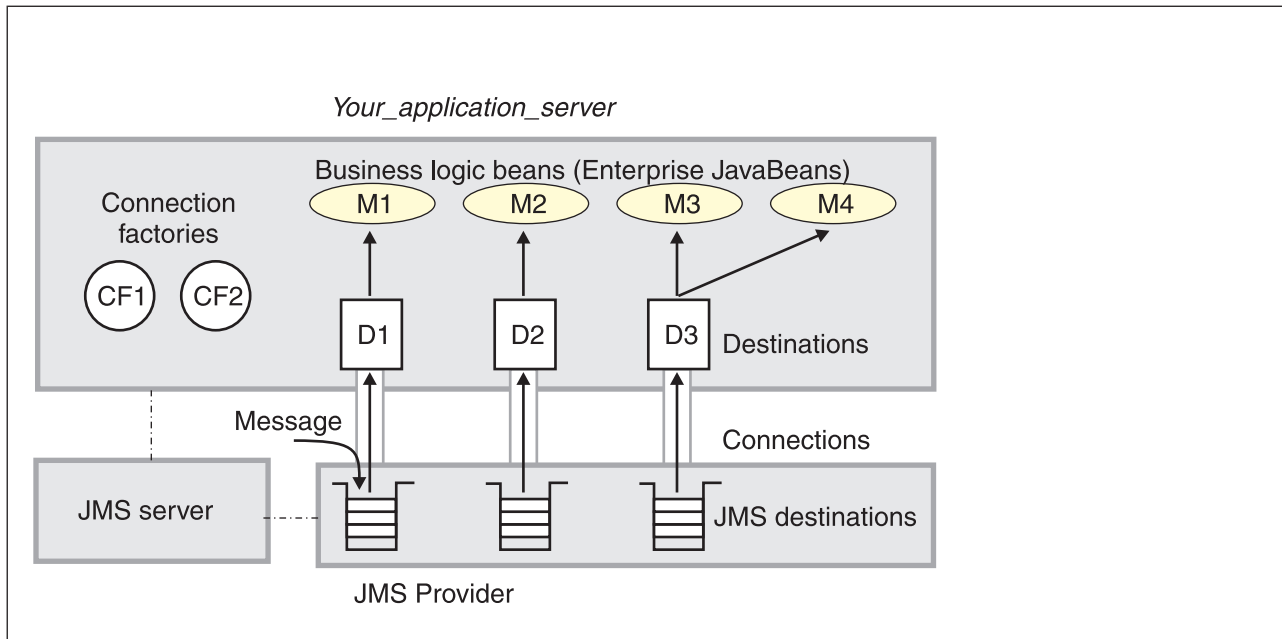

Figure 7. The main components of WebSphere JMS support. This figure shows the main components of WebSphere JMS support, from JMS provider through a connection to a destination, then to a WebSphere enterprise application (acting as a JMS client) that processes the message retrieved from the destination. For more information, see the text that accompanies this figure.

WebSphere Application Server supports asynchronous messaging based on the Java Messaging Service (JMS) of a JMS provider that conforms to the JMS specification version 1.0.2 and supports the Application Server Facility (ASF) function defined within that specification. WebSphere Application Server provides an embedded JMS provider and administration objects for WebSphere MQ as the JMS provider. You can use the embedded JMS provider, install WebSphere MQ JMS on top of the embedded WebSphere JMS, or install and configure another JMS provider.

JMS functions (of JMS providers) within the WebSphere Application Server administration domain are served by one or more JMS servers. There can be at most one JMS server on each node in the administration domain, and any application server within the domain can access JMS resources served by any JMS server on any node in the domain.

A connection factory is used to create connections with the JMS provider for a specific JMS queue or topic destination. Each connection factory encapsulates the configuration parameters needed to create a connection to a JMS destination.

A WebSphere J2EE application can explicitly poll for messages on a destination then retrieve messages for processing by business logic beans (enterprise beans).

The WebSphere Application Server support for message-driven beans and extended messaging builds on this base JMS support. For more information, see the related topics.

WebSphere MQ JMS connection pooling

To improve the overall performance of JMS within the system, the message listener service enables the connection pooling facility provided by the WebSphere MQ JMS implementation. This support does not affect the performance of a message listener, because it retains its connections while listening on a destination, but does affect the overall JMS system performance. When a connection is no longer required, WebSphere MQ can pool the connection then reuse it later instead of destroying it.

Note: This support is only available if WebSphere MQ is configured as the JMS provider.

To enable WebSphere MQ connection pooling and configure the characteristics of the WebSphere MQ connection pool, see [Enabling WebSphere MQ JMS connection pooling](#).

Administering WebSphere JMS support

Use these tasks with the WebSphere administrative console to manage JMS providers and their resources, and other runtime components of WebSphere JMS support.

You can use the WebSphere administrative console to configure the embedded WebSphere JMS provider or an WebSphere MQ JMS provider. If you install another JMS provider, you need to configure that JMS provider by using the tools and information provided with the JMS provider. For each JMS provider, you can configure the properties of JMS resources.

You can also use the WebSphere administrative console to configure and control other runtime components of WebSphere JMS support, including the following:

- The WebSphere JMS server
- The message listener service, listener ports, and the listener for each message-driven bean
- Input and output ports for extended messaging.

You can update the configuration data at any time, but if it is updated, the updates only take effect when the appropriate server is next started.

For information about the specific tasks used to administer WebSphere JMS support, see the following topics:

- [Installing and configuring a JMS provider](#)
- [Moving from the internal JMS provider to WebSphere MQ](#)
- [Securing messaging directories and log files](#)
- [Enabling security for the embedded WebSphere JMS provider](#)
- [Displaying administrative lists of JMS resources](#)
- [Managing JMS servers on Application Server](#)
- [Managing JMS servers in a deployment manager cell](#)
- [Configuring JMS provider resources](#)

For more information about JMS resources, see the JMS documentation at <http://java.sun.com/products/jms/docs.html>.

Installing and configuring a JMS provider

This topic describes the different ways that you can implement a JMS provider for use with WebSphere Application Server.

For IBM WebSphere Application Server to support bean-managed messaging, you need to install and configure one or more JMS providers that conform to the JMS specification version 1.0.2. To use message-driven beans the JMS provider must support the Application Server Facility (ASF) function defined within that specification.

You can install and use the Embedded Messaging Server option of WebSphere Application Server, install WebSphere MQ as the JMS provider, or install another “generic” JMS provider. If you install both embedded messaging and WebSphere MQ as JMS providers, for example, WebSphere applications can use JMS resources provided by both the embedded WebSphere JMS provider and the WebSphere MQ JMS provider.

WebSphere Application Server provides default JMS support with its Embedded Messaging Server component. This function is installed with WebSphere Application Server, administered through the administrative console and managed as part of the WebSphere Application Server runtime. This function is only accessible from WebSphere Application Server Web, EJB and client containers, and is not interoperable with WebSphere MQ. If access is required to heterogeneous non-JMS applications, WebSphere MQ clustering, or other WebSphere MQ functions, you should install WebSphere Application

Server without the Embedded Messaging Server component, and should install WebSphere MQ instead as the JMS provider. You are recommended to install and use the WebSphere Application Server Embedded Messaging Client for communication with the WebSphere MQ queue manager.

To provide the supported levels of messaging, you should apply the latest service for WebSphere Application Server and WebSphere MQ while a production application is in Quality-Assurance or Product-Validation Test.

For more information about WebSphere Application Server messaging scenarios, and the relationship between embedded messaging and WebSphere MQ, see the following articles:

- WebSphere Application Server solutions White paper: Selecting the most appropriate JMS provider for your applications (<ftp://ftp.software.ibm.com/software/websphere/resourcefinder/2318-00.pdf>). This white paper describes the different Java Message Service (JMS) options that are available from IBM for WebSphere Application Server applications. It compares the messaging technology built into WebSphere Application Server, Version 5 with IBM WebSphere MQ, IBM WebSphere Business Integration Event Broker and IBM WebSphere Business Integration Message Broker.
- JMS Topologies and Configurations with WebSphere Application Server and WebSphere Studio Version 5 (http://www7b.boulder.ibm.com/wsdd/library/techarticles/0310_barciabarci.html). This technical article helps you understand configuration options within WebSphere Application Server for Java Message Service (JMS) applications, including using embedded messaging and WebSphere MQ (formerly MQSeries). It covers setting up your development environment to support various JMS scenarios, development and runtime topologies, and scripting and security.

You can install and configure a JMS provider in one or more of the following ways:

- Installing WebSphere embedded messaging as the JMS provider.

Note:

- WebSphere embedded messaging as the JMS provider supports both queues (for point-to-point messaging) and topics (for publish/subscribe messaging).
 - You can install IBM WebSphere Application Server with embedded messaging on the same host as an existing WebSphere MQ installation, which must be at a supported level of MQ features.
 - You can install IBM WebSphere Application Server with embedded messaging then later install WebSphere MQ for use as a JMS provider.
- Installing WebSphere MQ as the JMS provider.

Note:

- You can install WebSphere MQ before IBM WebSphere Application Server. If you then want to install embedded messaging, you must ensure that the WebSphere MQ installation is at a supported level of MQ features.
- If you do not want to use the embedded WebSphere JMS provider, you can install IBM WebSphere Application Server without the **Embedded Messaging Server** option. You are recommended to install and use the WebSphere Application Server **Embedded Messaging Client**.
- You can install WebSphere MQ for use as a JMS provider on top of WebSphere Application Server embedded messaging; this results in a single JMS installation.
 - For point-to-point messaging WebSphere applications can continue to use WebSphere queue resources (through the embedded messaging JMS provider) or WebSphere MQ queue resources that you define to IBM WebSphere Application Server.
 - For publish/subscribe messaging, WebSphere applications can continue to use WebSphere topic resources (through the embedded messaging JMS provider) or WebSphere MQ topic resources that you define to IBM WebSphere Application Server, and which are provided by a Publish/Subscribe broker installed in addition to the base WebSphere MQ.

The preferred solution for publish/subscribe messaging with WebSphere MQ as the JMS provider is a full broker such as WebSphere MQ Event Broker. Failing this, you can install the MAOC SupportPac with WebSphere MQ.

- If you install WebSphere MQ as the JMS provider, you can use the WebSphere administrative console to administer the WebSphere MQ JMS provider resources, such as queue connection factories. However, you cannot administer MQ security, which is administered through WebSphere MQ.
- You can change from using WebSphere embedded messaging to WebSphere MQ as the JMS provider for WebSphere enterprise applications, as described in Moving from the embedded WebSphere JMS provider to WebSphere MQ.

For more information about scenarios and considerations for using WebSphere MQ with IBM WebSphere Application Server, see the White Papers and Red books provided by WebSphere MQ; for example, through the WebSphere MQ library Web page at <http://www-3.ibm.com/software/ts/mqseries/library/>

- Installing another JMS provider, which must conform to the JMS specification and, to use message-driven beans, support the ASF function. If you want to use a JMS provider other than the embedded WebSphere JMS provider or a WebSphere MQ JMS provider, you should complete the following steps:
 1. Installing and configuring the JMS provider and its resources by using the tools and information provided with the JMS provider.
 2. Defining the JMS provider to WebSphere Application Server as a generic JMS provider.

Note: You cannot use the WebSphere administrative console to administer the JMS provider or its resources.

To install a JMS provider for IBM WebSphere Application Server, consider the following scenarios:

A new IBM WebSphere Application Server server machine, hostA.

This scenario starts with adding embedded messaging as the JMS provider, then optionally adding WebSphere MQ as an alternative JMS provider. Each stage summarizes the messaging functions that can be added.

1. Installing embedded messaging as the only JMS provider.

You want to be able to run WebSphere applications that use the WebSphere JMS resources for both point-to-point and publish/subscribe messaging.

- a. Install and customize WebSphere Application Server with the **Embedded Messaging Server** and **Embedded Messaging Client** options. (See the Information Center for details.)
 - b. Use the administrative console to configure WebSphere JMS resources; for example, WebSphere Queue Connection Factories and WebSphere Topic Connection Factories.
 - c. On any client machines that are to use the WebSphere JMS resources, install IBM WebSphere Application Server with the **Embedded Messaging Client** option.
2. Adding WebSphere MQ as an alternative JMS provider for point-to-point messaging.

Besides the point-to-point and publish/subscribe messaging that uses the embedded WebSphere JMS resources (from the preceding step), you want to be use WebSphere MQ Queue resources for point-to-point messaging.

- a. Install WebSphere MQ 5.3 with the required features. For more information about installing WebSphere MQ, see the WebSphere MQ Quick Beginnings book for your machine's platform. When installing WebSphere MQ, perform the following actions:
 - 1) When asked if you want to remove or modify the version of WebSphere MQ currently installed, choose to remove the Server. (The WebSphere MQ install program recognizes the installed WebSphere embedded messaging as an installed version of WebSphere MQ.)
 - 2) Select the option to keep existing queue managers.

- 3) Proceed with the installation of the full WebSphere MQ Server by running the install program again, after the old WebSphere MQ server (the Embedded Messaging Server) has been removed.
 - 4) Do not install the WebSphere MQ Client. Use the WebSphere Application Server **Embedded Messaging Client** that was installed with WebSphere embedded messaging.
 - b. Use the administrative console to configure WebSphere MQ Queue Connection Factories and WebSphere MQ Queue Destinations.
3. Adding WebSphere MQ Event Broker for alternative publish/subscribe messaging.
- For publish/subscribe messaging, you want to be able to run WebSphere applications that use the WebSphere MQ Topic resources or the embedded WebSphere Topic resources (such as those configured in preceding steps).
- a. Install WebSphere MQ Event Broker. For more information about installing WebSphere MQ Event Broker, see the WebSphere MQ Event Broker Installation Guide for your machine's platform.
 - b. Use the administrative console to configure WebSphere MQ Topic Connection Factories and WebSphere MQ Topic Destinations.

An existing WebSphere MQ 5.2 server and broker machine, hostA, where you want to install embedded messaging as the JMS provider.

1. Upgrade to WebSphere MQ 5.3 with the required features. For more information about upgrading to WebSphere MQ 5.3, see "Migrating from an earlier version" in the WebSphere MQ Quick Beginnings book for your machine's platform.
2. To continue using publish/subscribe messaging, upgrade to a supported broker such as WebSphere MQ Event Broker.
3. Install IBM WebSphere Application Server with the **Embedded Messaging Server** and **Embedded Messaging Client** options. (See "Installing the product" in the Information Center.)
4. Use the administrative console to configure WebSphere JMS resources; for example, WebSphere Queue Connection Factories and WebSphere Topic Connection Factories.
5. If you want WebSphere applications to use the WebSphere MQ resources, use the administrative console to configure WebSphere MQ JMS resources; for example, WebSphere MQ Queue Connection Factories and WebSphere MQ Destinations.
6. On any client machines that are to use the WebSphere JMS resources, install IBM WebSphere Application Server with the **Embedded Messaging Client** option. (See "Installing the product" in the Information Center.)

You can run WebSphere applications that use both the WebSphere JMS resources and WebSphere MQ JMS resources for messaging.

An existing WebSphere MQ server machine, hostA, where you want to use WebSphere MQ as the only JMS provider.

1. For point-to-point messaging, ensure that you have installed WebSphere MQ 5.3 with required features. For publish/subscribe messaging, ensure that you have also installed a supported broker such as WebSphere MQ Event Broker. For more information about installing WebSphere MQ 5.3 and Event Broker, see the WebSphere MQ Quick Beginnings book and WebSphere MQ Event Broker Installation Guide for your machine's platform.
2. Install IBM WebSphere Application Server without any of the **Embedded Messaging Server** and **Embedded Messaging Client** options.
3. Use the administrative console to configure WebSphere MQ JMS resources; for example, WebSphere MQ Queue Connection Factories and WebSphere MQ Topic Connection Factories.
4. On any client machines that are to use the WebSphere JMS resources, install IBM WebSphere Application Server with the **Embedded Messaging Client** option.

You can run WebSphere applications that use the WebSphere MQ JMS resources for point-to-point or (with a supported broker installed) publish/subscribe messaging.

Installing WebSphere MQ as the JMS provider:

Use this task to install and configure WebSphere MQ with support for the Java Message Service (JMS) for use with the WebSphere Application Server.

(UNIX platforms only) Before you install WebSphere MQ, create and mount a journalized file system called /var/mqm for your messaging working data. Use a partition strategy with a separate volume for the WebSphere MQ data. This means that other system activity is not affected if a large amount of messaging work builds up in /var/mqm. You can also create separate file systems for your log data (var/mqm/log) and error files (var/mqm/errors). You should store log files on a different physical volume from the messaging queues (var/mqm). This ensures data integrity in the case of a hardware failure. If you are creating separate file systems, allow a minimum of 30 MB of storage for /var/mqm, 20 MB of storage for /var/mqm/log, and 4 MB of storage for /var/mqm/errors.

- The /var file system is used to store all the security logging information for the system, and is used to store the temporary files for email and printing. Therefore, it is critical that you maintain free space in /var for these operations. If you do not create a separate file system for messaging data, and /var fills up, all security logging will be stopped on the system until some free space is available in /var. Also, email and printing will no longer be possible until some free space is available in /var.
- **5.1+** It is not recommended to install WebSphere Studio Application Developer and WebSphere Application Server on the same machine when using WebSphere MQ.
- For more information the security logging issue, see "Security and WebSphere MQ" in the Information Center.
- For more information about creating file systems for WebSphere MQ, and WebSphere MQ space requirements for /var file systems, see the section "Preparing for Installation: Creating WebSphere MQ file systems" in the appropriate WebSphere MQ *Quick Beginnings* book.
- For other installation prerequisites, see the appropriate WebSphere MQ *Quick Beginnings* book, as follows:
 - *WebSphere MQ for Windows, V5.3 Quick Beginnings*, GC34-6073
 - *WebSphere MQ for AIX, V5.3 Quick Beginnings*, GC34-6076
 - *WebSphere MQ for Solaris, V5.3 Quick Beginnings*, GC34-6075
 - *WebSphere MQ for HP-UX, V5.3 Quick Beginnings*, GC34-6077
 - *WebSphere MQ for Linux for Intel and Linux for zSeries, V5.3 Quick Beginnings*, GC34-6078

You can get these books from the WebSphere MQ messaging platform-specific books Web page at <http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html>

To install and configure WebSphere MQ (MQSeries) for use as a JMS provider to IBM WebSphere Application Server, complete the following steps:

1. Install WebSphere MQ 5.3, with the required MQ features, as described in the installation instructions provided with WebSphere MQ.

If you are installing WebSphere MQ on top of WebSphere Application Server embedded messaging, perform the following actions when installing WebSphere MQ:

- a. When asked if you want to remove or modify the version of WebSphere MQ currently installed, choose to remove the Server. (The WebSphere MQ install program recognizes the installed WebSphere embedded messaging as an installed version of WebSphere MQ.)
- b. Select the option to keep existing queue managers.
- c. Proceed with the installation of the full WebSphere MQ Server by running the install program again, after the old WebSphere MQ server (the Embedded Messaging Server) has been removed.
- d. Do not install the WebSphere MQ Client. Use the WebSphere Application Server **Embedded Messaging Client** that was installed with WebSphere embedded messaging.

Note: **5.1+** The WBI Server Foundation package includes copies of the WebSphere MQ 5.3 and Event Broker installation packages, with restricted licensing for use with WBI Server Foundation. (WebSphere MQ Event Broker is not available for Linux.) For more information about the usage restrictions for the WebSphere MQ 5.3 and Event Broker installation packages, see the WBI Server Foundation licensing information.

If you want to use the original WebSphere MQ 5.3 release, ensure that you install the CSD03 update. If you want to use WebSphere MQ 5.3 on the same machine as WebSphere Application Server embedded messaging, ensure that you install the following MQ features:

- For a WebSphere Application Server **Embedded Messaging Server** installation, the required MQ features are “Server” and “Java Messaging”.
- For a WebSphere Application Server **Embedded Messaging Client** installation, the only required MQ feature is “Java Messaging”.

5.1+ You can use the WebSphere MQ 5.3 installation package provided with WBI Server Foundation to install the required MQ features into an existing WebSphere MQ 5.3 or to install a new WebSphere MQ 5.3 with the required MQ features for use with WBI Server Foundation subject to the licensing conditions.

For information about installing WebSphere MQ 5.3, or migrating to WebSphere MQ 5.3 from an earlier release, see the appropriate WebSphere MQ *Quick Beginnings* book, as listed above.

2. If you want to use WebSphere MQ - Publish/Subscribe support, you need to provide a Publish/Subscribe broker.

For example, you can do this by using either WebSphere MQ Event Broker or WebSphere MQ Integrator (formerly MQSeries Integrator). For more information about these products, see the following Web sites:

- WebSphere MQ Event Broker Web site at <http://www-4.ibm.com/software/ts/mqseries/platforms/#eventb>
- WebSphere MQ Integrator Web site at <http://www-4.ibm.com/software/ts/mqseries/platforms/#integrator>

3. Follow the WebSphere MQ 5.3 instructions for verifying your installation setup.
4. For AIX, see the WebSphere MQ 5.3 readme.txt for additional steps.
5. If you want to install IBM WebSphere Application Server on the same host as WebSphere MQ, and have not yet done so, install IBM WebSphere Application Server. If you do not want to use the embedded WebSphere JMS provider, you can install WebSphere MQ then install WebSphere Application Server without the **Embedded Messaging Server** option. You are recommended to install and use the WebSphere Application Server **Embedded Messaging Client**.
6. Set the MQJMS_LIB_ROOT environment variable to the directory where WebSphereMQJava\lib is installed. IBM WebSphere Application Server uses the MQJMS_LIB_ROOT to locate the WebSphere MQ libraries for the WebSphere MQ JMS Provider.

This task has installed WebSphere MQ for use as the JMS provider with WebSphere Application Server.

You can configure JMS resources to be provided by WebSphere MQ, by using the WebSphere administrative console to define WebSphere MQ resources.

(UNIX platforms only) Restrict access to the messaging errors directories and logging files, by using the following commands. This is part of the procedure to secure the directories and log files needed for WebSphere MQ, as described in *Securing messaging directories and log files*.

1. For the /var/mqm/errors directory:

```
chmod 3777 /var/mqm/errors
chown mqm:mqm /var/mqm/errors
```

```
touch /var/mqm/errors/AMQERR01.LOG
chown mqm:mqm /var/mqm/errors/AMQERR01.LOG
chmod 666 /var/mqm/errors/AMQERR01.LOG
```

```
touch /var/mqm/errors/AMQERR02.LOG
chown mqm:mqm /var/mqm/errors/AMQERR02.LOG
chmod 666 /var/mqm/errors/AMQERR02.LOG
```

```
touch /var/mqm/errors/AMQERR03.LOG
chown mqm:mqm /var/mqm/errors/AMQERR03.LOG
chmod 666 /var/mqm/errors/AMQERR03.LOG
```

2. For the `/var/mqm/qmgrs/@SYSTEM/errors` directory:

```
chmod 3777 /var/mqm/qmgrs/@SYSTEM/errors
chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors
```

```
touch /var/mqm/qmgrs/@SYSTEM/errors/AMQERR01.LOG
chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors/AMQERR01.LOG
chmod 666 /var/mqm/qmgrs/@SYSTEM/errors/AMQERR01.LOG
```

```
touch /var/mqm/qmgrs/@SYSTEM/errors/AMQERR02.LOG
chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors/AMQERR02.LOG
chmod 666 /var/mqm/qmgrs/@SYSTEM/errors/AMQERR02.LOG
```

```
touch /var/mqm/qmgrs/@SYSTEM/errors/AMQERR03.LOG
chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors/AMQERR03.LOG
chmod 666 /var/mqm/qmgrs/@SYSTEM/errors/AMQERR03.LOG
```

Defining a generic JMS provider:

Use this task to define a new JMS provider to WebSphere Application Server, for use instead of the embedded WebSphere JMS provider or a WebSphere MQ JMS provider.

Before starting this task, you should have installed and configured the JMS provider and its resources by using the tools and information provided with the JMS provider.

To define a new generic JMS provider to WebSphere Application Server, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> Generic JMS Providers** This displays the existing generic JMS providers in the content pane.
2. To define a new generic JMS provider, click **New** in the content pane. Otherwise, to change the definition of an existing JMS provider, click the JMS provider. This displays the properties used to define the JMS provider in the content pane.
3. Specify appropriate properties for the JMS provider.
4. Click **OK**.
5. To save your configuration, click **Save** on the task bar of the Administrative console window.
6. To have the changed configuration take effect, stop then restart the application server.

Installing WebSphere embedded messaging as the JMS provider:

Use this task to install the Embedded Messaging options of IBM WebSphere Application Server for use as the JMS provider.

Before you install the embedded messaging options of IBM WebSphere Application Server, you must complete the following steps:

1. If you want to install embedded messaging on a machine where you already have WebSphere MQ installed, you must ensure that you have upgraded to WebSphere MQ 5.3 with the required MQ features:
 - a. If you have the original WebSphere MQ 5.3 release installed, ensure that you have applied the CSD04 update.

To determine if your WebSphere MQ 5.3 installation is at the required level, run the **mqver** utility provided by WebSphere MQ. The required level as indicated by mqver is shown below:

```
Name:      WebSphere MQ
Version:   530.4 CSD04
...
```

For more information about CSD04 and other WebSphere MQ product support, see the WebSphere MQ support page for your platform.

- b. Ensure that you have installed the following WebSphere MQ features:
 - For a WebSphere Application Server **Embedded Messaging Server** installation, the required MQ features are “Server” and “Java Messaging”.
 - For a WebSphere Application Server **Embedded Messaging Client** installation, the only required MQ feature is “Java Messaging”.

If you have not installed WebSphere MQ 5.3 with the required MQ features, then installation of IBM WebSphere Application Server Embedded Messaging options fails with prerequisite check errors.

5.1+ The WBI Server Foundation package includes copies of the WebSphere MQ 5.3 and Event Broker installation packages, with restricted licensing. (WebSphere MQ Event Broker is not available for Linux.) You can use the provided packages to install the required MQ features or WebSphere MQ 5.3 for use with WBI Server Foundation.

For information about installing WebSphere MQ 5.3, or migrating to WebSphere MQ 5.3 from an earlier release, see the appropriate WebSphere MQ *Quick Beginnings* book, as follows:

- *WebSphere MQ for Windows, V5.3 Quick Beginnings*, GC34-6073
- *WebSphere MQ for AIX, V5.3 Quick Beginnings*, GC34-6076
- *WebSphere MQ for Solaris, V5.3 Quick Beginnings*, GC34-6075
- *WebSphere MQ for HP-UX, V5.3 Quick Beginnings*, GC34-6077
- *WebSphere MQ for Linux for Intel and Linux for zSeries, V5.3 Quick Beginnings*, GC34-6078

You can get these books from the WebSphere MQ messaging platform-specific books Web page at <http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html>

2. Ensure that there is enough space in the file systems where you want to install the Embedded Messaging options and store associated messaging data. On UNIX platforms, you also need to create the required file systems before installing the embedded messaging feature.
 - **(Windows only)** You can specify the file system into which the Embedded Messaging options are installed. The following table lists the default locations for the base messaging functions and the messaging broker functions (for publish/subscribe messaging). The table also provides figures for the file system sizes on which you can base your own calculations.

Table 1. Installation directory and space needed for embedded messaging - Windows platform

	Base messaging	Messaging broker
Installation directory	C:\Program Files\IBM\WebSphere MQ	C:\Program Files\IBM\WebSphere MQ\WEMPS
Typical space needed	70 MB (server) or 15 MB (client)	45 MB (server)

If you are using the Installation wizard to install IBM WebSphere Application Server, you can specify an install location for the Embedded Messaging options during either a Full or Custom install. If you want to use a silent install for IBM WebSphere Application Server, you can specify an install location for the Embedded Messaging options when you tailor the options response file before issuing the command to install silently. For more information about performing a silent installation (including editing the options response file), see “Installing silently” in the Information Center.

- **(UNIX platforms only)** The file system into which the Embedded Messaging options are installed is fixed. The following table lists the default locations for the base messaging functions and the messaging broker functions (for publish/subscribe messaging). The table also provides figures for the file system sizes on which you can base your own calculations.

Table 2. Installation directory and space needed for embedded messaging - UNIX platforms

	Base code	Broker code	Base data	Broker data
	/usr/mqm	/usr/opt/wemps	/var/mqm	/var/wemps
AIX	40MB (server) or 15MB (client)	80MB (server) or 15MB (client)	8MB (server) or 5MB (client)	5MB (server)

Table 2. Installation directory and space needed for embedded messaging - UNIX platforms (continued)

	Base code	Broker code	Base data	Broker data
	/opt/mqm	/opt/wemps	/var/mqm	/var/wemps
Linux/Intel	40MB (server) or 15MB (client)	100MB (server) or 15MB (client)	8MB (server) or 5MB (client)	5MB (server)
HP-UX	40MB (server) or 15MB (client)	105MB (server) or 15MB (client)	8MB (server) or 5MB (client)	5MB (server)
Solaris	40MB (server) or 15MB (client)	70MB (server) or 15MB (client)	20MB (server) or 15MB (client)	5MB (server)

Before you install WebSphere embedded messaging, create and mount a journalized file system called /var/mqm for your messaging working data. Use a partition strategy with a separate volume for the WebSphere MQ data. This means that other system activity is not affected if a large amount of messaging work builds up in /var/mqm. You can also create separate file systems for your log data (var/mqm/log) and error files (var/mqm/errors). Store log files on a different physical volume from the Embedded Messaging queues (var/mqm). This ensures data integrity in the case of a hardware failure. If you are creating separate file systems, allow a minimum of 30 MB of storage for /var/mqm, 20 MB of storage for /var/mqm/log, and 4 MB of storage for /var/mqm/errors.

Note: The /var file system is used to store all the security logging information for the system, and is used to store the temporary files for email and printing. Therefore, it is critical that you maintain free space in /var for these operations. If you do not create a separate file system for messaging data, and /var fills up, all security logging will be stopped on the system until some free space is available in /var. Also, email and printing will no longer be possible until some free space is available in /var.

You have the same options for creating file systems for Embedded Messaging as you do for WebSphere MQ. For example:

- If you cannot install the Embedded Messaging options in the required file system (for example, if it is too small), you can do one of the following *before* installing the Embedded Messaging options:
 - Create and mount a new file system for the installation directory.
 - Create a new directory anywhere on your machine, and create a symbolic link from the required installation directory to the new directory. For example, on AIX:

```
mkdir /bigdisk/mqm
ln -s /bigdisk/mqm /usr/mqm
```

3. Define the operating system groups and users needed for embedded messaging:

- **(UNIX platforms only)**
 - a. If you have not already done so, create the groups **mqm** and **mqbrkrs**.
 - b. Add the users **mqm** and **root** to the **mqm** group.
 - c. Add the user **root** to the **mqbrkrs** group.

Notes

Note:

- 1) You are recommended to run the JMS server process under the root user ID. If you run the JMS server process under another user ID, add that user ID to the **mqm** and **mqbrkrs** groups
For more information about running servers under a non-root user ID, see "Running an Application Server with a non-root user ID and the nodeagent as root" in the Information Center.
- 2) User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider.

- **(Windows only)** Define the process user ID with these authorizations:
 - Assign the user ID to the Administrator group.

- Give the user ID the advanced user right, Act as part of the operating system.
- Give the user ID the advanced user right, Log on as a service.

User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, Administrator, is not valid for use with embedded WebSphere messaging, because it contains 13 characters.

The IBM WebSphere Application Server installation wizard GUI grants your Windows user ID the advanced user rights, if the user ID belongs to the Administrator group. The silent installation does not. If you create a new user ID on a Windows platform to perform the silent installation, you must restart the system to activate the proper authorizations for the user ID, and to perform a successful silent installation.

This user ID, the WebSphere Application Server process user ID, is used to start the JMS server (for general JMS support) and the WebSphere Embedded Broker (for WebSphere topic connections).

Ensure that these operating system security settings are used when you next start IBM WebSphere Application Server; for example, either log off and then on again with the process user ID, or open a new shell in which to start IBM WebSphere Application Server.

You have the same options for creating user IDs and groups for Embedded Messaging as you do for WebSphere MQ. For more information about creating user IDs and groups for WebSphere MQ, see the section “Preparing for Installation: Setting up the user ID and group” in the appropriate WebSphere MQ *Quick Beginnings* book, as listed above.

4. **(Solaris only)** Several Solaris kernel values are typically too small for the Embedded Messaging options. Starting the internal JMS server or client with insufficient kernel resources produces a First Failure Support Technology (FFST) file in the `/var/mqm/errors` directory.

Before installing Embedded Messaging, review the machine’s configuration. To do this type the following command:

```
sysdef -i
```

The kernel values are set in the `/etc/system` file, as shown in the following example.

```
set shmsys:shminfo_shmmax = 4294967295
set shmsys:shminfo_shmseg = 1024
set shmsys:shminfo_shmmni = 1024
set semsys:seminfo_semaem = 16384
set semsys:seminfo_semmni = 1024
set semsys:seminfo_semmap = 1026
set semsys:seminfo_semmns = 16384
set semsys:seminfo_semmsl = 100
set semsys:seminfo_semopm = 100
set semsys:seminfo_semmnu = 2048
set semsys:seminfo_semume = 256
set msgsys:msginfo_msgmap = 1026
set msgsys:msginfo_msgmax = 65535
set rlim_fd_cur=1024
```

You can change kernel values by editing the `/etc/system` file then rebooting the operating system. For more information about setting up the Solaris system, see the Solaris System Administration documentation; for example, the *Solaris Tunable Parameters Reference Manual*.

Note: Queue managers are generally independent of each other. Therefore system kernel parameters, for example `shmmni`, `semmni`, `semmns`, and `semmnu` need to allow for the number of queue managers in the system.

5. **(HP-UX only)** Several HP-UX kernel values are typically too small for the Embedded Messaging options. Starting the internal JMS server or client with insufficient kernel resources produces a First Failure Support Technology (FFST) file in the `/var/mqm/errors` directory.

Before installing Embedded Messaging, review the machine’s configuration and, if needed, set appropriate HP-UX kernel settings.

You should set new values for the following messaging-related kernel parameters (along with the base set of kernel parameters required by IBM WebSphere Application Server):

Parameter	Value
sema	1
semaem	16384
semmns	16384
semvmx	32767
shmem	1

This table lists only those messaging-related kernel parameters that either are extra to the base set or need values that are greater than given in the base set.

For information about how to review and set the base set of kernel parameters for IBM WebSphere Application Server, see the item “Configure HP-UX kernel settings before installing” in “Platform-specific tips for installing and migrating (HP-UX platforms)” in the Information Center.

Note: Queue managers are generally independent of each other. Therefore system kernel parameters, for example shmmni, semmni, semmns, and semmnu need to allow for the number of queue managers in the system.

To install the Embedded Messaging options of WebSphere Application Server for use as the WebSphere JMS provider, complete the following steps:

1. Login with the WebSphere Application Server process user ID (defined as part of the prerequisites)

Note: (UNIX platforms only) Login as root.

2. On a machine where you want to host queues or topics, install IBM WebSphere Application Server with the **Embedded Messaging Server** option. If you also want application servers on the host to run messaging applications, install the **Embedded Messaging Client** option.

Both options are selected by default.

3. On a machine where you want application servers to run messaging applications that use a JMS provider on another host, install IBM WebSphere Application Server with the **Embedded Messaging Client** option.

This task has installed WebSphere Application Server with its embedded messaging as the JMS provider.

You can configure JMS resources to be provided by embedded messaging, by using the WebSphere administrative console to define WebSphere JMS resources.

(UNIX platforms only) Restrict access to the messaging errors directories and logging files; for example, by using the following commands:

1. For the /var/mqm/errors directory:

```
chmod 3777 /var/mqm/errors
chown mqm:mqm /var/mqm/errors
```

```
touch /var/mqm/errors/AMQERR01.LOG
chown mqm:mqm /var/mqm/errors/AMQERR01.LOG
chmod 666 /var/mqm/errors/AMQERR01.LOG
```

```
touch /var/mqm/errors/AMQERR02.LOG
chown mqm:mqm /var/mqm/errors/AMQERR02.LOG
chmod 666 /var/mqm/errors/AMQERR02.LOG
```

```
touch /var/mqm/errors/AMQERR03.LOG
chown mqm:mqm /var/mqm/errors/AMQERR03.LOG
chmod 666 /var/mqm/errors/AMQERR03.LOG
```

2. For the /var/mqm/qmgrs/@SYSTEM/errors directory:

```

chmod 3777 /var/mqm/qmgrs/@SYSTEM/errors
chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors

touch /var/mqm/qmgrs/@SYSTEM/errors/AMQERR01.LOG
chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors/AMQERR01.LOG
chmod 666 /var/mqm/qmgrs/@SYSTEM/errors/AMQERR01.LOG

touch /var/mqm/qmgrs/@SYSTEM/errors/AMQERR02.LOG
chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors/AMQERR02.LOG
chmod 666 /var/mqm/qmgrs/@SYSTEM/errors/AMQERR02.LOG

touch /var/mqm/qmgrs/@SYSTEM/errors/AMQERR03.LOG
chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors/AMQERR03.LOG
chmod 666 /var/mqm/qmgrs/@SYSTEM/errors/AMQERR03.LOG

```

This is part of the procedure to secure the directories and log files needed for WebSphere embedded messaging, as described in *Securing messaging directories and log files*.

If you have installed the Embedded Messaging Server option on top of WebSphere MQ, the MQ command **setmqcap** is set to use parameter 0 instead of -1, which results in:

- Issuing a license-unit message to the MQ console window whenever a queue manager starts
- Writing a message to the MQ error log

To prevent this, after you have completed the installation of IBM WebSphere Application Server, issue the `setmqcap -1` command from a command line.

Moving from the embedded WebSphere JMS provider to WebSphere MQ

Use this task to move from the embedded WebSphere JMS provider to WebSphere MQ as the provider of messaging services and resources for WebSphere enterprise applications.

To move from the embedded WebSphere JMS provider to WebSphere MQ as the provider of messaging services and resources for WebSphere enterprise applications, you need to install and configure a supported level of WebSphere MQ with the required MQ features.

Existing JMS resource definitions for the embedded WebSphere JMS provider continue to work with WebSphere MQ as the JMS provider, so you do not need to redefine those JMS resources. However, to take advantage of the extra configuration options for WebSphere MQ, you can use the administrative console to define new JMS resources as WebSphere MQ resources; for example, to define MQ Queue Connection Factories.

1. For WebSphere MQ point-to-point messaging, install the base WebSphere MQ product.

When installing WebSphere MQ, perform the following actions:

- a. When asked if you want to remove or modify the version of WebSphere MQ currently installed, choose to remove the Server. (The WebSphere MQ install program recognizes the installed WebSphere embedded messaging as an installed version of WebSphere MQ.)
- b. Select the option to keep existing queue managers.
- c. Proceed with the installation of the full WebSphere MQ Server by running the install program again, after the old WebSphere MQ server (the Embedded Messaging Server) has been removed.
- d. Do not install the WebSphere MQ Client. Use the WebSphere Application Server **Embedded Messaging Client** that was installed with WebSphere embedded messaging.

For information about installing WebSphere MQ 5.3, or migrating to WebSphere MQ 5.3 from an earlier release, see the appropriate WebSphere MQ *Quick Beginnings* book, as follows:

- *WebSphere MQ for Windows, V5.3 Quick Beginnings*, GC34-6073
- *WebSphere MQ for AIX, V5.3 Quick Beginnings*, GC34-6076
- *WebSphere MQ for Solaris, V5.3 Quick Beginnings*, GC34-6075
- *WebSphere MQ for Linux for Intel and Linux for zSeries, V5.3 Quick Beginnings*, GC34-6078

You can get WebSphere MQ messaging platform-specific books at this Web page:
<http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html>

2. Configure WebSphere MQ queue resources to IBM WebSphere Application Server.
 - For point-to-point messaging WebSphere applications can continue to use WebSphere queue resources (through the embedded messaging JMS provider) or WebSphere MQ queue resources.
 - For publish/subscribe messaging, WebSphere applications can continue to use WebSphere topic resources (through the embedded messaging JMS provider).
3. For WebSphere MQ publish/subscribe messaging, install a Publish/Subscribe broker, such as WebSphere MQ Event Broker.

For more information about installing WebSphere MQ Event Broker or WebSphere MQ Integrator (formerly MQSeries Integrator), see the following Web sites:

 - WebSphere MQ Event Broker Web site at <http://www-4.ibm.com/software/ts/mqseries/platforms/#eventb>
 - WebSphere MQ Integrator Web site at <http://www-4.ibm.com/software/ts/mqseries/platforms/#integrator>
4. Configure WebSphere MQ topic resources to IBM WebSphere Application Server. For publish/subscribe messaging, WebSphere applications can continue to use WebSphere topic resources (through the embedded messaging JMS provider) or WebSphere MQ topics.

Managing JMS servers on an Application Server node

Use this task to manage JMS servers on an Application Server node that is not part of a deployment manager cell.

On an Application Server node that is not part of a deployment manager cell, each application server has an internal JMS server that runs as part of the application server process and is administered as additional properties of the application server. A JMS server enables the application server to access JMS resources.

If you want to start a JMS server that is not part of a deployment manager cell, you start the associated application server. For more information about starting application servers, see "Starting servers" in the Information Center.

You can use the WebSphere administrative console to configure a general set of JMS server properties, which add to the default values of properties configured automatically for the embedded WebSphere JMS provider.

To configure JMS server properties, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers-> Application Servers** This displays a table of the application servers in the administrative domain.
2. In the content pane, click the name of the application server. This displays the properties of the application server in the content pane.
3. In the content pane, under Additional Properties, select **Server components-> JMS Server** This displays the JMS server properties in the content pane.
4. Specify appropriate properties for the JMS server.

If you want the JMS server to be started automatically when the application server is next started, set the **Initial state** property to started.

If you want to add a new queue to be hosted by the JMS server, add the administrative name of the queue to the Queue Names field. (The name must match the name of a WebSphere Queue administrative object, including the use of upper- and lowercase.) Similarly, if you want to remove a queue from the JMS server, remove its name from that field.

5. Click **OK**.
6. To save your configuration, click **Save** on the task bar of the administrative console window.
7. To have the changed configuration take effect, stop then restart the application server.

Managing JMS servers in a deployment manager cell

Use this task to manage JMS servers on nodes in a WebSphere Application Server deployment manager cell.

In a WebSphere Application Server deployment manager cell, each node can have at most one JMS server, and any application server within the cell can access JMS resources served by any of those JMS servers.

You can use the WebSphere administrative console to display a list of all JMS servers, to show and control their runtime status. You can also configure a general set of JMS server properties, which add to the default values of WebSphere MQ properties configured automatically for the embedded WebSphere JMS provider.

Note: In general, the default values of WebSphere MQ properties are adequate for WebSphere internal JMS servers. However, if you are running high messaging loads, you may need to change some WebSphere MQ properties; for example, WebSphere MQ properties for log file locations, file pages, and buffer pages. For more information about configuring WebSphere MQ properties, see the *WebSphere MQ System Administration* book, SC33-1873, which is available from the IBM Publications Center or from the WebSphere MQ collection kit, SK2T-0730.

To manage a WebSphere internal JMS server, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers-> JMS Servers**. This displays a table of the JMS servers, showing their runtime status.
2. If you want to change the runtime status of a JMS server, complete the following steps:
 - a. In the table of JMS servers, select the JMS servers that you want to act on.
 - To act on one or more specific JMS servers, select the checkbox next to the JMS server name.
 - To act on all JMS servers, select the checkbox next to the JMS servers title of the table.
 - b. Click one of the actions displayed to change the status of the JMS servers; for example, click **Stop** to stop a JMS server.

The status of the JMS servers that you have acted on is updated to show the result of your actions.

3. If you want to change the properties of a JMS server, click the name of the JMS server. This displays the properties of the JMS server in the content pane.
4. Specify appropriate properties for the JMS server.

If you want the JMS server to be started automatically, set the **Initial state** property to started.

If you want to add a new queue to be hosted by the JMS server, add the administrative name of the queue to the Queue Names field. (The name must match the name of a WebSphere Queue administrative object, including the use of upper- and lowercase.) Similarly, if you want to remove a queue from the JMS server, remove its name from that field.

5. Click **OK**.
6. To save your configuration, click **Save** on the task bar of the Administrative console window.
7. To have the changed configuration take effect, stop then restart the JMS Server.

Configuring JMS provider resources

Use the following tasks to configure JMS provider resources needed to support enterprise beans that exploit JMS services.

- Configuring resources for the embedded WebSphere JMS provider
 - Configuring a queue connection factory
 - Configuring a topic connection factory
 - Configuring a queue destination
 - Configuring a topic destination
- Configuring resources for the WebSphere MQ JMS provider
 - Configuring a queue connection factory

- Configuring a topic connection factory
- Configuring a queue destination
- Configuring a topic destination
- Configuring resources for a generic JMS provider
 - Configuring a JMS connection factory
 - Configuring a JMS destination

Configuring resources for the embedded WebSphere JMS provider:

Use the following tasks to configure the connection factories and destinations for the embedded WebSphere JMS provider.

You only need to complete these tasks if your WebSphere Application Server environment uses the embedded WebSphere JMS provider to support enterprise applications that use JMS.

- Configuring a queue connection factory
- Configuring a topic connection factory
- Configuring a queue destination
- Configuring a topic destination

Configuring a queue connection factory, embedded WebSphere JMS provider:

Use this task to configure the properties of a queue connection factory for use with the embedded WebSphere JMS provider. This task contains an optional step for you to create a new queue connection factory.

To configure the properties of a queue connection factory for use with the embedded WebSphere JMS provider, use the administrative console to complete the following steps:

1. Display the embedded WebSphere JMS provider.
 - a. In the navigation pane, click **Resources-> WebSphere JMS Provider**
 - b. In the content pane, click the name of the WebSphere JMS provider that you want to work with.

This displays in the content pane a table of properties for the WebSphere JMS provider, including links to the types of JMS resources supported by the JMS provider.
2. In the content pane, under Additional Properties, click **WebSphere Queue Connection Factories** This displays any existing queue connection factories for the WebSphere JMS provider in the content pane.
3. To create a new queue connection factory, click **New** in the content pane. Otherwise, to change the properties of an existing queue connection factory, click one of the connection factories displayed. This displays the properties for the queue connection factory in the content pane.
4. Specify appropriate properties for the queue connection factory.
5. Click **OK**.
6. To save your configuration, click **Save** on the task bar of the Administrative console window.
7. To have the changed configuration take effect, stop then restart the application server.

Configuring a topic connection factory, embedded WebSphere JMS provider:

Use this task to configure the properties of a topic connection factory for use with the embedded WebSphere JMS provider. This task contains an optional step for you to create a new topic connection factory.

To configure the properties of a topic connection factory for use with the embedded WebSphere JMS provider, use the administrative console to complete the following steps:

1. Display the embedded WebSphere JMS provider.
 - a. In the navigation pane, click **Resources-> WebSphere JMS Provider**
 - b. In the content pane, click the name of the WebSphere JMS provider that you want to work with.

This displays in the content pane a table of properties for the WebSphere JMS provider, including links to the types of JMS resources supported by the JMS provider.

2. In the content pane, under Additional Properties, click **WebSphere Topic Connection Factories** This displays any existing topic connection factories for the WebSphere JMS provider in the content pane.
3. To create a new topic connection factory, click **New** in the content pane. Otherwise, to change the properties of an existing topic connection factory, click one of the connection factories displayed. This displays the properties for the topic connection factory in the content pane.
4. Specify appropriate properties for the topic connection factory.
5. Click **OK**.
6. To save your configuration, click **Save** on the task bar of the Administrative console window.
7. To have the changed configuration take effect, stop then restart the application server.

Configuring a queue destination, embedded WebSphere JMS provider:

Use this task to configure the properties of a queue destination for use with the embedded WebSphere JMS provider. This task contains an optional step for you to create a new queue destination.

To configure the properties of a queue destination for use with the embedded WebSphere JMS provider, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> WebSphere JMS Provider** This displays in the content pane a table of properties for the WebSphere JMS provider, including links to the types of JMS resources supported by the JMS provider.
2. In the content pane, under Additional Properties, click **WebSphere Queue Destinations** This displays any existing queue destinations for the WebSphere JMS provider in the content pane.
3. To create a new queue destination, click **New** in the content pane. Otherwise, to change the properties of an existing queue destination, click one of the destinations displayed. This displays the properties for the queue destination in the content pane.
4. Specify appropriate properties for the queue destination.
5. Click **OK**.
6. To save your configuration, click **Save** on the task bar of the Administrative console window.
7. To make a queue destination available to applications, you need to host the queue on a JMS server. To add a new queue to a JMS server or to change an existing queue on a JMS server, you define the administrative name of the queue to the JMS server, as described in or Managing JMS servers in a deployment manager cell.
8. To have the changed configuration take effect, stop then restart the application server.

Configuring a topic destination, embedded WebSphere JMS provider:

Use this task to configure the properties of a topic destination for use with the embedded WebSphere JMS provider. This task contains an optional step for you to create a new topic destination factory.

To configure the properties of a topic destination factory for use with the embedded WebSphere JMS provider, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> WebSphere JMS Provider** This displays in the content pane a table of properties for the WebSphere JMS provider, including links to the types of JMS resources supported by the JMS provider.
2. In the content pane, under Additional Properties, click **WebSphere Topic Destinations** This displays any existing topic destinations for the WebSphere JMS provider in the content pane.
3. To create a new topic destination, click **New** in the content pane. Otherwise, to change the properties of an existing topic destination, click one of the destinations displayed. This displays the properties for the topic destination in the content pane.
4. Specify appropriate properties for the topic destination.

5. Click **OK**.
6. To save your configuration, click **Save** on the task bar of the Administrative console window.
7. To have the changed configuration take effect, stop then restart the application server.

Configuring resources for the WebSphere MQ JMS provider:

Use the following tasks to configure the connection factories and destinations for the WebSphere MQ JMS provider.

You only need to complete these tasks if your WebSphere Application Server environment uses the WebSphere MQ JMS provider to support enterprise applications that use JMS. To enable use of the WebSphere MQ JMS provider, you must have installed and configured WebSphere MQ JMS support, as described in *Installing and configuring WebSphere MQ as the JMS provider*.

- Configuring a queue connection factory
- Configuring a topic connection factory
- Configuring a queue destination
- Configuring a topic destination
- Enabling WebSphere MQ JMS connection pooling

Configuring a queue connection factory, WebSphere MQ JMS provider:

Use this task to configure the properties of a queue connection factory for use with the WebSphere MQ JMS provider. This task contains an optional step for you to create a new queue connection factory.

To configure the properties of a queue connection factory for use with the WebSphere MQ JMS provider, use the administrative console to complete the following steps:

1. Display the WebSphere MQ JMS provider.
 - a. In the navigation pane, click **Resources-> WebSphere MQ JMS Provider**
 - b. In the content pane, click the name of the WebSphere MQ JMS provider that you want to work with.

This displays in the content pane a table of properties for the WebSphere MQ JMS provider, including links to the types of JMS resources supported by the JMS provider.

2. In the contents pane, under Additional Properties, click **WebSphere MQ Queue Connection Factories**. This displays a table listing any existing queue connection factories, with a summary of their properties.
3. To create a new queue connection factory, click **New** in the content pane. Otherwise, to change the properties of an existing queue connection factory, click one of the connection factories displayed. This displays the properties for the queue connection factory in the content pane.
4. Specify appropriate properties for the queue connection factory.
5. **5.1+** Optional: Specify any of the following WebSphere MQ Secure Sockets Layer (SSL) properties that you need, as **Custom properties** of the connection factory: SSLPEERNAME, SSLCRL, and SSLCIPHERSUITE.

For more information about these custom properties, see *Custom properties*.

6. Click **OK**.
7. To save your configuration, click **Save** on the taskbar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

Configuring a topic connection factory, WebSphere MQ JMS provider:

Use this task to configure the properties of a topic connection factory for use with the WebSphere MQ JMS provider. This task contains an optional step for you to create a new topic connection factory.

To configure the properties of a topic connection factory for use with the WebSphere MQ JMS provider, use the administrative console to complete the following steps:

1. Display the WebSphere MQ JMS provider.
 - a. In the navigation pane, click **Resources-> WebSphere MQ JMS Provider**
 - b. In the content pane, click the name of the WebSphere MQ JMS provider that you want to work with.

This displays in the content pane a table of properties for the WebSphere MQ JMS provider, including links to the types of JMS resources supported by the JMS provider.

2. In the contents pane, under Additional Properties, click **WebSphere MQ Topic Connection Factories**. This displays a table listing any existing topic connection factories, with a summary of their properties.
3. To create a new topic connection factory, click **New** in the content pane. Otherwise, to change the properties of an existing topic connection factory, click one of the connection factories displayed. This displays the properties for the topic connection factory in the content pane.
4. Specify appropriate properties for the topic connection factory.
5. **5.1+** Optional: Specify any of the following WebSphere MQ properties that you need, as **Custom properties** of the connection factory: SSLPEERNAME, SSLCRL, SSLCIPHERSUITE, MSGSELECTION, and SUBSTORE.

For more information about these custom properties, see Custom properties.

6. Click **OK**.
7. To save your configuration, click **Save** on the taskbar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

Configuring a queue destination, WebSphere MQ JMS provider:

Use this task to configure the properties of a queue destination for use with the WebSphere MQ JMS provider. This task contains an optional step for you to create a new queue destination factory.

To configure the properties of a queue destination factory for use with the WebSphere MQ JMS provider, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources-> WebSphere MQ JMS Provider**. This displays in the content pane a table of properties for the WebSphere MQ JMS provider, including links to the types of JMS resources supported by the JMS provider.
2. In the contents pane, under Additional Properties, click **WebSphere MQ Queue Destinations**. This displays a table listing any existing queue destinations, with a summary of their properties.
3. To define a new queue destination, click **New** in the content pane. Otherwise, to change the properties of an existing queue destination, click one of the destinations displayed. This displays the properties for the queue destination in the content pane.
4. Configure appropriate properties for the queue destination.
5. Optional: If you want WebSphere Application Server to try to use the WebSphere MQ queue manager's remote administration utilities to create the queue, configure the WebSphere MQ Queue Connection properties.

If you have already created your underlying queue in WebSphere MQ using its administration tools (such as runmqsc or MQ Explorer), you do not need to configure any of the WebSphere MQ Queue Connection properties. You only need to configure these properties if you want WebSphere Application Server to try to use the WebSphere MQ queue manager's remote administration utilities to create the queue.

Note: For any changes to these properties to take effect on the queue manager, the WebSphere MQ Queue Manager on which the queue resides (or will reside) must be configured for remote administration and be running.

For more details about these properties, see WebSphere MQ config properties for the queue destination.

6. Click **Apply**.
7. To save your configuration, click **Save** on the task bar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

Configuring a topic destination, WebSphere MQ JMS provider:

Use this task to configure the properties of a topic destination for use with the WebSphere MQ JMS provider. This task contains an optional step for you to create a new topic destination factory.

To configure the properties of a topic destination factory for use with the WebSphere MQ JMS provider, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources-> WebSphere MQ JMS Provider** This displays in the content pane a table of properties for the WebSphere MQ JMS provider, including links to the types of JMS resources supported by the JMS provider.
2. In the content pane, under Additional Properties, click **WebSphere MQ Topic Destinations** This displays a table listing any existing topic destinations, with a summary of their properties.
3. To create a new topic destination, click **New** in the content pane. Otherwise, to change the properties of an existing topic destination, click one of the destinations displayed. This displays the properties for the topic destination in the content pane.
4. Specify appropriate properties for the topic destination.
5. Click **OK**.
6. To save your configuration, click **Save** on the task bar of the Administrative console window.
7. To have the changed configuration take effect, stop then restart the application server.

Configuring WebSphere MQ JMS connection pooling:

Use this task to configure properties of WebSphere MQ JMS connection pooling.

To enable WebSphere MQ JMS connection pooling, complete the following steps:

1. Start the WebSphere Administrative console.
2. In the navigation pane, select **Servers-> Application Servers-> your_app_server** This displays the properties of the application server, *your_app_server*, in the content pane.
3. In the Additional Properties table, select **Message Listener Service properties** This displays the Message Listener Service properties in the content pane.
4. Select Custom Properties, then add the following properties:
mjms.pooling.threshold
The maximum number of unused connections in the pool.
mjms.pooling.timeout
The timeout in milliseconds for unused connections in the pool.
5. Click **OK**.
6. To save your configuration, click **Save** on the task bar of the administrative console window.
7. To have the changed configuration take effect, stop then restart the application server.

Configuring resources for a generic JMS provider:

Use the following tasks to configure the connection factories and destinations for a generic JMS provider (not the embedded WebSphere JMS provider or the WebSphere MQ JMS provider).

You only need to complete these tasks if your WebSphere Application Server environment uses another JMS provider to support enterprise applications that use JMS. To enable use of another JMS provider, you must have installed and configured the JMS provider, as described in *Defining a new JMS provider to WebSphere Application Server*.

- Configuring a JMS connection factory
- Configuring a JMS destination

Configuring a JMS connection factory, generic JMS provider:

Use this task to configure the properties of a JMS connection factory for use with a generic JMS provider other than the embedded WebSphere JMS provider or WebSphere MQ.

To configure the properties of a JMS connection factory for use with a generic JMS provider, use the administrative console to complete the following steps:

1. Display the JMS provider.
 - a. In the navigation pane, click **Resources-> Generic JMS Providers**
 - b. In the content pane, click the name of the JMS provider that you want to work with.

This displays in the content pane a table of properties for the JMS provider, including links to the types of JMS resources supported by the JMS provider.
2. In the Additional Properties list in the contents pane, select **JMS Connection Factories** This displays a table listing any existing JMS connection factories, with a summary of their properties.
3. To create a new JMS connection factory, click **New** in the content pane. Otherwise, to change the properties of an existing JMS connection factory, click one of the connection factories displayed. This displays the properties for the JMS connection factory in the content pane.
4. Specify appropriate properties for the JMS connection factory.
5. Click **OK**.
6. To save your configuration, click **Save** on the task bar of the Administrative console window.
7. To have the changed configuration take effect, stop then restart the application server.

Configuring a JMS destination, a generic JMS provider:

Use this task to configure the properties of a JMS destination for use with a generic JMS provider (other than the embedded WebSphere JMS provider or the WebSphere MQ JMS provider).

To configure the properties of a JMS destination for use with a generic JMS provider, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources-> Generic JMS Providers** This displays in the content pane a list of any existing generic JMS providers.
2. In the content pane, click the JMS provider that you want to support the JMS destination. This displays in the content pane a table of properties for the JMS provider, including links to the types of JMS resources supported by the JMS provider.
3. In the Additional Properties list in the contents pane, select **JMS Destinations** This displays a table listing any existing JMS destinations, with a summary of their properties.
4. To create a new JMS destination, click **New** in the content pane. Otherwise, to change the properties of an existing queue destination, click one of the destinations displayed. This displays the properties for the JMS destination in the content pane.
5. Specify appropriate properties for the JMS destination.
6. Click **OK**.
7. To save your configuration, click **Save** on the task bar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

Securing messaging directories and log files

Use this task to restrict access to the /var/mqm directories and log files needed for WebSphere embedded messaging or WebSphere MQ as the JMS provider.

You need to set the permissions described in this topic, to reduce the risk of severe security exposures.

Note: The /var file system is used to store all the security logging information for the system, and is used to store the temporary files for email and printing. Therefore, it is critical that you maintain free space in /var for these operations and prevent unauthorized access to the file system. If you do not create a separate file system for messaging data, and /var fills up, all security logging will be stopped on the system until some free space is available in /var. Also, email and printing will no longer be possible until some free space is available in /var.

This procedure involves steps that you complete at different stages of installing and using IBM WebSphere Application Server, as described below. The steps are also described at appropriate points in other tasks, but are collected here for completeness.

This procedure applies only to the ordinary UNIX file system. If your site uses access-control lists, secure the files by using that mechanism. Any site-specific requirements can affect the desired owner, group and corresponding privileges. For example, on AIX, complete the following steps:

1. Before installing WebSphere embedded messaging or WebSphere MQ, create and mount a journaled file system called /var/mqm. Use a partition strategy with a separate volume for the messaging data. This means that other system activity is not affected if a large amount of messaging work builds up in /var/mqm.
2. Install WebSphere embedded messaging or WebSphere MQ as the JMS provider.

This stage is described in the following topics:

- Installing WebSphere embedded messaging as the JMS provider
- Installing WebSphere MQ as the JMS provider

As part of this stage, the installation program creates the /var/mqm/errors and /var/mqm/qmgrs/@SYSTEM/errors directories used to hold messaging logging files.

3. Restrict access to the /var/mqm/errors directory and the logging files, by using the following commands:

```
chmod 3777 /var/mqm/errors
chown mqm:mqm /var/mqm/errors
```

```
touch /var/mqm/errors/AMQERR01.LOG
chown mqm:mqm /var/mqm/errors/AMQERR01.LOG
chmod 666 /var/mqm/errors/AMQERR01.LOG
```

```
touch /var/mqm/errors/AMQERR02.LOG
chown mqm:mqm /var/mqm/errors/AMQERR02.LOG
chmod 666 /var/mqm/errors/AMQERR02.LOG
```

```
touch /var/mqm/errors/AMQERR03.LOG
chown mqm:mqm /var/mqm/errors/AMQERR03.LOG
chmod 666 /var/mqm/errors/AMQERR03.LOG
```

4. Restrict access to the /var/mqm/qmgrs/@SYSTEM/errors directory and the logging files, by using the following commands:

```
chmod 3777 /var/mqm/qmgrs/@SYSTEM/errors
chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors
```

```
touch /var/mqm/qmgrs/@SYSTEM/errors/AMQERR01.LOG
chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors/AMQERR01.LOG
chmod 666 /var/mqm/qmgrs/@SYSTEM/errors/AMQERR01.LOG
```

```
touch /var/mqm/qmgrs/@SYSTEM/errors/AMQERR02.LOG
chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors/AMQERR02.LOG
chmod 666 /var/mqm/qmgrs/@SYSTEM/errors/AMQERR02.LOG
```

```
touch /var/mqm/qmgrs/@SYSTEM/errors/AMQERR03.LOG
chown mqm:mqm /var/mqm/qmgrs/@SYSTEM/errors/AMQERR03.LOG
chmod 666 /var/mqm/qmgrs/@SYSTEM/errors/AMQERR03.LOG
```

5. For each application server that uses WebSphere embedded messaging or WebSphere MQ, restrict access to the server's `/var/mqm/qmgrs/long_server_name/errors` directory and its messaging logging files. You should restrict access to the server's directory and logging files, as soon after creating the application server as possible.

To restrict access to the server's directory and logging files, use the following commands:

```
chmod 3775 /var/mqm/qmgrs/long_server_name/errors
chown mqm:mqm /var/mqm/qmgrs/long_server_name/errors
```

```
touch /var/mqm/qmgrs/long_server_name/errors/AMQERR01.LOG
chown mqm:mqm /var/mqm/qmgrs/long_server_name/errors/AMQERR01.LOG
chmod 666 /var/mqm/qmgrs/long_server_name/errors/AMQERR01.LOG
```

```
touch /var/mqm/qmgrs/long_server_name/errors/AMQERR02.LOG
chown mqm:mqm /var/mqm/qmgrs/long_server_name/errors/AMQERR02.LOG
chmod 666 /var/mqm/qmgrs/long_server_name/errors/AMQERR02.LOG
```

```
touch /var/mqm/qmgrs/long_server_name/errors/AMQERR03.LOG
chown mqm:mqm /var/mqm/qmgrs/long_server_name/errors/AMQERR03.LOG
chmod 666 /var/mqm/qmgrs/long_server_name/errors/AMQERR03.LOG
```

Where `long_server_name` is the long name assigned to the server, in the following form:

`WAS_nodename_server_name`. For example, if you created an application server called `server1` to run on the node called `apnode1`, the long server name would be: `WAS_apnode1_server1`.

This task has restricted access to the `/var/mqm` directories and log files needed for WebSphere embedded messaging or WebSphere MQ as the JMS provider, such that only the user ID `mqm` or members of the `mqm` user group have write access.

Configuring authorization security for the embedded WebSphere JMS provider

Use this task to configure authorization security for the embedded WebSphere JMS provider.

To configure authorization security for the embedded WebSphere JMS provider complete the following steps.

Security for the embedded WebSphere JMS provider is enabled when you enable global security for WebSphere Application Server. For more information about enabling global security, see "Managing secured applications" in the Information Center.

1. Configure authorization settings to access JMS resources owned by the embedded WebSphere JMS provider. Authorization to access JMS resources owned by the embedded WebSphere JMS provider is controlled by settings in the `WAS_install_root\config\cells\your_cell_name\integral-jms-authorizations.xml` file.

The settings grant or deny authenticated userids access to internal JMS provider resources (queues or topics). As supplied, the `integral-jms-authorisations.xml` file grants the following permissions:

- Read and write permissions to all queues.
- Pub, sub, and persist to all topics.

To configure authorization settings, edit the `integral-jms-authorisations.xml` file according to the information in this topic and in that file. Please note the file is in Unicode, which requires a binary FTP to the host from a workstation.

2. Edit the `queue-admin-userids` element to create a list of userids with administrative access to all queues. Administrative access is needed to create queues and perform other administrative activities on queues. For example, consider the following `queue-admin-userids` section:

```
<queue-admin-userids>
  <userid>adminid1</userid>
  <userid>adminid2</userid>
</queue-admin-userids>
```

In this example the userids adminid1 and adminid2 are defined to have administrative access to all queues.

3. Edit the queue-default-permissions element to define the default queue access permissions. These permissions are used for queues for which you do not define specific permissions (in queue sections). If this section is not specified, then access permissions exist only for those queues for which you have specifically created queue elements.

For example, consider the following queue-default-permissions element:

```
<queue-default-permissions>
  <permission>write</permission>
</queue-default-permissions>
```

In this example the default access permission for all queues is **write**. This can be overridden for a specific queue by creating a queue element that sets its access permission to **read**.

4. If you want to define specific access permissions for a queue, create a queue element, then define the following elements:

For example, consider the following queue element:

```
<queue>
  <name>q1</name>
  <public>
  </public>
  <authorize>
    <userid>useridr</userid>
    <permission>read</permission>
  </authorize>
  <authorize>
    <userid>useridw</userid>
    <permission>write</permission>
  </authorize>
  <authorize>
    <userid>useridrw</userid>
    <permission>read</permission>
    <permission>write</permission>
  </authorize>
</queue>
```

In this example for the queue q1, the userid useridr has read permission, the userid useridw has write permission, the userid useridrw has both read and write permissions, and all other userids have no access permissions (<public></public>).

5. Edit topic elements to define the access permissions for publish/subscribe topic destinations. For topics, you can grant and deny access permissions. Full permission inheritance is supported on topics. If you do not define specific access permissions for a userid on a specific topic then permissions are inherited first from the public permissions on that topic then from the parent topic. The inheritance of access permissions continues until the root topic from which the root permissions are assumed.
 - a. If you want to define default access permissions for the root topic, edit a topic element with an empty name element. If you omit such a topic section, topics have no default topic permissions other than those defined by specific topic elements. For example, consider the following topic element for the root topic:

```
<topic>
  <name></name>
  <public>
    <permission>+pub</permission>
  </public>
</topic>
```

In this example, the default access permission for all topics is set to publish. This can be overridden by other topic elements for specific topic names.

- b. If you want to define access permissions for a specific topic, create a topic element with the name for the topic then define the access permissions in the public and authorize elements of the topic element. For example, consider the following topic section:

```
<topic>
  <name>a/b/c</name>
  <public>
    <permission>+sub</permission>
  </public>
  <authorize>
    <userid>useridpub</userid>
    <permission>+pub</permission>
  </authorize>
</topic>
```

In this example, the subscribe permission is granted to anyone accessing any topic whose name starts with a/b/c. Also, the userid `useridpub` is granted publish permission for any topic whose name starts with a/b/c.

6. Save the `integral-jms-authorizations.xml` file.

If the dynamic update setting is selected, changes to the `integral-jms-authorizations.xml` file become active when the changed file is saved, so there is no need to stop and restart the JMS server. If the dynamic update setting is not selected, you need to stop and restart the JMS server to make changes active.

Authorization settings for embedded WebSphere JMS provider resources:

Use the `integral-jms-authorisations.xml` file to view or change the authorization settings for JMS resources owned by the embedded WebSphere JMS provider.

Authorization to access JMS resources owned by the embedded WebSphere JMS provider is controlled by the following settings in the `was_install\config\cells\your_cell_name\integral-jms-authorisations.xml` file.

This structure of the settings in `integral-jms-authorisations.xml` is shown in the following example. Descriptions of these settings are provided after the example. To configure authorization settings, follow the instructions provided in *Configuring authorization security for the embedded WebSphere JMS provider*

```
<integral-jms-authorizations>
```

```
  <dynamic-update>true</dynamic-update>
```

```
  <queue-admin-userids>
    <userid>adminid1</userid>

```

dynamic-update: Controls whether or not the JMS Server checks dynamically for updates to this file.

true (Default) Enables dynamic update support.

false Disables dynamic update checking and improves authorization performance.

queue-admin-userids: This element lists those userids with administrative access to all WebSphere queue destinations. Administrative access is needed to create queues and perform other administrative activities on queues. You define each userid within a separate userid sub element:

<userid>adminid</userid>

Where *adminid* is a user ID that can be authenticated by IBM WebSphere Application Server.

queue-default-permissions: This element defines the default queue access permissions that are assumed if no permissions are specified for a specific queue name. These permissions are used for queues for which you do not define specific permissions (in queue elements). If this element is not specified, then no access permissions exist unless explicitly authorized for individual queues.

You define the default permission within a separate permission sub element:

<permission>read-write</permission>

Where *read-write* is one of the following keywords:

read By default, userids have read access to WebSphere queue destinations.

write By default, userids have write access to WebSphere queue destinations.

queue: This element contains the following authorization settings for a single queue destination:

name The name of the queue.

public The default public access permissions for the queue. This is used only for those userids that have no specific authorize element. If you leave this element empty, or do not define it at all, only those userids with authorize elements can access the queue.

You define each default permission within a separate permission element.

authorize

The access permissions for a specific userid. Within each authorize element, you define the following elements:

userid The userid that you want to assign a specific access permission.

permission

An access permission for the associated userid.

You define each permission within a separate permission element. Each permission element can contain the keyword read or write to define the access permission.

For example, consider the following queue element:

```
<queue>
  <name>q1</name>
  <public>
</public>
  <authorize>
    <userid>useridr</userid>
    <permission>read</permission>
  </authorize>
  <authorize>
    <userid>useridw</userid>
    <permission>write</permission>
  </authorize>
  <authorize>
    <userid>useridrw</userid>
    <permission>read</permission>
    <permission>write</permission>
  </authorize>
</queue>
```

topic: This element contains the following authorization settings for a single topic destination:

Each topic element has the following sub elements:

name The name of the topic, without wildcards or other substitution characters.

public The default public access permissions for the topic. This is used only for those userids that have no specific authorize element. If you leave this element empty, or do not define it at all, only those userids with authorize elements can access the topic.

You define each default permission within a separate permission element.

authorize

The access permissions for a specific userid. Within each authorize element, you define the following elements:

userid The userid that you want to assign a specific access permission.

permission

An access permission for the associated userid.

You define each permission within a separate permission element. Each permission element can contain one of the following keywords to define the access permission:

+pub Grant publish permission

+sub Grant subscribe permission

+persist

Grant persist permission

-pub Deny publish permission

-sub Deny subscribe permission

-persist

Deny persist permission

Displaying administrative lists of JMS resources

Use this task with the WebSphere administrative console to display administrative lists of JMS resources.

You can use the WebSphere administrative console to display lists of the following types of JMS resources. You can use the panels displayed to select JMS resources to administer, or to create or delete JMS resources (where appropriate).

To display administrative lists of JMS resources, complete the following general steps:

1. Start the WebSphere administrative console.
2. In the navigation pane, expand the appropriate path to select the type of JMS provider (as shown in the following table).
3. If appropriate, in the content pane, select a specific JMS provider. This displays the properties for the JMS provider, and an Additional Properties list of links to the types of JMS resources provided.
4. In the content pane, under Additional Resources, select the link for the type of JMS resource. This displays a list of the selected JMS resource type in the content pane.

Table 3. Network Deployment and Enterprise - Administrative panels for JMS resources

Path	Panel	Description
Servers-> JMS servers	JMS servers	List all JMS servers within the administration domain
Servers-> JMS servers-> <i>server_name</i>	JMS servers	List properties of the selected JMS server <i>server_name</i>
Embedded WebSphere JMS providers		
Resources-> WebSphere JMS Provider	WebSphere JMS providers	List all WebSphere JMS providers within the administration domain
Resources-> WebSphere JMS Providers-> (In content pane) <i>WebSphereJMSProvider</i>	WebSphere JMS provider	List properties and resources of the selected WebSphere JMS provider
Resources-> WebSphere JMS Providers-> (In content pane) <i>WebSphereJMSProvider</i> -> (Under Additional Properties) WebSphere JMS Queue Connection Factories	WebSphere queue connection factories	List all queue connection factories of the selected WebSphere JMS provider
Resources-> WebSphere JMS Providers-> (In content pane) <i>WebSphereJMSProvider</i> -> (Under Additional Properties) WebSphere Topic Connection Factories	WebSphere topic connection factories	List all topic connection factories of the selected WebSphere JMS provider
Resources-> WebSphere JMS Providers-> (In content pane) <i>WebSphereJMSProvider</i> -> (Under Additional Properties) WebSphere Queue Destinations	WebSphere queue destinations	List all queue destinations of the selected WebSphere JMS provider
Resources-> WebSphere JMS Providers-> (In content pane) <i>WebSphereJMSProvider</i> -> (Under Additional Properties) WebSphere Topic Destinations	WebSphere topic destinations	List all topic destinations of the selected WebSphere JMS provider
WebSphere MQ JMS provider		
Resources-> WebSphere MQ JMS Providers	WebSphere MQ JMS providers	List properties and resource types for the WebSphere MQ JMS provider
Resources-> WebSphere MQ JMS Providers-> (In content pane) <i>MQJMSProvider</i>	WebSphere MQ JMS provider	List properties and resources of the selected WebSphere MQ JMS provider

Table 3. Network Deployment and Enterprise - Administrative panels for JMS resources (continued)

Path	Panel	Description
Resources-> WebSphere MQ JMS Providers-> (In content pane) <i>MQJMSProvider</i> -> (Under Additional Properties) WebSphere MQ Queue connection factories	WebSphere MQ queue connection factories	List all queue connection factories of the selected WebSphere MQ JMS provider
Resources-> WebSphere MQ JMS providers-> (In content pane) <i>MQJMSProvider</i> -> (Under Additional Properties) WebSphere MQ Topic connection factories	WebSphere MQ topic connection factories	List all topic connection factories of the selected WebSphere MQ JMS provider
Resources-> WebSphere MQ JMS Providers-> (In content pane) <i>MQJMSProvider</i> -> (Under Additional Properties) WebSphere MQ Queue destinations	WebSphere MQ queue destination	List all queue destinations of the selected WebSphere MQ JMS provider
Resources-> WebSphere MQ JMS providers-> (In content pane) <i>MQJMSProvider</i> -> WebSphere MQ Topic destinations	WebSphere MQ topic destination	List all topic destinations of the selected WebSphere MQ JMS provider
Generic JMS providers		
A JMS provider other than the embedded WebSphere JMS provider or the WebSphere MQ JMS provider		
Resources-> Generic JMS Providers	Generic JMS providers	List all generic JMS providers within the administration domain
Resources-> Generic JMS Providers-> (In content pane) <i>provider_name</i>	Generic JMS provider <i>provider_name</i>	List properties and resources of the selected generic JMS provider <i>provider_name</i>
Resources-> Generic JMS Providers-> (In content pane) <i>provider_name</i> ->(Under Additional Properties) JMS connection factories	Generic JMS connection factories	List all JMS connection factories of the selected generic JMS provider <i>provider_name</i>
Resources-> Generic JMS Providers-> (In content pane) <i>provider_name</i> -> (Under Additional Properties) JMS destinations	Generic JMS destinations	List all JMS destinations (queues and topics) of the selected generic JMS provider <i>provider_name</i>

JMS server collection:

Each JMS server provides the functions of the JMS provider for a node in your administrative domain. Use this panel to list the JMS servers within the administration domain, or to select a JMS server to view or change its configuration properties.

There can be at most one JMS server on each node in the administration domain, and any application server within the domain can access JMS resources served by any JMS server on any node in the domain.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers-> JMS Servers**.

To view or change the properties of a JMS server, select its name in the list displayed.

To act on one or more of the JMS servers listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

JMS provider collection:

Use this panel to list JMS providers, or to select a JMS provider to view or change its configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand one of the following paths:

- **Resources-> WebSphere JMS Provider**
- **Resources-> WebSphere MQ JMS Provider**
- **Resources-> Generic JMS Providers**

To view or change the properties of a JMS provider or its resources, select its name in the list displayed.

To define a new generic JMS provider, on the **Resources-> Generic JMS Providers** page click **New**.

To act on one or more of the JMS providers listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

Name The name by which this JMS provider is known for administrative purposes.

Description

A description of this JMS provider for administrative purposes.

WebSphere JMS provider settings:

Use this panel to view the configuration properties of the embedded WebSphere JMS provider that is installed with WebSphere Application Server. *You cannot change these properties.*

To view this administrative console page, click **Resources-> WebSphere JMS Provider**

Name:

The name by which the JMS provider is known for administrative purposes.

Data type	String
Default	WebSphereJMSPProvider

Description:

A description of the JMS provider, for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Built-in WebSphere JMS Provider

WebSphere MQ JMS provider settings:

Use this panel to view the configuration properties of the WebSphere MQ JMS provider. These properties apply only if you have installed WebSphere MQ as the JMS provider over the internal JMS provider installed with WebSphere Application Server. *You cannot change these properties.*

To view this administrative console page, click **Resources-> WebSphere MQ JMS Provider**

Name:

The name by which the WebSphere MQ JMS provider is known for administrative purposes.

Data type	String
Default	WebSphereMQJMSProvider

Description:

A description of the JMS provider, for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	WebSphere MQ JMS provider

Classpath:

The Java classpath for the JMS provider. The list of paths or JAR file names that together form the location for the JMS provider classes.

Data type	String
Default	\$MQJMS_LIB_ROOT

Native Library Path:

The native library path for the JMS provider. An optional path to any native libraries needed by the JMS provider.

Data type	String
Default	\$MQJMS_LIB_ROOT

The Native Library Path property is set to the directory where the WebSphere MQ Java feature is installed.

JMS provider settings:

If you want to use a JMS provider other than the embedded WebSphere JMS provider or the WebSphere MQ JMS provider, use this panel to configure properties of the JMS provider.

To view this administrative console page, click **Resources-> Generic JMS Providers-> provider_name**

Name:

The name by which the JMS provider is known for administrative purposes.

Data type	String
Default	Null

Description:

A description of the JMS provider, for administrative purposes

Data type	String
Default	Null

Classpath:

The Java classpath for the JMS provider. The list of paths or JAR file names that together form the location for the JMS provider classes.

Data type	String
Default	Null

Native Library Path:

The native library path for the JMS provider. An optional path to any native libraries needed by the JMS provider.

Data type	String
Default	Null

External initial context factory:

The Java classname of the initial context factory for the JMS provider.

For example, for an LDAP service provider the value has the form: com.sun.jndi.ldap.LdapCtxFactory.

Data type	String
Default	Null

External provider URL:

The JMS provider URL for external JNDI lookups.

For example, an LDAP URL for a JMS provider has the form: ldap://hostname.company.com/contextName.

Data type	String
Default	Null

WebSphere Queue connection factory collection:

The queue connection factories configured in the embedded WebSphere JMS provider for point-to-point messaging with JMS queues.

This panel shows a list of the WebSphere queue connection factories with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> WebSphere JMS Provider**.
2. In the content pane, select the JMS provider that you want to support the connection factory.
3. In the Additional Properties list in the contents pane, select **WebSphere Queue Connection Factory**.

To view or change the properties of a connection factory, select its name in the list displayed.

To act on one or more of the connection factories listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

WebSphere queue connection factory settings:

Use this panel to view or change the configuration properties of the selected queue connection factory for use with the embedded WebSphere JMS provider that is installed with WebSphere Application Server. These configuration properties control how connections are created to the associated JMS queue destination.

A queue connection factory is used to create JMS connections to queue destinations. The queue connection factory is created by the embedded WebSphere JMS provider. A queue connection factory for the embedded WebSphere JMS provider has the following properties:

To view this administrative console page, click **Resources-> WebSphere JMS Provider-> (In content pane, under Additional Properties) WebSphere Queue Connection Factories-> *connection_factory***

Scope:

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JMS Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell. For example, if you set **Max Connections** to 10, then each server in that Cell can have 10 connections.

Cell The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

Node The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

Server The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

Data type String

Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String

Default Null

JNDI name:

The JNDI name that is used to bind the connection factory into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

Category:

A category used to classify or group this connection factory, for your IBM WebSphere Application Server administrative records.

Data type String

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (`res-auth`) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

Data type Pick-list

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for container-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

Data type Pick-list

Mapping-Configuration Alias:

Allows users to select from the **Security > JAAS Configuration > Application Logins Configuration** list.

The **DefaultPrincipalMapping** JAAS configuration maps the authentication alias to the userid and password. You may define and use other mapping configurations. For more information about the mapping configurations, see "Java Authentication and Authorization service configuration entry settings" in the Information center.

Data type Pick-list

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type	String
Units	Enum
Default	Null
Range	Pull-down list of nodes in the WebSphere administrative domain.

XA Enabled:

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are not used in the same transaction.

If you clear this checkbox property (for non-XA coordination), the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (session.commit and session.rollback) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server.

5.1 + In WBI Server Foundation the last participant support enables you to enlist one non-XA resource with other XA-capable resources.

For a WebSphere Topic Connection Factory with the **Port** property set to DIRECT this property does not apply, and always adopts non-XA coordination.

Data type	Checkbox
Default	Selected (enabled for XA coordination)

Range**Selected**

The connection factory is enabled for XA-coordination of messages

Cleared

The connection factory is not enabled for XA coordination of messages

Recommended

Do not enable XA coordination when the message queue or topic received is the only resource in the transaction. Enable XA coordination when other resources, including other queues or topics, are involved.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis. See the following table for details.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Session pool settings:

Use this page to configure session pool settings.

This administrative console page is common to a range of resource types; for example, JMS queue connection factories. To view this page, the path depends on the type of resource, but generally you select an instance of the resource provider, then an instance of the resource type, then click **Session Pool**. For example: click **Resources > WebSphere JMS Providers > WebSphere Queue Connection Factories > connection_factory > Session Pool**.

Scope:

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JDBC Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource

property settings are local to each server in the Cell. For example, if you set **Max Connections** to 10, then each server in that Cell can have 10 connections.

Cell The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

Node The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

Server The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

Data type String

Connection Timeout:

Specifies the interval, in seconds, after which a connection request times out and a `ConnectionWaitTimeoutException` is thrown.

The wait is necessary when the maximum value of connections (**Max Connections**) to a particular connection pool is reached. For example, if *Connection Timeout* is set to 300 and the maximum number of connections is reached, the Pool Manager waits for 300 seconds for an available physical connection. If a physical connection is *not* available within this time, the Pool Manager throws a `ConnectionWaitTimeoutException`. It usually does not make sense to retry the `getConnection()` method, because if a longer wait time is required, you should set the **Connection Timeout** setting to a higher value. Therefore, if this exception is caught by the application, the administrator should review the expected usage of the application and tune the connection pool and the database accordingly.

If *Connection Timeout* is set to 0, the Pool Manager waits as long as necessary until a connection is allocated (which happens when the number of connections falls below the value of **Max Connections**).

If *Max Connections* is set to 0, which enables an infinite number of physical connections, then the *Connection Timeout* value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Max Connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a `ConnectionWaitTimeoutException` is thrown.

For example, if the Max Connections value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in Connection Timeout for a physical connection to become free.

If Max Connections is set to 0, the Connection Timeout value is ignored.

For better performance, set the value for the connection pool lower than the value for the Max Connections option in the Web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

If clones are used, one data pool exists for each clone. Knowing the number of data pools is important when configuring the database maximum connections.

You can use the Tivoli Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the CPU load is not close to 100%, consider increasing the connection pool size. If the Percent Used value is consistently low under normal workload, consider decreasing the number of connections in the pool.

Data type	Integer
Default	10
Range	0 to max int

Min Connections:

Specifies the minimum number of physical connections to maintain.

Until this number is reached, the pool maintenance thread does not discard physical connections. However, no attempt is made to bring the number of connections up to this number. If you set a value for Aged Timeout, the minimum is not maintained. All connections with an expired age are discarded.

For example if the **Min Connections** value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the **Min Connections** setting.

Data type	Integer
Default	1
Range	0 to max int

Reap Time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if **Reap Time** is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the **Unused Timeout** and **Aged Timeout** settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in **Min Connections**. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in

which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections which timeout due to non-zero timeout values are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused Timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections not in use exceeds the **Min Connections** setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded. Note that accuracy of this timeout, as well as performance, is affected by the **Reap Time** value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged Timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting **Aged Timeout** to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the **Reap Timeout** value for optimal performance. For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. Note that accuracy of this timeout, as well as performance, are affected by the Reap Time value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge Policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**. JCA data sources can have either option. WebSphere Version 4.0 data sources always have a purge policy of **EntirePool**.

Data type	String
Default	FailingConnectionOnly

Range

EntirePool

All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and throws a *StaleConnectionException* during the next operation on that connection. Subsequent *getConnection* requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly

Only the connection that caused the *StaleConnectionException* is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next *getConnection* request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

WebSphere topic connection factory collection:

The topic connection factories configured in the embedded WebSphere JMS provider for publish/subscribe messaging with JMS topics.

This panel shows a list of the WebSphere topic connection factories with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> WebSphere JMS Provider**.
2. In the content pane, select the JMS provider that you want to support the connection factory.
3. In the Additional Properties list in the contents pane, select **WebSphere Topic Connection Factory**.

To view or change the properties of a connection factory, select its name in the list displayed.

To act on one or more of the connection factories listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

WebSphere topic connection factory settings:

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the embedded WebSphere JMS provider. These configuration properties control how connections are created to the associated JMS topic destination.

A topic connection factory is used to create JMS connections to topic destinations. The topic connection factory is created by the associated JMS provider. A topic connection factory for the embedded WebSphere JMS provider has the following properties.

To view this administrative console page, click **Resources-> WebSphere JMS Provider-> (In content pane, under Additional Properties) WebSphere Topic Connection Factories-> connection_factory**

Scope:

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JMS Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell. For example, if you set **Max Connections** to 10, then each server in that Cell can have 10 connections.

Cell The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

Node The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

Server The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

Data type String

Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String
Default Null

JNDI name:

The JNDI name that is used to bind the topic connection factory into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Category:

A category used to classify or group this topic connection factory, for your IBM WebSphere Application Server administrative records.

Data type	String
------------------	--------

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type	Enum
Default	Null
Range	Pull-down list of nodes in the WebSphere administrative domain.

Port:

Which of the two ports that connections use to connect to the JMS Server. The QUEUED port is for full-function JMS publish/subscribe support, the DIRECT port is for non-persistent, non-transactional, non-durable subscriptions only.

Note: Message-driven beans cannot use the direct listener port for publish/subscribe support. Therefore, any topic connection factory configured with **Port** set to `Direct` cannot be used with message-driven beans.

Data type	Enum
Units	Not applicable
Default	QUEUED
Range	QUEUED The listener port used for full-function JMS-compliant, publish/subscribe support. DIRECT The listener port used for direct TCP/IP connection (non-transactional, non-persistent, and non-durable subscriptions only) for publish/subscribe support. The TCP/IP port numbers for these ports are defined on the WebSphere Internal JMS Server.

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for container-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

Mapping-Configuration Alias:

Allows users to select from the **Security > JAAS Configuration > Application Logins Configuration** list.

The **DefaultPrincipalMapping** JAAS configuration maps the authentication alias to the userid and password. You may define and use other mapping configurations. For more information about the mapping configurations, see "Java Authentication and Authorization service configuration entry settings" in the Information center.

Data type Pick-list

Clone Support:

Select this checkbox to enable clone support to allow the same durable subscription across topic clones.

Data type Enum
Default Cleared

Range**Selected**

Clone support is enabled.

Cleared

Clone support is disabled.

If you select this property, you must also specify a value for the **Client ID** property.

Client ID:

The JMS client identifier used for connections to the queue manager.

Data type

String

Range

A valid JMS client ID

XA Enabled:

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are not used in the same transaction.

If you clear this checkbox property (for non-XA coordination), the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (`session.commit` and `session.rollback`) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server.

5.1+ In WBI Server Foundation the last participant support enables you to enlist one non-XA resource with other XA-capable resources.

For a WebSphere Topic Connection Factory with the **Port** property set to DIRECT this property does not apply, and always adopts non-XA coordination.

Data type

Checkbox

Default

Selected (enabled for XA coordination)

Range**Selected**

The connection factory is enabled for XA-coordination of messages

Cleared

The connection factory is not enabled for XA coordination of messages

Recommended

Do not enable XA coordination when the message queue or topic received is the only resource in the transaction. Enable XA coordination when other resources, including other queues or topics, are involved.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis. See the following table for details.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

WebSphere Queue destination collection:

The queue destinations configured in the embedded WebSphere JMS provider for point-to-point messaging with JMS queues.

This panel shows a list of the WebSphere queue destinations with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> WebSphere JMS Provider**.
2. In the content pane, select the JMS provider that you want to support the queue destination.
3. In the Additional Properties list in the contents pane, select **WebSphere Queue Destination**.

To view or change the properties of a queue destination, select its name in the list displayed.

To act on one or more of the queue destinations listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

WebSphere queue settings:

Use this panel to view or change the configuration properties of the selected queue destination for use with the WebSphere JMS provider.

A queue destination is used to configure the properties of a JMS queue. Connections to the queue are created by the associated queue connection factory for the embedded WebSphere JMS provider. A queue for use with the internal WebSphere JMS provider has the following properties.

To view this administrative console page, click **Resources-> WebSphere JMS Provider-> (In content pane, under Additional Properties) WebSphere Queue Destinations-> *destination_name***

Scope:

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JMS Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource

property settings are local to each server in the Cell. For example, if you set **Max Connections** to 10, then each server in that Cell can have 10 connections.

Cell The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

Node The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

Server The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

Data type String

Name:

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

To enable applications to use this queue, you must add the queue name to the list of queue names in the configuration of the JMS servers that host the queue.

Data type String

JNDI name:

The JNDI name that is used to bind the queue into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the queue, for administrative purposes

Data type String

Default Null

Category:

A category used to classify or group this queue, for your IBM WebSphere Application Server administrative records.

Data type String

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

Data type	Enum
Default	APPLICATION DEFINED
Range	APPLICATION DEFINED Messages on the destination have their persistence defined by the application that put them onto the queue. NON-PERSISTENT Messages on the destination are not persistent. PERSISTENT Messages on the destination are persistent. When a persistent message is put to a queue, all of the message data is written to the messaging log (under the <i>embedded_messaging_install</i> log directory) to make recovery of the message possible.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property

Data type	Enum
Units	Not applicable
Default	APPLICATION DEFINED
Range	APPLICATION DEFINED The priority of messages on this destination is defined by the application that put them onto the destination. QUEUE DEFINED [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. SPECIFIED The priority of messages on this destination is defined by the Specified priority property. <i>If you select this option, you must define a priority on the Specified priority property.</i>

Specified priority:

If the **Priority** property is set to Specified, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest)

If the **Priority** property is set to Specified, messages sent to this queue have the priority value specified by this property.

Data type	Integer
Units	Message priority level
Default	0

Range 0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

Data type	Enum
Units	Not applicable
Default	APPLICATION DEFINED
Range	APPLICATION DEFINED The expiry timeout for messages on this queue is defined by the application that put them onto the queue. UNLIMITED Messages on this queue have no expiry timeout, so those messages never expire. SPECIFIED The expiry timeout for messages on this queue is defined by the Specified expiry property. <i>If you select this option, you must define a timeout on the Specified expiry property.</i>

Specified expiry:

If the **Expiry timeout** property is set to *Specified*, type here the number of milliseconds (greater than 0) after which messages on this queue expire

Data type	Integer
Units	Milliseconds
Default	0
Range	Greater than or equal to 0 <ul style="list-style-type: none">• 0 indicates that messages never timeout• Other values are an integer number of milliseconds

WebSphere topic destination collection:

The topic destinations configured in the embedded WebSphere JMS provider for publish/subscribe messaging with JMS topics. Use this panel to create or delete topic destinations, or to select a topic destination to view or change its configuration properties.

This panel shows a list of the WebSphere topic destinations with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> WebSphere JMS Provider**.
2. In the content pane, select the JMS provider that you want to support the topic destination.
3. In the Additional Properties list in the contents pane, select **WebSphere Topic Destination**.

To view or change the properties of a topic destination, select its name in the list displayed.

To act on one or more of the topic destinations listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

WebSphere topic settings:

Use this panel to view or change the configuration properties of the selected topic destination for use with the embedded WebSphere JMS provider.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. Connections to the topic are created by the associated topic connection factory. A topic for use with the embedded WebSphere JMS provider has the following properties.

To view this administrative console page, click **Resources-> WebSphere JMS Provider-> (In content pane, under Additional Properties) WebSphere Topic destinations-> *destination_name***

Scope:

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JMS Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell. For example, if you set **Max Connections** to 10, then each server in that Cell can have 10 connections.

Cell The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

Node The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

Server The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

Data type String

Name:

The name by which the topic is known for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI name:

The JNDI name that is used to bind the topic into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the topic, for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

Category:

A category used to classify or group this topic, for your IBM WebSphere Application Server administrative records.

Data type String

Topic:

The name of the topic as defined to the JMS provider.

Data type String
Default Null
Range The topic value can be dot notation and include wildcard characters.

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

Data type Enum
Default APPLICATION DEFINED
Range **APPLICATION DEFINED**
Messages on the destination have their persistence defined by the application that put them onto the queue.
NON-PERSISTENT
Messages on the destination are not persistent.
PERSISTENT
Messages on the destination are persistent.
QUEUE DEFINED
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property

Data type
Units
Default
Range

Enum
Not applicable
APPLICATION DEFINED
APPLICATION DEFINED
The priority of messages on this destination is defined by the application that put them onto the destination.
QUEUE DEFINED
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
SPECIFIED
The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified priority:

If the **Priority** property is set to Specified, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest)

If the **Priority** property is set to Specified, messages sent to this queue have the priority value specified by this property.

Data type
Units
Default
Range

Integer
Message priority level
0
0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

Data type
Units
Default
Range

Enum
Not applicable
APPLICATION DEFINED
APPLICATION DEFINED
The expiry timeout for messages on this queue is defined by the application that put them onto the queue.
UNLIMITED
Messages on this queue have no expiry timeout, so those messages never expire.
SPECIFIED
The expiry timeout for messages on this queue is defined by the **Specified expiry** property. *If you select this option, you must define a timeout on the **Specified expiry** property.*

Specified expiry:

If the **Expiry timeout** property is set to Specified, type here the number of milliseconds (greater than 0) after which messages on this queue expire

Data type	Integer
Units	Milliseconds
Default	0
Range	Greater than or equal to 0 <ul style="list-style-type: none"> • 0 indicates that messages never timeout • Other values are an integer number of milliseconds

WebSphere MQ queue connection factory collection:

The queue connection factories configured in the WebSphere MQ JMS provider for point-to-point messaging with JMS queues.

This panel shows a list of the WebSphere MQ queue connection factories with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> WebSphere MQ JMS Provider**.
2. In the content pane, select the JMS provider that you want to support the connection factory.
3. In the Additional Properties list in the contents pane, select **WebSphere MQ Queue Connection Factory**.

To view or change the properties of a connection factory, select its name in the list displayed.

To act on one or more of the connection factories listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

WebSphere MQ queue connection factory settings:

Use this panel to view or change the configuration properties of the selected queue connection factory for use with the WebSphere MQ JMS provider. These configuration properties control how connections are created to the associated JMS queue destination.

A queue connection factory is used to create JMS connections to queue destinations. The queue connection factory is created by the WebSphere MQ JMS provider. A queue connection factory for the WebSphere MQ JMS provider has the following properties.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *WebSphere MQ Using Java* book, and the *WebSphere MQ System Administration* book, SC33-1873, which are available from the WebSphere MQ messaging platform-specific books Web page at <http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html>, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.
- **5.1+** You can use the Custom properties page to define WebSphere MQ Secure Sockets Layer (SSL) properties. For more information about setting those properties, see Custom properties.

To view this administrative console page, click **Resources-> WebSphere MQ JMS Provider-> (In content pane, under Additional Properties) WebSphere MQ Queue Connection Factories-> connection_factory**

Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String

JNDI name:

The JNDI name that is used to bind the connection factory into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

Category:

A category used to classify or group this connection factory, for your IBM WebSphere Application Server administrative records.

Data type String

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (`res-auth`) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Restriction:

1. User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

2. If you want to use a WebSphere MQ JMS Provider JMS connection when using Bindings transport mode, you set the property **Transport type**=BINDINGS on the WebSphere MQ Queue Connection Factory. You must also choose one of the following options:
 - To use security credentials, ensure that the user specified is the currently logged on user for the WebSphere Application Server process. If the user specified is not the current logged on user for the WebSphere Application Server process, then the WebSphere MQ JMS Bindings authentication throws the error MQJMS2013 invalid security authentication supplied for MQQueueManager.
 - Do not specify security credentials. On the WebSphere MQ Connection Factory, ensure that both the **Component-managed Authentication Alias** and the **Container-managed Authentication Alias** properties are not set.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for container-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Restriction:

1. User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.
2. If you want to use a WebSphere MQ JMS Provider JMS connection when using Bindings transport mode, you set the property **Transport type**=BINDINGS on the WebSphere MQ Queue Connection Factory. You must also choose one of the following options:
 - To use security credentials, ensure that the user specified is the currently logged on user for the WebSphere Application Server process. If the user specified is not the current logged on user for the WebSphere Application Server process, then the WebSphere MQ JMS Bindings authentication throws the error MQJMS2013 invalid security authentication supplied for MQQueueManager.
 - Do not specify security credentials. On the WebSphere MQ Connection Factory, ensure that both the **Component-managed Authentication Alias** and the **Container-managed Authentication Alias** properties are not set.

Queue manager:

The name of the WebSphere MQ queue manager for this connection factory. Connections created by this factory connect to that queue manager.

Data type	String
Default	Null
Range	A valid WebSphere MQ queue manager name, as 1 through 48 ASCII characters

Host:

The name of the host on which the WebSphere MQ queue manager runs, for client connection only.

Data type	String
Default	Null
Range	A valid TCP/IP hostname

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Data type	Integer
Default	Null
Range	A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Channel:

The name of the channel used for connection to the WebSphere MQ queue manager, for client connection only.

Data type	String
Default	Null
Range	1 through 20 ASCII characters

Transport type:

Specifies whether the WebSphere MQ client connection or JNI bindings are used for connection to the WebSphere MQ queue manager. The external JMS provider controls the communication protocols between JMS clients and JMS servers. Tune the transport type when you are using non-ASF non-persistent, non-durable, non-transactional messaging or when you want to satisfy security issues and the client is local to the queue manager node.

Data type	Enum
Units	Not applicable
Default	BINDINGS
Range	BINDINGS JNI bindings are used to connect to the queue manager. BINDINGS is a shared memory protocol and can only be used when the queue manager is on the same node as the JMS client and comes at some security risks that should be addressed through the use of EJB roles.
	CLIENT WebSphere MQ client connection is used to connect to the queue manager. CLIENT is a typical TCP-based protocol.
Recommended	BINDINGS is faster by 30% or more, but it lacks security. When you have security concerns, BINDINGS is more desirable than CLIENT.

Model queue definition:

The name of the model queue definition that can be used by the queue manager to create temporary queues if a queue requested does not already exist.

Data type	String
Default	Null
Range	1 through 48 ASCII characters

Client ID:

The JMS client identifier used for connections to the WebSphere MQ queue manager.

Data type	String
Default	Null

CCSID:

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type	String
Units	Integer
Default	Null
Range	1 through 65535

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at <http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html>, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

Message retention:

Select this check box to specify that unwanted messages are to be left on the queue. Otherwise, unwanted messages are dealt with according to their disposition options.

Data type	Enum
Units	Not applicable
Default	Cleared
Range	Selected Unwanted messages are left on the queue. Cleared Unwanted messages are dealt with according to their disposition options.

XA Enabled:

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are not used in the same transaction.

If you set this property to `NON_XA`, the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (`session.commit` and `session.rollback`) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server.

5.1 + In WBI Server Foundation the last participant support enables you to enlist one non-XA resource with other XA-capable resources.

Data type	Enum
Units	Not applicable
Default	XA enabled
Range	<p>XA The connection factory is for XA-coordination of messages</p> <p>NON_XA The connection factory is for non-XA coordination of messages</p>
Recommended	Do not enable XA when the message queue received is the only resource in the transaction. Enable XA when other resources, including other queues or topics, are involved.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Custom properties:

An optional set of name and value pairs for custom properties passed to WebSphere MQ.

You can use the Custom properties page to define the following WebSphere MQ Secure Sockets Layer (SSL) properties. These properties apply only if you set the property **Transport type=CLIENT**.

- SSLCIPHERSUITE
- SSLCRL
- SSLPEERNAME

For more information about setting these properties, see the section SSL properties in the *WebSphere MQ Using Java* book.

WebSphere MQ queue connection factory custom properties:

Use this panel to view or change an optional set of name and value pairs for custom properties of the selected queue connection factory for use with the WebSphere MQ JMS provider. These custom properties are passed to WebSphere MQ.

To view this administrative console page, click **Resources-> WebSphere MQ JMS Provider-> (In content pane, under Additional Properties) WebSphere MQ Queue Connection Factories-> connection_factory-> Custom Properties**

You can use the Custom properties page to define the following WebSphere MQ Secure Sockets Layer (SSL) properties. These properties apply only if you set the property **Transport type=CLIENT** on the connection factory.

- SSLCIPHERSUITE
- SSLCRL
- SSLPEERNAME

For more information about setting these properties for WebSphere MQ, see the section SSL properties in the *WebSphere MQ Using Java* book.

SSLCIPHERSUITE:

The cipher suite to use for SSL connection.

Set this property to a valid cipher suite provided by your JSSE provider; it must match the CipherSpec named on the SVRCONN channel named by the **Channel** property.

You must set this property if the SSLPEERNAME is to be set.

SSLCRL:

A list of zero or more CRL (Certificate Revocation List) servers used to check for SSL certificate revocation. (Use of this property requires a WebSphere MQ JVM at Java 2 version 1.4.)

The value is a space-delimited list of entries of the form:

`ldap://hostname:[port]`

optionally followed by a single / (forward slash). If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the section “Working with Certificate Revocation Lists” in the *WebSphere MQ Security book*; for example at:

<http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas012w.htm#IDX2254>.

SSLPEERNAME:

For SSL, a *distinguished name* skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connect-time.

If SSLPEERNAME is not set, such checking is performed. SSLPEERNAME is ignored if SSLCIPHERSUITE is not specified.

The SSLPEERNAME property is a list of attribute name and value pairs separated by commas or semicolons. For example:

```
SSLPEERNAME(CN=QMGR.*, OU=IBM, OU=WEBSHERE)
```

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the *WebSphere MQ Security* book; for example, the section “Distinguished Names” at <http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas010p.htm#HDRDCDN>.

WebSphere MQ topic connection factory collection:

The topic connection factories configured in the WebSphere MQ JMS provider for publish/subscribe messaging with JMS topics.

This panel shows a list of the WebSphere MQ topic connection factories with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> WebSphere MQ JMS Provider**.
2. In the content pane, select the JMS provider that you want to support the connection factory.
3. In the Additional Properties list in the contents pane, select **WebSphere MQ Topic Connection Factory**.

To view or change the properties of a connection factory, select its name in the list displayed.

To act on one or more of the connection factories listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

WebSphere MQ topic connection factory settings:

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the WebSphere MQ JMS provider. These configuration properties control how connections are created to the associated JMS topic destination.

A topic connection factory is used to create JMS connections to topic destinations. The topic connection factory is created by the WebSphere MQ JMS provider. A topic connection factory for the WebSphere MQ JMS provider has the following properties.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *WebSphere MQ Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.
- **5.1+** You can use the Custom properties page to define a subset of WebSphere MQ properties. For more information about setting those properties, see Custom properties.

To view this administrative console page, click **Resources-> WebSphere MQ JMS Provider-> (In content pane, under Additional Properties) WebSphere MQ Topic Connection Factories-> connection_factory**

Name:

The name by which this topic connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS provider.

Data type String

JNDI name:

The JNDI name that is used to bind the topic connection factory into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

Category:

A category used to classify or group this topic connection factory, for your IBM WebSphere Application Server administrative records.

Data type String

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (`res-auth`) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for container-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

Queue manager:

The name of the WebSphere MQ queue manager for this connection factory. Connections created by this factory connect to that queue manager.

Data type	String
Default	Null
Range	A valid WebSphere MQ queue manager name, as 1 through 48 ASCII characters

Host:

The name of the host on which the WebSphere MQ queue manager runs, for client connection only.

Data type	String
Default	Null
Range	A valid TCP/IP hostname

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Data type	Integer
Default	Null
Range	A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Channel:

The name of the channel used for connection to the WebSphere MQ queue manager, for client connection only.

Data type	String
Default	Null

Range 1 through 20 ASCII characters

Transport type:

Specifies whether the WebSphere MQ client connection or JNI bindings are used for connection to the WebSphere MQ queue manager. The external JMS provider controls the communication protocols between JMS clients and JMS servers. Tune the transport type when you are using non-ASF nonpersistent, non-durable, non-transactional messaging or when you want to satisfy security issues and the client is local to the queue manager node.

Data type	Enum
Units	Not applicable
Default	BINDINGS
Range	BINDINGS JNI bindings are used to connect to the queue manager. BINDINGS is a shared memory protocol and can only be used when the queue manager is on the same node as the JMS client and comes at some security risks that should be addressed through the use of EJB roles. CLIENT WebSphere MQ client connection is used to connect to the queue manager. CLIENT is a typical TCP-based protocol. DIRECT For WebSphere MQ Event Broker using DIRECT mode. DIRECT is a lightweight sockets protocol used in non-transactional, non-durable and non-persistent Publish/Subscribe messaging. DIRECT works only for clients and message-driven beans using the non-ASF protocol.

Recommended DIRECT is the fastest transport type and should be used where possible. Use BINDINGS when you want to satisfy additional security tasks and the queue manager is local to the JMS client. QUEUED is fallback for all other cases. **Note:** WebSphere MQ 5.3 before CSD2 with the DIRECT setting can lose messages when used with message-driven beans and under load. This also happens with client-side based applications unless the broker's maxClientQueueSize is set to 0. You can set this to 0 with the command `#wempschangeproperties WAS_nodeName_server1 -e default -o DynamicSubscriptionEngine -n maxClientQueueSize -v 0 -x executionGroupUUID`, where executionGroupUUID can be found by starting the broker and looking in the Event Log/Applications for event 2201. This value is usually ffffffff-0000-0000-000000000000.

Broker control queue:

The name of the broker's control queue, to which all command messages (except publications and requests to delete publications) are sent

The name of the broker's control queue. Publisher and subscriber applications, and other brokers, send all command messages (except publications and requests to delete publications) to this queue.

Data type	String
Units	En_US ASCII characters
Default	Null
Range	1 through 48 ASCII characters

Broker queue manager:

The name of the WebSphere MQ queue manager that provides the publish/subscribe message broker.

Data type	String
Units	En_US ASCII characters
Default	Null
Range	1 through 48 ASCII characters

Broker publication queue:

The name of the broker's input queue that receives all publication messages for the default stream

The name of the broker's input queue (stream queue) that receives all publication messages for the default stream. Applications can also send requests to delete publications on the default stream to this queue.

Data type	String
Units	En_US ASCII characters
Default	Null
Range	1 through 48 ASCII characters

Broker subscription queue:

The name of the broker's queue from which non-durable subscription messages are retrieved

The name of the broker's queue from which non-durable subscription messages are retrieved. The subscriber specifies the name of the queue when it registers a subscription.

Data type	String
Units	En_US ASCII characters
Default	Null
Range	1 through 48 ASCII characters

Broker CC subscription queue:

The name of the broker's queue from which non-durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the Web container.

The name of the broker's queue from which non-durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the Web container.

Data type	String
Units	En_US ASCII characters
Default	Null
Range	1 through 48 ASCII characters

Broker version:

Whether the message broker is provided by the WebSphere MQ MA0C Supportpac or newer versions of WebSphere message broker products

Data type	Enum
Units	Not applicable
Default	Advanced
Range	Advanced The message broker is provided by newer versions of WebSphere message broker products, such as WebsSphere MQ Integrator and EventBroker. Basic The message broker is provided by the WebSphere MQ MA0C SupportPac (MQSeries - Publish/Subscribe) or MQSI working in MA0C compatibility mode.

Model queue definition:

The name of the model queue definition that the broker can use to create dynamic queues for non-default streams if the stream queue does not already exist

The name of the model queue definition that the broker can use to create dynamic queues to receive publications for streams other than the default stream. This is only used if the stream queue does not already exist. If this model queue definition does not exist, all stream queues must be defined by the administrator.

Data type	String
Units	En_US ASCII characters
Default	Null
Range	1 through 48 ASCII characters

CCSID:

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type	String
Units	Integer
Default	Null
Range	1 through 65535

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at <http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html>, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

Clone Support:

Select this checkbox to enable clone support to allow the same durable subscription across topic clones.

Data type	Enum
Units	Not applicable

Default Range

Cleared
Selected Clone support is enabled.
Cleared Clone support is disabled.

If you select this property, you must also specify a value for the **Client ID** property.

Client ID:

The JMS client identifier used for connections to the queue manager.

Data type Range

String
A valid JMS client ID, as ASCII characters

XA Enabled:

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are not used in the same transaction.

If you set this property to `NON_XA`, the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (`session.commit` and `session.rollback`) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server.

5.1+ In WBI Server Foundation the last participant support enables you to enlist one non-XA resource with other XA-capable resources.

For a WebSphere Topic Connection Factory with the **Port** property set to `DIRECT` this property does not apply, and always takes the value `NON_XA`.

Data type Units Default Range

Enum
Not applicable
XA enabled
XA The connection factory is for XA-coordination of messages
NON_XA The connection factory is for non-XA coordination of messages
Do not enable XA when the message queue or topic received is the only resource in the transaction. Enable XA when other resources, including other queues or topics, are involved.

Recommended

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis. See the following table for details.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Custom properties:

An optional set of name and value pairs for custom properties passed to WebSphere MQ.

You can use the Custom properties page to define the following WebSphere MQ properties. These properties apply only if you set the property **Transport type=CLIENT**.

- SSLCIPHERSUITE
- SSLCRL
- SSLPEERNAME
- MSGSELECTION
- SUBSTORE

WebSphere MQ topic connection factory custom properties:

Use this panel to view or change an optional set of name and value pairs for custom properties of the selected topic connection factory for use with the WebSphere MQ JMS provider. These custom properties are passed to WebSphere MQ.

To view this administrative console page, click **Resources-> WebSphere MQ JMS Provider-> (In content pane, under Additional Properties) WebSphere MQ Topic Connection Factories-> connection_factory-> Custom Properties**

You can use the Custom properties page to define the following WebSphere MQ properties. These properties apply only if you set the property **Transport type=CLIENT**.

- SSLCIPHERSUITE
- SSLCRL
- SSLPEERNAME
- MSGSELECTION
- SUBSTORE

For more information about setting the SSL properties for WebSphere MQ, see the section SSL properties in the *WebSphere MQ Using Java* book.

SSLCIPHERSUITE:

The cipher suite to use for SSL connection.

Set this property to a valid cipher suite provided by your JSSE provider; it must match the CipherSpec named on the SVRCONN channel named by the **Channel** property.

You must set this property if the SSLPEERNAME is to be set.

SSLCRL:

A list of zero or more CRL (Certificate Revocation List) servers used to check for SSL certificate revocation. (Use of this property requires a WebSphere MQ JVM at Java 2 version 1.4.)

The value is a space-delimited list of entries of the form:

```
ldap://hostname:[port]
```

optionally followed by a single / (forward slash). If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the section “Working with Certificate Revocation Lists” in the *WebSphere MQ Security book*; for example at: <http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas012w.htm#IDX2254>.

SSLPEERNAME:

For SSL, a *distinguished name* skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connect-time.

If SSLPEERNAME is not set, such checking is performed. SSLPEERNAME is ignored if SSLCIPHERSUITE is not specified.

The SSLPEERNAME property is a list of attribute name and value pairs separated by commas or semicolons. For example:

```
SSLPEERNAME(CN=QMGR.*, OU=IBM, OU=WEBSHERE)
```

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the *WebSphere MQ Security book*; for example, the section “Distinguished Names” at <http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas010p.htm#HDRDCDN>.

MSGSELECTION:

Determines whether message selection is done by the JMS Client or by the Broker.

If you set the property **Transport type=BINDINGS**, message selection is always done by the Broker and the setting of this property is ignored.

Data type	String
Default	CLIENT

Range

CLIENT

Message selection is done by the JMS Client.

BROKER

Message selection is done by the Broker.

SUBSTORE:

Where WebSphere MQ JMS should store persistent data relating to active subscriptions.

Data type

String

Default

MIGRATE

Range

BROKER

Subscription information is stored by the publish/subscribe broker used by the application.

If a non-durable subscriber fails, the subscription is deregistered from the broker as soon as possible. The broker adds a response to this deregistration onto the SYSTEM.JMS.REPORT.QUEUE, which is used to clean up after the failed subscriber. With SUBSTORE(BROKER), a separate cleanup thread is run regularly in the background of each JMS publish/subscribe application.

MIGRATE

This option dynamically selects the queue-based or broker-based subscription store based on the levels of queue manager and publish/subscribe broker installed. If both queue manager and broker are capable of supporting SUBSTORE(BROKER), this behaves as SUBSTORE(BROKER); otherwise it behaves as SUBSTORE(QUEUE). Additionally, SUBSTORE(MIGRATE) transfers durable subscription information from the queue-based subscription store to the broker-based store.

This provides an easy migration path from older versions of WebSphere MQ JMS, WebSphere MQ, and publish/subscribe broker.

QUEUE

Subscription information is stored on SYSTEM.JMS.ADMIN.QUEUE and SYSTEM.JMS.PS.STATUS.QUEUE on the local queue manager. SUBSTORE(QUEUE) is provided for compatibility with versions of MQSeries JMS.

For more information about the use of this property in WebSphere MQ, see the section Subscription stores in the *WebSphere MQ Using Java* book.

WebSphere MQ queue destination collection:

The queue destinations configured in the WebSphere MQ JMS provider for point-to-point messaging with JMS queues.

This panel shows a list of the WebSphere MQ queue destinations with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> WebSphere MQ JMS provider**.
2. In the content pane, select the JMS provider that you want to support the queue destination.
3. In the Additional Properties list in the contents pane, select **WebSphere MQ Queue Destination**.

To view or change the properties of a queue destination, select its name in the list displayed.

To act on one or more of the queue destinations listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

WebSphere MQ queue settings:

Use this panel to view or change the configuration properties of the selected queue destination for use with the WebSphere MQ JMS provider.

A queue destination is used to configure the properties of a JMS queue. Connections to the queue are created by the associated queue connection factory for the WebSphere MQ JMS provider. A queue for use with the WebSphere MQ JMS provider has the following properties.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *WebSphere MQ Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

To view this administrative console page, click **Resources-> WebSphere MQ JMS Provider-> (In content pane, under Additional Properties) WebSphere MQ Queue Destinations-> *destination_name***

Name:

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI name:

The JNDI name that is used to bind the queue into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the queue, for administrative purposes

Data type String
Default Null

Category:

A category used to classify or group this queue, for your IBM WebSphere Application Server administrative records.

Data type String

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

Data type Enum
Units Not applicable
Default APPLICATION_DEFINED
Range

- Application defined**
Messages on the destination have their persistence defined by the application that put them onto the queue.
- Queue defined**
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
- Persistent**
Messages on the destination are persistent.
- Non persistent**
Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property

Data type Enum
Units Not applicable
Default APPLICATION_DEFINED
Range

- Application defined**
The priority of messages on this destination is defined by the application that put them onto the destination.
- Queue defined**
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
- Specified**
The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified priority:

If the **Priority** property is set to *Specified*, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest)

If the **Priority** property is set to *Specified*, messages sent to this queue have the priority value specified by this property.

Data type	Integer
Units	Message priority level
Default	Null
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

Data type	Enum
Units	Not applicable
Default	APPLICATION_DEFINED
Range	Application defined The expiry timeout for messages on this queue is defined by the application that put them onto the queue. Specified The expiry timeout for messages on this queue is defined by the Specified expiry property. <i>If you select this option, you must define a timeout on the Specified expiry property.</i> Unlimited Messages on this queue have no expiry timeout, so those messages never expire.

Specified expiry:

If the **Expiry timeout** property is set to *Specified*, type here the number of milliseconds (greater than 0) after which messages on this queue expire

Data type	Integer
Units	Milliseconds
Default	Null
Range	Greater than or equal to 0 • 0 indicates that messages never timeout • Other values are an integer number of milliseconds

Base queue name:

The name of the queue to which messages are sent, on the queue manager specified by the **Base queue manager name** property

Data type	String
Default	Null
Range	1 through 48 ASCII characters

Base queue manager name:

The name of the WebSphere MQ queue manager to which messages are sent

This queue manager provides the queue specified by the **Base queue name** property.

Data type	String
Units	En_US ASCII characters
Default	Null
Range	A valid WebSphere MQ Queue Manager name, as 1 through 48 ASCII characters

CCSID:

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type	String
Units	Integer
Default	Null
Range	1 through 65535

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at <http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html>, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

Use native encoding:

Select this checkbox to indicate that the queue destination should use native encoding (appropriate encoding values for the Java platform).

Data type	Enum
Units	Not applicable
Default	Cleared
Range	Cleared Native encoding is not used, so specify the properties below for integer, decimal, and floating point encoding. Selected Native encoding is used (to provide appropriate encoding values for the Java platform). For more information about encoding properties, see the WebSphere MQ <i>Using Java</i> document.

Integer encoding:

If native encoding is not enabled, select whether integer encoding is normal or reversed.

Data type	Enum
Units	Not applicable
Default	NORMAL

Range**NORMAL**

Normal integer encoding is used.

REVERSED

Reversed integer encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Decimal encoding:

If native encoding is not enabled, select whether decimal encoding is normal or reversed.

Data type

Enum

Units

Not applicable

Default

NORMAL

Range**NORMAL**

Normal decimal encoding is used.

REVERSED

Reversed decimal encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Floating point encoding:

If native encoding is not enabled, select the type of floating point encoding.

Data type

Enum

Units

Not applicable

Default

IEEEENORMAL

Range**IEEEENORMAL**

IEEE normal floating point encoding is used.

IEEEEVERSED

IEEE reversed floating point encoding is used.

S390 S390 floating point encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Target client:

Whether the receiving application is JMS-compliant or is a traditional WebSphere MQ application

Data type

Enum

Units

Not applicable

Default

MQSeries

Range**MQSeries**

The target is a non-JMS, traditional WebSphere MQ application.

JMS The target is a JMS-compliant application.*Queue manager host:*

The name of host for the queue manager on which the queue destination is created.

Data type

String

Default	Null
Range	A valid TCP/IP hostname

Queue manager port:

The number of the port used by the queue manager on which this queue is defined.

Data type	String
Units	A valid TCP/IP port number.
Default	Null
Range	A valid TCP/IP port number. This port must be configured on the WebSphere MQ queue manager.

Server connection channel name:

The name of the channel used for connection to the WebSphere MQ queue manager.

Data type	String
Default	Null
Range	1 through 20 ASCII characters

User name:

The user ID used, with the **Password** property, for authentication when connecting to the queue manager to define the queue destination.

If you specify a value for the **User name** property, you must also specify a value for the **Password** property.

Data type	String
Default	Null

Password:

The password, used with the **User name** property, for authentication when connecting to the queue manager to define the queue destination.

If you specify a value for the **User name** property, you must also specify a value for the **Password** property.

Data type	String
Default	Null

WebSphere MQ queue settings (MQ Config):

Use this panel to view or change the configuration properties defined to WebSphere MQ for the selected queue destination.

A queue destination is used to configure the properties of a JMS queue. A queue for use with the WebSphere MQ JMS provider has the following extra properties defined to WebSphere MQ.

Notes

Note:

- Some properties displayed are read-only and cannot be changed.
- These MQ Config properties can be used only to view or change the properties of local queues. You cannot use MQ Config to administer alias or remote queues.
- To be able to view or change properties, the WebSphere MQ Queue Manager on which the queue resides must be configured for remote administration and be running.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *WebSphere MQ: Using Java* book; for example from the WebSphere MQ multiplatform library Web page at <http://www.ibm.com/software/ts/mqseries/library/manualsa/manuals/crosslatest.html>.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

To view this administrative console page, click **Resources-> WebSphere MQ JMS Provider-> (In content pane, under Additional Properties) WebSphere MQ Queue Destinations-> destination_name-> (In content pane, under Additional Properties) MQ Config**

Base queue name:

The name of the local queue to which messages are sent, on the queue manager specified by the **Base queue manager name** property.

Data type String

Base queue manager name:

The name of the WebSphere MQ queue manager to which messages are sent.

This queue manager provides the queue specified by the **Base queue name** property.

Data type String

Queue manager host:

The name of host for the queue manager on which the queue destination is created.

Data type String

Queue manager port:

The number of the port used by the queue manager on which this queue is defined.

Data type Integer
Range A valid TCP/IP port number. This port must be configured on the WebSphere MQ queue manager.

Server connection channel name:

The name of the channel used for connection to the WebSphere MQ queue manager.

Data type String
Range 1 through 20 ASCII characters

User ID:

The user ID used, with the **Password** property, for authentication when connecting to the queue manager to define the queue destination.

If you specify a value for the **User name** property, you must also specify a value for the **Password** property.

Data type String

Password:

The password, used with the **User name** property, for authentication when connecting to the queue manager to define the queue destination.

If you specify a value for the **User name** property, you must also specify a value for the **Password** property.

Data type String

Name:

The name of the queue defined to the WebSphere MQ queue manager.

Data type String
Range 1 through 48 ASCII characters.

Description:

The WebSphere MQ queue description, for administrative purposes within WebSphere MQ.

Data type String
Default Null
Range 1 through 64 ASCII characters.

Inhibit Put:

Whether or not put operations are allowed for this queue.

Data type Enum
Units Not applicable
Default Cleared
Range **Allowed** Put operations are allowed for this queue.
Not allowed Put operations are not allowed for this queue.

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

Data type Enum
Units Not applicable

Default
Range

APPLICATION_DEFINED

Application defined

Messages on the destination have their persistence defined by the application that put them onto the queue.

Queue defined

[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Persistent

Messages on the destination are persistent.

Non persistent

Messages on the destination are not persistent.

Cluster name:

The name of the cluster to which the WebSphere MQ queue manager belongs.

If you specify a value for **Cluster name**, you cannot specify a value for **Cluster name list**. Cluster names must conform to the rules described in the *WebSphere MQ MQSC Command Reference* book.

Data type

String

Default

Null

Range

A valid WebSphere MQ name for a queue manager cluster, as 1 through 48 ASCII characters

Cluster name list:

The name of the cluster namelist to which the WebSphere MQ queue manager belongs.

If you specify a value for **Cluster name**, you cannot specify a value for **Cluster name list**.

Data type

String

Default

Null

Range

A valid WebSphere MQ name for a list of queue manager clusters, as 1 through 48 ASCII characters

Default Binding:

The default binding to be used when the queue is defined as a cluster queue.

Data type

Enum

Default

Null

Range

A

On open

The queue handle is bound to a specific instance of the cluster queue when the queue is opened.

Not fixed

The queue handle is not bound to any particular instance of the cluster queue. This allows the queue manager to select a specific queue instance when the message is put, and to change that selection subsequently should the need arise.

Inhibit Get:

Whether or not get operations are allowed for this queue.

Data type	Enum
Units	Not applicable
Default	Cleared
Range	Allowed Get operations are allowed for this queue. Not allowed Get operations are not allowed for this queue.

Maximum queue depth:

The maximum number of messages allowed on the queue.

Data type	Integer
Units	Messages
Default	
Range	A value greater than or equal to zero, and less than or equal to: <ul style="list-style-type: none">• 999 999 999 if the queue is on OS/390• 640 000 if the queue is on any other WebSphere MQ platform For more information about the maximum value allowed, see the <i>WebSphere MQ MQSC Command Reference</i> . If this value is reduced, any message that is already on the queue are not affected, even if the number of messages exceeds the new maximum.

Maximum Message Length:

The maximum length, in bytes, of messages on this queue.

Data type	Integer
Units	Bytes
Default	
Range	A value greater than or equal to zero, and less than or equal to the maximum message length for the queue manager and WebSphere MQ platform. For more information about the maximum value allowed, see the <i>WebSphere MQ MQSC Command Reference</i> . If this value is reduced, any message that is already on the queue are not affected, even if the message length exceeds the new maximum.

Shareability:

Whether multiple applications can get messages from this queue.

Data type	Enum
Units	Not applicable
Default	Not shareable

Range**Not shareable**

Only one application instance can get messages from the queue.

Shareable

More than one application instance can get messages from the queue.

Input Open Option:

The default share option for applications opening this queue for input

Data type

Enum

Units

Not applicable

Default

Cleared

Range**Exclusive**

The open request is for exclusive input from the queue.

Shared

The open request is for shared input from the queue.

Message Delivery Sequence:

The order in which messages are delivered from the queue in response to get requests.

Data type

Enum

Units

Not applicable

Default

Priority

Range**Priority**

Messages are delivered in first-in-first-out (FIFO) order within priority. This is the default supplied with WebSphere MQ, but your installation might have changed it.

FIFO

Messages are delivered in FIFO order. Priority is ignored for messages on this queue.

Backout threshold:

The maximum number of times that a message can be backed out. If this threshold is reached, the message is requeued on the backout queue specified by the **Backout Requeue name** property.

The WebSphere MQ queue manager keeps a record of the number of times that each message has been backed out. When this number reaches a configurable threshold, the connection consumer requeues the message on a named backout queue. If this requeue fails for any reason, the message is removed from the queue and either requeued to the dead-letter queue, or discarded.

Data type

Integer

Default

0

Range

0 Never requeue messages

1 or more

The number of times that a message has been backed, at which the message is requeued on a named backout queue.

Backout Requeue name:

The name of the backout queue to which messages are requeued if they have been backed out more than the backout threshold.

The WebSphere MQ queue manager keeps a record of the number of times that each message has been backed out. When this number reaches a configurable threshold, the connection consumer requeues the message on a named backout queue. If this requeue fails for any reason, the message is removed from the queue and either requeued to the dead-letter queue, or discarded.

Data type	String
Default	Null
Range	1 through 48 characters.

Harden Get Backout:

Whether hardening should be used to ensure that the count of the number of times that a message has been backed out is accurate.

Data type	Enum
Units	Not applicable
Default	Cleared
Range	Not hardened The count is not hardened. This is the default supplied with WebSphere MQ, but your installation might have changed it. Hardened The count is hardened.

WebSphere MQ topic destination collection:

The topic destinations configured in the WebSphere MQ JMS provider for publish/subscribe messaging with JMS topics. Use this panel to create or delete topic destinations, or to select a topic destination to view or change its configuration properties.

This panel shows a list of the WebSphere MQ topic destinations with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> WebSphere MQ JMS provider**.
2. In the content pane, select the JMS provider that you want to support the topic destination.
3. In the Additional Properties list in the contents pane, select **WebSphere MQ Topic Destination**.

To view or change the properties of a topic destination, select its name in the list displayed.

To act on one or more of the topic destinations listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

WebSphere MQ topic settings:

Use this panel to view or change the configuration properties of the selected topic destination for use with the WebSphere MQ JMS provider.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. Connections to the topic are created by the associated topic connection factory. A topic for use with the WebSphere MQ JMS provider has the following properties.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ JMS resources. For more information about configuring WebSphere MQ JMS resources, see the WebSphere MQ *Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

To view this administrative console page, click **Resources-> WebSphere MQ JMS Provider-> (In content pane, under Additional Properties) WebSphere MQ Topic Destinations-> destination_name**

Name:

The name by which the topic is known for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI name:

The JNDI name that is used to bind the topic into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the topic, for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

Category:

A category used to classify or group this topic, for your IBM WebSphere Application Server administrative records.

Data type String

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

Data type Enum
Units Not applicable
Default APPLICATION_DEFINED

Range

Application defined

Messages on the destination have their persistence defined by the application that put them onto the queue.

Queue defined

[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Persistent

Messages on the destination are persistent.

Non persistent

Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property

Data type
Units
Default
Range

Enum
Not applicable
APPLICATION_DEFINED

Application defined

The priority of messages on this destination is defined by the application that put them onto the destination.

Queue defined

[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Specified

The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified priority:

If the **Priority** property is set to Specified, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest)

If the **Priority** property is set to Specified, messages sent to this queue have the priority value specified by this property.

Data type
Units
Default
Range

Integer
Message priority level
Null
0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

Data type
Units
Default

Enum
Not applicable
APPLICATION_DEFINED

Range**Application defined**

The expiry timeout for messages on this queue is defined by the application that put them onto the queue.

Specified

The expiry timeout for messages on this queue is defined by the **Specified expiry** property. *If you select this option, you must define a timeout on the **Specified expiry** property.*

Unlimited

Messages on this queue have no expiry timeout, so those messages never expire.

Specified expiry:

If the **Expiry timeout** property is set to Specified, type here the number of milliseconds (greater than 0) after which messages on this queue expire

Data type

Integer

Units

Milliseconds

Default

Null

Range

Greater than or equal to 0

- 0 indicates that messages never timeout
- Other values are an integer number of milliseconds

Base topic name:

The name of the topic to which messages are sent

Data type

String

Range

Depends on the broker used. For details, see the documentation for your broker; for example the *WebSphere MQ Event Broker* library at <http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/wsmqebv21.html>.

CCSID:

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type

String

Units

Integer

Default

Null

Range

1 through 65535

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at <http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html>, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

Use native encoding:

Select this checkbox to indicate that the queue destination should use native encoding (appropriate encoding values for the Java platform).

Data type	Enum
Units	Not applicable
Default	Cleared
Range	Cleared Native encoding is not used, so specify the properties below for integer, decimal, and floating point encoding. Selected Native encoding is used (to provide appropriate encoding values for the Java platform).

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Integer encoding:

If native encoding is not enabled, select whether integer encoding is normal or reversed.

Data type	Enum
Units	Not applicable
Default	NORMAL
Range	NORMAL Normal integer encoding is used. REVERSED Reversed integer encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Decimal encoding:

If native encoding is not enabled, select whether decimal encoding is normal or reversed.

Data type	Enum
Units	Not applicable
Default	NORMAL
Range	NORMAL Normal decimal encoding is used. REVERSED Reversed decimal encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Floating point encoding:

If native encoding is not enabled, select the type of floating point encoding.

Data type	Enum
Units	Not applicable
Default	IEEE NORMAL

Range**IEEEENORMAL**

IEEE normal floating point encoding is used.

IEEEEVERSED

IEEE reversed floating point encoding is used.

S390 S390 floating point encoding is used.For more information about encoding properties, see the *WebSphere MQ Using Java* document.*Target client type:*

Whether the receiving application is JMS-compliant or is a traditional WebSphere MQ application

Data type

Enum

Units

Not applicable

Default

MQ

Range**MQ** The target is a non-JMS, traditional WebSphere MQ application.**JMS** The target is a JMS-compliant application.*Broker Dur Sub Queue:*

The name of the broker's queue from which durable subscription messages are retrieved

The name of the broker's queue from which durable subscription messages are retrieved. The subscriber specifies the name of the queue when it registers a subscription.

Data type

String

Units

En_US ASCII characters

Default

Null

Range

1 through 48 ASCII characters

Broker CC Dur Sub Queue:

The name of the broker's queue from which durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the Web container.

The name of the broker's queue from which durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the Web container.

Data type

String

Units

En_US ASCII characters

Default

Null

Range

1 through 48 ASCII characters

JMS connection factory collection:

The JMS connection factories configured in the associated JMS provider for both point-to-point and publish/subscribe messaging. Use this panel to create or delete JMS connection factories, or to select a connection factory to view or change its configuration properties.

This panel shows a list of the generic JMS connection factories with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> Generic JMS Providers**.
2. In the content pane, select the JMS provider that you want to support the JMS connection factory.
3. In the Additional Properties list in the contents pane, select **Generic JMS Connection Factory**.

To view or change the properties of a JMS connection factory, select its name in the list displayed.

To act on one or more of the JMS connection factories listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

Generic JMS connection factory settings:

Use this panel to view or change the configuration properties of the selected JMS connection factory for use with the associated JMS provider. These configuration properties control how connections are created to the associated JMS destination.

A JMS connection factory is used to create connections to JMS destinations. The JMS connection factory is created by the associated JMS provider. A JMS connection factory for a generic JMS provider (other than the embedded WebSphere JMS provider or the WebSphere MQ JMS provider) has the following properties:

To view this administrative console page, click **Resources-> Generic JMS Providers-> *provider_name*-> JMS Connection Factories-> *connection_factory***

Scope:

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JMS Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell. For example, if you set **Max Connections** to 10, then each server in that Cell can have 10 connections.

Cell The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

Node The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

Server The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

Data type String

Name:

The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the associated JMS provider.

Data type String

Type:

Whether this connection factory is for creating JMS queue destinations or JMS topic destinations.

Select one of the following options:

Queue

A JMS queue connection factory for point-to-point messaging.

Topic A JMS topic connection factory for publish/subscribe messaging.

JNDI name:

The JNDI name that is used to bind the connection factory into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

Default Null

Category:

A category used to classify or group this connection factory, for your IBM WebSphere Application Server administrative records.

Data type String

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use

of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for container-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

Mapping-Configuration Alias:

Allows users to select from the **Security > JAAS Configuration > Application Logins Configuration** list.

The **DefaultPrincipalMapping** JAAS configuration maps the authentication alias to the userid and password. You may define and use other mapping configurations. For more information about the mapping configurations, see "Java Authentication and Authorization service configuration entry settings" in the Information center.

Data type Pick-list

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis. See the following table for details.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Custom properties:

An optional set of name and value pairs for custom properties passed to the JMS provider.

Generic JMS destination collection:

The JMS destinations configured in the associated JMS provider for point-to-point and publish/subscribe messaging. Use this panel to create or delete JMS destinations, or to select a JMS destination to view or change its configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> Generic JMS Providers**.
2. In the content pane, select the JMS provider that you want to support the JMS destination.
3. In the Additional Properties list in the contents pane, select **Generic JMS Destination**.

To view or change the properties of a JMS destination, select its name in the list displayed.

To act on one or more of the JMS destinations listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

Generic JMS destination settings:

Use this panel to view or change the configuration properties of the selected JMS destination for use with the associated JMS provider.

A JMS destination is used to configure the properties of a JMS destination for the associated generic JMS provider. Connections to the JMS destination are created by the associated JMS connection factory. A JMS destination for use with a generic JMS provider (not the embedded WebSphere JMS provider or WebSphere MQ JMS provider) has the following properties.

To view this administrative console page, click **Resources-> Generic JMS Providers-> provider_name-> JMS Destinations-> destination**

Name:

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

Data type String

Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publish/subscribe).

Select one of the following options:

Queue

A JMS queue destination for point-to-point messaging.

Topic A JMS topic destination for publish/subscribe messaging.

JNDI name:

The JNDI name that is used to bind the queue into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the queue, for administrative purposes

Category:

A category used to classify or group this queue, for your IBM WebSphere Application Server administrative records.

Data type String

External JNDI name:

The JNDI name that is used to bind the queue into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Asynchronous messaging - security considerations

This topic describes considerations that you should be aware of if you want to use security for asynchronous messaging with WebSphere Application Server.

Security for messaging operates as a part of the WebSphere Application Server global security, and is enabled only when global security is enabled.

When global security is enabled, JMS connections made to the JMS provider are authenticated, and access to JMS resources owned by the JMS provider are controlled by access authorizations. Also, all requests to create new connections to the JMS provider must provide a user ID and password for authentication. The user ID and password do not need to be provided by the application. If authentication is successful, then the JMS connection is created; if the authentication fails then the connection request is ended.

Standard J2C authentication is used for a request to create a new connection to the JMS provider. You can specify a Component-managed Authentication Alias and a Container-managed Authentication Alias for each JMS connection factory. The use of the associated J2C authentication data entries depends on the resource authentication (res-auth) setting, as follows:

- If your resource authentication (res-auth) is set to Application, set the alias in the Component-managed Authentication Alias. If the application that tries to create a connection to the JMS provider specifies a user ID and password, those values are used to authenticate the creation request. If the application does not specify a user ID and password, the values defined by the Component-managed Authentication Alias are used. If the connection factory is not configured with a Component-managed Authentication Alias, then you receive a runtime JMS exception when an attempt is made to connect to the JMS provider.
- If your res-auth is set to Container, set the Container-managed Authentication Alias. The values defined by the Container-managed Authentication Alias are used to authenticate the creation request. If you do not specify an alias, then you receive a runtime JMS exception when an attempt is made to connect to the JMS provider.

Restriction:

1. User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.
2. If you want to use a WebSphere MQ JMS Provider JMS connection when using Bindings transport mode, you set the property **Transport type=BINDINGS** on the WebSphere MQ Queue Connection Factory. You must also choose one of the following options:
 - To use security credentials, ensure that the user specified is the currently logged on user for the WebSphere Application Server process. If the user specified is not the current logged on user for the WebSphere Application Server process, then the WebSphere MQ JMS Bindings authentication throws the error MQJMS2013 invalid security authentication supplied for MQQueueManager error.
 - Do not specify security credentials. On the WebSphere MQ Connection Factory, ensure that both the **Component-managed Authentication Alias** and the **Container-managed Authentication Alias** properties are not set.

Authorization to access JMS resources owned by the embedded WebSphere JMS provider is controlled by authorization data in the config\integral-jms-authorisations.xml file. For information about editing this file, see Configuring security for the embedded WebSphere JMS provider.

Process choreographer tuning tips

Use the following tuning suggestions to improve performance to the process engine:

- Tune the database using a tuning wizard such as DB2's Performance Wizard.
- Use a faster disk, or use RAID volumes and distribute the MQ logs, MQ data, DB2 logs, DB2 data and WebSphere Application Server transaction logs across separate disks.
- Tune the WebSphere Application Server runtime to efficiently handle data and messages, and use maximum capacity with the following configuration settings:
 - Increase the Java Message Service (JMS) Listener port Max sessions parameter to higher than the default value by Configuring the listener port. Increasing the value enables efficient message handling by the flow message-driven beans. Based on the amount of work and the resources available, a value between 15 and 25 gives best performance and scaling on enterprise systems.
 - Increase the database connection pool size (see "Connection pool settings" in the Information Center) and the Statement cache size (see "Data source settings" in the Information Center) to optimize the data handling. In performance tests, when using a value of 50 for both settings on a NetFinity 5500 machine with an enterprise workload on long running processes, best performance is achieved.

- Increase the JMS provider connection pool size and session pool settings to improve message handling efficiency. In performance tests, both pool values were set to 600 on a NetFinity 5500 machine to increase message handling efficiency.

Designing an enterprise application to use JMS

This topic describes things to consider when designing an enterprise application to use the JMS API directly for asynchronous messaging.

This topic describes things to consider when designing an enterprise application to use the JMS API directly for asynchronous messaging.

1. The application refers to JMS resources that are predefined, as administered objects, to WebSphere Application Server.

Details of JMS resources that are used by enterprise applications are defined to WebSphere Application Server and bound into the JNDI namespace by the WebSphere administrative support. An enterprise application can retrieve these objects from the JNDI namespace and use them without needing to know anything about their implementation. This enables the underlying messaging architecture defined by the JMS resources to be changed without requiring changes to the enterprise application. When designing an enterprise application, you need to identify the details of the following types of JMS resources:

Point-to-Point	Publish/Subscribe
QueueConnectionFactory Queue	TopicConnectionFactory Topic

A connection factory is used to create connections with the JMS provider for a specific JMS queue or topic destination. Each connection factory encapsulates the configuration parameters needed to create a connection to a JMS destination.

For more information about the properties of these JMS resources, see *Configuring JMS provider resources*.

2. The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.
3. Applications can cache JMS connections, sessions, and producers or consumers. Due to the pooling mentioned above this may not give as much of a performance improvement as you might expect. You *must not* cache session handles in stateless session beans that operate in transactions started by a client of the bean. Caching handles in this way causes the bean to be returned to the pool while the session is still involved in the transaction. Also, you should not cache non-durable subscribers due to the restriction mentioned above.
4. A non-durable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created. For more information about this context restriction, see *The effect of transaction context on non-durable subscribers*.
5. If you want to use authentication with embedded WebSphere messaging, you cannot have user IDs longer than 12 characters. For example, the default Windows NT user ID, **administrator**, is not valid for use with WebSphere internal messaging, because it contains 13 characters.
6. For messaging operations, you should write application programs that use only references to the interfaces defined in Sun's `javax.jms` package.

JMS defines a generic view of a messaging that maps onto the underlying transport. An enterprise application that uses JMS, makes use of the following interfaces that are defined in Sun's `javax.jms` package:

Connection

Provides access to the underlying transport, and is used to create Sessions.

Session

Provides a context for producing and consuming messages, including the methods used to create MessageProducers and MessageConsumers.

MessageProducer

Used to send messages.

MessageConsumer

Used to receive messages.

The generic JMS interfaces are subclassed into the following more specific versions for Point-to-Point and Publish/Subscribe behavior:

Point-to-Point	Publish/Subscribe
QueueConnection	TopicConnection
QueueSession,	TopicSession,
QueueSender	TopicSender
QueueReceiver	TopicReceiver

The section “J2EE.6.7 Java Message Service (JMS) 1.0 Requirements” of the J2EE specification gives a list of methods that must not be called in Web and EJB containers:

```
javax.jms.Session method setMessageListener
javax.jms.Session method getMessageListener
javax.jms.Session method run
javax.jms.QueueConnection method createConnectionConsumer
javax.jms.TopicConnection method createConnectionConsumer
javax.jms.TopicConnection method createDurableConnectionConsumer
javax.jms.MessageConsumer method getMessageListener
javax.jms.MessageConsumer method setMessageListener
javax.jms.Connection method setExceptionListener
javax.jms.Connection stop
javax.jms.Connection setClientID
```

This method restriction is enforced in IBM WebSphere Application Server by throwing a `javax.jms.IllegalStateException`.

- The following points, as defined in the EJB specification, apply to the use of flags on `createxxxSession` calls:
 - The transacted flag passed on `createxxxSession` is ignored inside a global transaction and all work is performed as part of the transaction. Outside of a transaction the transacted flag is not used and, if set to true, the application should use `session.commit()` and `session.rollback()` to control the completion of the work. In an EJB2.0 module, if the transacted flag is set to true and outside of an XA transaction, then the session is involved in the WebSphere local transaction and the unresolved action attribute of the method applies to the JMS work.
 - Clients cannot use using `Message.acknowledge()` to acknowledge messages. If a value of `CLIENT_ACKNOWLEDGE` is passed on the `createxxxSession` call, then messages are automatically acknowledged by the application server and `Message.acknowledge()` is not used.
- Decide what message selectors are needed.

You can use the JMS message selector mechanism to select a subset of the messages on a queue so that this subset is returned by a receive call. The selector can refer to fields in the JMS message header and fields in the message properties.

- Acting on messages received.

When a message is received, you can act on it as needed by the business logic of the application. Some general JMS actions are to check that the message is of the correct type and extract the content of the message. To extract the content from the body of the message, you need to cast from the generic `Message` class (which is the declared return type of the receive methods) to the more specific subclass, such as `TextMessage`. It is good practice always to test the message class before casting, so that unexpected errors can be handled gracefully.

In this example, the `instanceof` operator is used to check that the message received is of the `TextMessage` type. The message content is then extracted by casting to the `TextMessage` subclass.

```
        if ( inMessage instanceof TextMessage )
```

```
    ...
```

```
        String replyString = ((TextMessage) inMessage).getText();
```

10. Using a listener to receive messages asynchronously.

An alternative to making calls to `QueueReceiver.receive()` is to register a method that is called automatically when a suitable message is available; for example:

```
    ...
    MyClass listener =new MyClass();
    queueReceiver.setMessageListener(listener);
    //application continues with other application-specific behavior.
    ...
```

When a message is available, it is retrieved by the `onMessage()` method on the listener object.

```
import javax.jms.*;
public class MyClass implements MessageListener
{
    public void onMessage(Message message)
    {
        System.out.println("message is "+message);
        //application specific processing here
        ...
    }
}
```

Note: A `MessageListener` can only be used in the client container. (The J2EE specification forbids the use of the JMS `MessageListener` mechanism for the asynchronous receipt of messages in the EJB and Web containers.)

For asynchronous message delivery, the application code cannot catch exceptions raised by failures to receive messages. This is because the application code does not make explicit calls to `receive()` methods. To cope with this situation, you can register an `ExceptionListener`, which is an instance of a class that implements the `onException()` method. When an error occurs, this method is called with the `JMSException` passed as its only parameter.

For more details about using listeners to receive messages asynchronously, see the [Java Message Service Documentation](#).

Note: An alternative to developing your own JMS listener class, you can use a message-driven bean, as described in [Implementing WebSphere enterprise applications that use message-driven beans](#).

11. Warning when receiving messages within a server-side application component.

Take care when performing a JMS `receive()` from a server-side application component if that `receive()` invocation is waiting on a message produced by another application component that is deployed in the same server. Such a JMS `receive()` is synchronous, so blocks until the response message is received.

This type of application design can lead to the consumer/producer problem where the entire set of work threads can be exhausted by the receiving component, which has been blocked waiting for responses, leaving no available worker thread for which to dispatch the application component that would generate the response JMS message.

To illustrate this problem, picture a servlet and a message-driven bean deployed in the same server. When this servlet dispatches a request it sends a message to a queue which is serviced by the message-driven bean (that is, messages produced by the servlet are consumed by the message-driven bean's `onMessage()` method). The servlet subsequently issues a `receive()`, waiting for a reply on a temporary `ReplyTo` queue. The message-driven bean's `onMessage()` method performs a database query and sends back a reply to the servlet on the temporary queue. If a large number of servlet requests occur at once (relative to the number of server worker threads), then it is likely that all available server worker threads will be used to dispatch a servlet request, send a message, and wait for a reply. The application server enters a deadly-embrace condition whereby no

threads remain to process any of the message-driven beans that are now pending. Since the servlets are waiting in blocking receives, the server hangs, likely leading to application failure.

Possible solutions are:

- a. Ensure that the number of worker threads (# of threads per server region * # of server regions per server) exceeds the number of concurrent dispatches of the application component doing the receive() so that there is always a worker thread available to dispatch the message producing component.
- b. Use an application topology that places the receiver application component in a separate server than the producer application component. While worker thread usage can still need to be carefully considered under such a deployment scenario, this separation ensures that there are always threads that cannot be blocked by the message receiving component. There can be other interactions to consider, such as an application server that has multiple applications installed.
- c. Refactor your application to do the message receives from a client component, which will not compete with the producer component for worker threads. Furthermore, the client component can do asynchronous (non-blocking) receives, which are prohibited from J2EE servers. So, for example, the example application above could be refactored to have a client sending messages to a queue and then waiting for a response from the MDB.

The effect of transaction context on non-durable subscribers

A non-durable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created. A non-durable subscriber is invalidated whenever a sharing boundary (in general, a local or global transaction boundary) is crossed, resulting in a `javax.jms.IllegalStateException` with message text `Non-durable subscriber invalidated on transaction boundary`.

For example, in the following scenario the non-durable subscriber is invalidated at the begin user transaction. This is because the local transaction context in which the subscriber was created ends when the user transaction begins:

```
...
create subscriber
...
begin user transaction -
...
complete user transaction -
...
use subscriber
...
```

If you want to cache a subscriber (to wait to receive messages that arrived since it was created), then use a durable subscriber (for which this restriction does not apply). Do not cache non-durable subscribers.

Developing a J2EE application to use JMS

Use this task to develop a J2EE application to use the JMS API directly for asynchronous messaging.

This topic gives an overview of the steps needed to develop a J2EE application (servlet or enterprise bean) to use the JMS API directly for asynchronous messaging.

This topic only describes the JMS-related considerations; it does not describe general J2EE application programming, which you should already be familiar with. For detailed information about these steps, and for examples of developing a J2EE application to use JMS, see the *Java Message Service Documentation* and the *WebSphere MQ Using Java* book, SC34-5456.

Details of JMS resources that are used by J2EE applications are defined to WebSphere Application Server and bound into the JNDI namespace by the WebSphere administrative support.

To use JMS, any method of a J2EE application completes the following general steps:

1. Import JMS packages. A J2EE application that uses JMS starts with a number of import statements for JMS, which should include at least the following:

```
import javax.jms.*;           //JMS interfaces
import javax.naming.*;       //Used for JNDI lookup of administered objects
```

2. Get an initial context.

```
try {
    ctx = new InitialContext(env);
    ...
}
```

3. Retrieve administered objects from the JNDI namespace. The `InitialContext.lookup()` method is used to retrieve administered objects (a queue connection factory and the queue destinations); for example, to receive a message from a queue

```
qcf = (QueueConnectionFactory)ctx.lookup( qcfName );
...
inQueue = (Queue)ctx.lookup( qnameIn );
...
```

4. Create a connection to the messaging service provider. The connection provides access to the underlying transport, and is used to create sessions. The `createQueueConnection()` method on the factory object is used to create the connection.

```
connection = qcf.createQueueConnection();
```

The JMS specification defines that connections should be created in the stopped state. Until the connection starts, `MessageConsumers` that are associated with the connection cannot receive any messages. To start the connection, issue the following command:

```
connection.start();
```

5. Create a session, for sending or receiving messages. The session provides a context for producing and consuming messages, including the methods used to create `MessageProducers` and `MessageConsumers`. The `createQueueSession` method is used on the connection to obtain a session. The method takes two parameters:

- A boolean that determines whether or not the session is transacted.
- A parameter that determines the acknowledge mode.

```
boolean transacted = false;
session = connection.createQueueSession( transacted,
                                         Session.AUTO_ACKNOWLEDGE);
```

In this example, the session is not transacted, and it should automatically acknowledge received messages. With these settings, a message is backed out only after a system error or if the application terminates unexpectedly.

The following points, as defined in the EJB specification, apply to these flags:

- The transacted flag passed on `createQueueSession` is ignored inside a global transaction and all work is performed as part of the transaction. Outside of a transaction the transacted flag is not used and, if set to true, the application should use `session.commit()` and `session.rollback()` to control the completion of the work. In an EJB2.0 module, if the transacted flag is set to true and outside of an XA transaction, then the session is involved in the WebSphere local transaction and the unresolved action attribute of the method applies to the JMS work.
- Clients cannot use using `Message.acknowledge()` to acknowledge messages. If a value of `CLIENT_ACKNOWLEDGE` is passed on the `createQueueSession` call, then messages are automatically acknowledged by the application server and `Message.acknowledge()` is not used.

6. Send a message.

- a. Create `MessageProducers` to create messages. For point-to-point messaging the `MessageProducer` is a `QueueSender` that is created by passing an output queue object (retrieved earlier) into the `createSender` method on the session. A `QueueSender` is normally created for a specific queue, so that all messages sent using that sender are sent to the same destination.

```
QueueSender queueSender = session.createSender(inQueue);
```

- b. Create the message. Use the session to create an empty message and add the data passed.

JMS provides several message types, each of which embodies some knowledge of its content. To avoid referencing the vendor-specific class names for the message types, methods are provided on the Session object for message creation.

In this example, a text message is created from the `outString` property:

```
TextMessage outMessage = session.createTextMessage(outString);
```

- c. Send the message.

To send the message, the message is passed to the `send` method on the `QueueSender`:

```
queueSender.send(outMessage);
```

7. Receive replies.

- a. Create a correlation ID to link the message sent with any replies. In this example, the client receives reply messages that are related to the message that it has sent, by using a provider-specific message ID in a `JMSCorrelationID`.

```
messageID = outMessage.getJMSMessageID();
```

The correlation ID is then used in a message selector, to select only messages that have that ID:

```
String selector = "JMSCorrelationID = '"+messageID+"'";
```

- b. Create a `MessageReceiver` to receive messages. For point-to-point the `MessageReceiver` is a `QueueReceiver` that is created by passing an input queue object (retrieved earlier) and the message selector into the `createReceiver` method on the session.

```
QueueReceiver queueReceiver = session.createReceiver(outQueue, selector);
```

- c. Retrieve the reply message. To retrieve a reply message, the `receive` method on the `QueueReceiver` is used:

```
Message inMessage = queueReceiver.receive(2000);
```

The parameter in the `receive` call is a timeout in milliseconds. This parameter defines how long the method should wait if there is no message available immediately. If you omit this parameter, the call blocks indefinitely. If you do not want any delay, use the `receiveNoWait()` method. In this example, the `receive` call returns when the message arrives, or after 2000ms, whichever is sooner.

- d. Act on the message received. When a message is received, you can act on it as needed by the business logic of the client. Some general JMS actions are to check that the message is of the correct type and extract the content of the message. To extract the content from the body of the message, it is necessary to cast from the generic `Message` class (which is the declared return type of the `receive` methods) to the more specific subclass, such as `TextMessage`. It is good practice always to test the message class before casting, so that unexpected errors can be handled gracefully.

In this example, the `instanceof` operator is used to check that the message received is of the `TextMessage` type. The message content is then extracted by casting to the `TextMessage` subclass.

```
if ( inMessage instanceof TextMessage )
```

```
...
```

```
String replyString = ((TextMessage) inMessage).getText();
```

8. Closing down. If the application needs to create many short-lived JMS objects at the Session level or lower, it is important to close all the JMS resources used. To do this, you call the `close()` method on the various classes (`QueueConnection`, `QueueSession`, `QueueSender`, and `QueueReceiver`) when the resources are no longer required.

```
queueReceiver.close();
```

```
...
```

```
queueSender.close();
```

```
...
```

```
session.close();
```

```

    session = null;
...
    connection.close();
    connection = null;

```

9. Publishing and subscribing messages. To use JMS Publish/Subscribe support instead of point-to-point messaging, the general actions are the same; for example, to create a session and connection. The exceptions are that topic resources are used instead of queue resources (such as TopicPublisher instead of QueueSender), as shown in the following example to publish a message:

```

// Creating a TopicPublisher
    TopicPublisher pub = session.createPublisher(topic);
...
    pub.publish(outMessage);
...
    // Closing TopicPublisher
    pub.close();

```

10. Handling errors Any JMS runtime errors are reported by exceptions. The majority of methods in JMS throw JMSEExceptions to indicate errors. It is good programming practice to catch these exceptions and display them on a suitable output.

Unlike normal Java exceptions, a JMSEException can contain another exception embedded in it. The implementation of JMSEException does not include the embedded exception in the output of its toString() method. Therefore, you need to check explicitly for an embedded exception and print it out, as shown in the following example:

```

    catch (JMSEException je)
    {
        System.out.println("JMS failed with "+je);
        Exception le = je.getLinkedException();
        if (le != null)
        {
            System.out.println("linked exception "+le);
        }
    }

```

After you have packaged your application, you can next deploy the application into WebSphere Application Server, as described in Deploying a J2EE application to use JMS.

Developing a JMS client

Use this task to develop a JMS client application to use messages to communicate with enterprise applications.

This topic gives an overview of the steps needed to develop a JMS client application, based on a sample client provided with WebSphere Application Server. This topic only describes the JMS-related considerations; it does not describe general client programming, which you should already be familiar with. For detailed information about these steps, and for examples of developing JMS clients, see the Java Message Service Documentation and the WebSphere MQ *Using Java* book, SC34-5456.

A JMS client assumes that the JMS resources (such as a queue connection factory and queue destination) already exist. A client application can use JMS resources administered by the application server or administered by the client container regardless of whether the client application is running on the same machine as the server or remotely.

- If you want your client application to use server-administered JMS objects, configure the client application to use those resources as Resource Environment References.
- If you want your client application to use client container-administered JMS resources, then configure those resources as Resource References.

For more information about developing client applications and configuring JMS resources for them, see Developing J2EE application client code and related tasks.

To use JMS, a typical JMS client program completes the following general steps:

1. Import JMS packages. An enterprise application that uses JMS starts with a number of import statements for JMS; for example:

```
import javax.naming.Context;
import javax.naming.InitialContext;
import javax.rmi.PortableRemoteObject;
import javax.jms.*;
```

2. Get an initial context.

```
try {
    ctx = new InitialContext(env);
    ...
}
```

3. Define the parameters that the client wants to use; for example, to identify the queue connection factory and to assemble a message to be sent.

```
public class JMSppSampleClient
{
    public static void main(String[] args)
        throws JMSEException, Exception
    {
        String messageID           = null;
        String outString           = null;
        String qcfName             = "java:comp/env/jms/ConnectionFactory";
        String qnameIn             = "java:comp/env/jms/Q1";
        String qnameOut           = "java:comp/env/jms/Q2";
        boolean verbose            = false;

        QueueSession session      = null;
        QueueConnection connection = null;
        Context ctx               = null;

        QueueConnectionFactory qcf = null;
        Queue inQueue             = null;
        Queue outQueue            = null;

        ...
    }
}
```

4. Retrieve administered objects from the JNDI namespace. The `InitialContext.lookup()` method is used to retrieve administered objects (a queue connection factory and the queue destinations):

```
qcf = (QueueConnectionFactory)ctx.lookup( qcfName );
...
inQueue = (Queue)ctx.lookup( qnameIn );
outQueue = (Queue)ctx.lookup( qnameOut );
...
```

5. Create a connection to the messaging service provider. The connection provides access to the underlying transport, and is used to create sessions. The `createQueueConnection()` method on the factory object is used to create the connection.

```
connection = qcf.createQueueConnection();
```

The JMS specification defines that connections should be created in the stopped state. Until the connection starts, `MessageConsumers` that are associated with the connection cannot receive any messages. To start the connection, issue the following command:

```
connection.start();
```

6. Create a session, for sending and receiving messages. The session provides a context for producing and consuming messages, including the methods used to create `MessageProducers` and `MessageConsumers`. The `createQueueSession` method is used on the connection to obtain a session. The method takes two parameters:

- A boolean that determines whether or not the session is transacted.
- A parameter that determines the acknowledge mode.

```

boolean transacted = false;
session = connection.createQueueSession( transacted,
                                         Session.AUTO_ACKNOWLEDGE);

```

In this example, the session is not transacted, and it should automatically acknowledge received messages. With these settings, a message is backed out only after a system error or if the client application terminates unexpectedly.

7. Send the message.

- a. Create MessageProducers to create messages. For point-to-point the MessageProducer is a QueueSender that is created by passing an output queue object (retrieved earlier) into the createSender method on the session. A QueueSender is normally created for a specific queue, so that all messages sent using that sender are sent to the same destination.

```
QueueSender queueSender = session.createSender(inQueue);
```

- b. Create the message. Use the session to create an empty message and add the data passed. JMS provides several message types, each of which embodies some knowledge of its content. To avoid referencing the vendor-specific class names for the message types, methods are provided on the Session object for message creation.

In this example, a text message is created from the outString property, which could be provided as an input parameter on invocation of the client program or constructed in some other way:

```
TextMessage outMessage = session.createTextMessage(outString);
```

- c. Send the message.

To send the message, the message is passed to the send method on the QueueSender:

```
queueSender.send(outMessage);
```

8. Receive replies.

- a. Create a correlation ID to link the message sent with any replies. In this example, the client receives reply messages that are related to the message that it has sent, by using a provider-specific message ID in a JMSCorrelationID.

```
messageID = outMessage.getJMSMessageID();
```

The correlation ID is then used in a message selector, to select only messages that have that ID:

```
String selector = "JMSCorrelationID = '"+messageID+"'";
```

- b. Create a MessageReceiver to receive messages. For point-to-point the MessageReceiver is a QueueReceiver that is created by passing an input queue object (retrieved earlier) and the message selector into the createReceiver method on the session.

```
QueueReceiver queueReceiver = session.createReceiver(outQueue, selector);
```

- c. Retrieve the reply message. To retrieve a reply message, the receive method on the QueueReceiver is used:

```
Message inMessage = queueReceiver.receive(2000);
```

The parameter in the receive call is a timeout in milliseconds. This parameter defines how long the method should wait if there is no message available immediately. If you omit this parameter, the call blocks indefinitely. If you do not want any delay, use the receiveNoWait() method. In this example, the receive call returns when the message arrives, or after 2000ms, whichever is sooner.

- d. Act on the message received. When a message is received, you can act on it as needed by the business logic of the client. Some general JMS actions are to check that the message is of the correct type and extract the content of the message. To extract the content from the body of the message, you need to cast from the generic Message class (which is the declared return type of the receive methods) to the more specific subclass, such as TextMessage. It is good practice always to test the message class before casting, so that unexpected errors can be handled gracefully.

In this example, the instanceof operator is used to check that the message received is of the TextMessage type. The message content is then extracted by casting to the TextMessage subclass.

```
if ( inMessage instanceof TextMessage )
```

```
...  
    String replyString = ((TextMessage) inMessage).getText();
```

9. Closing down. If the application needs to create many short-lived JMS objects at the Session level or lower, it is important to close all the JMS resources used. To do this, you call the close() method on the various classes (QueueConnection, QueueSession, QueueSender, and QueueReceiver) when the resources are no longer required.

```
    queueReceiver.close();  
...  
    queueSender.close();  
...  
    session.close();  
    session = null;  
...  
    connection.close();  
    connection = null;
```

10. Publishing and subscribing messages. To use publish/subscribe support instead of point-to-point messaging, the general client actions are the same; for example, to create a session and connection. The exceptions are that topic resources are used instead of queue resources (such as TopicPublisher instead of QueueSender), as shown in the following example to publish a message:

```
// Creating a TopicPublisher  
    TopicPublisher pub = session.createPublisher(topic);  
...  
    pub.publish(outMessage);  
...  
    // Closing TopicPublisher  
    pub.close();
```

11. Handling errors Any JMS runtime errors are reported by exceptions. The majority of methods in JMS throw JMSEExceptions to indicate errors. It is good programming practice to catch these exceptions and display them on a suitable output.

Unlike normal Java exceptions, a JMSEException can contain another exception embedded in it. The implementation of JMSEException does not include the embedded exception in the output of its toString() method. Therefore, you need to check explicitly for an embedded exception and print it out, as shown in the following example:

```
    catch (JMSEException je)  
    {  
        System.out.println("JMS failed with "+je);  
        Exception le = je.getLinkedException();  
        if (le != null)  
        {  
            System.out.println("linked exception "+le);  
        }  
    }
```

Deploying a J2EE application to use JMS

This topic describes how to deploy a J2EE application to use JMS.

This task description assumes that you have an .EAR file, which contains an application enterprise bean with code for JMS, that can be deployed in WebSphere Application Server.

To deploy a J2EE application to use JMS, complete the following steps:

1. **5.1+** Configure the deployment attributes for the application, as described in Assembling applications with the Assembly Toolkit.
2. Use the WebSphere administrative console to install the application.

This stage is a standard WebSphere Application Server task, as described in Installing applications.

Tuning Java messaging service

You can tune Java messaging service (JMS) run-time components, resources, and the embedded messaging server through the administrative console with the following parameters:

- **Configure the message listening service.**
 - Thread pool
 - Custom properties Application Server Facilities and Non-Application Server Facilities
 - Listener port Maximum sessions
 - Listener port Maximum messages
- **Configure JMS resources.**
 - XA enabled
 - Connection pool size
 - WebSphere MQ queue connection factory Transport type
 - WebSphere MQ topic connection factory Transport type
 - Transaction log directory
 - **WebSphere MQ**
 - **Description:** Includes the WebSphere MQ folder where WebSphere MQ is installed and indirectly where its data files reside since they are always under the directory *WebSphereMQHome/data*. Use this parameter during installation when extra disks are available.
 - **How to view or set:** To view, search your system for a folder named WebSphere MQ. Set during installation.
 - **Default value:** *c:\Program Files\IBM\WebSphere MQ*
 - **Recommended value:** Locate this directory away from any other disk input or output, on the fastest disk available. Redundant Array of Inexpensive Disks (RAID) is recommended.
 - **WebSphere MQ**
 - **Description:** Includes the WebSphere MQ folder where WebSphere MQ is installed and indirectly where its data files reside since they are always under the directory *WebSphereMQHome/data*. Use this parameter during installation when extra disks are available.
 - **How to view or set:** To view, search your system for a folder named WebSphere MQ. Set during installation.
 - **Default value:** *c:\Program Files\IBM\WebSphere MQ*
 - **Recommended value:** Locate this directory away from any other disk input or output, on the fastest disk available. Redundant Array of Inexpensive Disks (RAID) is recommended.
 - **Log buffer pages**
 - **Description:** Controls the size of the queue manager buffer to log file writes in number of pages. Use this parameter when high volumes of messages are being sent through a server.
 - **How to view or set:** In the registry, navigate to **HKEY_LOCAL_MACHINE > SOFTWARE > IBM > MQSeries > CurrentVision > Configuration > QueueManager > QM_name > Log > LogBufferPages**. For embedded JMS, edit the *createmq.properties* setting *LogFilePages* in the *install_root\properties* directory to the desired value. Run the **deletemq** and **createmq** commands to delete or recreate the queue manager. For external JMS, set *LogFilePages* to the desired value. Do this before creating the queue manager in the registry. Run the **amqmdain regsec** command to secure the registry value and create the queue manager.
 - **Default value:** 0
 - **Recommended value:** There is no performance penalty for setting this value too high. Therefore, set the value to its maximum of 512 pages.
 - **Log primary files**
 - **Description:** Controls the number of primary or permanent log files for the queue manager. Use this parameter when high volumes of messages are being sent through a server.
 - **How to view or set:** In the registry, navigate to **HKEY_LOCAL_MACHINE > SOFTWARE > IBM > MQSeries > CurrentVision > Configuration > QueueManager > QM_name > Log > LogPrimaryFiles**. For embedded JMS, edit the *createmq.properties* setting *LogFilePages* in the *install_root\properties* directory to the desired value. Run the **deletemq** and **createmq** commands

to delete or recreate the queue manager. For external JMS, set LogPrimaryFiles to the desired value. Do this before creating the queue manager in the registry. Run the **amqmdain regsec** command to secure the registry value and create the queue manager.

- **Default value:** External: 3, embedded: 0

- **Recommended value:** There is no performance penalty for setting this value too high. Set the value to its maximum of 63 pages.

– Log secondary files

- **Description:** Controls the number of secondary log files for the queue manager. Secondary files are files created when the primary files are not enough and deleted when they are no longer needed.

- **How to view or set:** In the registry, navigate to **HKEY_LOCAL_MACHINE > SOFTWARE > IBM > MQSeries > CurrentVersion > Configuration > QueueManager > QM_name > Log > LogSecondaryFiles**. For embedded JMS, edit the `createmq.properties` setting LogSecondaryFiles in the `install_root\properties` directory to the desired value. Run the **deletemq** and **createmq** commands to delete or recreate the queue manager. For external JMS, set LogPrimaryFiles to the desired value. Do this before creating the queue manager in the registry. Run the **amqmdain regsec** command to secure the registry value and create the queue manager.

- **Default value:** External: 2, embedded: 60

- **Recommended value:** There is a limit of 63 total files from the primary and secondary combined and because secondary logs are slower, setting this 0 is ideal for performance.

- **Log default path**

- **Description:** Controls the location of the queue manager log files. Use this parameter when high volumes of messages are sent through a server.

- **How to view or set:** In the registry, navigate to **HKEY_LOCAL_MACHINE > SOFTWARE > IBM > MQSeries > CurrentVersion > Configuration > QueueManager > QM_name > Log > LogDefaultPath**. For embedded JMS, edit the `createmq.properties` setting LogPath in the `install_root\properties` directory to the desired value. Run the **deletemq** and **createmq** commands to delete or recreate the queue manager. For external JMS, set LogDefaultPath to the desired value. Do this before creating the queue manager in the registry. Run the **amqmdain regsec** command to secure the registry value and create the queue manager.

- **Default value:** `WebSphereMQHome\log`

- **Recommended value:** It is ideal to have a disk dedicated to this task because WebSphere MQ tries to keep the head of the disk positioned at the place in the file where it needs to write next. A fast RAID volume is best.

- **Default queue buffer size**

- **Description:** Controls the size in bytes of an in-memory buffer for nonpersistent queues. Use this parameter when large message sizes are used, or large bursts of messages cause the queue to back up. If the queue backs up past this buffer, messages are flushed out to the disk.

- **How to view or set:** In the registry, navigate to **HKEY_LOCAL_MACHINE > SOFTWARE > IBM > MQSeries > CurrentVersion > Configuration > QueueManager > QM_name > TuningParameters > DefaultQBufferSize**. Embedded JMS is not currently supported; you need MQ5.3 CSD2 and an accompanying Version 5.0 fix. For external JMS, set DefaultQBufferSize to the desired value. Do this before creating the queue manager. Run the **amqmdain regsec** command to secure the registry value and create the queue manager.

- **Default value:** 64K (registry key does not exist)

- **Recommended value:** Set this parameter to accommodate the typical number of messages sitting on the queue at any given time. This should be $\text{numberOfMessages} * (500 + \text{messageSizeInBytes})$. The maximum value is 100MB, but typically 1MB is enough.

- **Default persistent queue buffer size**

- **Description:** Controls the size in bytes of an in-memory buffer for nonpersistent queues. Use this parameter whenever memory is available.

- **How to view or set:** In the registry, navigate to **HKEY_LOCAL_MACHINE > SOFTWARE > IBM > MQSeries > CurrentVersion > Configuration > QueueManager > QM_name > TuningParameters > DefaultPQBufferSize**. Embedded JMS is not currently supported; you need MQ5.3 CSD2 and an accompanying Version 5.0 fix. For external JMS, set

DefaultPQBufferSize to the desired value. Create the queue manager. This is a permanent queue setting. To make a change, delete and recreate the queue.

- **Default value:** 0 (registry key does not exist)
- **Recommended value:** Set this parameter to accommodate the number of typical concurrently processed messages, plus a little more for read-ahead capabilities. Do this by calculating $\text{numOfCocurrentMessages} * (\text{msgSizeInBytes} + 500) * 2$. Typically, 1MB is enough.
- **Maximum channels**
 - **Description:** Controls the allowable number of concurrent CLIENT transport clients. Use this parameter when large numbers of clients are being used.
 - **How to view or set:** In the registry, navigate to **HKEY_LOCAL_MACHINE > SOFTWARE > IBM > MQSeries > CurrentVersion > Configuration > QueueManager > QM_name > Channels > MaxChannels**. Embedded JMS is not currently supported; you need MQ5.3 CSD2 and an accompanying Version 5.0 fix. For external JMS, set MaxChannels to the desired value. Restart the queue manager.
 - **Default value:** External: 100 (registry key does not exist), embedded: 1000
 - **Recommended value:** Set this parameter high enough to contain the maximum number of concurrent JMS clients.
- **Channel application bind type**
 - **Description:** Controls if the channel application is an MQ FASTPATH application. Use this parameter at all times.
 - **How to view or set:** In the registry, navigate to **HKEY_LOCAL_MACHINE > SOFTWARE > IBM > MQSeries > CurrentVersion > Configuration > QueueManager > QM_name > Channels > MQIBindType**. Embedded JMS is not currently supported; you need MQ5.3 CSD2 and an accompanying Version 5.0 fix. For external JMS, set MQIBindType to the desired value. Restart the queue manager.
 - **Default value:** Not FASTPATH (registry key does not exist)
 - **Recommended value:** FASTPATH
- **Configure resources for the embedded WebSphere JMS provider.**
 - **Number of threads**
 - **Description:** With the embedded JMS publications and subscriptions server, this value is the number of threads to use for the publications and subscriptions matching engine, which matches publications to subscribers. Use this parameter when concurrent publications and subscriptions exist that would exceed the capacity of the default value.
 - **How to view or set:**
 1. Open the administrative console.
 2. Click **Servers > Application Servers > server_name**.
 3. Click the *Server Component* > **JMS servers**.
 4. Click **Apply** or **OK**.
 5. Click **Save**.
 6. Stop and restart the application server.
 - **Default value:** 1
 - **Recommended value:** Set this value a little higher than the number of concurrent message publishers. If large numbers of subscribers exist, increasing this value can also provide some benefit.

Troubleshooting WebSphere Messaging

Use this overview task to help resolve a problem that you think is related to the WebSphere Messaging.

To identify and resolve problems that you think are related to WebSphere Messaging, you can use the standard WebSphere Application Server troubleshooting facilities. If you encounter a problem that you think might be related to WebSphere Messaging, complete the following stages. Some problems and their troubleshooting are specific to whether you are using the embedded WebSphere Messaging or WebSphere MQ as the JMS provider.

1. Check for common problems related to WebSphere Messaging. For example, check that the JMS server has been started, that you have added queue names to the list on the JMS server page of the Administrative Console, and that you have successfully installed the WebSphere Messaging function. For tips about solving problems related to the WebSphere Messaging, see *Tips for troubleshooting WebSphere Messaging*. If those tips do not help you fix the problem, complete the following general stages.
2. Check the Release Notes for specific problems and workarounds The section *Possible Problems and Suggested Fixes* of the Release Notes, available from the WebSphere Application Server library web site, is updated regularly to contain information about known defects and their workarounds. Check the latest version of the Release Notes for any information about your problem. If the Release Notes do not contain any information about your problem, you can also search the Technotes database on the WebSphere Application Server web site.
3. Check for WebSphere Messaging error messages.
Check in the application server's SystemOut log at `was_home\logs\server\SystemOut` for error messages with the prefixes MSGS and WMSG.
The associated message reference information provides an explanation and any user actions to resolve the problem. (See "Message reference" in the Information Center.)
4. Check for more informational and error messages that might provide a clue to a related problem. If the JMS server is running, but you have problems accessing JMS resources, check for more error messages and extra details about the problem.
For messages related to WebSphere Messaging, look for the prefixes: MSGS and WMSG.
5. Check your JMS resource configurations If the WebSphere Messaging functions seem to be running properly (the JMS server is running without problems), check that the JMS resources have been configured correctly. For example, check that queue destinations and their connection factories have corresponding JNDI names, that the JNDI names match those configured for the messaging applications, and that the connection factories are configured onto nodes that can provide the JMS resources.
6. Get a detailed exception dump for WebSphere Messaging. If the information obtained in the preceding steps is still inconclusive, you can enable the application server debug trace for the "Messaging" group to provide a detailed exception dump.

Tips for troubleshooting WebSphere Messaging

This topic provides a set of tips to help you troubleshoot problems with WebSphere Messaging.

- The JMS server does not start by default when WebSphere Messaging is installed
- The JMS server tries to start, but fails
- An MDB listener fails to start
- Failure to create a queue connection
- Embedded WebSphere Messaging failed to install on top of an existing WebSphere MQ product
- Problems running JMS applications with security enabled
- Queue manager fails to stop on Redhat Linux
- Application server fails to start in zh_TW.EUC locale on Solaris

The JMS server does not start when starting the WebSphere administrative server

During installation, the system PATH setting is updated to include the WebSphere Messaging directories. If you try to start the WebSphere administrative server from a session that does not use the updated system PATH, the JMS Server fails to start properly. To resolve this after installing WebSphere Application Server stop then restart your host or open a new session that uses the updated system PATH.

Also, when installing WebSphere Application Server, the JMS server is not configured to start automatically by default, except on Windows if the messaging samples are installed. So, generally, if you want to use JMS resources on that host, use the administrative console to configure the JMS server to start automatically. For more information about managing JMS servers, see *Administering WebSphere JMS support*.

Finally, check that the JMS server has started before trying to use WebSphere Messaging. For messages that indicate the JMS server has started successfully, see the following tip The JMS server tries to start, but fails.

The JMS server tries to start, but fails

To see if the JMS Server has started, check the `was_home\logs\server\SystemOut` log. If the JMS server started successfully, you should see the following messages:

```
MSG0050I: Starting the Queue Manager
MSG0051I: Queue Manager open for business
MSG0052I: Starting the Broker
MSG0053I: Broker open for business
```

If the JMS server tries to start, but fails, you should see messages indicating that the queue manager could not start, like the following:

```
MSG0153E: The Queue Manager process could not be started - error: com.ibm.ws.process.exception.
InvalidExecutableException: The system cannot find the file specified.
002: No such file or directory
```

An MDB listener fails to start

If an MDB listener fails to start, you should see the following message:

```
WMSG0019E: Unable to start MDB Listener {0}, JMSDestination {1} : {2}
```

To troubleshoot the cause of an MDB listener not starting, check the following factors:

- Check that the administrative resources have been configured correctly; for example, use the administrative console to check the listener port properties: Destination JNDI name and Connection factory JNDI name. Check that other properties of the listener port, destination, and connection factory are correct.
- Check that the queue exists and has been added to the JMS server.
- Check that the queue manager and JMS server have started.
- Check that the Remote Queue Manager Listener has started.
- If security is enabled, check that a component-managed authentication alias has been specified on the queue connection factory or topic connection factory used by the message-driven bean. This is not required if security is not enabled.
- Check that the user ID used to start the MDB listener has 12 characters or less.

For example, the default Windows NT user ID, **administrator**, is not valid for use with WebSphere embedded messaging, because it contains 13 characters.

(UNIX platforms only) Check that this user ID is a member of the mqm and mqbrkrs groups.

Failure to create a queue connection

If WebSphere Application Server fails to create a queue connection, the SystemOut.log contains error messages like the following:

```
J2CA0046E: Method addNewConnection caught javax.resource.spi.ResourceAdapterInternalException:
createQueueConnection failed
```

Check that the JMS server is running (including that the Internal WebSphere Messaging or WebSphere MQ JMS provider was installed correctly) as described in preceding tips.

Note: In a Network Deployment or Enterprise multi-node cell, the JMS server used by a messaging application can be on a different node to the application. Either check that all JMS servers in the cell have started, or use the Administrative console to determine which JMS server the application is trying to connect to (look at the Node property of the appropriate connection factory), then check that the JMS server has started.

Embedded WebSphere Messaging failed to install on top of an existing WebSphere MQ product

When preparing to install WebSphere Application Server on a host that already has WebSphere MQ installed, you should ensure that WebSphere MQ is at a prerequisite level, as described in the Release Notes and Supported hardware, software, and APIs page of the WebSphere Application Server library web site. You can also check the WebSphere MQ Support service summary Web page at <http://www-3.ibm.com/software/ts/mqseries/support/summary/>.

If you have a problem installing the embedded WebSphere Messaging function, first check the `mq_install.log`. Failures during the WebSphere Messaging prereq stage usually indicate a shortage of space. Failures after this stage are usually due to a conflict between messaging components already installed on the machine and the levels required to support the J2EE 1.3 specification.

If the embedded WebSphere Messaging function installed successfully, you should see messages like the following in `mq_install.log`:

```
...
date time MsiInstallProduct() returning ERROR_SUCCESS (0)
date time ===== Exiting Publish_And Subscribe Install =====
date time <<Function Successful>> return code WASM_ERROR_SUCCESS (0)
date time ===== End of WebSphere Messaging Install Log =====
```

You can also check the `createMQ.log` for any messages that indicate a configuration problem with the installation of WebSphere Messaging.

Problems running JMS applications with security enabled

When trying to run a JMS application with security enabled, you can encounter problems indicated by one of the error messages:

MSG50508E: The JMS Server security service was unable to authenticate userid:

This indicates that the JMS connection has not provided the WebSphere JMS server with any security credentials.

WMSG0019E: Unable to start MDB Listener PSSampleMDB, JMSDestination Sample/JMS/listen : javax.jms.JMSSecurityException:

This indicates that the security credentials supplied are not valid.

In both cases the problem can be removed by doing one of the following:

- If the authentication mechanism is set to `Application`, then the application needs to supply valid credentials.
- If the authentication mechanism is set to `Container`, then you need to configure the JMS `ConnectionFactory` with a container-managed Authentication Alias and ensure that the associated username and password are valid.

MQJMS2013 invalid security authentication supplied for MQQueueManager

If using a WebSphere MQ JMS Provider JMS connection when using Bindings transport mode, and the user specified is not the current logged on user for the WebSphere Application Server process, then the WebSphere MQ JMS Bindings authentication throws the error MQJMS2013 invalid security authentication supplied for MQQueueManager.

If you want to use a WebSphere MQ JMS Provider JMS connection when using Bindings transport mode, you set the property **Transport type=BINDINGS** on the WebSphere MQ Queue Connection Factory. You must also choose one of the following options:

- To use security credentials, ensure that the user specified is the currently logged on user for the WebSphere Application Server process.
- Do not specify security credentials. On the WebSphere MQ Connection Factory, ensure that both the **Component-managed Authentication Alias** and the **Container-managed Authentication Alias** properties are not set.

For more information about messaging security, see [Asynchronous messaging - security considerations](#).

Queue manager fails to stop on Redhat Linux

When trying to stop an application server on Redhat Linux, the queue manager can hang with a Java core dump, and the last message in the SystemOut.log file is Stopping Queue manager....

This is caused by a known RedHat problem (https://bugzilla.linux.ibm.com/show_bug.cgi?id=2336), that was introduced in libstdc++-2.96-116.7.2 and beyond.

The workaround is to go back to the libstdc++-2.96-108.1 level.

Application server fails to start in zh_TW.EUC locale on Solaris

If you have set the locale to zh_TW.EUC on Solaris, and are using the WebSphere embedded JMS provider or WebSphere MQ as the JMS provider, you can encounter problems that stop application servers starting up.

If you intend using the WebSphere embedded JMS provider or WebSphere MQ as the JMS provider on Solaris, do not set the LANG and LC_ALL variables to zh_TW.EUC (Traditional Chinese locale) to avoid problems when starting application servers. Set the LANG and LC_ALL variables to zh_TW instead of zh_TW.EUC.

Using message-driven beans in applications

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface.

Message-driven beans (a type of enterprise bean defined in the EJB 2.0 specification) extend the base JMS support and the Enterprise JavaBean component model to provide automatic asynchronous messaging. When a message arrives on a destination, a listener passes the message to a new instance of a user-developed message-driven bean for processing.

You can use WebSphere Studio Application Developer to develop applications that use message-driven beans. You can use the WebSphere Application Server runtime tools, like the administrative console, to deploy and administer applications that use message-driven beans.

For more information about implementing WebSphere enterprise applications that use message-driven beans, see the following topics:

- An overview of message-driven beans
- Designing an enterprise application to use a message-driven bean
- Developing an enterprise application to use a message-driven bean
- Deploying an enterprise application to use a message-driven bean
- Configuring message listener resources for message-driven beans
- Troubleshooting problems with message-driven beans

Message-driven beans - an overview

WebSphere Application Server supports automatic asynchronous messaging with message-driven beans (a type of enterprise bean defined in the EJB 2.0 specification). Messaging with message-driven beans is shown in the figure “Message-driven beans - an overview.”

The support for message-driven beans is based on the message listener service, which comprises a listener manager that controls and monitors one or more listeners. Each listener monitors a JMS destination for incoming messages. When a message arrives on the destination, the listener passes the

message to a new instance of a user-developed message-driven bean (an enterprise bean) for processing. The listener then looks for the next message without waiting for the bean to return.

Messages arriving at a destination being processed by a listener have no client credentials associated with them; the messages are anonymous. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component. For more information about EJB security, see "Enterprise bean component security" in the Information Center.

You are recommended to develop a message-driven bean to delegate the business processing of incoming messages to another enterprise bean, to provide clear separation of message handling and business processing. This also enables the business processing to be invoked by either the arrival of incoming messages or, for example, from a WebSphere J2EE client.

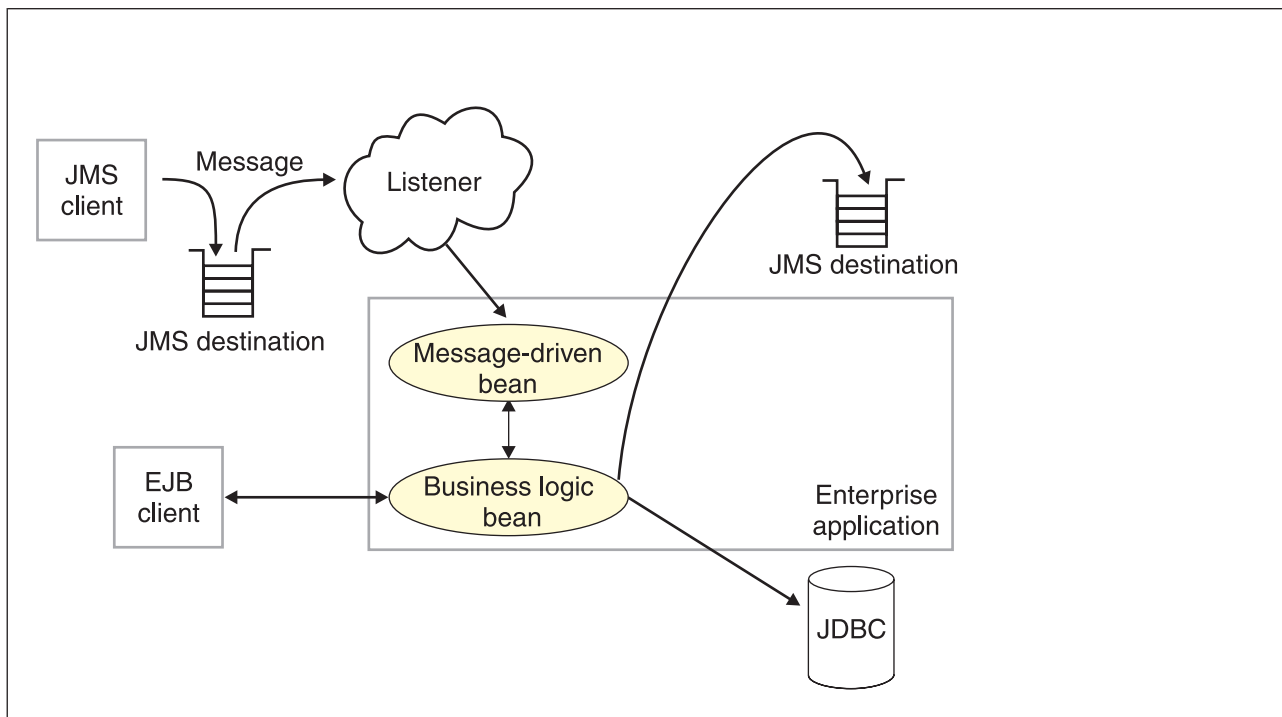

Figure 8. Message-driven beans and the message listener service. This figure shows an incoming message being passed by a JMS listener to a message-driven bean, which passes the message on to a business logic bean for business processing. This messaging is controlled by the listener manager. For more information, see the text that accompanies this figure.

Message-driven beans - components

The WebSphere Application Server support for message-driven beans is based on JMS message listeners and the message listener service, and builds on the base support for JMS. The main components of WebSphere Application Server support for message-driven beans are shown in the following figure and described after the figure:

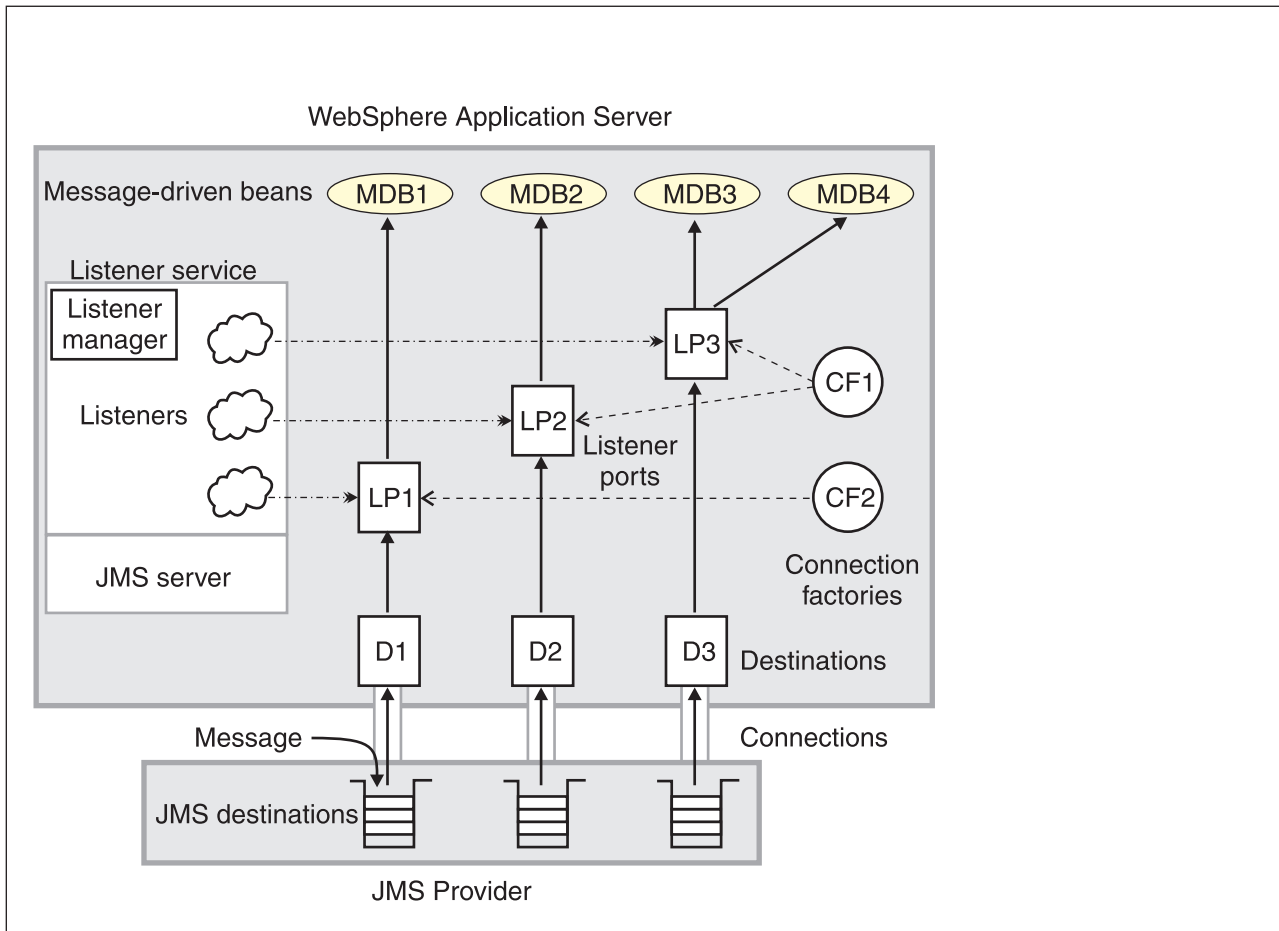

Figure 9. The main components for message-driven beans. This figure shows the main components of WebSphere support for message-driven beans, from JMS provider through a connection to a destination, listener port, then deployed message-driven bean that processes the message retrieved from the destination. Each listener port defines the association between a connection factory, destination, and a deployed message-driven bean. The other main components are the message listener service, which comprises a listener for each listener port, all controlled by the same listener manager. For more information, see the text that accompanies this figure.

The message listener service is an extension to the JMS functions of the JMS provider and provides a listener manager, which controls and monitors one or more JMS listeners.

Each listener monitors either a JMS queue destination (for point-to-point messaging) or a JMS topic destination (for publish/subscribe messaging).

A connection factory is used to create connections with the JMS provider for a specific JMS queue or topic destination. Each connection factory encapsulates the configuration parameters needed to create a connection to a JMS destination.

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. Listener ports are used to simplify the administration of the associations between these resources.

When a deployed message-driven bean is installed, it is associated with a listener port and the listener for a destination. When a message arrives on the destination, the listener passes the message to a new instance of a message-driven bean for processing.

When an application server is started, it initializes the listener manager based on the configuration data. The listener manager creates a dynamic session thread pool for use by listeners, creates and starts

listeners, and during server termination controls the cleanup of listener message service resources. Each listener completes several steps for the JMS destination that it is to monitor, including:

- Creating a JMS server session pool, and allocating JMS server sessions and session threads for incoming messages.
- Interfacing with JMS ASF to create JMS connection consumers to listen for incoming messages.
- If specified, starting a transaction and requesting that it is committed (or rolled back) when the EJB method has completed.
- Processing incoming messages by invoking the `onMessage()` method of the specified enterprise bean.

Message-driven beans - transaction support

Message-driven beans can handle messages read from JMS destinations within the scope of a transaction. If transaction handling is specified for a JMS destination, the JMS listener starts a global transaction *before* it reads any incoming message from that destination. When the message-driven bean processing has finished, the JMS listener commits or rolls back the transaction (using JTA transaction control).

Note:

- All messages retrieved from a specific destination have the same transactional behavior.

If messages are queued to be sent within a global transaction they are sent when the transaction is committed. If the processing of a message causes the transaction to be rolled back, then the message that caused the bean instance to be invoked is left on the JMS destination.

You can configure the **Maximum retries** property of the listener port to define the maximum number of times the listener attempts to read a message from a destination. When the Max retries limit is reached, the listener for that destination is stopped. When you have resolved the problem, you must then restart the listener.

Designing an enterprise application to use message-driven beans

This topic describes things to consider when designing an enterprise application to use message-driven beans.

The considerations in this topic are based on a generic enterprise application that uses one message-driven bean to retrieve messages from a JMS queue destination and passes the messages on to another enterprise bean that implements the business logic.

To design an enterprise application to use message-driven beans, complete the following steps:

1. Identify the JMS resources that the application is to use. This helps to identify the properties of resources that need to be used within the application and configured as application deployment descriptors or within WebSphere Application Server.

JMS resource type	Properties
Queue connection factory	Name: SamplePtoPQueueConnectionFactory JNDI Name: Sample/JMS/QCF
Queue destination	Name: Q1 JNDI Name: Sample/JMS/Q1
Listener port (for the destination)	Name: SamplePtoPListenerPort Connection Factory JNDI Name: Sample/JMS/QCF Destination JNDI Name: Sample/JMS/Q1 Maximum Sessions: 5 Maximum Retries: 10 Maximum Messages: 1

JMS resource type	Properties
Message-driven bean (deployment properties)	Name: JMSppSampleMDBBean Transaction type: Container Destination type: Queue Listener port name: SamplePtoPListenerPort
Business logic bean	Name: MyLogicBean

Ensure that you use consistent values where needed; for example, the JNDI names for the connection factory and destination must be the same for both those resources and the equivalent properties of the listener port.

2. Separation of business logic. You are recommended to develop a message-driven bean to delegate the business processing of incoming messages to another enterprise bean. This provides clear separation of message handling and business processing. This also enables the business processing to be invoked by either the arrival of incoming messages or, for example, from a WebSphere J2EE client.

3. Security considerations.

Messages arriving at a destination being processed by a listener have no client credentials associated with them; the messages are anonymous. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component. For more information about EJB security, see "Enterprise bean component security" in the Information center.

4. General JMS considerations For Publish/Subscribe messaging, choose the JMS server port to be used depending on your needs for transactions or performance:

Queued port

The TCP/IP port number of the listener port used for all point-to-point and Publish/Subscribe support.

Direct port

The TCP/IP port number of the listener port used for direct TCP/IP connection (non-transactional, non-persistent, and non-durable subscriptions only) for Publish/Subscribe support.

Note: Message-driven beans cannot use the direct listener port for Publish/Subscribe support. Therefore, any topic connection factory configured with **Portset** to **Direct** cannot be used with message-driven beans.

A non-durable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created. For more information about this context restriction, see The effect of transaction context on non-durable subscribers.

Developing an enterprise application to use message-driven beans

Use this task to develop an enterprise application to use a message-driven bean. The message-driven bean is invoked by a JMS listener when a message arrives on the input queue that the listener is monitoring.

You are recommended to develop the message-driven bean to delegate the business processing of incoming messages to another enterprise bean, to provide clear separation of message handling and business processing. This also enables the business processing to be invoked by either the arrival of incoming messages or, for example, from a WebSphere J2EE client. Responses can be handled by another enterprise bean acting as a sender bean, or handled in the message-driven bean.

You develop an enterprise application to use a message-driven bean like any other enterprise bean, except that a message-driven bean does not have a home interface or a remote interface.

This topic describes how to develop a completely new message-driven bean class. If you have a WAS 4.0 enterprise application that uses the JMS listener, you can migrate that application to use message-driven beans, as described in *Migrating a WAS 4.0 JMS listener application to use message-driven beans*.

For more information about writing the message-driven bean class, see *Creating a message-driven bean* in the WebSphere Studio help bookshelf.

To develop an enterprise application to use a message-driven bean, complete the following steps:

1. Creating the Enterprise Application project, as described in the WebSphere Studio article *Creating an Enterprise Application project*.
2. Creating the message-driven bean class.

You can use the New Enterprise Bean wizard of WebSphere Studio Application Developer to create an enterprise bean with a bean type of Message-driven bean. The wizard creates appropriate methods for the type of bean.

By convention, the message bean class is named *nameBean*, where *name* is the name you assign to the message bean; for example:

```
public class MyJMSPMDBBean implements MessageDrivenBean, MessageListener
```

The message-driven bean class must define and implement the following methods:

- `onMessage(message)`, which must meet the following requirements:
 - The method must have a single argument of type `javax.jms.Message`.
 - The throws clause must *not* define any application exceptions.
 - If the message-driven bean is configured to use bean-managed transactions, it must call the `javax.transaction.UserTransaction` interface to scope the transactions. Because these calls occur inside the `onMessage()` method, the transaction scope does not include the initial message receipt. This means the application server is given one attempt to process the message.

To handle the message within the `onMessage()` method (for example, to pass the message on to another enterprise bean), you use standard JMS. (This is known as bean-managed messaging.)

- `ejbCreate()`

You must define and implement an `ejbCreate` method for each way in which you want a new instance of an enterprise bean to be created.

- `ejbRemove()`.

This method is invoked by the container when a client invokes the remove method inherited by the enterprise bean's home interface from the `javax.ejb.EJBHome` interface. This method must contain any code that you want to execute before an enterprise bean instance is removed from the container (and the associated data is removed from the data source).

For example, the following code extract shows how to access the text and the JMS MessageID, from a JMS message of type `TextMessage`:

```

public void onMessage(javax.jms.Message msg)
{
    String text      = null;
    String messageID = null;

    try
    {
        text = ((TextMessage)msg).getText();

        System.out.println("senderBean.onMessage(), msg text2: "+text);

        //
        // store the message id to use as the Correlator value
        //
        messageID = msg.getJMSMessageID();

        // Call a private method to put the message onto another queue
        putMessage(messageID, text);
    }
    catch (Exception err)
    {
        err.printStackTrace();
    }
    return;
}

```

Figure 10. Code example: The `onMessage()` method of a message bean. This figure shows a code extract for a basic `onMessage()` method of a sample message-driven bean. The method unpacks the incoming text message to extract the text and message identifier and calls a private `putMessage` method (defined within the same message bean class) to put the message onto another queue.

The result of this step is a message-driven bean that can be assembled into an .EAR file for deployment.

3. Assembling and packaging the application for deployment.

You can use WebSphere Studio to assemble and package the application for deployment.

The result of this task is an .EAR file, containing an application message-driven bean, that can be deployed in WebSphere Application Server.

After you have developed an enterprise application to use message-driven beans, configure and deploy the application; for example, define the listener ports for the message-driven beans and, optionally, change the deployment descriptor attributes for the application. For more information about configuring and deploying an application that uses message-driven beans, see [Deploying an enterprise application to use message-driven beans](#)

Migrating a JMS listener application to use message-driven beans

Use this task to migrate an enterprise application that uses message beans with the JMS Listener from WebSphere Application Server 4.0 to use EJB 2.0 message-driven beans.

This task uses a command line utility, `mb2mdb`, that takes as its input either a deployed `MessageBean.jar` module or a deployed Enterprise Application (.ear) that contains a message bean, along with the JMS listener configuration XML file that defines the WebSphere Application Server 4.0 message beans. The result is a new .jar/.ear module that can then be deployed directly into a WebSphere Application Server 5.0 application server.

You can display the usage help for the migration utility, by typing the command `mb2mdb` at a command line.

To migrate a WebSphere Application Server 4.0 enterprise application that uses message beans to use EJB 2.0 message-driven beans, type the following command at an operating system command line:

```
mb2mdb inputMB.jar-ear jmsListenerConfig.xml workingDirectory outputMDB.jar-ear options
```

Where:

inputMB.jar-ear

The name of the deployed WebSphere Application Server 4.0 jar or ear file containing a stateless session message bean.

jmsListenerConfig.xml

The name of the XML configuration file used to configure the WebSphere Application Server 4.0 JMS listeners.

workingDirectory

The name of a new or existing directory that is used to generate the new message-driven bean and package the outputMDB.jar or .ear file.

Note: By default, the tool clears the working directory after it has completed. If you want to preserve the contents of the working directory, you must specify the `-keep` option.

outputMDB.jar-ear

The name of the output .jar or .ear file for the migrated message-driven bean application.

options

An optional set of parameters that you can use to control the mb2mdb utility.

-keep This prevents the tool from clearing out the working directory after completion.

-verbose

This causes the tool to display informational messages as to the progress of the migration and its parameters.

-map listenerHome=bindingHome

This option provides a mechanism to map between the JNDIHomeName specified for a listener in the JMS listener configuration XML file and the default binding home name specified in the *inputMB.jar-ear* file.

If the *jmsListenerConfig.xml* file contains a deployed EJB home JNDI name that is different to the default binding within the *inputMB.jar-ear*, use this option to map between the two names.

This enables you to install the output .jar or .ear file for the message-driven bean into an application server and bind the bean with a different JNDIHomeName than is specified in the bean's bindings.xmi.

The result of this task is a new .jar or .ear file for a message-driven bean that can then be deployed directly into a WebSphere Application Server 5.0 application server.

To successfully install the .jar or .ear file, you need to bind the message-driven bean against a listener port defined to the message listener service of the application server. You need to have used the WebSphere Application Server administrative console to define the listener port, which defines the JMS connection factory and destination that a message-driven bean bound to it listens on. For more information about installing and configuring a .jar or .ear file for a message-driven bean, see *Deploying an enterprise application to use message-driven beans*.

Deploying an enterprise application to use message-driven beans

Use this task to deploy an enterprise application to use message-driven beans.

This task description assumes that you have an .EAR file, which contains an application enterprise bean with code for message-driven beans, that can be deployed in WebSphere Application Server.

To deploy an enterprise application to use message-driven beans, complete the following steps:

1. Use the WebSphere administrative console to define the listener ports for the application, as described in *Adding a new listener port*.

2. **5.1+** For each message-driven bean in the application, configure the deployment attributes to match the listener port definitions, as described in *Configuring deployment attributes using the Assembly Toolkit*.

3. Use the WebSphere administrative console to install the application.

This stage is a standard WebSphere Application Server task, as described in *Installing a new application*.

When you install the application, you are prompted to specify the name of the listener port that the application is to use for late responses. Select the listener port, then click **OK**.

Configuring deployment attributes using the Assembly Toolkit

Use this task to configure the message-driven beans deployment attributes for an enterprise bean, to override the deployment attributes defined within the application EAR file.

You can configure the deployment attributes of an application by using the Deployment Descriptor Editor of WebSphere Studio Application Developer or the Assembly Toolkit.

This topic describes the use of the Assembly Toolkit to configure the deployment attributes of an application. This task description assumes that you have an EAR file, which contains an application enterprise bean developed as a message-driven bean, that can be deployed in WebSphere Application Server. For more details about using the Assembly Toolkit, see *Assembling applications with the Assembly Toolkit*.

To configure the message-driven beans deployment attributes for an enterprise bean, use the Assembly Toolkit to configure the deployment attributes of the application to match the listener port definitions:

1. Start the Assembly Toolkit.
2. Create or edit the application EAR file. For example, to change attributes of an existing application, use the import wizard to import the EAR file into the Assembly Toolkit. To start the import wizard:
 - a. Click **File-> Import-> EAR file**
 - b. Click **Next**, then select the EAR file.
 - c. Click **Finish**
3. In the J2EE Hierarchy view, right-click the EJB module for the message-driven bean, then click **Open With > Deployment Descriptor Editor**. A property dialog notebook for the message-driven bean is displayed in the property pane.
4. Specify general deployment properties.
 - a. In the property pane, select the Beans tab.
 - b. Specify the following properties:

Transaction type

Whether the message bean manages its own transactions or the container manages transactions on behalf of the bean. All messages retrieved from a specific destination have the same transactional behavior. To enable the transactional behavior that you want, you must configure the JMS destination with the same transactional behavior as you configure for the message bean.

Bean The message bean manages its own transactions

Container

The container manages transactions on behalf of the bean

5. Specify advanced deployment properties.
 - a. Specify the following properties:

Message selector

The JMS message selector to be used to determine which messages the message bean receives; for example:

```
JMSType='car' AND color='blue' AND weight>2500
```

The selector string can refer to fields in the JMS message header and fields in the message properties. Message selectors cannot reference message body values.

Acknowledge mode

How the session acknowledges any messages it receives.

This property applies only to message-driven beans that uses bean-managed transaction demarcation (**Transaction type** is set to Bean).

Auto Acknowledge

The session automatically acknowledges a message when it has either successfully returned from a call to receive, or the message listener it has called to process the message successfully returns.

Dups OK Acknowledge

The session lazily acknowledges the delivery of messages. This is likely to result in the delivery of some duplicate messages if JMS fails, so it should be used only by consumers that are tolerant of duplicate messages.

As defined in the EJB specification, clients cannot use using Message.acknowledge() to acknowledge messages. If a value of CLIENT_ACKNOWLEDGE is passed on the createxxxSession call, then messages are automatically acknowledged by the application server and Message.acknowledge() is not used.

Destination type

Whether the message bean uses a queue or topic destination.

Queue

The message bean uses a queue destination.

Topic The message bean uses a topic destination.

Subscription durability

Whether a JMS topic subscription is durable or non-durable.

Durable

A subscriber registers a durable subscription with a unique identity that is retained by JMS. Subsequent subscriber objects with the same identity resume the subscription in the state it was left in by the earlier subscriber. If there is no active subscriber for a durable subscription, JMS retains the subscription's messages until they are received by the subscription or until they expire.

Nondurable

Non-durable subscriptions last for the lifetime of their subscriber object. This means that a client sees the messages published on a topic only while its subscriber is active. If the subscriber is not active, the client is missing messages published on its topic.

A non-durable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created. For more information about this context restriction, see The effect of transaction context on non-durable subscribers.

6. Specify bindings deployment properties.
 - a. Specify the following property:
Listener port name
Type the name of the listener port for this message-driven bean.
7. Save your changes to the deployment descriptor.
 - a. Close the deployment descriptor editor.
 - b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.
8. Verify the archive files.
9. Generate code for deployment for EJB modules or for enterprise applications that use EJB modules.
10. Optional: Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard. Note that **Run on**

Server works on the Windows, Linux/Intel, and AIX operating systems only; you cannot deploy remotely from the Assembly Toolkit to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

Important

Important: Use **Run On Server** for unit testing only. Assembly Server Toolkit controls the WebSphere Application Server installation and, when an application is published remotely, the Toolkit overwrites the server configuration file for that server. Do not use on production servers.

For instructions on remote testing, see the article “Setting Up a Remote WebSphere Application Server in WebSphere Studio V5” at http://www7b.boulder.ibm.com/wsdd/techjournal/0303_yuen/yuen.html.

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that is to run the application; for example, using the administrative console as described in Deploying and managing applications.

Configuring message listener resources for message-driven beans

Use the following tasks to configure resources needed by the message listener service to support message-driven beans.

- Configuring the message listener service
- Adding a new listener port
- Configuring a listener port
- Configuring security for message-driven beans

Configuring the message listener service

Use this task to configure the properties of the message listener service for an application server.

To configure the properties of the message listener service for an application server, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers-> Application Servers** This displays a table of the application servers in the administrative domain.
2. In the content pane, click the name of the application server. This displays the properties of the application server in the content pane.
3. In the Additional Properties table, select **Message Listener Service** This displays the Message Listener Service properties in the content pane.
4. Specify appropriate properties of the message listener service.
5. Optional: Specify any of the following optional properties that you need, as **Custom properties** of the message listener service: `NON.ASF.RECEIVE.TIMEOUT`, `MQJMS.POOLING.TIMEOUT`, `MQJMS.POOLING.THRESHOLD`, `MAX.RECOVERY.RETRIES`, and `RECOVERY.RETRY.INTERVAL`.
For more information about these custom properties, see Custom Properties.
6. Click **OK**.
7. Save your configuration.
8. To have the changed configuration take effect, stop then restart the Application Server.

Message listener service:

The message listener service is an extension to the JMS functions of the JMS provider. It provides a listener manager that controls and monitors one or more JMS listeners, which each monitor a JMS destination on behalf of a deployed message-driven bean.

This panel displays links to the Additional Properties pages for Listener Ports, Thread Pool, and Custom Properties for the message listener service.

To view this administrative console page, click **Servers-> Application Servers-> *application_server*-> Message Listener Service**

Thread pool:

Controls the maximum number of threads the Message Listener Service is allowed to run. Select this link to display the service thread pool properties.

Adjust this parameter when multiple message-driven beans are deployed in the same application server and the sum of their maximum session values exceeds the default value of 10.

Data type	Integer
Units	Not applicable
Default	Minimum: 10, maximum 50
Range	Not applicable
Recommended	Set the minimum to the sum of all message-driven beans maximum session values. Set the maximum to anything equal or greater than the minimum.

Custom Properties:

An optional set of name and value pairs for custom properties of the message listener service.

You can use the Custom properties page to define the following properties for use by the message listener service.

- NON.ASF.RECEIVE.TIMEOUT
- MQJMS.POOLING.TIMEOUT
- MQJMS.POOLING.THRESHOLD
- MAX.RECOVERY.RETRIES
- RECOVERY.RETRY.INTERVAL

Message listener service custom properties:

Use this panel to view or change an optional set of name and value pairs for custom properties of the message listener service.

To view this administrative console page, click **Servers-> *application_server*-> Message Listener Service-> (In content pane, under Additional Properties) Custom Properties**

You can use the Custom properties page to define the following properties for use by the message listener service.

- NON.ASF.RECEIVE.TIMEOUT
- MQJMS.POOLING.TIMEOUT
- MQJMS.POOLING.THRESHOLD
- MAX.RECOVERY.RETRIES
- RECOVERY.RETRY.INTERVAL

NON.ASF.RECEIVE.TIMEOUT:

The timeout in milliseconds for synchronous message receives performed by message-driven bean listener sessions in the non-ASF mode of operation.

You should set this property to a non-zero value only if you want to enable the non-ASF mode of operation for all message-driven bean listeners on the application server.

The message listener service has two modes of operation, Application Server Facilities (ASF) and non-Application Server Facilities (non-ASF).

- The ASF mode is meant to provide concurrency and transactional support for applications. For publish/subscribe message-driven beans, the ASF mode provides better throughput and concurrency, because in the non-ASF mode the listener is single-threaded.
- The non-ASF mode is mainly for use with generic JMS providers that do not support JMS ASF, which is an optional extension to the JMS specification. The non-ASF mode is also transactional but, because the path length is shorter than the ASF mode, usually provides improved performance.

Use non-ASF if:

- Your generic JMS provider does not provide JMS ASF support
- You are using message-driven beans with WebSphere topic connections with the DIRECT port, because the embedded publish/subscribe broker using that port does not support XA transactions or JMS ASF.
- Message order is a strict requirement

Data type	Integer
Units	Milliseconds
Default	ASF mode (custom property not created)
Range	0 or greater milliseconds
	0 non-ASF mode is disabled
	1 or more
	The timeout in milliseconds for non-ASF message-driven bean listener synchronous session receives
Recommended	If a transaction timeout occurs, the message must recycle causing extra work. If you want to use the non-ASF mode, set this property to lower than the transaction timeout, but leave spare at least the maximum duration of your message-driven bean's onMessage() method. For example, if your message-driven bean's onMessage() method typically takes a maximum of 10 seconds, and the transaction timeout is set to 120 seconds, you might set the NON.ASF.RECEIVE.TIMEOUT property to no more than 110000 (110000 milliseconds, that is 110 seconds).

MQJMS.POOLING.TIMEOUT:

The number of milliseconds after which a connection in the pool is destroyed if it has not been used.

An MQSimpleConnectionManager allocates connections on a most-recently-used basis, and destroys connections on a least-recently-used basis. By default, a connection is destroyed if it has not been used for five minutes.

Data type	Integer
Units	Milliseconds
Default	5 minutes
Range	

MQJMS.POOLING.THRESHOLD:

The maximum number of unused connections in the pool.

An MQSimpleConnectionManager allocates connections on a most-recently-used basis, and destroys connections on a least-recently-used basis. By default, a connection is destroyed if there are more than ten unused connections in the pool.

Data type	Integer
Units	Number of connections
Default	10
Range	

MAX.RECOVERY.RETRIES:

The maximum number of times that the listener service tries to get a message from a listener port before the associated listener is stopped, in the range 0 through 2147483647.

Data type	Integer
Units	Retry attempts
Default	0 (no retries)
Range	0 (no retries) through 2147483647

RECOVERY.RETRY.INTERVAL:

The time in seconds between retry attempts by the listener service to get a message from a listener port.

Data type	Integer
Units	Seconds
Default	10
Range	1 through 2147483647

Message listener port collection:

The message listener ports configured in the administrative domain

This panel displays a list of the message listener ports configured in the administrative domain. Each listener port is used with a message-driven bean to automatically receive messages from an associated JMS destination. You can use this panel to add new listener ports or to change the properties of existing listener ports. For more information about the property fields for listener ports, see Listener port properties.

To view this administrative console page, click **Servers-> application_server-> Message Listener Service-> Listener Ports**

Listener port settings:

A listener port is used to simplify administration of the association between a connection factory, destination, and deployed message-driven bean.

Use this panel to view or change the configuration properties of the selected listener port.

To view this administrative console page, click **Servers-> Application Servers-> application_server-> Message Listener Service-> Listener Ports-> listener_port**

Name:

The name by which the listener port is known for administrative purposes.

Data type	String
------------------	--------

Default Null

Initial state:

The state that you want the listener port to have when the application server is next restarted

Data type	Enum
Units	Not applicable
Default	Started
Range	Started When the application server is next started, the listener port is started automatically. Stopped When the application server is next started, the listener port is not started automatically. If message-driven beans are to use this listener port on the application server, the system administrator must start the port manually or select the Started value of this property then restart the application server.

Description:

A description of the listener port, for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Connection factory JNDI name:

The JNDI name for the JMS connection factory to be used by the listener port; for example, jms/connFactory1.

Data type	String
Default	Null

Destination JNDI name:

The JNDI name for the destination to be used by the listener port; for example, jms/destn1.

If the extended messaging service is to use this listener port to handle late responses, the value of this property must match the JMS response destination on the output port used by the sender bean.

You cannot use a temporary destination for late responses.

Data type	String
Default	Null

Maximum sessions:

Specifies the maximum number of concurrent sessions that a listener can have with the JMS server to process messages.

Each session corresponds to a separate listener thread and therefore controls the number of concurrently processed messages. Adjust this parameter when the JMS server does not fully use the available capacity of the machine and if you do not need to process messages in a specific message order.

Data type	Integer
Units	Sessions
Default	1
Range	1 through 2147483647
Recommended	<ul style="list-style-type: none"> • If you want to process messages in a strict message order, set the value to 1, so only one thread is ever processing messages. • If you want to process multiple messages simultaneously (known as “message concurrency”), set this property to a value greater than 1. Keep this value as low as possible to prevent overloading client applications. A good starting point for a 100% JMS workload with short transaction times is 2 to 4 sessions per processor. If longer running transactions exist, you may need more sessions, which should be determined by experimentation. • If you are using XA transactions, this property should always be set to 1. If it this property is set to a higher value, multiple messages are delivered in the same transaction, which is usually not the desired behavior.

Maximum retries:

The maximum number of times that the listener tries to deliver a message before the listener is stopped, in the range 0 through 2147483647.

The maximum number of times that the listener tries to deliver a message to a message-driven bean instance before the listener is stopped.

Data type	Integer
Units	Retry attempts
Default	0 (no retries)
Range	0 (no retries) through 2147483647

Maximum messages:

The maximum number of messages that the listener can process in one session with the JMS server.

For WebSphere embedded messaging or WebSphere MQ as the JMS provider, the listener processes all messages in the session as one batch within the same transaction. For a generic JMS provider, the listener processes each message in the session within a separate transaction.

Data type	Integer
Units	Number of messages
Default	1
Range	1 through 2147483647

Recommended

For WebSphere embedded messaging or WebSphere MQ as the JMS provider, if you want to process multiple messages in a single transaction, then set this value to more than 1. This enables multiple messages to be batch-processed into a single transaction, and eliminates much of the overhead of transactions on JMS messages.

CAUTION:

- If one message in the batch fails processing with an exception, the entire batch of messages is put back on the queue for processing.
- Any resource lock held by any of the interactions for the individual messages are held for the duration of the entire batch.
- Depending on the amount of processing that messages need, and if XA transactions are being used, setting a value greater than 1 can cause the transaction to time out. If an XA transaction does time out routinely because processing multiple messages exceeds the transaction timeout, reduce this property to 1 (to limit processing to one message per transaction) or increase your transaction timeout.

Configuring a listener port to handle late responses:

Use this task to configure the listener port extensions to handle late responses for an application that uses extended messaging.

To configure a listener port to handle late responses, use the administrative console to complete the following steps:

1. Define the properties of the listener port to be used for late responses, as described in Adding a new listener port or Configuring a listener port.
2. Configure the listener port extensions properties, to indicate that you want to handle late responses, as follows:
 - a. In the navigation pane, expand **Servers-> Application Servers-> application_server-> Extended Messaging Service-> Listener Port Extensions**
This displays a panel in the content pane for configuring the extensions properties of listener ports.
 - b. From the pull-down list, select the listener port that you want to configure to handle late responses.
 - c. Select the **Enable** checkbox to enable handling of late responses.
 - d. Optionally, change the values for the Request Interval and Request Timeout properties.
 - e. Click **OK**.

Adding a new listener port

Use this task to add a new listener port to the message listener service, so that message-driven beans can be associated with the port to retrieve messages.

To add a new listener port, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers-> Application Servers** This displays a table of the application servers in the administrative domain.
2. In the content pane, click the name of the application server. This displays the properties of the application server in the content pane.
3. In the Additional Properties table, select **Message Listener Service** This displays the Message Listener Service properties in the content pane.
4. In the content pane, select **Listener Ports**. This displays a list of the listener ports.

5. In the content pane, click **New**.
6. Specify appropriate properties for the listener port.
7. Click **OK**.
8. To save your configuration, click **Save** on the task bar of the Administrative console window.
9. To have the changed configuration take effect, stop then restart the application server.

If enabled, the listener port is started automatically when a message-driven bean associated with that port is installed.

Configuring a listener port

Use this task to change the properties of an existing listener port, used by message-driven beans associated with the port to retrieve messages.

To configure the properties of a listener port, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers-> Application Servers** This displays a table of the application servers in the administrative domain.
2. In the content pane, click the name of the application server. This displays the properties of the application server in the content pane.
3. In the Additional Properties table, select **Message Listener Service** This displays the Message Listener Service properties in the content pane.
4. In the content pane, click **Listener Ports**. This displays a list of the listener ports.
5. Click the listener port that you want to modify. This displays the properties of the listener port in the content pane.
6. Specify appropriate properties for the listener port.
7. Click **OK**.
8. To save your configuration, click **Save** on the task bar of the Administrative console window.
9. To have the changed configuration take effect, stop then restart the application server.

Deleting a listener port

Use this task to delete a listener port from the message listener service, to prevent message-driven beans associated with the port from retrieving messages.

To delete a listener port, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers-> Application Servers** This displays a table of the application servers in the administrative domain.
2. In the content pane, click the name of the application server. This displays the properties of the application server in the content pane.
3. In the Additional Properties table, select **Message Listener Service** This displays the Message Listener Service properties in the content pane.
4. In the content pane, select **Listener Ports**. This displays a list of the listener ports.
5. In the content pane, select the checkbox for the listener port that you want to delete.
6. Click **Delete**. This action stops the port (needed to allow the port to be deleted) then deletes the port.
7. To save your configuration, click **Save** on the task bar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

Configuring security for message-driven beans

Use this task to configure resource security and security permissions for message-driven beans.

Messages arriving at a listener port have no client credentials associated with them. The messages are anonymous.

To call secure enterprise beans from a message-driven bean, the message-driven bean needs to be configured with a RunAs Identity deployment descriptor. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component.

For more information about EJB security, see "Enterprise bean component security" in the Information Center. For more information about configuring security for your application, see "Assembling secured applications" in the Information Center.

JMS connections used by message-driven beans can benefit from the added security of using J2C container-managed authentication. To enable the use of J2C container authentication aliases and mapping, define a J2C container-managed alias on the JMS connection factory definition that the MDB is using to listen upon (defined by the **Connection factory JNDI name** property of the listener port). If defined, the listener uses the container-managed authentication alias for its JMSConnection security credentials instead of any application-managed alias. To set the container-managed alias, use the administrative console to complete the following steps:

1. To display the listener port settings, click **Servers-> application_server-> Message Listener Service-> Listener Ports-> listener_port**
2. To get the name of the JMS connection factory, look at the **Connection factory JNDI name** property.
3. Display the JMS connection factory properties. For example, to display the properties of a queue connection factory provided by the embedded WebSphere JMS provider, click **Resources-> WebSphere JMS Provider-> (In content pane, under Additional Properties) WebSphere Queue Connection Factories-> connection_factory**
4. Set the **Container-managed Authentication Alias** property.
5. Click **OK**

Administering listener ports

Use the following tasks to administer listener ports, which each define the association between a connection factory, a destination, and a message-driven bean.

You can use the WebSphere administrative console to administer listener ports, as described in the following tasks.

- Adding a new listener port
Use this task to create a new listener port, to specify a new association between a connection factory, a destination, and a message-driven bean. This enables deployed message-driven beans associated with the port to retrieve messages from the destination.
- Configuring a listener port
Use this task to view or change the configuration properties of a listener port.
- Starting a listener port
Use this task to start a listener port manually.
- Stopping a listener port
Use this task to stop a listener port manually.

Note: If configured as enabled, a listener port is started automatically when a message-driven bean associated with that port is installed. You do not normally need to start or stop a listener port manually.

Starting a listener port:

Use this task to start a listener port on an application server, to enable the listeners for message-driven beans associated with the port to retrieve messages.

A listener is active, that is able to receive messages from a destination, if the deployed message-driven bean, listener port, and message listener service are all started. Although you can start these components in any order, they must all be in a started state before the listener can retrieve messages.

If configured as enabled, a listener port is started automatically when a message-driven bean associated with that port is installed. However, you can start a listener port manually, as described in this topic.

When a listener port is started, the listener manager tries to start the listeners for each message-driven bean associated with the port. If a message-driven bean is stopped, the port is started but the listener is not started, and remains stopped. If you start a message-driven bean, the related listener is started.

To start a listener port on an application server, use the administrative console to complete the following steps:

1. If you want the listener for a deployed message-driven bean to be able to receive messages at the port, check that the message-driven bean has been started.
2. In the navigation pane, select **Servers-> Application Servers** This displays a table of the application servers in the administrative domain.
3. In the content pane, click the name of the application server. This displays the properties of the application server in the content pane.
4. In the Additional Properties table, select **Message Listener Service** This displays the Message Listener Service properties in the content pane.
5. In the content pane, select **Listener Ports**. This displays a list of the listener ports.
6. Select the checkbox for the listener port that you want to start.
7. Click **Start**.
8. To save your configuration, click **Save** on the task bar of the Administrative console window.

Stopping a listener port:

Use this task to stop a listener port on an application server, to prevent the listeners for message-driven beans associated with the port from retrieving messages.

When you stop a listener port as described in this topic, the listener manager stops the listeners for all message-driven beans associated with the port.

To stop a listener port on an application server, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers-> Application Servers** This displays a table of the application servers in the administrative domain.
2. In the content pane, click the name of the application server. This displays the properties of the application server in the content pane.
3. In the Additional Properties table, select **Message Listener Service** This displays the Message Listener Service properties in the content pane.
4. In the content pane, select **Listener Ports**. This displays a list of the listener ports.
5. In the content pane, select the listener port that you want to stop.
6. Click **Stop**.
7. To save your configuration, click **Save** on the task bar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

Important files for message-driven beans and extended messaging

The following files in the WAS_HOME/temp directory are important for the operation of the WebSphere Application Server messaging service, so should not be deleted. If you do need to delete the WAS_HOME/temp directory or other files in it, ensure that you preserve the following files.

server_name-durableSubscriptions.ser

You should not delete this file, because the messaging service uses it to keep track of durable subscriptions for message-driven beans. If you uninstall an application that contains a message-driven bean, this file is used to unsubscribe the durable subscription.

`server_name-AsyncMessageRequestLog.ser`

You should not delete this file, because the messaging service uses it to keep track of late responses that need to be delivered to the late response message handler for the extended messaging provider.

Troubleshooting message-driven beans

Use this overview task to help resolve a problem that you think is related to message-driven beans.

Message-driven beans support uses the standard WebSphere Application Server troubleshooting facilities. If you encounter a problem that you think might be related to the message-driven beans, complete the following stages:

1. Check for error messages about message-driven beans.

Check in the application server's SystemOut log at `was_home\logs\server\SystemOut` for error messages that indicate a problem with JMS resources for message-driven beans, such as listener ports.

The associated message reference information provides an explanation and any user actions to resolve the problem. (See "Message reference" in the Information Center.)

2. Check for more informational and error messages that might provide a clue to a related problem. If the JMS server is running, but you have problems accessing JMS resources, check for more error messages and extra details about the problem.

For messages related to WebSphere Messaging, look for the prefixes: MSGS and WMSG.

3. Check the Release Notes for specific problems and workarounds The section *Possible Problems and Suggested Fixes* of the Release Notes, available from the WebSphere Application Server library web site, is updated regularly to contain information about known defects and their workarounds. Check the latest version of the Release Notes for any information about your problem. If the Release Notes does not contain any information about your problem, you can also search the Technotes database on the WebSphere Application Server web site.
4. Check that message listener service has started. The message listener service is an extension to the JMS functions of the JMS provider. It provides a listener manager that controls and monitors one or more JMS listeners, which each monitor a JMS destination on behalf of a deployed message-driven bean.
5. Check your JMS resource configurations If the WebSphere Messaging functions seem to be running properly (the JMS server is running without problems), check that the JMS resources have been configured correctly. For example, check that the listener ports have been configured correctly and have been started.
6. Check for problems with the WebSphere Messaging functions For more information about troubleshooting WebSphere Messaging, see the related topics.
7. Get a detailed exception dump for messaging. If the information obtained in the preceding steps is still inconclusive, you can enable the application server debug trace for the "Messaging" group to provide a detailed exception dump.

Message-driven beans samples

The following examples are provided, as part of the WebSphere Samples Gallery, to illustrate use of the message-driven beans support. When the Samples are installed on your local machine, they are available to try out. Locate them at <http://localhost:9080/WSSamples/>. (The default port is 9080.) For more information about where to find the Samples Gallery, see "Samples Gallery" in the Information Center.

- Point-to-point samples:

- "Tutorial: Creating JMS message sample"

This tutorial is designed to help you develop and deploy a JMS message sample application that tests the WebSphere Application Server message-driven beans support in a point-to-point scenario. This sample illustrates how to develop and deploy an application that comprises the following components:

- A Java/JMS program that writes a message to a queue.
- A message-driven bean that is invoked by a JMS listener when a message arrives on a defined queue.

For more information about this sample, see the samples article "Tutorial: Creating JMS message sample" that is installed with the Samples option.

- "Sample: Message Listener (point-to-point)"

This sample is designed to demonstrate the use and behavior of message-driven beans for a simple point-to-point scenario. This sample uses the JMS message sample deployed in the sample above.

For more information about this sample, see the samples article "Sample: Message Listener (Point-to-Point)" that is installed with the Samples option.

- Publish/subscribe samples

- "Tutorial: Creating JMS message publish/subscribe sample"

This tutorial is designed to help you develop and deploy a JMS message sample application that tests the WebSphere Application Server message-driven beans support in a publish/subscribe scenario. This sample illustrates how to develop and deploy an application that comprises the following components:

- A client program that starts the message sequence by publishing a message to a selected topic.
- A message-driven bean that is invoked by a JMS listener when the broker passes a message to the listener from a topic to which it has subscribed.

For more information about this sample, see the samples article "Tutorial: Creating JMS message publish/subscribe sample" that is installed with the Samples option.

- "Sample: Message Listener (publish/subscribe)"

This sample is designed to demonstrate the use and behavior of message-driven beans for a simple publish/subscribe scenario. This sample uses the JMS message sample deployed in the publish/subscribe sample above.

For more information about this sample, see the samples article "Sample: Message Listener (publish/subscribe)" that is installed with the Samples option.

Chapter 7. Using application clients

An application client module is a Java ARchive (JAR) file that contains a client for accessing a Java application. Complete the following steps for developing different types of application clients.

1. Decide on a type of application client.
2. Develop the application client code.
 - a. Develop ActiveX application client code.
 - b. Develop J2EE application client code.
 - c. Develop pluggable application client code.
 - d. Develop thin application client code.

View the Samples gallery for more information about application clients. (See "Samples Gallery" in the Information Center.) Before you run the `basicCalculator` sample, verify that the Java Messaging Service (JMS) server is started.

These samples do not include client applications that communicate with Enterprise server-side examples.

Application clients

In a traditional client server environment, the client requests a service and the server fulfills the request. Multiple clients use a single server. Clients can also access several different servers. This model persists for Java clients except that now these requests use a client run-time environment.

In this model, the client application requires a servlet to communicate with the enterprise bean, and the servlet must reside on the same machine as the WebSphere Application Server.

With WebSphere Application Server Version 5, application clients now consist of the following models:

- ActiveX application client
- Applet client
- J2EE application client
- Pluggable and thin application clients

The *ActiveX application client* model, uses the Java Native Interface (JNI) architecture to programmatically access the Java virtual machine (JVM) API. Therefore the JVM code exists in the same process space as the ActiveX application (Visual Basic, VBScript, or Active Server Pages (ASP) files) and remains attached to the process until that process terminates.

In the *Applet client* model, a Java applet embeds in a HyperText Markup Language (HTML) document residing on a remote client machine from the WebSphere Application Server. With this type of client, the user accesses an enterprise bean in the WebSphere Application Server through the Java applet in the HTML document.

The *J2EE application client* is a Java application program that accesses enterprise beans, Java Database Connectivity (JDBC) APIs, and Java Message Service message queues. The J2EE application client program runs on client machines. This program follows the same Java programming model as other Java programs; however, the J2EE application client depends on the application client run time to configure its execution environment, and uses the Java Naming and Directory Interface (JNDI) name space to access resources.

The *pluggable and thin application clients* provide a lightweight Java client programming model. These clients are useful in situations where a Java client application exists but the application needs enhancements to use enterprise beans, or where the client application requires a thinner, more lightweight environment than the one offered by the J2EE application client. The difference between the thin

application client and the pluggable application client is that the thin application client includes a Java virtual machine (JVM) API, and the pluggable application client requires the user to provide this code. The pluggable application client uses the Sun Java Development Kit, and the thin application client uses the IBM Developer Kit for the Java platform.

The J2EE application client programming model provides the benefits of the J2EE platform for the Java client application. Use the J2EE application client to seamlessly develop, assemble, deploy and launch a client application. The tooling provided with the WebSphere platform supports the seamless integration of these stages to help the developer create a client application from start to finish.

When you develop a client application using and adhering to the J2EE platform, you can put the client application code from one J2EE platform implementation to another. The client application package can require redeployment using each J2EE platform deployment tool, but the code that comprises the client application remains the same.

The application client run time supplies a container that provides access to system services for the client application code. The client application code must contain a main method. The application client run time invokes this main method after the environment initializes and runs until the Java virtual machine code terminates.

The J2EE platform supports the application client use of *nicknames* or *short names*, defined within the client application deployment descriptor. These deployment descriptors identify enterprise beans or local resources (JDBC, Java Message Service (JMS), JavaMail and URL APIs) for simplified resolution through JNDI. This simplified resolution to the enterprise bean reference and local resource reference also eliminates changes to the client application code, when the underlying object or resource either changes or moves to a different server. When these changes occur, the application client can require redeployment.

The application client also provides initialization of the run-time environment for the client application. The deployment descriptor defines this unique initialization for each client application. The application client run time also provides support for security authentication to enterprise beans and local resources.

The application client uses the Java Remote Method Invocation-Internet InterORB Protocol (RMI-IIOP). Using this protocol enables the client application to access enterprise bean references and to use Common Object Request Broker Architecture (CORBA) services provided by the J2EE platform implementation. Use of the RMI-IIOP protocol and the accessibility of CORBA services assist users in developing a client application that requires access to both enterprise bean references and CORBA object references.

When you combine the J2EE and CORBA environments or programming models in one client application, you must understand the differences between the two programming models to use and manage each appropriately.

View the Samples gallery for more information about application clients. (See "Samples Gallery" in the Information Center.) Before you run the `basicCalculator` sample, verify that the Java Messaging Service (JMS) server is started.

These samples do not include client applications that communicate with Enterprise server-side examples.

Application client functions

Use the following table to identify the available functions in the different types of clients.

Available functions	ActiveX client	Applet client	J2EE client	Pluggable client	Thin client
Provides all the benefits of a J2EE platform	Yes	No	Yes	No	No

Portable across all J2EE platforms	No	No	Yes	No	No
Provides the necessary run-time support for communication between a client and a server	Yes	Yes	Yes	Yes	Yes
Supports the use of nicknames in the deployment descriptor files. Note: Although you can edit deployment descriptor files, do not use the administrative console to modify them.	Yes	No	Yes	No	No
Supports use of the RMI-IIOP protocol	Yes	Yes	Yes	Yes	Yes
Browser-based application	No	Yes	No	No	No
Enables development of client applications that can access enterprise bean references and CORBA object references	Yes	Yes	Yes	Yes	Yes
Enables the initialization of the client application run-time environment	Yes	No	Yes	No	No
Supports security authentication to enterprise beans (see "Configuring authentication mechanisms" in the Information Center)	Yes	Limited	Yes	Yes	Yes
Supports security authentication to local resources (see "Configuring authentication mechanisms" in the Information Center)	Yes	No	Yes	No	No
Requires distribution of application to client machines	Yes	No	Yes	Yes	Yes
Enables access to enterprise beans and other Java classes through Visual Basic, VBScript, and Active Server Pages (ASP) code	Yes	No	No	No	No
Provides a lightweight client suitable for download	No	Yes	No	Yes	Yes
Enables access JNDI APIs for enterprise bean resolution	Yes	Yes	Yes	Yes	Yes
Runs on client machines that use the Sun Java Runtime Environment	No	No	No	Yes	No
Supports CORBA services (using CORBA services can render the application client code nonportable)	No	No	Yes	No	No

ActiveX application clients

WebSphere Application Server provides an ActiveX to EJB bridge that enables ActiveX programs to access enterprise beans through a set of ActiveX automation objects.

The bridge accomplishes this access by loading the Java virtual machine (JVM) into any ActiveX automation container such as Visual Basic, VBScript, and Active Server Pages (ASP).

There are two main environments in which the ActiveX to EJB bridge runs:

- **Client applications**, such as Visual Basic and VBScript, are programs that a user starts from the command line, desktop icon, or Start menu shortcut.
- **Client services**, such as Active Server Pages, are programs started by some automated means like the Services control panel applet.

The ActiveX to EJB bridge uses the Java Native Interface (JNI) architecture to programmatically access the JVM code. Therefore the JVM code exists in the same process space as the ActiveX application (Visual Basic, VBScript, or ASP) and remains attached to the process until that process terminates. To create JVM code, an ActiveX client program calls the XJBInit() method of the XJB.JClassFactory object. For more information about creating JVM code for an ActiveX program, see ActiveX to EJB bridge, initializing JVM code.

After an ActiveX client program has initialized the JVM code, the program calls several methods to create a proxy object for the Java class. When accessing a Java class or object, the real Java object exists in the JVM code; the automation container contains the proxy for that Java object. The ActiveX program can use the proxy object to access the Java class, object fields, and methods. For more information about using Java proxy objects, see ActiveX to EJB bridge, using Java proxy objects. For more information about calling methods and access fields, see ActiveX to EJB bridge, calling Java methods and ActiveX to EJB bridge, accessing Java fields.

The client program performs primitive data type conversion through the COM IDispatch interface (use of the IUnknown interface is not directly supported). Primitive data types are automatically converted between native automation types and Java types. All other types are handled automatically by the proxy objects. For more information about data type conversion, see ActiveX to EJB bridge, converting data types.

Any exceptions thrown in Java code are encapsulated and thrown again as a COM error, from which the ActiveX program can determine the actual Java exceptions. For more information about handling exceptions, see ActiveX to EJB bridge, handling errors.

The ActiveX to EJB bridge supports both free-threaded and apartment-threaded access and implements the free threaded marshaler (FTM) to work in a hybrid environment such as Active Server Pages. For more information about the support for threading, see ActiveX to EJB bridge, using threading.

Applet clients

The applet client provides a browser-based Java run time capable of interacting with enterprise beans directly, instead of indirectly through a servlet.

This client is designed to support users who want a browser-based Java client application programming environment that provides a richer and more robust environment than the one offered by the **Applet > Servlet > enterprise bean** model.

The programming model for this client is a hybrid of the Java application thin client and a servlet client. When accessing enterprise beans from this client, the applet can consider the enterprise bean object references as CORBA object references.

No tooling support exists for this client to develop, assemble or deploy the applet. You are responsible for developing the applet, generating the necessary client bindings for the enterprise beans and CORBA

objects, and bundling these pieces together to install or download to the client machine. The Java applet client provides the necessary run time to support communication between the client and the server. The applet client run time is provided through the Java applet browser plug-in that you install on the client machine using the WebSphere Application Server Client CD.

Generate client-side bindings using the Application Assembly Tool **5.1+** Chapter 29, “Assembling applications with the Assembly Toolkit,” on page 1391. An applet can utilize these bindings, or you can generate client-side bindings using the **rmic** command. This command is part of the IBM Developer Kit, Java edition that is installed with the WebSphere Application Server.

The applet client uses the RMI-IIOP protocol. Using this protocol enables the applet to access enterprise bean references and CORBA object references, but the applet is restricted in using some supported CORBA services.

If you combine the enterprise bean and CORBA environments in one applet, you must understand the differences between the two programming models, and you must use and manage each model appropriately.

The applet environment restricts access to external resources from the browser run-time environment. You can make some of these resources available to the applet by setting the correct security policy settings in the WebSphere Application Server `client.policy` file. If given the correct set of permissions, the applet client must explicitly create the connection to the resource using the appropriate API. This client does not perform initialization of any service that the client applet can need. For example, the client application is responsible for the initialization of the naming service, either through the CosNaming, or the Java Naming and Directory Interface (JNDI) APIs.

J2EE application clients

The J2EE application client programming model provides the benefits of the Java 2 Platform for WebSphere Application Server Enterprise product.

The J2EE platform offers the ability to seamlessly develop, assemble, deploy and launch a client application. The tooling provided with the WebSphere platform supports the seamless integration of these stages to help the developer create a client application from start to finish.

When you develop a client application using and adhering to the J2EE platform, you can put the client application code from one J2EE platform implementation to another. The client application package can require redeployment using each J2EE platform deployment tool, but the code that comprises the client application does not change.

The J2EE application client run time supplies a container that provides access to system services for the application client code. The J2EE application client code must contain a main method. The J2EE application client run time invokes this main method after the environment initializes and runs until the Java virtual machine application terminates.

Application clients can use *nicknames* or *short names*, defined within the client application deployment descriptor with the J2EE platform. These deployment descriptors identify enterprise beans or local resources (Java Database Connectivity (JDBC), Java Message Service (JMS), JavaMail and URL APIs) for simplified resolution through JNDI use. This simplified resolution to the enterprise bean reference and local resource reference also eliminates changes to the application client code, when the underlying object or resource either changes or moves to a different server. When these changes occur, the application client can require redeployment. Although you can edit deployment descriptor files, do not use the administrative console to modify them.

The J2EE application client also provides initialization of the run-time environment for the client application. The deployment descriptor defines this unique initialization for each client application. The J2EE application client run time also provides support for security authentication to the enterprise beans and local resources.

The J2EE application client uses the Java Remote Method Invocation technology run over Internet Inter-Orb Protocol (RMI-IIOP). Using this protocol enables the client application to access enterprise bean references and to use Common Object Request Broker Architecture (CORBA) services provided by the J2EE platform implementation. Use of the RMI-IIOP protocol and the accessibility of CORBA services assist users in developing a client application that requires access to both enterprise bean references and CORBA object references.

When you combine the J2EE and the CORBA WebSphere Application Server Enterprise environments or programming models in one client application, you must understand the differences between the two programming models to use and manage each appropriately.

Pluggable application clients

The pluggable application client provides a lightweight, downloadable Java application run time capable of interacting with enterprise beans.

The pluggable application client requires that you have previously installed the Sun Java Runtime Environment (JRE) files. In all other aspects, the pluggable application client, and the thin application client are similar.

Note: The pluggable client is only available on the Windows platform.

This client is designed to support those users who want a lightweight Java client application programming environment, without the overhead of the J2EE platform on the client machine. The programming model for this client is heavily influenced by the CORBA programming model, but supports access to enterprise beans.

When accessing enterprise beans from this client, the client application can consider the enterprise beans object references as CORBA object references.

Tooling does not exist on the client; however, tooling does exist on the server. You are responsible for developing the client application, generating the necessary client bindings for the enterprise bean and CORBA objects, and after bundling these pieces together, installing them on the client machine.

The pluggable application client provides the necessary run time to support the communication needs between the client and the server.

The pluggable application client uses the RMI-IIOP protocol. Using this protocol enables the client application to access enterprise bean references and CORBA object references and use any supported CORBA services. Using the RMI-IIOP protocol along with the accessibility of CORBA services can assist a user in developing a client application that needs to access both enterprise bean references and CORBA object references.

When you combine the J2EE and CORBA environments in one client application, you must understand the differences between the two programming models to use and manage each appropriately.

The pluggable application client run time provides the necessary support for the client application for object resolution, security, Reliability Availability and Serviceability (RAS), and other services. However, this client does not support a container that provides easy access to these services. For example, no support exists for using *nicknames* for enterprise beans or local resource resolution. When resolving to an

enterprise bean (using either the Java Naming and Directory Interface (JNDI) API or CosNaming) sources, the client application must know the location of the name server and the fully qualified name used when the reference was bound into the name space.

When resolving to a local resource, the client application cannot resolve to the resource through a JNDI lookup. Instead the client application must explicitly create the connection to the resource using the appropriate API (JDBC, Java Message Service (JMS), and so on). This client does not perform initialization of any of the services that the client application might require. For example, the client application is responsible for the initialization of the naming service, either through CosNaming or JNDI APIs.

The pluggable application client offers access to most of the available client services in the J2EE application client. However, you cannot access the services in the pluggable client as easily as you can in the J2EE application client. The J2EE client has the advantage of performing a simple Java Naming and Directory Interface (JNDI) name space lookup to access the desired service or resource. The pluggable client must code explicitly for each resource in the client application. For example, looking up an enterprise bean Home object requires the following code in a J2EE application client:

```
        java.lang.Object ejbHome = initialContext.lookup("java:/comp/env/ejb/MyEJBHome"
);
    MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome,
MyEJBHome.class);
```

However, you need more explicit code in a Java pluggable application client:

```
        java.lang.Object ejbHome = initialContext.lookup("the/fully/qualified
/path/to/actual/home/in/namespace/MyEJBHome");
    MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome,
MyEJBHome.class);
```

In this example, the J2EE application client accesses a logical name from the `java:/comp` name space. The J2EE client run time resolves that name to the physical location and returns the reference to the client application. The pluggable client must know the fully qualified physical location of the enterprise bean Home object in the name space. If this location changes, the pluggable client application must also change the value placed on the `lookup()` statement.

In the J2EE client, the client application is protected from these changes because it uses the logical name. A change can require a redeployment of the EAR file, but the actual client application code remains the same.

The pluggable application client is a traditional Java application that contains a *main* function. The WebSphere pluggable application client provides run-time support for accessing remote enterprise beans, and provides the implementation for various services (security, Workload Management (WLM), and others). This client can also access CORBA objects and CORBA-based services. When using both environments in one client application, you need to understand the differences between the enterprise bean and the CORBA programming models to manage both environments.

For instance, the CORBA programming model requires the CORBA CosNaming name service for object resolution in a name space. The enterprise beans programming model requires the JNDI name service. The client application must initialize and properly manage these two naming services.

Another difference applies to the enterprise bean model. Use the Java Naming and Directory Interface (JNDI) implementation in the enterprise bean model to initialize the Object Request Broker (ORB). The client application is unaware that an ORB is present. The CORBA model, however, requires the client application to explicitly initialize the ORB through the `ORB.init()` static method.

The pluggable application client provides a batch command that you can use to set the `CLASSPATH` and `JAVA_HOME` environment variables to enable the pluggable application client run time.

Thin application clients

The thin application client provides a lightweight, downloadable Java application run time capable of interacting with enterprise beans.

This client is designed to support those users who want a lightweight Java client application programming environment, without the overhead of the J2EE platform on the client machine. The programming model for this client is heavily influenced by the CORBA programming model, but supports access to enterprise beans.

When accessing enterprise beans from this client, the client application can consider the enterprise beans object references as CORBA object references.

Tooling does not exist on the client, it exists on the server. You are responsible for developing the client application, generating the necessary client bindings for the enterprise bean and CORBA objects, and bundling these pieces together to install on the client machine.

The thin application client provides the necessary run-time to support the communication needs between the client and the server.

The thin application client uses the RMI-IIOP protocol. Using this protocol enables the client application to access not only enterprise bean references and CORBA object references, but also allows the client application to use any supported CORBA services. Using the RMI-IIOP protocol along with the accessibility of CORBA services can assist a user in developing a client application that needs to access both enterprise bean references and CORBA object references.

When you combine the J2EE and CORBA environments in one client application, you must understand the differences between the two programming models, to use and manage each appropriately.

The thin application client run time provides the necessary support for the client application for object resolution, security, Reliability Availability and Servicability (RAS), and other services. However, this client does not support a container that provides easy access to these services. For example, no support exists for using *nicknames* for enterprise beans or local resource resolution. When resolving to an enterprise bean (using either Java Naming and Directory Interface (JNDI) or CosNaming) sources, the client application must know the location of the name server and the fully qualified name used when the reference was bound into the name space. When resolving to a local resource, the client application cannot resolve to the resource through a JNDI lookup. Instead the client application must explicitly create the connection to the resource using the appropriate API (JDBC, Java Message Service (JMS), and so on). This client does not perform initialization of any of the services that the client application might require. For example, the client application is responsible for the initialization of the naming service, either through CosNaming or JNDI APIs.

The thin application client offers access to most of the available client services in the J2EE application client. However, you cannot access the services in the thin client as easily as you can in the J2EE application client. The J2EE client has the advantage of performing a simple Java Naming and Directory Interface (JNDI) name space lookup to access the desired service or resource. The thin client must code explicitly for each resource in the client application. For example, looking up an enterprise bean Home requires the following code in a J2EE application client:

```
java.lang.Object ejbHome = initialContext.lookup("java:/comp/env/ejb/MyEJBHome");
MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome, MyEJBHome.class);
```

However, you need more explicit code in a Java thin application client:

```
java.lang.Object ejbHome =
initialContext.lookup("the/fully/qualified/path/to/actual/home/in/namespac/MyEJBHome");
MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome, MyEJBHome.class);
```

In this example, the J2EE application client accesses a logical name from the `java:/comp` name space. The J2EE client run time resolves that name to the physical location and returns the reference to the client application. The thin client must know the fully qualified physical location of the enterprise bean Home in the name space. If this location changes, the thin client application must also change the value placed on the `lookup()` statement.

In the J2EE client, the client application is protected from these changes because it uses the logical name. A change might require a redeployment of the EAR file, but the actual client application code remains the same.

The thin application client is a traditional Java application that contains a *main* function. The WebSphere thin application client provides run-time support for accessing remote enterprise beans, and provides the implementation for various services (security, Workload Management (WLM), and others). This client can also access CORBA objects and CORBA based services. When using both environments in one client application, you need to understand the differences between the enterprise bean and CORBA programming models to manage both environments.

For instance, the CORBA programming model requires the CORBA CosNaming name service for object resolution in a name space. The enterprise beans programming model requires the JNDI name service. The client application must initialize and properly manage these two naming services.

Another difference applies to the enterprise bean model. Use the Java Naming and Directory Interface (JNDI) implementation in the enterprise bean model to initialize the Object Request Broker (ORB). The client application is unaware that an ORB is present. The CORBA model, however, requires the client application to explicitly initialize the ORB through the `ORB.init()` static method.

The thin application client provides a batch command that you can use to set the `CLASSPATH` and `JAVA_HOME` environment variables to enable the thin application client run time.

Migration tips for application clients

Tips for migrating thin application client code:

The Java invocation used to run non-J2EE application clients has changed in Version 5.0. You must specify `-Xbootclasspath/p:%WAS_BOOTCLASSPATH%` on Windows systems or `-Xbootclasspath/p:$WAS_BOOTCLASSPATH` on UNIX systems when you invoke the Java command. Set the `WAS_BOOTCLASSPATH` environment variable in one of the following:

- `setupClient.bat` for Windows systems or `setupClient.sh` for UNIX systems on a WebSphere Application Server client installation.
- `setupCmdLine.bat` for Windows systems or `setupCmdLine.sh` for UNIX systems on a WebSphere Application Server installation.

For more information about using `-Xbootclasspath`, view sample code at the following path after you preform the application client installation:

```
install_root\samples\bin\ActiveXBridgeClients\VB\XJBExamples\modXJBHelpers.bat
```

Tips for migrating J2EE application client code:

If your J2EE application client uses resource references and you configured those resources using the Application Client Resource Configuration Tool (ACRCT), you must run the **ClientUpgrade** command to migrate the resource configuration information in WebSphere Application Server Version 5.

Installing application clients

All client applications run on a machine with the WebSphere Application Server installed. However, if the system does not have the Application Server installed, you can install Application Server clients, which provide a stand-alone client run-time environment for your client applications. See the Supported Prerequisites page on the IBM external Web site for more information on supported product platforms.

This article describes how to install the WebSphere Application Server clients using the installation image on the product CD-ROM labelled, **Application Clients**. The steps that follow provide enough detail to guide you through preparing for, choosing, and installing the variety of options and features provided. To prepare for installation and to make yourself familiar with installation options, complete the steps in this article and read the related topics, before you start to use the installation tools. Specifically, read these topics before installing the product:

- Tips for installing the embedded messaging feature
- Installing silently
- Best practices for installing

As a general rule, if you launch an installation and there is a problem such as not having enough temporary space or not having the right packages on your Linux or UNIX-based systems, then cancel the installation, make the required changes, and restart the installation to pick up changes you made.

Although it is not supported or recommended, you can install this product as a non-root user on a UNIX operating system, or from a user ID that is not part of the Administrator group on a Windows platform. However, there are certain components, such as the Embedded Messaging Client feature, that require you to install as root or as part of the Administrator group.

As previously mentioned, this installation method is not supported or recommended, but you can install the application client product on a machine with WebSphere Application Server installed. However, there are certain components, such as the Embedded Messaging Client feature, which might not install if the feature has already been installed during the WebSphere Application Server installation. On Windows platforms, WebSphere Application Server clients assume that the Embedded Messaging Client is installed in its default location; whereas, the WebSphere Application Server installation can install the messaging client in a different location.

1. Prepare a Linux or UNIX operating platform for the Embedded Messaging Client feature.

If you are installing the embedded messaging feature, you must create two operating system groups as described in Installing WebSphere embedded messaging as the JMS provider.

The Solaris Operating Environment and HP-UX also require you to increase kernel settings as described in Installing WebSphere embedded messaging as the JMS provider.

For other platform-specific information about using the embedded messaging feature, see "Tips for installing the embedded messaging feature" in the Information Center.

2. Start the installation.

- a. Issue `launchpad.sh` (or `launchpad.bat`) to initiate the launchpad tool and begin the installation process.

- b. Click **Install the product** from the launchpad tool to launch the InstallShield for MultiPlatforms installation wizard. This action launches the installation wizard.

The Readme documentation to which the launchpad links is the `readme.html` file in the CD root directory. The `readme` directory off the root of the CD has more detailed Readme files. The Installation Guide is in the `/docs` directory of the CD root directory.

When you install application clients, the current working directory must be the directory where the installer binary program is located. This placement is important because the resolution of the class files location is done in the current working directory. For example:

```
cd /install_root
./install
```

or when installing from the product CD-ROM:

```
cd <CD mount point>
./install
```

Failing to use the correct working directory can cause ISMP errors that abort the installation.

The installation wizard does not upgrade or remove previous WebSphere Application Server clients installation automatically. However, you must uninstall any previous installation manually or the installation wizard aborts the installation.

- c. As indicated in the previous example, you can start the installation wizard from the product CD-ROM, using the command line. The installation program is in the operating system platform directory on the product CD-ROM.

On other Linux platforms and UNIX-based platforms, run the `./install` command.

On Windows platforms, run the `Install.exe` command.

- d. You can also perform a silent installation using the `-options responsefile` parameter, which causes the installation wizard to read your responses from the options response file, instead of from the interactive graphical user interface. Customize the response file before installing silently. After customizing the file, issue the command to silently install. Silent installation is particularly useful if you install the product often.

The rest of this procedure assumes that you are using the installation wizard. There are corresponding entries in the response file for every prompt that is described as part of the wizard. Review the description of the response file for more information. Comments in the file describe how to customize its options.

3. Click **Next** to continue when the Welcome panel is displayed. The license displayed during the GUI installation can contain characters that display incorrectly in Japanese. For example, the section labeled Part 1 does not show the number 1. These missing characters do not significantly affect the content of the license agreement.
 - a. Click the radio button beside the **I accept the terms in the license agreement** message if you agree to the license agreement, and click **Next** to continue.

4. Choose a type of installation, and click **Next**.

If you use the GUI, you can choose a Typical installation type, which installs J2EE and Java Thin Application Client, Samples and Embedded Messaging Client features, or a Custom installation type.

The Custom installation type lets you select which features to install. However you can not install the J2EE and Java Thin Application Client feature and the Pluggable Application Client feature together.

(Windows Only) If you select the **ActiveX to EJB Bridge** feature, then the following is displayed in a dialog box: Do you want to add Java runtime to the system path and make it the default JRE? If you answer **Yes**, then the Java run time is added to the beginning of the system path. If you answer **No**, then the ActiveX to EJB Bridge does not function from the Active Server Pages (ASP), unless you add the Java run time to the path. To add the Java run time later, see the topic **ActiveX application clients** or **reinstall Application clients**.(Windows Only) If you select the **Applet Client** feature, then the following message might be displayed: An existing JDK or JRE has been detected on your computer. You chose to install the Applet Client, which will overwrite the registry entries for this JDK or JRE. Do you want to continue and install the Applet Client? If you select **Yes**, the installation overrides the registry on your machine. If you select **No**, the applet client feature is not installed, and you are directed back feature dialog box.

5. Install the samples development environment. If you choose to install any of the Samples features, a message box is displayed requesting conformation to install the Samples development environment.
 - a. Click **Yes** to install the Samples development environment that includes the IBM Developer Kit and the Apache Ant Tool.
 - b. Click **No** to skip installing the Samples development environment.
6. Specify a destination directory. Click **Next** to continue.

- a. Ensure that there is adequate space available in the target directory.
 - b. Specify a target directory for the WebSphere Application Server clients product. If you install the Embedded Messaging Client feature, then you cannot change its default installation directory.
 - c. Enter the required target directory to proceed to the next panel. Deleting the default target location and leaving an installation directory field empty prevents you from continuing the installation process.
7. Enter the host name of the WebSphere Application Server machine. Click **Next** to continue. If you are connecting to a product Version 4 server or you are not using the default port, you must specify the server port number. The default port number for product Version 4 server is 900, and the default port number for product Version 5 is 2809.
 8. Review the summary information, and click **Next** to install the product code or you might also click **Back** to change your specifications. When the installation is complete, the wizard displays the `install_root\logs\mq_install.log` installation log, if you selected the Embedded Messaging Client feature, and there are errors with its installation.
 9. Review the `mq_install.log` installation log, if it appears. Click **Next** to continue.
 10. Click **Finish** to exit the wizard, after the WebSphere Application Server client installs.

You successfully installed WebSphere Application Server clients and the features you selected.

If the installation is not successful, fix the error as indicated in the installation error message. For example, if you do not have enough disk space, add more space, and reinstall application clients.

Best practices for installing application clients

The following table offers tips for installing application clients on multiple platforms.

Operating environment	Tip
Linux and UNIX systems	Spaces are not supported in the name of the installation directory on Linux and UNIX platforms.
UNIX systems	When client application installations are successful, the return code 1 is issued from the UNIX shell where you issued the <code>/install</code> command. Any other return code indicates an unsuccessful installation.
Solaris systems	Double-byte character set (DBCS) characters are not supported in the name of the installation directory on Solaris systems.
Windows NT systems	Spaces are not supported in the name of the installation directory. Note: WebSphere Application Server Version 5.1 does not support the Windows NT platform.
All platforms	Reserve at least 4 to 5MB free space in the target platform temporary directory.
All platforms	When specifying a different temporary directory while installing application clients, the following message is displayed if the target platform default temporary directory does not have enough free space to install application clients: <pre>Error writing file = There may not be enough temporary disk space. Try using -is:tempdir to use a temporary directory on a partition with more disk space.</pre> <p>Use the <code>-is:tempdir</code> installation option to specify a different temporary directory. For example, the following command uses <code>/swap</code> as a temporary directory during installation:</p> <pre>./install -is:tempdir /swap</pre>

All platforms	<p>After the installation, when changing the installation settings for the WebSphere Application Server host name and the port number, edit the <code>setupClient.bat</code> for Windows or <code>setupClient.sh</code> for UNIX. Change the <code>DEFAULTSERVERNAME</code> and <code>SERVERPORTNUMBER</code> to the new WebSphere Application Server host name and port number, respectively. If the <code>SERVERPORTNUMBER</code> is not set, then the default is 2809. Review the following example:</p> <pre>set DEFAULTSERVERNAME=NDServerName set SERVERPORTNUMBER=9810</pre> <p>The <code>setupClient.bat</code> file or <code>setupClient.sh</code> file is located in the <code>bin</code> sub-directory under the application clients installation destination.</p>
---------------	---

Installing application clients silently

Use these steps to perform a silent installation, which uses the installation wizard to install the product. Instead of displaying a user interface, the silent installation provides interaction between you and the wizard by reading all of your responses from a file that you must customize.

1. Ensure that the user ID that you are using to run the silent installation has sufficient authority to perform the task.

If you are installing the embedded messaging feature, you must create two operating system groups as described in the article, [Installing WebSphere embedded messaging as the JMS provider](#).

Although it is not supported or recommended, you can install this product as a non-root user on a UNIX-based operating system, or from a user ID that is not apart of the Administrator group on a Windows platform. However, there are certain components, such as the Embedded Messaging Client feature, that require you to install as root or as part of the Administrator group.

2. Customize the option response file.
 - a. Locate the sample options response file. The file name is `setup.response` in the operating system platform directory on the product CD-ROM.
 - b. Make a copy to preserve the original response file. For example, copy the file as `myoptionsfile`.
 - c. Edit the copy in your flat file editor of choice, on the target operating system. Read the directions within the response file to choose appropriate values.

Note: To prepare the file for a silent installation on AIX, use UNIX line-end characters (0x0D0A) to terminate each line of the options response file.

- d. Make the first non-commented option `-silent` to have a silent install.
 - e. Include custom option responses that reflect parameters for your system.
 - f. Follow the instructions in the response file to choose appropriate values.
 - g. Save the file.
3. Issue a command to use your custom response file: `Install.exe -options myoptionsfile` for Windows platforms `install -options ./myoptionsfile` for Linux and UNIX platforms
The sample options response file is located in the operating-system platform directory on the product CD-ROM.
 4. Optional: Restart your machine in response to the prompt that appears on Windows platforms. If you install the Embedded Messaging Client feature, `-P JMSsupport.active="true"`, certain conditions, such as a locked file, might require you to restart your system. You have the option of restarting immediately, after which the installation program resumes the installation process. You can also defer restarting to a more convenient time, such as after the installation is complete.

You installed application clients silently by using the response file.

To further verify that the silent installation was successful, examine the `WAS.Client.Install.log` file for a line similar to:

```
The InstallShield Wizard has successfully installed IBM WebSphere Application Server clients, Version 5.1.
```

If you installed the Embedded Messaging Client feature, you can search the `mq_install.log` for any errors.

Developing application clients

This topic provides the steps for programming application clients to access resource objects defined on the server.

To use application clients to access a remote object on the server, develop your application clients as described in the following steps:

1. Create an instance of the object that you want to access from the remote server.
2. Specify the user ID and password on the connection method, when you create a connection to the server. Security must be enabled.
3. Assemble the application client `.ear` file using the Assembly Toolkit. Assemble the application client `.ear` file on any development machine where the Assembly Toolkit is installed.
4. Add the resource to the client deployment descriptor by completing the binding JNDI name for the resource object on the server.
5. Distribute the configured `.ear` file to the client machines.
6. Deploy the application client.
7. Configure the application client resources.

After you develop the application client code, run the application client.

Developing ActiveX application client code

This topic provides an outline for developing an ActiveX program, such as Visual Basic, VBScript, and Active Server Pages, to use the WebSphere ActiveX to EJB bridge to access enterprise beans.

This topic assumes that you are familiar with ActiveX programming. Consider the information given in ActiveX to EJB bridge as good programming guidelines.

To use the ActiveX to EJB bridge to access a Java class, develop your ActiveX program to complete the following steps:

1. Create an instance of the `XJB.JClassFactory` object.
2. Create Java Virtual Machine (JVM) code within the ActiveX program process, by calling the `XJBInit()` method of the `XJB.JClassFactory` object. After the ActiveX program has created an `XJB.JClassFactory` object and called the `XJBInit()` method, the JVM code is initialized and ready for use.
3. Create a proxy object for the Java class, by using the `XJB.JClassFactory FindClass()` and `NewInstance()` methods. The ActiveX program can use the proxy object to access the Java class, object fields, and methods.
4. Call methods on the Java class, using the Java method invocation syntax, and access Java fields as required.
5. Use the helper functions to do the conversion in cases where automatic conversion is not possible. You can convert between the following data types:
 - Java Byte and Visual Basic Byte
 - Visual Basic Currency types and Java 64-bit

6. Implement methods to handle any errors returned from the Java class. In Visual Basic or VBScript, use the Err.Number and Err.Description fields to determine the actual Java error.

After you develop the ActiveX client code, start the ActiveX application.

Starting an ActiveX application

To run an ActiveX client application that is to use the ActiveX to Enterprise Java Beans (EJB) bridge, you must perform some initial configuration to set appropriate environment variables and to enable the ActiveX to EJB bridge to find its XJB.JAR file and the Java run time. This initial configuration sets up the environment within which the ActiveX client application can run.

To perform the required configuration, complete one or more of the following subtasks:

1. Start an ActiveX application and configure service programs.
2. Start an ActiveX application and configuring non-service programs

Starting an ActiveX application and configuring service programs

To run an ActiveX service program such as Active Server Page (ASP) that is to use the ActiveX to the Enterprise Java Bean (EJB) bridge, you must perform some initial configuration to set appropriate environment variables and to enable the ActiveX to EJB bridge to find its XJB.JAR file and the Java run time. This configuration sets up the environment within which the ActiveX service program can run.

The XJB.JClassFactory must find the Java run time dynamic link library (DLL) when initializing. In a service program such as Internet Information Server you cannot specify a path for its processes independently; you must set the process paths in the system PATH variable. This limitation means that you can only have a single Java Virtual Machine (JVM) version available on a machine using ASP.

To add the Java Runtime Environment (JRE) directories to your system path, complete one of the following subtasks:

1. On Windows 2000 systems, complete the following substeps:
 - a. Open the Control Panel, then double-click the **System** icon.
 - b. Click the **Advanced** tab on the System Properties window.
 - c. Click **Environment Variables**.
 - d. Edit the Path variable in the System Variables window.
 - e. Add the following information to the beginning of the path that is displayed in the Variable Value field:

`C:\WebSphere\AppClient\Java\jre\bin;C:\WebSphere\AppClient\Java\jre\bin\classic;`

where C:\WebSphere\AppClient is the directory in which you installed the Java client in the WebSphere product.

- f. Click **OK** in the Edit System Variable window to apply the changes.
- g. Click **OK** in the Environment Variables window.
- h. Click **OK** in the System Properties window.
- i. Restart Windows 2000.

2. On Windows NT, complete the following substeps:

Note: WebSphere Application Server Version 5.1 does not support the Windows NT platform.

- a. Open the Control Panel, then double-click the System icon.
- b. Click the Environment tab on the System Properties window.
- c. In the System Variables window, edit the Path variable.
- d. Add the following to the beginning of the path displayed in the Value input box:

`C:\WebSphere\AppClient\Java\jre\bin;C:\WebSphere\AppClient\Java\jre\bin\classic;`

Where C:\WebSphere\AppClient is the directory in which you installed the Java client in the WebSphere product.

- e. Click **Set** to apply the changes.
- f. Click **OK**.
- g. Restart your Windows NT system.

After you change the system PATH variable you must reboot the Internet Information Server machine so that Internet Information Server can see the change.

Starting an ActiveX application and configuring non-service programs

To run an ActiveX program initiated from an icon or command line (a non-service program) that is to use the ActiveX to the Enterprise Java Beans (EJB) bridge, you must perform some initial configuration to set appropriate environment variables and to enable the ActiveX to EJB bridge to find its XJB.JAR file and the Java run-time environment. This uses a batch file to set up the environment within which the ActiveX program can run.

To perform the required configuration, complete the following steps:

1. Edit the setupCmdLineXJB.bat file to specify appropriate values for the environment variables required by the ActiveX to EJB bridge. For more information about these environment variables, see ActiveX to EJB bridge, environment and configuration. For more information about creating a JVM for an ActiveX program, see ActiveX to EJB bridge, initializing the Java Virtual Machine (JVM). After the ActiveX program has created an XJB.JClassFactory object and called the XJBInit() method, the JVM is initialized and ready for use.
2. Start the ActiveX client application by using one of the following methods:
 - Use the launchClientXJB.bat file to start the application. For example:

```
launchClientXJB MyApplication.exe parm1 parm2
```

or

```
launchClientXJB MyApplication.vbp
```
 - Use the setupCmdLineXJB.bat file to create an environment in which to run the application, then start the application from within that environment.

setupCmdLineXJB.bat, launchClientXJB.bat and other ActiveX batch files

This topic provides reference information about the aids that client applications and client services can use to access the ActiveX to EJB bridge. These enable the ActiveX to Enterprise Java Beans (EJB) bridge to find its XJB.JAR file and the Java run-time environment.

Location

The include file is located in the *was_client_home*\aspIncludes directory. You can include the file into your Active Server Pages (ASP) application with the following syntax in your ASP page:

```
<-- #include virtual ="/WSASPIncludes/setupASPXJB.inc" -->
```

This syntax assumes that you have created a virtual directory in Internet Information Server called WSASPIncludes that points to the *was_client_home*\aspIncludes directory.

Usage notes

The following batch files are provided for client applications to use the ActiveX to EJB bridge:

- **setupCmdLineXJB.bat**
Sets the client environment variables.
- **launchClientXJB.bat**
Calls the setupCmdLineXJB.bat file and launches the application you specify as its arguments; for example:

```
launchClientXJB.bat myapp.exe parm1 parm2
```

or

launchClientXJB MyApplication.vbp

- **Active Server Pages (ASP) include file**

An include file is provided for ASP users to automatically set the following page-level (local) environment variables:

- **com_ibm_websphere_javahome.** Path to the Java run-time directory installed with the WebSphere advanced server client.
- **com_ibm_websphere_washome.** Path to the WebSphere advanced server client directory.
- **com_ibm_websphere_namingfactory.** Sets the Java java.naming.factory.initial system property.
- **com_ibm_websphere_computername.** (Optional) Name of the computer where the WebSphere Advanced Server Client is installed. If you intend to talk to a single specific computer, you are recommended to change this value to become the server name that you intend to access.

- **System settings**

To enable the ActiveX to EJB bridge to access the Java run-time dynamic link library (DLL), the following directories must exist in the system PATH environment variable:

```
was_client_home\java\jre\bin;was_client_home\java\jre\bin\classic
```

Where *was_client_home* is the name of the directory where you installed the WebSphere Application Server client (for example, C:\WebSphere\AppClient).

Note: This technique enables only one Java run time to activate on a machine, therefore all client services on that machine must use the same Java run time. Client applications do not have this limitation because they each have their own private, non-system scope.

JClassProxy and JObjectProxy classes

This topic provides reference information about the object classes of the ActiveX to Enterprise Java Beans (EJB) bridge.

JClassFactory is the object used to access the majority of Java Virtual Machine (JVM) features. This object handles JVM initialization, accesses classes and creates class instances (objects). The majority of tasks for accessing your Java classes and objects are handled with the JClassProxy and JObjectProxy objects:

- XJBInit(String astrJavaParameterArray())

Initializes the JVM environment using an array of strings that represent the command line parameters you normally send to the `java.exe` file.

If you have invalid parameters in the XJBInit() string array, the following error is displayed:

```
Error: 0x6002 "XJBJNI::Init() Failed to create VM" when calling XJBInit()
```

If you have C++ logging enabled, the activity log displays the invalid parameter.

- JClassProxy FindClass(String strClassName)

Uses the current thread class loader to load the specified fully qualified class name and returns a JClassProxy object representing the Java Class object.

- JObjectProxy NewInstance()

Creates a Class instance for the specified JClassProxy object using the parameters supplied to call the Class constructor. For more information about using the JMethodArgs method, see ActiveX to EJB bridge, calling Java methods.

```
JObjectProxy NewInstance(JClassFactory obj, Variant vArg1, Variant vArg2, Variant vArg3, ...)
```

```
JObjectProxy NewInstance(JClassFactory obj, JMethodArgs args)
```

- JMethodArgs GetArgsContainer()

Returns a JMethodArgs object (Class instance).

You can create a JClassProxy object from the JClassFactory.FindClass() method and from any Java method call that normally return a Java Class object. You can use this object as if you had direct access to the Java Class object. All of the class static methods and fields are accessible as are the

java.lang.Class methods. In case of a clash between static method names of the reflected user class and those of the java.lang.Class (for example, getName()), the reflected static methods would execute first.

For example, the following is a static method called getName(). The java.lang.Class object also has a method called getName():

– In Java:

```
class foo{
    foo();
    public static String getName(){return "abcdef";}
    public static String getName2(){return "ghijkl";}
    public String toString2(){return "xyz";}
}
```

– In Visual Basic:

```
...
Dim clsFoo as Object
set clsFoo = oXJB.FindClass("foo")
clsFoo.getName() ' Returns "abcdef" from the static foo class
clsFoo.getName2() ' Returns "ghijkl" from the static foo class
clsFoo.toString() ' Returns "class foo" from the java.lang.Class object.
oFoo = oXJB.NewInstance(clsFoo)
oFoo.toString() ' Returns some text from the java.lang.Object's
                 ' toString() method which foo inherits from.
oFoo.toString2() ' Returns "xyz" from the foo class instance
```

You can create a JObjectProxy object from the JClassFactory.NewInstance() method, and can be created from any Java method call that normally returns a Class instance object. You can use this object as if you had direct access to the Java object and can access all the static methods and fields of the object. All of object instance methods and fields are accessible (including those accessible through inheritance).

The JMethodArgs object is created from the JClassFactory.GetArgsContainer() method. Use this object as a container for method and constructor arguments. You must use this object when overriding the object type when calling a method (for example, when sending a java.lang.String JProxyObject type to a constructor that normally takes a java.lang.Object type).

You can use two groups of methods to add arguments to the collection: Add and Set. You can use Add to add arguments in the order that they are declared. Alternatively, you can use Set to set an argument based on its position in the argument list (where the first argument is in position 1).

For example, if you had a Java Object Foo that took a constructor of Foo (int, String, Object), you could use a JMethodArgs object as shown in the following code extract:

```
...
Dim oArgs as Object
set oArgs = oXJB.GetArgsContainer()

oArgs.AddInt(CLng(12345))
oArgs.AddString("Apples")
oArgs.AddObject("java.lang.Object", oSomeJObjectProxy)

Dim clsFoo as Object
Dim oFoo as Object
set clsFoo = oXJB.FindClass("com.mypackage.foo")
set oFoo = oXJB.NewInstance(clsFoo, oArgs)

' To reuse the oArgs object, just clear it and use the add method
' again, or alternatively, use the Set method to reset the parameters
' Here, we will use Set
oArgs.SetInt(1, CLng(22222))
oArgs.SetString(2, "Bananas")
oArgs.SetObject(3, "java.lang.Object", oSomeOtherJObjectProxy)

Dim oFoo2 as Object
set oFoo2 = oXJB.NewInstance(clsFoo, oArgs)
```

- AddObject (String strObjectName, Object oArg)

Adds an arbitrary object to the argument container in the next available position, casting the object to the class name specified in the first parameter. Arrays are specified using the traditional [] syntax; for example:

```
AddObject("java.lang.Object[][]", oMy2DArrayOfFooObjects)
```

or

```
AddObject("int[]", oMyArrayOfInts)
```

- **AddByte** (Byte byteArg)

Adds a primitive byte value to the argument container in the next available position.

- **AddBoolean** (Boolean bArg)

Adds a primitive boolean value to the argument container in the next available position.

- **AddShort** (Integer iArg)

Adds a primitive short value to the argument container in the next available position.

- **AddInt** (Long lArg)

Adds a primitive int value to the argument container in the next available position.

- **AddLong** (Currency cyArg)

Adds a primitive long value to the argument container in the next available position.

- **AddFloat** (Single fArg)

Adds a primitive float value to the argument container in the next available position.

- **AddDouble** (Double dArg)

Adds a primitive double value to the argument container in the next available position.

- **AddChar** (String strArg)

Adds a primitive char value to the argument container in the next available position.

- **AddString** (String strArg)

Adds the argument in string form to the argument container in the next available position.

- **SetObject** (Integer iArgPosition, String strObjectTypeName, Object oArg)

Adds an arbitrary object to the argument container in the specified position casting it to the class name or primitive type name specified in the second parameter. Arrays are specified using the traditional [] syntax; for example:

```
SetObject(1, "java.lang.Object[][]", oMy2DArrayOfFooObjects)
```

or

```
SetObject(2, "int[]", MyArrayOfInts)
```

- **SetByte** (Integer iArgPosition, Byte byteArg)

Sets a primitive byte value to the argument container in the position specified.

- **SetBoolean** (Integer iArgPosition, Boolean bArg)

Sets a primitive boolean value to the argument container in the position specified.

- **SetShort** (Integer iArgPosition, Integer iArg)

Sets a primitive short value to the argument container in the position specified.

- **SetInt** (Integer iArgPosition, Long lArg)

Sets a primitive int value to the argument container in the position specified.

- **SetLong** (Integer iArgPosition, Currency cyArg)

Sets a primitive long value to the argument container in the position specified.

- **SetFloat** (Integer iArgPosition, Single fArg)

Sets a primitive float value to the argument container in the position specified.

- **SetDouble** (Integer iArgPosition, Double dArg)

Sets a primitive double value to the argument container in the position specified.

- **SetChar** (Integer iArgPosition, String strArg)

Sets a primitive char value to the argument container in the position specified.

- **SetString** (Integer iArgPosition, String strArg)

Sets a java.lang.String value to the argument container in the position specified.

- **Object Item**(Integer iArgPosition)

Returns the value of an argument at a specific argument position.

- Clear()

Removes all arguments from the container and resets the next available position to one.

- Long Count()

Returns the number of arguments in the container.

Java virtual machine initialization tips

Initialize the Java virtual machine (JVM) code with the ActiveX to Enterprise Java Beans (EJB) bridge. For an ActiveX client program (Visual Basic, VBScript, or ASP) to access Java classes or objects, the first step that the program must do is to create Java virtual machine (JVM) code within its process. To create JVM code, the ActiveX program calls the XJBInit() method of the XJB.JClassFactory object. When an XJB.JClassFactory object is created and the XJBInit() method called, the JVM is initialized and ready to use.

- To enable the XJB.JClassFactory to find the Java run-time description definition language (DLL) when initializing, the Java Runtime Environment (JRE) bin and bin\classic directories must exist in the system path environment variable.
- The XJBInit() method accepts only one parameter: an array of strings. Each string in the array represents a command line argument that for a Java program you would normally specify on the Java.exe command line. This string interface is used to set the classpath, stack size, heap size and debug settings. You can get a listing of these parameters by typing java -? from the command line.
- If you set a parameter incorrectly, you receive a 0x6002 "Failed to initialize VM" error message.
- Due to the current limitations of Java Native Interface (JNI), you cannot unload or reinitialize the JVM code after it has loaded. Therefore, after the XJBInit() method has been called once, subsequent calls have no effect other than to create a duplicate JClassFactory object for you to access. It is best to store your XJB.JClassFactory object globally and continue to reuse that object.
- The following Visual Basic extract shows an example of initializing JVM code:

```
Dim oXJB as Object
set oXJB = CreateObject("XJB.JClassFactory")
Dim astrJavaInitProps(0) as String
astrJavaInitProps(0) = _
    "-Djava.class.path=.;c:\myjavaclasses;c:\myjars\myjar.jar"
oXJB.XJBInit(astrJavaInitProps)
```

Example: Developing an ActiveX application client to Enterprise Bean bridge using Java proxy objects

To use Java proxy objects with the ActiveX to Enterprise Java Beans (EJB) bridge:

- After an ActiveX client program (Visual Basic, VBScript, or Active Server Pages (ASP)) has initialized the XJB.JClassFactory object (and thereby, the Java virtual machine (JVM)), it can access Java classes and initialize Java objects. To complete this action, the client program uses the XJB.JClassFactory FindClass() and NewInstance() methods.
- In Java programming, two ways exists to access Java classes: direct invocation through the Java compiler and through the Java Reflection interface. Because the ActiveX to Java bridge needs no compilation and is a complete run-time interface to the Java code, the bridge depends on the latter Reflection interface to access its classes, objects, methods and fields. The XJB.JClassFactory FindClass() and NewInstance() methods behave very similarly to the Java Class.forName() and the Method.invoke() and Field.invoke() methods.
- XJB.JClassFactory.FindClass() takes the fully qualified class name as its only parameter and returns a Proxy Object (JClassProxy). You can use the returned Proxy object like a normal Java Class object and call static methods and access static fields. You can also create a Class Instance (or object), as described below. For example, the following Visual Basic code extract returns a Proxy object for the java.lang.Integer Java class:

```
...
Dim clsMyString as Object
Set clsMyString = oXJB.FindClass("java.lang.Integer")
```

- After the proxy is created, you can access its static information directly. For example, you can use the following code extract to convert a decimal integer to its hexadecimal representation:

```
...
Dim strHexValue as String
strHexValue = clsMyString.toHexString(CLng(255))
```

- The equivalent Java syntax is: `static String toHexString(int i)`. Because ints in Java programming are really 32-bits (which translates to Long in VB), the `CLng()` function converts the value from the default int to a long. Also, even though the `toHexString()` function returns a `java.lang.String`, the code extract does not return an Object proxy. Instead, the returned `java.lang.String` is automatically converted to a native Visual Basic string.

To create an object from a class, you use the `JClassFactory.NewInstance()` method. This method creates an Object instance and takes whatever parameters your class constructor needs. Once the object is created, you have access to all of its public instance methods and fields. For example, you can use the following Visual Basic code extract to create an instance of the `java.lang.Integer` string:

```
...
Dim oMyInteger as Object
set oMyInteger = oXJB.NewInstance(CLng(255))
```

```
Dim strMyInteger as String
strMyInteger = oMyInteger.toString
```

Example: Calling Java methods in the ActiveX to enterprise bean bridge

In the ActiveX to Enterprise Java Beans (EJB) bridge, methods are called using the native language method invocation syntax.

- The following differences between Java invocation and ActiveX Automation invocation exist:
 - Unlike Java methods, ActiveX does not support method (and constructor) polymorphism; that is, you cannot have two methods in the same class with the same name.
 - Java methods are case-sensitive, but ActiveX Automation is not case-sensitive.
- Take care when invoking Java methods through ActiveX Automation. If you use the wrong case on a method call or use the wrong parameter type, you get an Automation Error 438 "Object doesn't support this property or method" thrown.
- To compensate for Java polymorphic behavior, give the exact parameter types to the method call. The parameter types determine the correct method to invoke. For a listing of correct types to use, see ActiveX to EJB bridge, converting data types.
- For example, the following Visual Basic code fails if the `CLng()` method was not present or the `toHexString` syntax was incorrectly typed as `ToHexString`:

```
...
Dim strHexValue as String
strHexValue = clsMyString.toHexString(CLng(255))
```

- Sometimes it is difficult to force some development environments to leave the case of your method calls unchanged. For example, in Visual Basic if you want to call a method `close()` (uncapitalized), the Visual Basic code capitalizes it "`Close()`". In Visual Basic, the only way to effectively work around this behavior is to use the `CallByName()` method. For example:

```
o.Close(123) 'Incorrect...
CallByName(o, "close", vbMethod, 123) 'Correct...
```

or in VBScript, use the `Eval` function:

```
o.Close(123) 'Incorrect...
Eval("o.Close(123)") 'Correct...
```

- The return value of a function is always converted dynamically to the correct type. However, you must take care to use the `set` keyword in Visual Basic. If you expect a non-primitive data type to return, you must use `set`. (If you expect a primitive data type to return, you do not need to use `set`.) For example:

```
Set oMyObject = o.getObject
iMyInt = o.getInt
```

- In some cases, you might not know the type of object returning from a method call, because wrapper classes are converted automatically to primitives (for example, `java.lang.Integer` returns an ActiveX

Automation Long). In such cases, you might need to use your language built-in exception handling techniques to try to coerce the returned type (for example, On Error and Err.Number in Visual Basic).

- **Methods with character arguments**

Because ActiveX Automation does not natively support character types supported by Java methods, the ActiveX to EJB bridge uses strings (byte or VT_11 do not work because characters have multiple bytes in Java code). If you try to call a method that takes a char or java.lang.Character type you must use the JMethodArgs argument container to pass character values to methods or constructors. For more information about how this argument container is used, see *Methods with "Object" Type as Argument and Abstract Arguments*.

- **Methods with "Object" Type as Argument and Abstract Arguments**

Because of the polymorphic nature of Java programming, the ActiveX to Java bridge uses direct argument type mapping to find a method. This method works well in most cases, but sometimes methods are declared with a Parent or Abstract class as an argument type (for example, java.lang.Object). You need the ability to send an object of arbitrary type to a method. To acquire this ability, you must use the XJB.JMethodArgs object to coerce your parameters to match the parameters on your method. You can get a JMethodArgs instance by using the JClassFactory.GetArgsContainer() method.

The JMethodArgs object is a container for method parameters or arguments. This container enables you to add parameters to it one-by-one and then you can send the JMethodArgs object to your method call. The JClassProxy and JObjectProxy objects recognize the JMethodArgs object and attempt to find the correct method and let the Java language coerce your parameters appropriately.

For example, to add an element to a Hashtable object the method syntax is Object put(Object key, Object value). In Visual Basic, the method usage looks like the following example code:

```
Dim oMyHashtable as Object
Set oMyHashtable = _
    oXJB.NewInstance(oXJB.FindClass("java.util.Hashtable"))

' This line will not work. The ActiveX to EJB bridge cannot find a method
' called "put" that has a short and String as a parameter:
oMyHashtable.put 100, "Dogs"
oMyHashtable.put 200, "Cats"

' You must use a XJB.JMethodArgs object instead:
Dim oMyHashtableArgs as Object
Set oMyHashtableArgs = oXJB.GetArgsContainer
oMyHashtableArgs.AddObject("java.lang.Object", 100)
oMyHashtableArgs.AddObject("java.lang.Object", "Dogs")

oMyHashtable.put oMyHashTableArgs
' Reuse the same JMethodArgs object by clearing it.
oMyHashtableArgs.Clear
oMyHashtableArgs.AddObject("java.lang.Object", 200)
oMyHashtableArgs.AddObject("java.lang.Object", "Cats")

oMyHashtable.put oMyHashTableArgs
```

Java field programming tips

Using the ActiveX to Enterprise Java Beans (EJB) bridge to access Java fields has the same case sensitivity issue that it has when invoking methods. Field names must use the same case as the Java field syntax.

- Visual Basic code has the same problem with unsolicited case changing on fields as it does with methods. (For more information about this problem, see *ActiveX to EJB bridge, calling Java methods*). You might need to use the CallByName() function to set a field in the same way that you call a method in some cases. For Fields, you use VBLet for primitive types and VBSet for objects. For example:

```
o.MyField = 123 'Incorrect...
CallByName(o, "MyField", vbLet, 123) 'Correct...
or in VBScript:
```

```
o.MyField = 123
Eval("o.myField = 123")
```

```
'Incorrect...
'Correct...
```

ActiveX to Java primitive data type conversion values

All primitive Java data types are automatically converted to native ActiveX Automation types. However, not all Automation data types are converted to Java types (for example, VT_DATE). Variant data types are used for data conversion. Variant data types are a requirement of any Automation interface, and are used automatically by Visual Basic and VBScript. The tables below provide details about how primitive data types are converted between Automation types and Java types.

Table 4. ActiveX to Java primitive data type conversion

Visual Basic Type	Variant Type	Java Type	Notes
Byte	VT_I1	byte	Byte in Visual Basic is unsigned, but is signed in Java data type.
Boolean	VT_BOOL	boolean	
Integer	VT_I2	short	
Long	VT_I4	int	
Currency	VT_CY	long	
Single	VT_R4	float	
Double	VT_R8	double	
String	VT_BSTR	java.lang.String	
String	VT_BSTR	char	
Date	VT_DATE	n/a	

Example: Using helper methods for data type conversion

Generally, data type conversion between ActiveX (Visual Basic and VBScript) and Java methods occurs automatically, as described in ActiveX to EJB bridge, converting data types. However, the following helper functions are provided for cases where automatic conversion is not possible:

- Byte helper function
- Currency helper function
- Byte helper function

Because the Java Byte data type is signed (-127 through 128) and the Visual Basic Byte data type is unsigned (0 through 255), convert unsigned Bytes to a Visual Basic Integers, which look like the Java signed byte. To make this conversion, you can use the following helper function:

```
Private Function GetIntFromJavaByte(Byte jByte) as Integer
    GetIntFromJavaByte = (CInt(jByte) + 128) Mod 256 - 128
End Function
```

- Currency helper function

Visual Basic 6.0 cannot properly handle 64-bit integers like Java methods can (as the Long data type). Therefore, Visual Basic uses the Currency type, which is intrinsically a 64-bit data type. The only side effect of using the Currency type (the Variant type VT_CY) is that a decimal point is inserted into the type. To extract and manipulate the 64-bit Long value in Visual Basic, use code like the following example. For more details on this technique for converting Currency data types, see Q189862, "HOWTO: Do 64-bit Arithmetic in VBA", on the Microsoft Knowledge Base.

```
' Currency Helper Types
Private Type MungeCurr
    Value As Currency
End Type
Private Type Munge2Long
    LoValue As Long
    HiValue As Long
```

```

End Type

' Currency Helper Functions
Private Function CurrToText(ByVal Value As Currency) As String
    Dim Temp As String, L As Long
    Temp = Format$(Value, "#.0000")
    L = Len(Temp)
    Temp = Left$(Temp, L - 5) & Right$(Temp, 4)
    Do While Len(Temp) > 1 And Left$(Temp, 1) = "0"
        Temp = Mid$(Temp, 2)
    Loop
    Do While Len(Temp) > 2 And Left$(Temp, 2) = "-0"
        Temp = "-" & Mid$(Temp, 3)
    Loop
    CurrToText = Temp
End Function

Private Function TextToCurr(ByVal Value As String) As Currency
    Dim L As Long, Negative As Boolean
    Value = Trim$(Value)
    If Left$(Value, 1) = "-" Then
        Negative = True
        Value = Mid$(Value, 2)
    End If
    L = Len(Value)
    If L < 4 Then
        TextToCurr = CCur(IIf(Negative, "-0.", "0.") & _
            Right$("0000" & Value, 4))
    Else
        TextToCurr = CCur(IIf(Negative, "-", "") & _
            Left$(Value, L - 4) & "." & Right$(Value, 4))
    End If
End Function

' Java Long as Currency Usage Example
Dim LC As MungeCurr
Dim L2 As Munge2Long

' Assign a Currency Value (really a Java Long)
' to the MungeCurr type variable
LC.Value = cyTestIn

' Coerce the value to the Munge2Long type variable
LSet L2 = LC

' Perform some operation on the value, now that we
' have it available in two 32-bit chunks
L2.LoValue = L2.LoValue + 1

' Coerce the Munge value back into a currency value
LSet LC = L2
cyTestIn = LC.Value

```

Array tips for ActiveX application clients

Arrays are very similar between Java and Automation containers like Visual Basic and VBScript. Here are some important points to consider when passing arrays back and forth between these containers:

- Java arrays cannot mix types. All Java arrays contain a single type, so when passing arrays of variants to a Java array, you must make sure that all of the elements in the variant array are of the same base type. For example, in Visual Basic code:

```

...
Dim VariantArray(1) as Variant
VariantArray(0) = CLng(123)
VariantArray(1) = CDb1(123.4)
oMyJavaObject.foo(VariantArray) ' Illegal!

```

```
VariantArray(0) = CLng(123)
VariantArray(1) = CLng(1234)
oMyJavaObject.foo(VariantArray) ' This works
```

- Arrays of primitive types are converted using the rules defined in primitive data type conversion.
- Arrays of Java objects are handled through arrays of JObjectProxy objects.
- Arrays of JObjectProxy objects must be fully initialized and of the correct associated Java type. When initializing an array in Visual Basic (for example, Dim oJavaObjects(1) as Object), you must set each object to a JObjectProxy object before you send the array to a Java object. The bridge is unable to determine the type of null or empty object values.
- When receiving an array from a Java method, the lower-bound is always zero. Java methods only support zero-based arrays.
- Nested or multidimensional arrays are treated as zero-based multidimensional arrays in Visual Basic and VBScript containers.
- Uninitialized arrays or Array Types are unsupported. When calling a Java method that takes an array of objects as a parameter, you must fully initialize the array of JObjectProxy objects.

Error handling codes for ActiveX application clients

All exceptions thrown in Java code are encapsulated and thrown again as a COM error through the ISupportErrorInfo interface and the EXCEPINFO structure of IDispatch::Invoke(); the Err object in Visual Basic and VBScript. Because there are no error numbers associated with Java exceptions, whenever a Java exception is thrown, the entire stack trace is stored in the error description text and the error number assigned is 0x6003.

In Visual Basic or VBScript, you need to use the Err.Number and Err.Description fields to determine the actual Java error. Non-Java errors are thrown as you would expect via the IDispatch interface; for example, if a method cannot be found, then error 438 "Object doesn't support this property or method" is thrown.

Error number	Description
0x6001	Java Native Interface (JNI) error
0x6002	Initialization error
0x6003	Java exception. Error description is the Java Stack Trace.
0x6FFF	General Internal Failure

Threading tips

The ActiveX to Enterprise Java Beans (EJB) bridge supports both free-threaded and apartment-threaded access and implements the Free Threaded Marshaler to work in a hybrid environment such as Active Server Pages (ASP). Each thread created in the ActiveX process is mirrored in the Java environment when the thread communicates through the ActiveX to EJB bridge. In addition, once all references to Java objects (there are no JObjectProxy or JClassProxy objects) are loaded in an ActiveX thread, the ActiveX to EJB bridge detaches the thread from the Java virtual machine (JVM) code. Therefore, you must be careful that any Java code that you access from a multithreaded Windows application is thread safe. Visual Basic code and VBScript applications are both essentially single threaded. Therefore, Visual Basic and VBScript applications do not have threading issues in the Java programs they access. Active Server Pages and multithreaded C and C++ programs can have issues.

Consider the following scenario:

1. A multithreaded Windows Automation Container (our ActiveX Process) starts. It exists on Thread A.
2. The ActiveX Process initializes the ActiveX to EJB bridge, which starts the JVM code. The JVM attaches to the same thread and internally calls it Thread 1.
3. The ActiveX Process starts two threads: B and C.
4. Thread B in the ActiveX Process uses the ActiveX to EJB bridge to access an object that was created in Thread A. The JVM attaches to thread B and calls it Thread 2.

5. Thread C in the ActiveX Process never talks to the JVM code, so the JVM never needs to attach to it. This is a case where the JVM code does not have a one-to-one relationship between ActiveX threads and Java threads.
6. Thread B later releases all of the JObjectProxy and JClassProxy objects that it used. The Java Thread 2 is detached.
7. Thread B again uses the ActiveX to EJB bridge to access an object that was created in Thread A. The JVM code attaches again to the thread and calls it Thread 3.

ActiveX process	JVM access by ActiveX process
Thread A - Created in 1	Thread 1 - Attached in 2
Thread B - Created in 4	Thread 2 - Attached in 4, detached in 6 Thread 3 - Attached in 7
Thread C - Created in 4	

Threads and Active Server Pages

Active Server Pages (ASP) in Microsoft Internet Information Server is a multithreaded environment. When you create the XJB.JClassFactory object, you can store it in the Application collection as an Application-global object. All threads within your ASP environment can now access the same ActiveX to EJB bridge object. Active Server Pages by default creates 10 Apartment Threads per ASP process per CPU. This means that when your ActiveX to EJB bridge object is initialized any of the 10 threads can call this object, not just the thread that created it.

If you need to simulate single-apartment behavior, you can create a Single-Apartment Threaded ActiveX dynamic link library (DLL) in Visual Basic code and encapsulate the ActiveX to the EJB bridge object. This encapsulation guarantees that all access to the JVM object is on the same thread. You need to use the <OBJECT> tag to assign the XJB.JClassFactory to an Application object and must be aware of the consequences of introducing single-threaded behavior to a Web application.

The Microsoft KnowledgeBase has several articles about ASP and threads, including:

- Q243543 INFO: Do Not Store STA Objects in Session or Application
- Q243544 INFO: Component Threading Model Summary Under Active Server Pages
- Q243548 INFO: Design Guidelines for VB Components Under ASP

Example: Viewing a System.out message

The ActiveX to Enterprise Java Beans (EJB) bridge does not have a console available to view Java System.out messages. To view these messages when running a stand-alone client program (such as Visual Basic), you need to redirect the output to a file. For example:

```
launchClientXJB.bat MyProgram.exe > output.txt
```

- To view the System.out messages when running a Service program such as Active Server Pages, you need to override the Java System.out OutputStream object to FileOutputStream. For example, in VBScript:

```
'Redirect system.out to a file
' Assume that oXJB is an initialized XJB.JClassFactory object
Dim clsSystem
Dim oOS
Dim oPS
Dim oArgs

' Get the System class
Set clsSystem = oXJB.FindClass("java.lang.System")

' Create a FileOutputStream object
' Create a PrintStream object and assign to it our FileOutputStream
Set oArgs = oXJB.GetArgsContainer oArgs.AddObject "java.io.OutputStream", oOS
```

```
Set oPS = oXJB.NewInstance(oXJB.FindClass("java.io.PrintStream"), oArgs)
```

```
' Set our System OutputStream to our file  
clsSystem.setOut oPS
```

Example: Enabling logging and tracing for application clients

The ActiveX to EJB bridge provides two logging and tracing formats: Windows Application Event Log and Java Trace Log.

- Windows Event Log

The Windows Application Event Log shows JNI errors, Java console error messages, and XJB initialization messages. This log is most useful for determining XJBInit() errors and any unusual exceptions that do not come from the Java environment. By default, critical error logging will be enabled and debug and event logging is disabled.

To enable or disable logging of certain event types to the Windows Event Log, specify one or more parameters to XJBInit(). If more than one parameter is set, they will be processed in the order in which they appear in the input string array to the XJBInit() method. Once the XJBInit() method is initialized, these parameters can no longer be set/reset for the life of the process. Using Java java.lang.System.setProperty() to set these values also has no effect.

- -Dcom.ibm.ws.client.xjb.native.logging.debug=enabled|disabled

Enables or disables debug level messages from displaying in the Windows operating system event log. This level of logging is most useful and shows most internal errors, user programming issues or configuration problems.

- -Dcom.ibm.ws.client.xjb.native.logging.event=enabled|disabled

Enables or disables event level messages from appearing in the Windows operating system event log.

- -Dcom.ibm.ws.client.xjb.native.logging.*=enabled|disabled

Enables or disables both event and debug level messages from appearing in the Windows operating system event log. It is not possible to disable some critical error messages from being displayed in the error log. Only debug and event level messages can be disabled.

Viewing the Windows application event log with the event viewer:

To open the event viewer in the Windows operating system:

1. Click **Start > Settings > Control Panel**.
2. Double-click **Administrative Tools**.
3. Double-click **Event Viewer**.

All ActiveX to EJB bridge events display the text WebSphere XJB in the source column and in the application log. For information about using Event Viewer, click the **Action** menu in Event Viewer, and then click **Help**.

To open the even viewer in the Windows operating system, click **Start > Programs > Administrative Tools > Event Viewer**. All ActiveX to EJB bridge events have the text WebSphere XJB in the source column and display in the application log. For information about using Event Viewer, click the **Help** menu in Event Viewer.

- Java trace log

The Java trace log displays information that you can use to debug method calls, class lookups, and argument coercion problems. Since the Java portion of the bridge mirrors the function of the COM IDispatch interface, the information in the trace log is similar to what you have come to expect from an IDispatch interface. To understand the trace log, you need a fundamental understanding of IDispatch.

To enable user-logging, add the following parameters to the XJBInit() input string array:

```
"-DtraceString=com.ibm.ws.client.xjb.*=event=enabled"  
"-DtraceFile=C:\MyTrace.txt"
```

ActiveX client programming best practices

In general, the best way to access Java components is to use the Java language. It is recommended that you do as much programming as possible in the Java language and use a small simple interface between

your COM Automation container (for example, Visual Basic) and the Java code. This interface avoids any overhead and performance problems that can occur when moving across the interface.

- Visual Basic guidelines
- Active Server Pages guidelines
- J2EE guidelines

Visual Basic guidelines

The following guidelines are intended to help optimize your use of the ActiveX to EJB bridge with Visual Basic:

- Launch the Visual Basic replication through the `launchClientXJB.bat` file. If you want to run your Visual Basic application through the Visual Basic debugger, run the Visual Basic integrated development environment (IDE) within the ActiveX to EJB bridge environment. After you create your Visual Basic project, you can launch it from a command line; for example, `launchClientXJB MyApplication.vbp`. You can also launch the Visual Basic application alone in the ActiveX to EJB environment, by changing the Visual Basic shortcut on the Windows Start menu so that the `launchClientXJB.bat` file precedes the call to the `VB6.EXE` file.
- Exit the Visual Basic IDE before debugging programs.

Because the Java virtual machine (JVM) code attaches to the running process, you must exit the Visual Basic editor before debugging your program. If you run the process, then exit your program within the Visual Basic IDE, the JVM code continues to run and you reattach the same JVM code when `XJBInit()` is called by the debugger. This causes problems if you try to update `XJBInit()` arguments (for example, classpath) because the changes are not be applied until you restart the Visual Basic program.

- Store the `XJB.JClassFactory` object globally.

Because you cannot unload or reinitialize the JVM code, cache the resulting `XJB.JClassFactory` object as a global variable. The overhead of treating this object as a global variable or passing a single reference around is much less than recreating a new `XJB.JClassFactory` object and calling the `XJBInit()` argument more than once.

CScript and Windows Scripting Host

The following guidelines intend to help optimize your use of the ActiveX to EJB bridge with CScript and Windows Scripting Host (WSH):

- Launch in ActiveX to EJB environment.

Launch the VBScript files in the ActiveX to EJB bridge environment, to run VBScript files in `.vbs` files.

Two common ways exist to launch your script:

- `launchClientXJB MyScript.vbs`
- `launchClientXJB cscript MyScript.vbs`

Active Server Pages guidelines

The following guidelines intend to help optimize your use of the ActiveX to EJB bridge with Active Server Pages software:

- Use the ActiveX to EJB Helper functions from the Active Server Pages Application.

Because Active Server Pages (ASP) code typically use VBScript, you can use the included helper functions in any VBScript environment with minor changes. For more information about these helper functions, see *Helper functions for data type conversion*. To run outside of the ASP environment, remove or change all references to the `Server`, `Request`, `Response`, `Application` and `Session` objects; for example, change `Server.CreateObject` to `CreateObject`.

- Set JRE path globally in system.

The `XJB.JClassFactory` object must be able to find the Java run time dynamic link library (DLL) when initializing. In Internet Information Server, you cannot specify a path for its processes independently; you must set the process paths in the system `PATH` variable. You can only have a single JVM version

available on a machine using the ASP application. Also, remember that after you change the system PATH variable you must reboot the Internet Information Server machine so that the Internet Information Server can see the change.

- Set the system TEMP environment variable.

If the system TEMP environment variable is not set, Internet Information Server stores all temporary files in the WINNT directory, which is usually not desired.

- Use high isolation or an isolated process.

When using the ActiveX to Java bridge with Active Server Pages software, creating your Web application in its own process is recommended. You can only load one JVM instruction in a single process and if you want to have more than one application running with different JVM environment options (for example, different classpaths), then you need to have separate processes.

- Use the Application Unload option.

When debugging your application, use **Unload** when viewing your ASP application properties in the Internet Information Server administration console to unload the process from memory and thereby unload the JVM code.

- Run one process per application.

Use only one ASP application per J2EE application or JVM environment, in your ASP environment. If you need separate class paths or JVM settings, you need separate ASP applications (virtual directories with high isolation or an isolated process).

- Store the XJB.JClassFactory object in application scope.

Because of the one-to-one relationship required between a JVM instruction and a process, and because the JVM code can never detach or shut down from a process independently, cache the XJB.JClassFactory object at application scope and call the XJBInit() method only once.

Because the ActiveX to EJB bridge employs a free-threaded marshaler, take advantage of the multi-threaded nature of Internet Information Server and the ASP environment. If you choose to reinitialize the XJB.JClassFactory object at Page scope (local variables), then the XJBInit() method can only initialize your local XJB.JClassFactory variable. It is more efficient to use the XJBInit() method once.

- Use VBScript conversion functions.

Because VBScript code only supports variant data types, use the CStr(), CByte(), CBool(), CCur(), CInt(), CInq(), CSng() and CDbl() functions to tell the activeX to EJB bridge which data type you are using; for example `oMyObject.Foo(CDb1(1.234))`.

J2EE guidelines

The following guidelines are intended to help optimize your use of the ActiveX to EJB bridge with the J2EE environment;

- Store client container objects globally.

Because you can only have one JVM instruction per process, and a single J2EE client container (`com.ibm.websphere.client.applicationclient.launchClient`) per JVM instruction, initialize your J2EE client container only once and reuse it. For ASP applications, store the J2EE client container in an application level variable and initialize it only once (either on the `Application_OnStart()` event in the `global.asa` file or by checking to see if it `IsEmpty()`).

A side effect to storing the client container object globally is that you cannot change the client container parameters without destroying the object and creating a new one. These parameters include the EAR file, BootstrapHost, class path, and so on. If you run a Visual Basic application and want to change the client container parameters, you must end the application and restart it. If you run an Active Server Pages application, you must first unload the application from Internet Information Server (see "Use the Application Unload Button" under Active Server Pages guidelines). Then load the Active Server Pages application with the different client container parameters. The parameters set the first time the Active Server Pages application loads. Since the client container is stored on the Internet Information Server, all the browser clients share the parameters using the Active Server Pages application. This behavior is normal for Active Server Pages code, but can be confusing when you try to run to different WebSphere Application Servers using the same Active Server Pages application, which is not supported.

- Reuse custom temporary directory for EAR file extraction.

By default, the client container launches and extracts the application .ear file to your temp directory and then sets up the thread class loader to use the extracted EAR file directory and the JAR files included in the client JAR manifest. This process is time consuming and because of some limitations with JVM shutdown through Java Native Interface (JNI) and file locking, these files are never cleaned up.

Specifically, each time the client container launch() method is called, it extracts the EAR file to a random directory name in your temporary directory on your hard drive. The current Java thread class loader is then changed to point to this extracted directory which in turn locks the files within. In a normal J2EE Java client, these files automatically clean up after the application exits. This cleanup occurs when the client container shutdown hook is called (which never happens in the ActiveX to EJB bridge), which leaves the temporary directory there.

To avoid these problems, you can specify a directory to extract the EAR file by setting the com.ibm.websphere.client.applicationclient.archivedir Java system property before calling the client container launch() method. If the directory does not exist or is empty, you extract the EAR file normally. If the EAR file was previously extracted, the directory is reused. This feature is particularly important for server processes (for example, ASP), which can stop and restart, potentially calling the launchClient() method several times.

If you need to update your EAR file, delete the temporary directory first. The next time you create the client container object, it extracts the new EAR file to the temporary directory. If you do not delete the temporary directory or change the system property value to point to a different temporary directory, the client container reuses the currently extracted EAR file, and does not use your changed EAR file.

Note: When specifying the com.ibm.websphere.client.applicationclient.archivedir property, ensure that the directory you specify *is unique* for each EAR file you use. For example, do not point MyEar1.ear and MyEar2.ear files to the same directory.

If you choose not to use this system property, go regularly to your Windows temp directory and delete the WSTMP* subdirectories. Over a relatively short period of time, these subdirectories can waste a significant amount of space on the hard drive.

Developing applet client code

Applet clients have the following setup requirements:

- These clients are available on the Windows XP, Windows NT or Windows 2000 platforms. Check the prerequisites page for information on new platform support.
- They require one of these browsers:
 - Internet Explorer version 5.0 and later
 - Netscape Navigator 4.7 and later
- The browser installation precedes the client code installation.

Unlike typical applets that reside on either Web servers or WebSphere Application Servers and can only communicate using the HTTP protocol, applet clients are capable of communicating over the HTTP protocol and the RMI-IIOP protocol. This additional capability gives the applet direct access to enterprise beans.

1. Run the application server client installation.
2. Select the applet client option.
3. Install an applet client.
4. Install the WebSphere Application Server plug-in for the browser. From the WebSphere Application Server Java Plug-in control panel, enter the following code:

```
-Djava.security.policy=<product_installation_dir>\properties\client.policy
-Dwas.install.root=<product_installation_dir>
-Djava.ext.dirs=<product_installation_dir>\classes;
<product_installation_dir>\java\jre\lib\ext;
```

```
<product_installation_dir>\java\jre\lib;  
<product_installation_dir>\lib;<product_installation_dir>\properties  
-Dcom.ibm.CORBA.ConfigURL=file:<product_installation_dir>\properties\sas.client.props  
-classpath <product_installation_dir>\properties
```

Note: The previously entries are automatically placed into the WebSphere Application Server control panel for the Java plug-in user who installed the WebSphere Application Server Application Client. If this sample is being run by a user other than the person who installed the client, the user must enter the entries.

- The Java **Run-Time Parameters** field is similar to the command prompt when using command line options. Therefore, you can enter most options available from the command prompt (for example, -cp, classpath, and others) in this field as well.
- Access the control panel from the **Start** menu. Click **Start > Control panel >** select the product Java plug-in.
- The applet container is the Web browser and the Java plug-in combination. You must first install the WebSphere Application Server Applet client so that the browser recognizes the IBM product Java plug-in.

View the Samples gallery for more information about application clients. Before you run the basicCalculator Sample, ensure the JMS Server is started. (See "Samples Gallery" in the Information Center.)

These samples do not include client applications that communicate with Enterprise server-side examples.

Accessing secure resources using SSL and applet clients

By default, the applet client is configured to have security enabled. If you have global security turned on at the server from which you are accessing resources, then you can use secure sockets layer (SSL) when needed. If you decide that the security requirements for the applet differ from other application client types, then create a new version of the sas.client.props file.

1. Make a copy of the following file so that you can use it for an applet:
`<product_install_directory>/properties/sas.client.props`
2. Edit the copy of sas.client.props file that you made with your changes.
3. Click **Start > Control panel >** select the product Java plug-in to open the Java control panel.
 - To use the file you created in step 1, modify the following value:

```
-Dcom.ibm.CORBA.ConfigURL=file:<product_install_directory>\properties\sas.client.props
```

For more information on the sas.client.props file and WebSphere Application Server security, see the Security section of the information center.

Applet client security requirements

When code is loaded, it is assigned permissions based on the security policy in effect. This policy specifies the permissions that are available for code from various locations. You can initialize this policy from an external policy file. By default, the client uses the `<product_installation_dir>/properties/client.policy` file. You must update this file with the following permission:

SocketPermission grants permission to open a port and make a connection to a host machine, which is your WebSphere Application Server. In the following example, yourserver.yourcompany.com is the complete host name of your WebSphere Application Server:

```
permission java.util.PropertyPermission "*", "read";  
permission java.net.SocketPermission "yourserver.yourcompany.com", "connect";
```

Applet client tag requirements

Standard applets require the HTML `<APPLET>` tag to identify the applet to the browser. The `<APPLET>` tag invokes the Java virtual machine (JVM) of the browser.

- For applets to communicate with Enterprise Java Beans (EJB) in the WebSphere Application Server environment, the <APPLET> tag must be replaced with the following tags:

```
<OBJECT>
<EMBED>
```

- The classid and type attributes cannot be modified, and must be entered as described in the applet client example. The codebase attribute on the <OBJECT> tag must be excluded. Do not confuse the codebase attribute on the <OBJECT> tag with the codebase attribute on the <PARAM> tag. Although both attributes are called codebase, they are separate entities.
- The following code example illustrates the applet code. In this example, MyApplet.class is the applet code, applet.jar is the file that contains the applet code, and EJB.jar is the file that contains the enterprise bean code:

```
<OBJECT classid="clsid:8AE2D840-EC04-11D4-AC77-006094334AA9"
width="600" height="500">
<PARAM NAME=CODE VALUE=MyAppletClass.class>
<PARAM NAME="archive" VALUE='Applet.jar, EJB.jar'>
<PARAM TYPE="application/x-java-applet;version=1.3">
<PARAM NAME="scriptable" VALUE="false">
<PARAM NAME="cache-option" VALUE="Plugin">
<PARAM NAME="cache-archive" VALUE="Applet.jar, EJB.jar">
<COMMENT>
<EMBED type="application/x-websphere-client" CODE=MyAppletClass.class
ARCHIVE="Applet.jar, EJB.jar" WIDTH="600" HEIGHT="500"
scriptable="false">
<NOEMBED>
</COMMENT>
</NOEMBED>WebSphere Java Application/Applet Thin Client for
Windows is required.
</EMBED>
</OBJECT>
```

- The value of the type attribute on the </EMBED> tag can also be, for example:

```
<EMBED type="application/x-websphere-client, version=4.0" ...
```

Applet client code requirements

The code used by an applet to talk to an enterprise bean is the same as that used by a stand-alone Java program or a servlet, except for one additional property called `java.naming.applet`. This property informs the `InitialContext` and the Object Request Broker (ORB) that this client is an applet rather than a stand-alone Java application or servlet.

- When you initialize an instance of the `InitialContext` class, the first two lines in this code snippet illustrate what both a stand-alone Java program and a servlet issue to specify the computer name, domain, and port. In this example, `<yourserver.yourdomain.com>` is the computer name and domain where WebSphere Application Server resides, and 900 is the configured port. After the bootstrap values (`<yourserver.yourdomain.com>:900`) are defined, the client to server communications occur within the underlying infrastructure. In addition to the first two lines for applets, you must add the highlighted third line to your code. That highlighted line identifies this program as an applet, for example:

```
prop.put(Context.INITIAL_CONTEXT_FACTORY, "com.ibm.websphere.naming.WsnInitialContextFactory");
prop.put(Context.PROVIDER_URL, "iiop://<yourserver.yourdomain.com>:900)
prop.put(Context.APPLET, this);
```

Developing J2EE application client code

A *J2EE application client* program operates similarly to a standard J2EE program in that it runs its own Java virtual machine (JVM) code and is invoked at its main method.

The Java Virtual Machine application client program differs from a standard Java program because it uses the Java Naming and Directory Interface (JNDI) namespace to access resources. In a standard Java program, the resource information is coded in the program.

Storing the resource information separately from the client application program makes the client application program portable and more flexible.

1. Write the client application program. Write the J2EE application client program on any development machine. At this stage, you do not require access to the WebSphere Application Server.

Using the `javax.naming.InitialContext` class, the client application program uses the look-up operation to access the Java Naming and Directory Interface (JNDI) namespace. The `InitialContext` class provides the `lookup` method to locate resources.

The following example illustrates how a client application program uses the `InitialContext` class:

```
import javax.naming.*

public class MyAppClient
{
    public static void main(String argv[])
    {
        InitialContext initCtx = new InitialContext();
        Object homeObject = initCtx.lookup("java:comp/env/ejb/BasicCalculator");
        BasicCalculatorHome bcHome = (BasicCalculatorHome)
        javax.rmi.PortableRemoteObject.narrow(homeObject, BasicCalculatorHome.class);
        BasicCalculatorHome bc = bcHome.create();          ...
    }
}
```

In this example, the program looks up an enterprise bean called `BasicCalculator`. The `BasicCalculator` EJB reference is located in the client JNDI namespace at `java:comp/env/ejb/BasicCalculator`. Since the actual Enterprise Java Bean runs on the server, the application client run time returns a reference to the `BasicCalculator` home interface.

If the client application program lookup was for a resource reference or an environment entry, then the look up function returns an instance of the configured type as defined by the client application deployment descriptor. For example, if the program lookup was a JDBC data source, the lookup would return an instance of `javax.sql.DataSource`. Although you can edit deployment descriptor files, do not use the administrative console to modify them.

2. Assemble the application client using the Assembly Toolkit.

The JNDI namespace knows what to return on a lookup because of the information assembled by the assembly tool.

Assemble the J2EE application client on any development machine with the assembly tool installed.

When you assemble your application client, provide the application client run time with the required information to initialize the execution environment for your client application program.

Remember following when you configure resources used by your client application program:

- Resource environment references are different than resource references. Resource environment references allow your application client to use a logical name to look-up a resource bound into the server JNDI namespace. A resource reference allows your application to use a logical name to look up a local J2EE resource. The J2EE specification does not specify a particular implementation of a resource. The following table contains supported resource types and identifies the resources to which the WebSphere Application Server provides a client implementation.

Resource Type	Client Configuration Notes	Client implementation provided by WebSphere Application Server
<code>javax.sql.DataSource</code>	Supports specification of any data source implementation class	No
<code>java.net.URL</code>	Supports specification of custom protocol handlers	Provided by Java Runtime Environment files
<code>javax.mail.Session</code>	Supports custom protocol configuration	Yes - POP3, SMTP, IMAP

Resource Type	Client Configuration Notes	Client implementation provided by WebSphere Application Server
javax.jms.QueueConnectionFactory, javax.jms.TopicConnectionFactory, javax.jms.Queue, javax.jms.Topic	Supports configuration of WebSphere embedded messaging, IBM MQ Series and other JMS providers	Yes - WebSphere embedded messaging

3. Assemble the Enterprise Archive (EAR) file.

The application is contained in an enterprise archive or .ear file. The .ear file is composed of:

- Enterprise bean, application client, and user-defined modules or .jar files
- Web applications or .war files
- Metadata describing the applications or application .xml files

You must assemble the .ear file on the server machine.

4. Distribute the EAR file.

The client machines configured to run this client must have access to the .ear file.

If all the machines in your environment share the same image and platform, run the Application Client Resource Configuration Tool (ACRCT) on one machine to configure the external resources, and then distribute the configured .ear file to the other machines.

If your environment is set up with a variety of client installations and platforms, run the ACRCT for each unique configuration.

You can either distribute the .ear files to the correct client machines, or make them available on a network drive.

Distributing the .ear files is the responsibility of the system and network administrator.

5. Deploy the application client.

6. Configure the application client resources.

If the client application defines the local resources, run the ACRCT (clientConfig command) on the local machine to reconfigure the .ear file. Use the ACRCT to change the configuration. For example, the .ear file can contain a DB2 resource, configured as C:\DB2. If, however, you installed DB2 in the D:\Program Files\DB2 directory, use the ACRCT to create a local version of the .ear file.

After developing the J2EE application client code, launch the application client.

J2EE application client class loading

When you run your J2EE application client, a hierarchy of class loaders is created to load classes used by your application.

The following list describes the hierarchy of class loaders:

- The topmost class loader, the bootstrap class loader, contains the JAR files that make up the Java virtual machine code, such as rt.jar, plus those JAR files defined by the -Xbootclasspath parameter on the Java command. The WebSphere application client run time sets this value to the WAS_BOOTCLASSPATH environment variable.
- The *extensions class loader* class loader is a child to the bootstrap class loader. This class loader contains JAR files in the java/jre/lib/ext directory or those JAR files defined by the -Djava.ext.dirs parameter on the Java command. The WebSphere application client run time does not set -Djava.ext.dirs parameters, so it uses the JAR files in the java/jre/lib/ext directory.
- The *system class loader* class loader contains JAR files and classes that are defined by the -classpath parameter on the Java command. The WebSphere application client run time sets this parameter to the WAS_CLASSPATH environment variable.
- The *WebSphere class loader* class loader loads the WebSphere application client run time and any classes placed in the WebSphere application client user directories. The directories used by this class loader are defined by the WAS_EXT_DIRS environment variable. The WAS_BOOTCLASSPATH, WAS_CLASSPATH,

and the `WAS_EXT_DIRS` environment variables are set in the `installation_root/bin/setupCmdLine` command shell for WebSphere Application Server installations, or in the `installation_root/bin/setupClient` command shell for client installations.

As the J2EE application client run time initializes, additional class loaders are created as children of the WebSphere class loader. If your client application uses resources such as Java Database Connectivity (JDBC) API, Java Message Service (JMS) API, or Uniform Resource Locator (URL), a different class loader is created to load each of those resources. Finally, the application client run time sets the WebSphere class loader to load classes within the `.ear` file by processing the client JAR manifest repeatedly. The system class path, defined by the `CLASSPATH` environment variable is never used and is not part of the hierarchy of class loaders.

To package your client application correctly, you must understand which class loader loads your classes. When the Java code loads a class, the class loader used to load that class is assigned to it. Any classes subsequently loaded by that class will use that class loader or any of its parents, but it will not use children class loaders.

In some cases the WebSphere application client run time can detect when your client application class is loaded by a different class loader from the one created for it by the WebSphere application client run time. When this detection occurs, you see the following message:

```
WSCL0205W: The incorrect class loader was used to load [0]
```

This message occurs when your client application class is loaded by one of the parent class loaders in the hierarchy. This situation is typically caused by having the same classes in the `.ear` file and on the hard drive. If one of the parent class loaders locates a class, that class loader loads it before the application client run time class loader. In some cases, your client application still functions correctly. In most cases, however, you receive "class not found" exceptions.

Configuring the classpath fields

When packaging your J2EE client application, you must configure various class path fields. Ideally, you should package everything required by your application into your `.ear` file. This is the easiest way to distribute your J2EE client application to your clients. However, you should not package such resources as JDBC APIs, JMS APIs, or URLs. In the case of these resources, use class path references to access those classes on the hard drive. You might also have other classes installed on your client machines that you do not need to redistribute. In this case, you also want to use classpath references to access the classes on the hard drive, as described below.

Referencing classes within the EAR file

WebSphere product J2EE applications do not use the system class path. Use the MANIFEST Class path entry to refer to other JAR files within the `.ear` file. Configure these values using the module Class path fields in the Application Assembly Tool Assembly Toolkit. For example, if your client application needs to access the path of the EJB JAR file, add the deployed enterprise bean module name to your application client Class path field in the Assembly Tool. The format of the Class path field for each of the different modules (Application Client, EJB, Web) is the same:

- The values must refer to `.jar` and `.class` files that are contained within the `.ear` file.
- The values must be relative to the root of the `.ear` file.
- The values cannot refer to absolute paths in the file systems.
- Multiple values must be separated by spaces, not colons or semi-colons.

Note: This is the Java method for allowing applications to function platform independent.

Typically, you add modules (`.jar` files) to the root of the `.ear` file. In this case, you only need to specify the name of the module (`.jar` file) in the Class path field. If you choose to add a module with a path, you need to specify the path relative to the root of the `.ear` file.

For referencing .class files, you must specify the directory relative to the root of the .ear file. With the Assembly Tool you can add individual class files to the .ear file. It is recommended that these additional class files are packaged in a .jar file. Add this .jar file to the module Class path fields. If you add .class files to the root of the .ear file, add ./ to the module Class path fields. Consider the following example directory structure in which the file myapp.ear contains an application client JAR file named client.jar and a mybeans.jar EJB module. Additional classes reside in class1.jar and utility/class2.zip files. A class named xyz.class is not packaged in a JAR file but is in the root of the EAR file. Specify **./ mybeans.jar utility/class2.zip class1.jar** as the value of the Classpath property. The search order is:
myapp.ear/client.jar myapp.ear/xyz.class myapp.ear/mybeans.jar myapp.ear/utility/class2.zip myapp.ear/class1.jar

Referencing classes that are not in the EAR file

Use the launchClient -CCclasspath parameter. This parameter is specified at run time and takes platform-specific class path values, which means multiple values are separated by semi-colons or colons. The client and the server are similar in this respect.

Resource class paths

When you configure resources used by your client application using the Application Client Resource Configuration Tool, you can specify class paths that are required by the resource. For example, if your application is using a JDBC to a DB2 database, add db2java.zip to the class path field of the database provider. These class path values are platform-specific and require semi-colons or colons to separate multiple values.

Using the launchClient API

If you use the launchClient shell and bat command, the WebSphere class loader hierarchy is created for you. However, if you use the launchClient API, you must perform this setup yourself. Copy the launchClient shell command in defining the Java system properties.

Developing pluggable application client code

As you prepare to install the pluggable application client, remember that pluggable clients are only available on Windows systems.

1. Install the pluggable application client from the WebSphere Application Client CD by selecting option **Pluggable Application Client** from the **Custom client installation** panel.
2. Set the Java application pluggable client environment by using the **setupClient** shell, located in:
install_root\AppClient\bin\setupClient.bat
3. Add your specific Java client application JAR files to the CLASSPATH and start your Java client application from this environment, after setting the environment variables.
4. Run the following Java command to invoke your client application:

```
%JAVA_HOME%/bin/java -Xbootclasspath/p:%WAS_BOOTCLASSPATH% -classpath  
<list of your application jars and classes> -Djava.ext.dirs=%WAS_EXT_DIRS%  
-Djava.naming.provider.url=iiop://<your WebSphere server machine name>  
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory  
%SERVER_ROOT% %CLIENTSAS% <fully qualified class name to run>  
  
$JAVA_HOME/bin/java -Xbootclasspath/p:$WAS_BOOTCLASSPATH -classpath  
<list of your application jars and classes> -Djava.ext.dirs=$WAS_EXT_DIRS  
-Djava.naming.provider.url=iiop://<your WebSphere server machine name>  
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory  
$SERVER_ROOT $CLIENTSAS <fully qualified class name to run>
```

View the Samples Gallery for more information about application clients. Before you run the basicCalculator Sample, ensure the JMS Server is started. (See "Samples Gallery" in the Information Center.)

These samples do not include client applications that communicate with Enterprise server-side examples.

Developing thin application client code

You can develop and run Java thin client applications on machines installed with either a client or a server. The client provides a setup command shell which sets up your environment for either a thin client application or a J2EE client application. The server provides a command shell which sets up your environment for J2EE application clients only. The Java invocation to run a thin application client varies between a client and a server. If your thin client application needs to run on both a client installation and a server installation, follow the steps for developing thin application clients on a server machine.

1. Install the Java application thin client from the WebSphere Application Client CD by selecting option **J2EE/Thin application client for the WebSphere Application Client**.
2. Perform one of the following:
 - Develop thin application client code for a client machine.
 - Develop thin application client code for a server machine.

View the Samples gallery for more information about application clients. (See "Samples Gallery" in the Information Center.)

These samples do not include client applications that communicate with Enterprise server-side examples.

Developing thin application client code on a client machine

You must install the thin application client from the WebSphere Application Client CD before performing this task. For more information, see Developing thin application client code.

1. Set the Java application thin client environment by using the setupClient shell, located in: Windows systems:

```
install_root\AppClient\bin\setupClient.bat
```

UNIX platforms:

```
install_root/AppClient/bin/setupClient.sh
```

2. Run the following Java compilation command to compile your client application. On Windows systems, enter:

```
"%JAVA_HOME%\bin\javac" -classpath "%WAS_CLASSPATH%";  
<list of your application jars and classes> " -extdirs %WAS_EXT_DIRS%  
<your application class>.java
```

On UNIX systems, enter:

```
$JAVA_HOME/bin/javac -classpath "$WAS_CLASSPATH:"  
<list of your application jars and classes> " -extdirs $WAS_EXT_DIRS  
<your application class>.java
```

3. Run the following Java command to invoke your client application: On Windows systems, enter:

```
"%JAVA_HOME%\bin\java" "-Xbootclasspath/p:%WAS_BOOTCLASSPATH%"  
-Djava.security.auth.login.config="%WAS_HOME%\properties\wsjaas_client.conf"  
-classpath "%WAS_CLASSPATH%";<list of your application jars and classes>"  
-Djava.ext.dirs=%WAS_EXT_DIRS% -Djava.naming.provider.url=<an iiop URL or  
a corbaloc URL to your WebSphere server machine name>  
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory  
"%SERVER_ROOT%" "%CLIENTSAS%" <fully qualified class name to run>  
<your application parameters>
```

On UNIX systems, enter:

```
$JAVA_HOME/bin/java -Xbootclasspath/p:$WAS_BOOTCLASSPATH
-classpath "$WAS_CLASSPATH:<list of your application jars and classes>"
-Djava.ext.dirs=$WAS_EXT_DIRS -Djava.naming.provider.url=
<an IIOP URL or a Corbaloc URL to your WebSphere server machine name>
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
"$SERVER_ROOT" "$CLIENTSAS" <fully qualified class name to run>
<your application parameters>
```

For more information on IIOP and corbaloc URLs, see Developing applications that use JNDI.

View the Samples gallery for more information about application clients. (See "Samples Gallery" in the Information Center.)

These samples do not include client applications that communicate with Enterprise server-side examples.

Developing thin application client code on a server machine

You must install WebSphere Application Server before performing this task.

1. Set the Java application thin client environment by using the **setupCmdLine** shell, located in:

```
install_root\bin\setupCmdLine.bat (on Windows systems)
install_root/bin/setupCmdLine.sh (on UNIX platforms)
```

2. Run the following Java compilation command to compile your client application: On Windows systems, enter:

```
"%JAVA_HOME%\bin\javac" -classpath "%WAS_CLASSPATH%";
<list of your application jars and classes> " -extdirs %WAS_EXT_DIRS%
<your application class>.java
```

On UNIX systems, enter:

```
$JAVA_HOME/bin/javac -classpath "$WAS_CLASSPATH:
<list of your application jars and classes>" -extdirs $WAS_EXT_DIRS
<your application class>.java
```

3. Run the application client. Perform one of the following methods:

- Use Java code to call your main class directly:

On Windows systems, enter:

```
"%JAVA_HOME%\bin\java" "-Xbootclasspath/p:%WAS_BOOTCLASSPATH%"
-Djava.security.auth.login.config="%WAS_HOME%\properties\wsjaas_client.conf"
-Djava.ext.dirs="%JAVA_HOME%\jre\lib\ext;%WAS_EXT_DIRS%"
-Djava.naming.provider.url=<an IIOP URL or a corbaloc URL to your
WebSphere server machine name>
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
-Dserver.root="%WAS_HOME%" "%CLIENTSAS%" %USER_INSTALL_PROP%
-classpath "%WAS_CLASSPATH%;<list of your application jars and classes>"
<fully qualified class name to run><your application parameters>
```

On UNIX systems, enter:

```
"$JAVA_HOME/bin/java" "-Xbootclasspath/p:$WAS_BOOTCLASSPATH"
-Djava.security.auth.login.config="$WAS_HOME/properties/wsjaas_client.conf"
-Djava.ext.dirs="$JAVA_HOME/jre/lib/ext;%WAS_EXT_DIRS%"
-Djava.naming.provider.url=<an IIOP URL or a corbaloc URL to your
WebSphere server machine name>
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
-Dserver.root="$WAS_HOME" $USER_INSTALL_PROP "$CLIENTSAS"
-classpath "$WAS_CLASSPATH;<list of your application jars and classes>
<fully qualified class name to run><your application parameters>
```

- Use the WebSphere Application Server launcher:

On Windows systems, enter:

```

"%JAVA_HOME%\bin\java" "-Xbootclasspath/p:%WAS_BOOTCLASSPATH%"
-Djava.security.auth.login.config="%WAS_HOME%\properties\wsjaas_client.conf"
"-Dws.ext.dirs=<list of your application jars and classes;
%WAS_EXT_DIRS%;%WAS_USER_DIRS%">
-Djava.naming.provider.url=<an IIOP URL or a corbaloc URL to your
WebSphere server machine name>
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
"-Dserver.root=%WAS_HOME%"
"%CLIENTSAS%" %USER_INSTALL_PROP% -classpath "%WAS_CLASSPATH%"
com.ibm.ws.bootstrap.WSLauncher
<fully qualified class name to run><your application parameters>

```

On UNIX systems, enter:

```

"$JAVA_HOME/bin/java" "-Xbootclasspath/p:$WAS_BOOTCLASSPATH"
-Djava.security.auth.login.config="$WAS_HOME/properties/wsjaas_client.conf"
"-Dws.ext.dirs=<list of your application jars and classes>
$WAS_EXT_DIRS;$WAS_USER_DIRS"
-Djava.naming.provider.url=<an IIOP URL or a corbaloc URL to your
WebSphere server machine name>
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
"-Dserver.root=$WAS_HOME"
"$CLIENTSAS" $USER_INSTALL_PROP -classpath "$WAS_CLASSPATH"
com.ibm.ws.bootstrap.WSLauncher
<fully qualified class name to run><your application parameters>

```

For more information on IIOP and corbaloc URLs, see *Developing applications that use JNDI*.

View the Samples gallery for more information about application clients. (See "Samples Gallery" in the Information Center.)

These samples do not include client applications that communicate with Enterprise server-side examples.

Assembling application clients

Assemble a client module to contain application client code. Group enterprise beans, Web components, and resource adapter code in separate modules.

Application client projects contain programs that run on networked client systems. An application client project is deployed as a JAR file.

Use the Assembly Toolkit to assemble an application client module in any of the following ways:

- Import an existing application client JAR file.
 - Create a new application client module.
1. Start the Assembly Toolkit.
 2. Optional: Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
 3. Optional: Open the J2EE Hierarchy view. Click **Window > Show View > J2EE Hierarchy**. Other helpful views include the Project Navigator view (**Window > Show View > Other > J2EE > Project Navigator**) and the Navigator view (**Window > Show View > Navigator**).
 4. **5.1+** Optional: To use application assembly services of WebSphere Business Integration (WBI) Server Foundation such as Application profiling, select the **Integration Server** target server.
 - a. Click **Project > Properties > J2EE**.
 - b. For **Target server**, select **Integration Server**. For this release, **Integration Server v5.1**.
 - c. Click **OK**.

You can set values for WBI Server Foundation services on the **Extended Services** tab of a deployment descriptor editor open on the module.

5. Migrate application client JAR files created with the Application Assembly Tool (AAT) or a different tool to the Assembly Toolkit. To migrate files, import your application client JAR files to the Assembly Toolkit.
6. Create a new application client.
7. Verify the contents of the new application client in either of the following ways:
 - In the J2EE Hierarchy view, expand **Application Client Modules** and view the new module.
 - Click **Window > Show View > Navigator** to see the associated files for the application client module in a Navigator view.

After you finish assembling all of your application's modules, you are ready to deploy your application.

Deploying application clients on workstation platforms

After developing an application client, deploy this application on client machines. *Deployment* consists of pulling together the various artifacts that the application client requires.

The *Application Client Resource Configuration Tool* (ACRCT) defines resources for the application client. These configurations are stored in the application client .ear file. The application client run time uses these configurations for resolving and creating an instance of the resources for the application client.

Note: This task only applies to J2EE application clients. Only perform this task if you configured your J2EE application client to use resource references.

1. Start the ACRCT and open an EAR file.
2. Configure new data source providers.
3. Configure mail providers and sessions.
4. Configure URL providers and sessions.
5. Configure Java messaging client resources.
6. Configure new environment entries.
7. (Optional) Remove application client resources.
8. Save the EAR file.

Starting the Application Client Resource Configuration Tool and opening an EAR file

Note: This task only applies to J2EE application clients.

1. Open a command prompt and change to the `install_root\bin` directory.
2. Run the `clientConfig.bat` file for a Windows system or the `clientConfig.sh` file for a UNIX system.
3. Open an EAR file within the Application Client Resource Configuration Tool (ACRCT):
 - Click **File > Open**.
 - Select the file and click **Open**.
4. Save your changes to the file and close the tool:
 - Click **File > Save**.
 - Click **File > Exit**.

Data sources for application clients

The J2EE application client does not support looking up or directly accessing data sources configured on WebSphere Application Server because the J2EE application client does not support Java 2 Connection Factories. To use a data source directly from the client application, you must use the ACRCT to configure your data source. In addition, WebSphere Application Server and WebSphere Application Server clients do not provide client database drivers to be used directly from a J2EE application client. If your application

client accesses a database directly, you must provide the database drivers on the client machine. You might contact your database vendor to acquire client database driver code and licenses. Instead of accessing the database directly, it is recommended that your client application use an enterprise bean. Accessing a database through an enterprise bean eliminates the need to have database drivers on the client machine, since the database access is handled by the enterprise bean running on the WebSphere Application Server. For a current list of providers that are supported on the WebSphere Application Server go the following site:

Supported hardware, software, and APIs

Configuring new data source providers (JDBC providers) for application clients

During this task, you create new data source providers, also known as JDBC providers, for your application client. In a separate administrative task, install the Java code for the required data source provider on the client machine on which the application client resides.

1. Start the tool and open the EAR file for which you want to configure the new data source provider. The EAR file contents display in a tree view.
2. Select the JAR file in which you want to configure the new data source provider from the tree.
3. Expand the JAR file to view its contents.
4. Click the **Data Source Providers** folder. Do one of the following:
 - Right-click the folder and click **New Provider**.
 - Click **Edit > New** on the menu bar.
5. Configure the data source provider properties in the resulting property dialog.
6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

Configuring new data source providers

During this task, you will create new data source providers, also known as JDBC drivers, for your application client. In a separate administrative task, install the Java code for the required data source provider on the client machine where the application client resides.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Click **File > Open**, and select the EAR file for which you want to configure the new data source provider. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new data source provider from the tree.
4. Expand the JAR file to view its contents.
5. Right click the **Data Source Providers** folder and select **New Provider**.
6. Configure the data source provider properties in the resulting property dialog.
7. Click **OK**.
8. Click **File > Save** to save your changes.

Example: Configuring data source provider and data source settings: The purpose of this article is to help you to configure data source provider and data source settings.

- Required fields:
 - Data Source Provider Properties page: name
 - Data Source Properties page: name, jndiName
- Special cases:
 - The user name and password fields have no equivalent XML tags. You must specify these fields in the custom properties.
 - The password is encrypted when you use the Application Client Resource Configuration Tool (ACRCT). If you do not use the ACRCT the field cannot be encrypted.

- **Example:**

```
<resources.jdbc:JDBCProvider xmi:id="JDBCProvider_1" name="jdbcProvider:name"
description="jdbcProvider:description" implementationClassName="jdbcProvider:
ImplementationClass">
<classpath>jdbcProvider:classpath</classpath>
<factories xmi:type="resources.jdbc:WAS40DataSource" xmi:id="WAS40DataSource_1"
name="jdbcFactory:name" jndiName="jdbcFactory:jndiName"
description="jdbcFactory:description" databaseName="jdbcFactory:databasename">
<propertySet xmi:id="J2EEResourcePropertySet_13">
<resourceProperties xmi:id="J2EEResourceProperty_13" name="jdbcFactory:customName"
value="jdbcFactory:customValue"/>
<resourceProperties xmi:id="J2EEResourceProperty_14" name="user"
value="jdbcFactory:user"/>
<resourceProperties xmi:id="J2EEResourceProperty_15" name="password"
value="{xor}NTs9PBk+PCswLSZ1MT4y0g==" />
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_14">
<resourceProperties xmi:id="J2EEResourceProperty_16" name="jdbcProvider:customName"
value="jdbcProvider:customeValue"/>
</propertySet>
</resources.jdbc:JDBCProvider>
```

Data source provider settings for application clients:

Use this page to create a data source under a JDBC provider which provides the specific JDBC driver implementation class.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File > Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right-click **Data Source Providers >** and click **New**. The following fields appear on the **General** tab:

Name:

Specifies the display name for the data source.

For example you can set this field to *Test Data Source*.

Data type String

Description:

Specifies a text description for the resource.

Data type String

Class Path:

A list of paths or .jar file names which together form the location for the resource provider classes.

Implementation class:

Use this setting to perform database specific functions.

Data type String
Default Dependent on JDBC driver implementation class

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Data source properties for application clients:

Use this page to create or modify the data sources.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File > Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Data Source Providers > Data source provider instance**. Right-click **Data Sources** and click **New**. The following fields are displayed on the **General** tab:

Name:

Specifies the display name of this data source.

Data type String

Description:

Specifies a text description of the data source.

Data type String

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Database Name:

The name of the database to which you want to connect.

User:

Use the user ID with the Password property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the User ID property, you must also specify a value for the Password property. The connection factory User ID and Password properties are used if the calling application does not provide a user ID and password explicitly.

Password:

Use the password with the User ID property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the User ID property, you must also specify a value for the Password property.

Re-Enter Password:

Confirms the password.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring new data sources for application clients

During this task, you create new data sources for your application client.

1. Click the data source provider for which you want to create a data source in the tree. Take one of the following actions as needed:
 - Configure a new data source provider.
 - Click an existing data source provider.
2. Expand the data source provider to view its **Data Sources** folder.
3. Click the data source folder. Take one of the following actions as needed:
 - Right click the data source folder and click **New Factory**.
 - Click **Edit > New** on the menu bar.
4. Configure the data source properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Configuring mail providers and sessions for application clients

Use the Application Client Resource Configuration Tool (ACRCT) to edit the configurations of JavaMail sessions and providers for your application clients to use.

1. Open the ACRCT.
2. Open an EAR file.
3. Locate the JavaMail objects in the tree that displays. For example, if your file contains JavaMail sessions, expand **Resources > application.jar > JavaMail Providers > java_mail_provider_instance > JavaMail Sessions**.

In this example, *java_mail_provider_instance* is a particular JavaMail provider.

The JavaMail session instances are located in the **JavaMail Sessions** folder.

Mail provider settings for application clients

Use this page to implement the JavaMail API and create mail sessions.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File > Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right-click **Mail Providers >** and click **New**. The following fields appear on the **General** tab:

Name:

The name of the JavaMail resource provider.

Description:

An optional description for the resource provider.

Class Path:

Specifies a list of paths or JAR file names which together form the location for the resource provider classes.

Protocol:

Specifies the name of the protocol.

Classname:

Specifies the name of the class implementing the protocol. Leave this field blank if you want to use the default implementation.

Type:

This menu contains the following two values: TRANSPORT or STORE.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Mail session settings for application clients

Use this page to configure mail session properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File > Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Mail Providers > mail provider instance**. Right-click **Mail Sessions** and click **New**. The following fields appear on the **General** tab:

Name:

Represents the administrative name of the JavaMail session object.

Description:

Provides an optional description for your administrative records.

JNDI Name:

The application client run time uses this field to retrieve configuration information. The name must match the value of the **Name** field on the General tab in the Application Client Resource Reference section of the Assembly Tool.

Mail Transport Host:

Specifies the server to connect to when sending mail.

Mail Transport Protocol:

Specifies the transport protocol to use when sending mail.

Mail Transport User:

Specifies the user ID to use when the mail transport host requires authentication.

Mail Transport Password:

Specifies the password to use when the mail transport host requires authentication.

Re-Enter Password:

Confirms the password.

Mail From:

Specifies the mail originator.

Mail Store Host:

Specifies the mail account host (or "domain") name.

Mail Store User:

Specifies the user ID of the mail account.

Mail Store Password:

Specifies the password of the mail account.

Re-Enter Password:

Confirms the password.

Mail Store Protocol:

Specifies the protocol to be used when receiving mail.

Mail Debug:

When true, JavaMail interaction with mail servers, along with these mail session properties are printed to the `stdout` file.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring JavaMail provider and JavaMail session settings for application clients

The purpose of this article is to help you configure JavaMail provider and JavaMail session settings.

- Required fields:
 - JavaMail Provider Properties page: name, and at least one protocol provider
 - JavaMail Session Properties page: name, jndiName, mail transport protocol, mail store protocol
- Special cases:
 - The password is encrypted when using the ACRCT tool. Without the tool, you cannot encrypt this field.
- Example:

```

<resources.mail:MailProvider xmi:id="MailProvider_1" name="Default Mail Provider"
description="IBM JavaMail Implementation">
<classpath>mailProvider:classpath</classpath>
<factories xmi:type="resources.mail:MailSession" xmi:id="MailSession_1"
name="mailSession:name" jndiName="mailSession:jndiName"
description="mailSession:description" mailTransportHost="mailSession:mailTransportHost"
mailTransportUser="mailSession:mailTransportUser"
mailTransportPassword="{xor}Mj42Mww6LCw2MDF1MT4y0g=="
mailFrom="mailSession:mailFrom" mailStoreHost="mailSession:mailStoreHost"
mailStoreUser="mailSession:mailStoreUser"
mailStorePassword="{xor}Mj42Mww6LCw2MDF1MT4y0g==" debug="true"
mailTransportProtocol="ProtocolProvider_1" mailStoreProvider="ProtocolProvider_1">
<propertySet xmi:id="J2EEResourcePropertySet_1">
<resourceProperties xmi:id="J2EEResourceProperty_1"
name="mailSession:customName" value="mailSession:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_2">
<resourceProperties xmi:id="J2EEResourceProperty_2" name="mailProvider:customName"
value="mailProvider:customValue"/>
</propertySet>
<protocolProviders xmi:id="ProtocolProvider_1" protocol="smtp"
classname="smtp:className"/>
<protocolProviders xmi:id="ProtocolProvider_2" protocol="pop3"
classname="pop3:className"/>
<protocolProviders xmi:id="ProtocolProvider_3" protocol="imap"
classname="imap:className"/>
</resources.mail:MailProvider>

```

Configuring new mail sessions for application clients

During this task, you configure new mail sessions for your application client. The mail sessions are associated with the pre-configured default mail provider supplied by the product.

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the EAR file. The EAR file contents are displayed in a tree view.
2. Select the JAR file in which you want to configure the new JavaMail session.
3. Expand the JAR file to view its contents.
4. Click **JavaMail Providers** > **MailProvider** > **JavaMail Sessions**. Complete one of the following actions:
 - Right click the **JavaMail Sessions** folder and select **New Factory**.
 - Click **Edit** > **New** on the menu bar.
5. Configure the JavaMail session properties in the displayed fields.
6. Click **OK**.
7. Click **File** > **Save** on the menu bar to save your changes.

URLs for application clients

A *Uniform Resource Locator* (URL) is an identifier that points to an electronically accessible resource, such as a directory file on a machine in a network, or a document stored in a database.

URLs appear in the format *scheme:scheme_information*.

You can represent a *scheme* as http, ftp, file, or another term that identifies the type of resource and the mechanism by which you can access the resource.

In a World Wide Web browser location or address box, a URL for a file available using HyperText Transfer Protocol (HTTP) starts with http:. An example is http://www.ibm.com. Files available using File Transfer Protocol (FTP) start with ftp:. Files available locally start with file:.

The *scheme_information* commonly identifies the Internet machine making a resource available, the path to that resource, and the resource name. The *scheme_information* for HTTP, FTP and File generally starts with two slashes (//), then provides the Internet address separated from the resource path name with one slash (/). For example,

```
http://www-4.ibm.com/software/webservers/appserv/library.html.
```

For HTTP and FTP, the path name ends in a slash when the URL points to a directory. In such cases, the server generally returns the default index for the directory.

URL providers for the Application Client Resource Configuration Tool

A URL provider implements the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP). This provider, comprised of a pair of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Configuring new URL providers for application clients

During this task, you create URL providers and URLs for your client application. In a separate administrative task, you must install the Java code for the required URL provider on the client machine on which the client application resides.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new URL provider. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new URL provider from the tree.
4. Expand the JAR file to view the contents.
5. Click the folder called **URL Providers**. Complete one of the following actions:
 - Right click the folder and select **New Provider**.
 - Click **Edit > New** on the menu bar.
6. Configure the URL provider properties in the resulting property dialog.
7. Click **OK**.
8. Click **File > Save** on the menu bar to save your changes.

Configuring URL providers and sessions using the Application Client Resource Configuration Tool

Use the Application Client Resource Configuration Tool (ACRCT) to edit the configurations of URL providers and URLs to be used by your application clients.

1. Open the ACRCT.
2. Open an EAR file.
3. Locate the URL objects in the tree that displays. For example, if your file contains URL providers and URLs, expand **Resources** -> **application.jar** -> **URL Providers** -> **url_provider_instance** where **url_provider_instance** is a particular URL provider.
4. If you expand the tree further, you will also see the **URLs** folders containing the URL instances for each URL provider instance.

URL settings for application clients:

Use this page to implement the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP).

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File > Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **URL Providers > URL provider instance**. Right-click **URLs** and click **New**. The following fields appear on the **General** tab.

This provider, comprised of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Name:

Administrative name for the URL

Description:

Optional description of the URL, for your administrative records

JNDI Name:

The application client run time uses this field to retrieve configuration information. The name must match the value of the **Name** field on the General tab in the Application Client Resource Reference section of the Application Assembly Tool.

URL:

A Uniform Resource Locator (URL) name that points to an Internet or intranet resource. For example:
`http://www.ibm.com`.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

URL provider settings for application clients:

Use this page create new URL providers.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File > Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right click **URL Providers**, and click **New**. The following fields appear on the **General** tab.

A URL provider implements the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP). This provider, comprised of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Name:

Administrative name for the URL

Description:

Optional description of the URL, for your administrative records

Class Path:

A list of paths or JAR file names which together form the location for the resource provider classes.

Protocol:

Protocol supported by this stream handler. For example, "nntp", "smtp", "ftp", and so on.

To use the default protocol, leave this field blank.

Stream handler class:

Fully qualified name of a User-defined Java class that extends the `java.net.URLStreamHandler` for a particular URL protocol, such as FTP.

To use the default stream handler, leave this field blank.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring URL and URL provider settings for application clients

The purpose of this article is to help you to configure URL and URL provider settings.

- Required fields:
 - URL Properties page: name, jndiName, url
 - URL Provider Properties page: name
- Example:

```
<resources.url:URLProvider xmi:id="URLProvider_1" name="urlProvider:name"
description="urlProvider:description"
streamHandlerClassName="urlProvider:streamHandlerClass"
protocol="urlProvider:protocol">
<classpath>urlProvider:classpath</classpath>
<factories xmi:type="resources.url:URL" xmi:id="URL_1" name="urlFactory:name"
jndiName="urlFactory:jndiName" description="urlFactory:description"
spec="urlFactory:url">
<propertySet xmi:id="J2EEResourcePropertySet_18">
<resourceProperties xmi:id="J2EEResourceProperty_20" name="urlFactory:customName"
value="urlFactory:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_19">
<resourceProperties xmi:id="J2EEResourceProperty_21" name="urlProvider:customName"
value="urlProvider:customValue"/>
</propertySet>
</resources.url:URLProvider>
```

Configuring new URLs with the Application Client Resource Configuration Tool

During this task, you create URLs for your client application.

1. Click the URL provider for which you want to create a URL in the tree. Do one of the following:
 - Configure a new URL provider.
 - Click an existing URL provider.
2. Expand the URL provider to view the **URLs** folder.
3. Click the URL folder. Complete one of the following actions:

- Right click the folder and click **New Factory**.
 - Click **Edit** -> **New** on the menu bar.
4. Configure the URL properties in the displayed fields.
 5. Click **OK** when you finish.
 6. Click **File** > **Save** in the menu bar to save your changes.

WebSphere asynchronous messaging using the Java Message Service API for the Application Client Resource Configuration Tool

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface. The JMS interface provides a common way for Java programs (clients and J2EE applications) to create, send, receive, and read asynchronous requests as JMS messages.

This topic provides an overview of asynchronous messaging using JMS support provided by the WebSphere Application Server.

The base support for asynchronous messaging using the JMS API provides the common set of JMS interfaces and associated semantics that define how a JMS client can access the facilities of a JMS provider. This support enables WebSphere product J2EE applications, as JMS clients, to exchange messages asynchronously with other JMS clients, by using JMS destinations (queues or topics). A J2EE application can use JMS queue destinations for point-to-point messaging and JMS topic destinations for Publisher and Subscriber messaging. A J2EE application can explicitly poll for messages on a destination, and then retrieve messages for processing by business logic beans (enterprise beans).

With the base JMS and XA support, the J2EE application uses standard JMS calls to process messages, including any responses or outbound messaging. An enterprise bean can handle responses acting as a sender bean, or within the enterprise bean that receives the incoming messages. Optionally, this process can use two-phase commit within the scope of a transaction. This level of function for asynchronous messaging is called *bean-managed messaging*, and gives an enterprise bean complete control over the messaging infrastructure, for example, connection and session pool management. The common container has no role in bean-managed messaging.

WebSphere Application Server also supports automatic asynchronous messaging using message-driven beans (a type of enterprise bean defined in the EJB 2.0 specification) and JMS listeners (part of the JMS application server facilities). Messages are automatically retrieved from JMS destinations, optionally within a transaction, then sent to the message-driven bean in a J2EE application, without the application having to explicitly poll JMS destinations.

Configuring Java messaging client resources

In a separate administrative task, install the Java Message Service (JMS) client on the client machine where the application client resides. The messaging product vendor must provide an implementation of the JMS client. For more information, see your messaging product documentation.

During this task, you create new JMS provider configurations for your application client. The application client can use a messaging service through the Java Message Service APIs. A JMS provider provides two kinds of J2EE factories. One is a *JMS connection factory*, and the other is a *JMS destination factory*.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new JMS provider. The EAR file contents are in the displayed tree view.
3. Select the JAR file in which you want to configure the new JMS provider from the tree.
4. Expand the JAR file to view its contents.
5. Click the **JMS Providers** folder and click **New Provider**.

6. Configure the JMS provider properties in the resulting property dialog.
7. Click **OK**.
8. Click **File > Save**.

Configuring new JMS providers with the Application Client Resource Configuration Tool

During this task, you will create new JMS provider configurations for your application client. The application client makes use of a messaging service through the Java Message Service (JMS) APIs. A JMS provider provides two kinds of J2EE factories. One is a JMS Connection factory, and the other is a JMS destination factory.

In a separate administrative task, you must install the JMS client on the client machine where the application client resides. The messaging product vendor must provide an implementation of the JMS client. For more information, see your messaging product documentation.

1. Start the tool and open the EAR file for which you want to configure the new JMS provider. The EAR file contents will be displayed in a tree view.
2. From the tree, select the JAR file in which you want to configure the new JMS provider.
3. Expand the JAR file to view its contents.
4. Click the **JMS Providers** folder. Complete one of the following actions:
 - Right click the folder and select **New Provider**.
 - On the menu bar, click **Edit > New**.
5. In the resulting property dialog, configure the JMS provider properties.
6. Click **OK** when finished.
7. Click **File -> Save** on the menu bar to save your changes.

JMS provider settings for application clients

Use this page to configure properties of the Java Messaging Service (JMS) provider, if you want to use a JMS provider other than the internal WebSphere product JMS provider or the MQSeries product JMS provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File > Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right click **JMS Providers**, and click **New**. The following fields appear on the **General** tab.

Name:

The name by which the JMS provider is known for administrative purposes.

Data type String

Description:

A description of the JMS provider, for administrative purposes

Data type String

Class Path:

A list of paths or .jar file names which together form the location for the resource provider classes.

Context factory class:

The Java class name of the initial context factory for the JMS provider.

For example, for an LDAP service provider the value has the form: `com.sun.jndi.ldap.LdapCtxFactory`.

Data type String

Provider URL:

The JMS provider URL for external JNDI lookups.

For example, an LDAP URL for a JMS provider has the form: `ldap://hostname.company.com/contextName`.

Data type String

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Version 5 Default Provider queue connection factory settings for application clients

Use this panel to view or change the configuration properties of the selected queue connection factory for use with the internal WebSphere Application Server product Java Messaging Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created to the associated JMS queue destination.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File > Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **JMS Providers > JMS provider instance**. Right-click **WAS Queue Connection Factories** and click **New**. The following fields appear on the **General** tab.

A queue connection factory is used to create JMS connections to queue destinations. The queue connection factory is created by the internal WebSphere Application Server product JMS provider. A queue connection factory for the internal WebSphere Application Server product JMS provider has the following properties:

Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

JNDI Name:

The application client run time uses this field to retrieve configuration information. The name must match the value of the Name field on the General tab in the Application Client Resource Reference section of the Application Assembly Tool.

User:

The User ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and password explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a User ID and password explicitly, for example, if the calling application uses the method `createQueueConnection()`. The JMS client flows the `userid` and password to the JMS server.

Data type String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and password explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Re-Enter Password:

Confirms the password.

Note:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type String

Application Server:

Enter the name of the application server. This name is not the host name of the machine, but the name of the configured application server.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Version 5 Default Provider topic connection factory settings for application clients

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the internal WebSphere Application Server product Java Messaging Service (JMS) provider. These configuration properties control how connections are created to the associated JMS topic destination.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File > Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **JMS Providers > JMS provider instance**. Right click **WAS Topic Connection Factories** and click **New**. The following fields appear on the **General** tab.

A topic connection factory is used to create JMS connections to topic destinations. The topic connection factory is created by the associated JMS provider. A topic connection factory for the internal WebSphere product JMS provider has the following properties.

Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

JNDI Name:

The application client run time uses this field to retrieve configuration information. The name must match the value of the **Name** field on the General tab in the Application Client Resource Reference section of the Assembly Tool.

User:

The user ID used, with the **Password** property, for authentication if the calling application does not provide a userid and password explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a userid and password explicitly, for example, if the calling application uses the method `createTopicConnection()`. The JMS client flows the userid and password to the JMS server.

Data type String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a userid and password explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type	String
Default	Null

Re-Enter Password:

Confirms the password.

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type	Enum
Default	Null
Range	Pull-down list of nodes in the WebSphere administrative domain.

Application Server:

Enter the name of the application server. This name is not the host name of the machine, but the name of the configured application server.

Port:

Which of the two ports that connections use to connect to the JMS Server. The QUEUED port is for full-function JMS publish/subscribe support, the DIRECT port is for non-persistent, non-transactional, non-durable subscriptions only.

Note: Message-driven beans cannot use the direct listener port for publish/subscribe support. Therefore, any topic connection factory configured with the Port set to Direct cannot be used with message-driven beans.

Data type	Enum
Units	Not applicable
Default	QUEUED
Range	QUEUED The listener port used for full-function JMS-compliant, publish/subscribe support. DIRECT The listener port used for direct TCP/IP connection (non-transactional, non-persistent, and non-durable subscriptions only) for publish/subscribe support. The TCP/IP port numbers for these ports are defined on the product internal JMS server.

Client ID:

The JMS client identifier used for connections to the MQSeries queue manager.

Data type	String
------------------	--------

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Version 5 Default Provider queue destination settings for application clients

Use this panel to view or change the configuration properties of the selected queue destination for use with WebSphere Application Server product Java Messaging Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File > Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **JMS Providers > JMS provider instance**. Right click **WAS Queue Destinations** and click **New**. The following fields are displayed on the **General** tab.

A queue destination is used to configure the properties of a JMS queue. Connections to the queue are created by the associated queue connection factory for the internal product JMS provider. A queue for use with the internal product JMS provider has the following properties.

Name:

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

Data type	String
------------------	--------

Description:

A description of the queue, for administrative purposes

Data type	String
Default	Null

JNDI Name:

The application client run time uses this field to retrieve configuration information. The name must match the value of the **Name** field on the General tab in the Application Client Resource Reference section of the Application Assembly Tool.

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

Data type	Enum
Units	Not applicable
Default	APPLICATION_DEFINED

Range

Application defined

Messages on the destination have their persistence defined by the application that put them onto the queue.

Queue defined

[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Persistent

Messages on the destination are persistent.

Non persistent

Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property

Data type
Units
Default
Range

Enum
Not applicable
APPLICATION_DEFINED
Application defined
The priority of messages on this destination is defined by the application that put them onto the destination.
Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
Specified
The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to Specified, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest)

If the **Priority** property is set to Specified, messages sent to this queue have the priority value specified by this property.

Data type
Units
Default
Range

Integer
Message priority level
Null
0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or whether messages on the queue expire (have an unlimited expiry timeout).

Data type
Units
Default

Enum
Not applicable
APPLICATION_DEFINED

Range**Application defined**

The expiry timeout for messages in this queue is defined by the application that put them onto the queue.

Specified

The expiry timeout for messages in this queue is defined by the **Specified expiry** property. If you select this option, you must define a time out on the **Specified expiry** property.

Unlimited

Messages in this queue have no expiry timeout, and those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to *Specified*, specify the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type

Integer

Units

Milliseconds

Default

Null

Range

Greater than or equal to 0

- 0 indicates that messages never timeout
- Other values are an integer number of milliseconds

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Version 5 Default Provider topic destination settings for application clients

Use this panel to view or change the configuration properties of the selected topic destination for use with the internal WebSphere Application Server product Java Messaging Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File > Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **JMS Providers > JMS provider instance**. Right click **WAS Topic Destinations** and click **New**. The following fields appear on the **General** tab.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. Connections to the topic are created by the associated topic connection factory. A topic used with the internal JMS provider has the following properties.

Name:

The name by which the topic is known for administrative purposes.

Data type

String

Description:

A description of the topic, for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

JNDI Name:

The application client run-time environment uses this field to retrieve configuration information. The name must match the value of the **Name** field on the General tab in the Application Client Resource Reference section of the Application Assembly Tool.

Topic Name: The name of the topic as defined to the JMS provider.

Data type	String
------------------	--------

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

Data type	Enum
Units	Not applicable
Default	APPLICATION_DEFINED
Range	Application defined Messages on the destination have their persistence defined by the application that put them onto the queue. Queue defined [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. Persistent Messages on the destination are persistent. Non persistent Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type	Enum
Units	Not applicable
Default	APPLICATION_DEFINED

Range**Application defined**

The priority of messages on this destination is defined by the application that put them onto the destination.

Queue defined

[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Specified

The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to Specified, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to Specified, messages sent to this queue have the priority value specified by this property.

Data type	Integer
Units	Message priority level
Default	Null
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

Data type	Enum
Units	Not applicable
Default	APPLICATION_DEFINED
Range	Application defined The expiry timeout for messages on this queue is defined by the application that put them onto the queue. Specified The expiry timeout for messages on this queue is defined by the Specified expiry property. <i>If you select this option, you must define a timeout on the Specified expiry property.</i> Unlimited Messages on this queue have no expiry timeout, so those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to Specified, type here the number of milliseconds (greater than 0) after which messages on this queue expire

Data type	Integer
Units	Milliseconds
Default	Null

Range

Greater than or equal to 0

- 0 indicates that messages never time out
- Other values are an integer number of milliseconds

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

WebSphere MQ Provider queue connection factory settings for application clients

Use this panel to view or change the configuration properties of the selected queue connection factory for use with the MQSeries product Java Messaging Service (JMS) provider. These configuration properties control how connections are created to the associated JMS queue destination.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File > Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **JMS Providers > JMS provider instance**. Right click **MQ Queue Connection Factories**, and click **New**. The following fields are displayed on the **General** tab.

A queue connection factory creates JMS connections to queue destinations. The queue connection factory is created by the MQSeries product JMS provider. A queue connection factory for the JMS provider has the following properties.

Note:

- The property values that you specify must match the values that you specified when configuring MQSeries for JMS resources. For more information about configuring MQSeries product JMS resources, see the MQSeries *Using Java* book, located in the WebSphere MQ Family library.
- In MQSeries, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type

String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type

String

Default

Null

JNDI Name:

The application client run time uses this field to retrieve configuration information. The name must match the value of the **Name** field on the General tab in the Application Client Resource Reference section of the Assembly Tool.

User:

The user ID used, with the **Password** property, for authentication if the calling application does not provide a userid and password explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a userid and password explicitly; for example, if the calling application uses the method `createQueueConnection()`. The JMS client flows the userid and password to the JMS server.

Data type String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a userid and password explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type String
Default Null

Re-Enter Password:

Confirms the password.

Queue Manager:

The name of the MQSeries queue manager for this connection factory.

Connections created by this factory connect to that queue manager.

Data type String

Host:

The name of the host on which the WebSphere MQ queue manager runs for client connection only.

Data type String
Default Null
Range A valid TCP/IP host name

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Data type	Integer
Default	Null
Range	A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Channel:

The name of the channel used for connection to the WebSphere MQ queue manager, for client connection only.

Data type	String
Default	Null
Range	1 through 20 ASCII characters

Transport type:

Specifies whether the WebSphere MQ client connection or JNI bindings are used for connection to the WebSphere MQ queue manager. The external JMS provider controls the communication protocols between JMS clients and JMS servers. Tune the transport type when you are using non-ASF nonpersistent, nondurable, nontransactional messaging or when you want to satisfy security issues and the client is local to the queue manager node.

Data type	Enum
Units	Not applicable
Default	BINDINGS
Range	BINDINGS JNI bindings are used to connect to the queue manager. BINDINGS is a shared memory protocol and can only be used when the queue manager is on the same node as the JMS client and poses security risks that should be addressed through the use of EJB roles. CLIENT WebSphere MQ client connection is used to connect to the queue manager. CLIENT is a typical TCP-based protocol. DIRECT For WebSphere MQ Event Broker using DIRECT mode. DIRECT is a lightweight sockets protocol used in nontransactional, nondurable and nonpersistent Publish/Subscribe messaging. DIRECT is only works for clients and message-driven beans using the non-ASF protocol. QUEUED QUEUED is a standard TCP protocol.

Recommended

Queue connection factory transport type

BINDINGS is faster by 30% or more, but it lacks security. When you have security concerns, BINDINGS is more desirable than CLIENT.

Topic connection factory transport type

DIRECT is the fastest type and should be used where possible. Use BINDINGS when you want to satisfy additional security tasks and the queue manager is local to the JMS client. QUEUED is the fallback for all other cases. WebSphere MQ 5.3 before CSD2 with the DIRECT setting can lose messages when used with message-driven beans and under load. This loss also happens with client-side applications unless the broker maxClientQueueSize is set to 0. You can set this to 0 with the command (shown on multiple line for publication):

```
#wempschangeproperties WAS_nodeName_server1 -e default -o
DynamicSubscriptionEngine -n maxClientQueueSize -v 0 -x executionGroupUUID
```

where executionGroupUUID can be found by starting the broker and looking in the Event Log/Applications for event 2201. This value is usually ffffffff-0000-0000-000000000000.

Client ID:

The JMS client identifier used for connections to the MQSeries queue manager.

Data type String

CCSID:

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type String

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These references are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at <http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html>, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

Message Retention:

Select this check box to specify that unwanted messages are to be left on the queue. Otherwise, unwanted messages are handled according to their disposition options.

Data type	Enum
Units	Not applicable
Default	Cleared
Range	Selected Unwanted messages are left on the queue.
	Cleared Unwanted messages are handled according to their disposition options.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

WebSphere MQ Provider topic connection factory settings for application clients

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the MQSeries product Java Messaging Service (JMS) provider. These configuration properties control how connections are created to the associated JMS topic destination.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File > Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **JMS Providers > JMS provider instance**. Right-click **MQ Topic Connection Factories** and click **New**.

A topic connection factory is used to create JMS connections to topic destinations. The topic connection factory is created by the MQSeries product JMS provider. A topic connection factory for the MQSeries product JMS provider has the following properties.

Note:

- The property values that you specify must match the values that you specified when configuring MQSeries product JMS resources. For more information about configuring MQSeries product JMS resources, see the MQSeries *Using Java* book.
- In MQSeries, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

Name:

The name by which this topic connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS provider.

Data type String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

Default Null

JNDI Name:

The Java Naming and Directory Interface (JNDI) name that is used to bind the topic connection factory into the application server name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Units	En_US ASCII characters
Default	Null
Range	1 through 45 ASCII characters

User:

The user ID used, with the **Password** property, for authentication if the calling application does not provide a userid and password explicitly.

If you specify a value for the **User** property, you must also specify a value for the **Password** property.

The connection factory **User** and **Password** properties are used if the calling application does not provide a userid and password explicitly, for example, if the calling application uses the method createTopicConnection(). The JMS client flows the userid and password to the JMS server.

Data type	String
------------------	--------

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a userid and password explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type	String
Default	Null

Re-Enter Password:

Confirms the password.

Queue Manager:

The name of the MQSeries queue manager for this connection factory. Connections created by this factory connect to that queue manager.

Data type	String
------------------	--------

Host:

The name of the host on which the WebSphere MQ queue manager runs for client connections only.

Data type	String
Default	Null
Range	A valid TCP/IP host name

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Data type	Integer
Default	Null
Range	A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Channel:

The name of the channel used for client connections to the WebSphere MQ queue manager for client connection only.

Data type	String
Default	Null
Range	1 through 20 ASCII characters

Transport Type:

Whether MQSeries client connection or JNDI bindings are used for connection to the MQSeries queue manager.

Data type	Enum
Units	Not applicable
Default	BINDINGS
Range	CLIENT MQSeries client connection is used to connect to the MQSeries queue manager. BINDINGS JNDI bindings are used to connect to the MQSeries queue manager.

Client ID:

The JMS client identifier used for connections to the MQSeries queue manager.

Data type	String
------------------	--------

CCSID:

The coded character set identifier to be used with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type	String
------------------	--------

Broker Control Queue:

The name of the broker control queue to which all command messages (except publications and requests to delete publications) are sent.

The name of the broker control queue. Publisher and subscriber applications as well as other brokers send all command messages (except publications and requests to delete publications) to this queue.

Data type	String
------------------	--------

Units	En_US ASCII characters
Default	Null
Range	1 through 48 ASCII characters

Broker Queue Manager:

The name of the MQSeries queue manager that provides the Publisher and Subscriber message broker.

Data type	String
Units	En_US ASCII characters
Default	Null
Range	1 through 48 ASCII characters

Broker Pub Queue:

The name of the broker input queue that receives all publication messages for the default stream

The name of the broker's input queue (stream queue) that receives all publication messages for the default stream. Applications can also send requests to delete publications on the default stream to this queue.

Data type	String
Units	En_US ASCII characters
Default	Null
Range	1 through 48 ASCII characters

Broker Sub Queue:

The name of the broker queue from which nondurable subscription messages are retrieved.

The name of the broker queue from which nondurable subscription messages are retrieved. The subscriber specifies the name of the queue when it registers a subscription.

Data type	String
Units	En_US ASCII characters
Default	Null
Range	1 through 48 ASCII characters

Broker CCSubQ:

The name of the broker queue from which nondurable subscription messages are retrieved for a ConnectionConsumer request. This property applies only for use of the Web container.

Data type	String
Units	En_US ASCII characters
Default	Null
Range	1 through 48 ASCII characters

Broker Version:

Specifies whether the message broker is provided by the MQSeries MA0C SupportPac or newer versions of WebSphere family message broker products.

Data type	Enum
Units	Not applicable
Default	Advanced
Range	<p>Advanced The message broker is provided by newer versions of WebSphere family message broker products (MQ Integrator and MQ Publish and Subscribe)</p> <p>Basic The message broker is provided by the MQSeries MA0C SupportPac (MQSeries - Publish and Subscribe)</p>

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

WebSphere MQ Provider queue destination settings for application clients

Use this panel to view or change the configuration properties of the selected queue destination for use with the MQSeries product Java Messaging Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File > Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **JMS Providers > JMS provider instance**. Right-click **MQ Queue Destinations** and click **New**. The following fields are displayed on the **General** tab.

A queue destination configures the properties of a JMS queue. Connections to the queue are created by the associated queue connection factory for the MQSeries product JMS provider. A queue for use with the MQSeries product JMS provider has the following properties.

Note:

- The property values that you specify must match the values that you specified when configuring MQSeries product JMS resources. For more information about configuring MQSeries product JMS resources, see the MQSeries *Using Java* book.
- In MQSeries, names can have a maximum of 48 characters.

Name:

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

Data type	String
------------------	--------

Description:

A description of the queue, for administrative purposes

Data type	String
Default	Null

JNDI Name:

The application client run-time environment uses this field to retrieve configuration information. The name must match the value of the **Name** field on the General tab in the Application Client Resource Reference section of the Application Assembly Tool.

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent or have their persistence defined by the application.

Data type	Enum
Units	Not applicable
Default	APPLICATION_DEFINED
Range	<p>Application defined Messages on the destination have their persistence defined by the application that put them onto the queue.</p> <p>Queue defined [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.</p> <p>Persistent Messages on the destination are persistent.</p> <p>Nonpersistent Messages on the destination are not persistent.</p>

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property

Data type	Enum
Units	Not applicable
Default	APPLICATION_DEFINED
Range	<p>Application defined The priority of messages on this destination is defined by the application that put them onto the destination.</p> <p>Queue defined [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.</p> <p>Specified The priority of messages on this destination is defined by the Specified priority property. <i>If you select this option, you must define a priority on the Specified priority property.</i></p>

Specified Priority:

If the **Priority** property is set to Specified, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

Data type	Integer
Units	Message priority level
Default	Null
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout value for this queue is defined by the application or the by **Specified expiry** property or whether messages on the queue never expire (have an unlimited expiry timeout).

Data type	Enum
Units	Not applicable
Default	APPLICATION_DEFINED
Range	Application defined The expiry timeout for messages on this queue is defined by the application that put them onto the queue. Specified The expiry timeout for messages on this queue is defined by the Specified expiry property. If you select this option, you must define a timeout on the Specified expiry property. Unlimited Messages on this queue have no expiry timeout and those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to **Specified**, type here the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type	Integer
Units	Milliseconds
Default	Null
Range	Greater than or equal to 0 <ul style="list-style-type: none">• 0 indicates that messages never time out• Other values are an integer number of milliseconds

Base Queue Name:

The name of the queue to which messages are sent, on the queue manager specified by the **Base queue manager name** property

Data type	String
------------------	--------

Base Queue Manager Name:

The name of the MQSeries queue manager to which messages are sent

This queue manager provides the queue specified by the **Base queue name** property.

Data type	String
Units	En_US ASCII characters
Default	Null
Range	A valid MQSeries Queue Manager name, as 1 through 48 ASCII characters

CCSID:

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSID identifier supported by WebSphere MQ queue manager.

Data type String

Integer encoding:

If native encoding is not enabled, select whether integer encoding is normal or reversed.

Data type Enum
Units Not applicable
Default NORMAL
Range **NORMAL**
Normal integer encoding is used.
REVERSED
Reversed integer encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Decimal encoding:

Indicates that if native encoding is not enabled to select whether decimal encoding is normal or reversed.

Data type Enum
Units Not applicable
Default NORMAL
Range **NORMAL**
Normal decimal encoding is used.
REVERSED
Reversed decimal encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Floating point encoding:

Indicates that if native encoding is not enabled to select the type of floating point encoding.

Data type Enum
Units Not applicable
Default IEEEENORMAL
Range **IEEEENORMAL**
IEEE normal floating point encoding is used.
IEEEEVERSED
IEEE reversed floating point encoding is used.
S390 S390 floating point encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Native encoding:

Indicates that the queue destination use native encoding (appropriate encoding values for the Java platform) when you select this check box.

Data type
Units
Default
Range

Enum
Not applicable
Cleared
Cleared

Native encoding is not used, so specify the following properties for integer, decimal and floating point encoding.

Selected

Native encoding is used (to provide appropriate encoding values for the Java platform).

For more information about encoding properties, see the MQSeries *Using Java* document.

Target client:

Whether the receiving application is JMS-compliant or is a traditional WebSphere MQ application

Data type
Units
Default
Range

Enum
Not applicable
MQSeries
MQSeries

The target is a traditional WebSphere MQ application that does not support JMS.

JMS

The target application supports JMS.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

WebSphere MQ Provider topic destination settings for application clients

Use this panel to view or change the configuration properties of the selected topic destination for use with the MQSeries product Java Messaging Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File > Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **JMS Providers > JMS provider instance**. Right click **MQ Topic Destinations**, and click **New**. The following fields are displayed on the **General** tab.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. Connections to the topic are created by the associated topic connection factory. A topic for use with the MQSeries product JMS provider has the following properties.

Note:

- The property values that you specify must match the values that you specified when configuring MQSeries product JMS resources. For more information about configuring MQSeries product JMS resources, see the MQSeries *Using Java* book.
- In MQSeries, names can have a maximum of 48 characters.

Name:

The name by which the topic is known for administrative purposes.

Data type String

Description:

A description of the topic for administrative purposes within IBM WebSphere Application Server.

JNDI Name:

The application client run time uses this field to retrieve configuration information. The name must match the value of the **Name** field on the General tab in the Application Client Resource Reference section of the Application Assembly Tool.

Persistence:

Specifies whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Data type	Enum
Units	Not applicable
Default	APPLICATION_DEFINED
Range	Application defined Messages on the destination have their persistence defined by the application that put them in the queue. Queue defined [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. Persistent Messages on the destination are persistent. Nonpersistent Messages on the destination are not persistent.

Priority:

Specifies whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type	Enum
Units	Not applicable
Default	APPLICATION_DEFINED
Range	Application defined The priority of messages on this destination is defined by the application that put them in the destination. Queue defined [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. Specified The priority of messages on this destination is defined by the Specified priority property. If you select this option, you must define a priority for the Specified priority property.

Specified Priority:

If the **Priority** property is set to *Specified*, type the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to *Specified*, messages sent to this queue have the priority value specified by this property.

Data type	Integer
Units	Message priority level
Default	Null
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or by the **Specified expiry** property or by messages on the queue never expire (have an unlimited expiry timeout).

Data type	Enum
Units	Not applicable
Default	APPLICATION_DEFINED
Range	Application defined The expiry timeout for messages on this queue is defined by the application that put them in the queue. Specified The expiry timeout for messages in this queue is defined by the Specified expiry property. If you select this option, you must define a timeout value for the Specified expiry property. Unlimited Messages on this queue have no expiry timeout, and these messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to *Specified*, type the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type	Integer
Units	Milliseconds
Default	Null
Range	Greater than or equal to 0 <ul style="list-style-type: none">• 0 indicates that messages never time out• Other values are an integer number of milliseconds

Base Topic Name:

The name of the topic to which messages are sent.

Data type	String
------------------	--------

CCSID:

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSID identifiers that WebSphere MQ supports.

Data type String

Integer encoding:

Indicates whether integer encoding is normal or reversed when native encoding is not enabled.

Data type	Enum
Units	Not applicable
Default	NORMAL
Range	NORMAL Normal integer encoding is used. REVERSED Reversed integer encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Decimal encoding:

If native encoding is not enabled, select whether decimal encoding is normal or reversed.

Data type	Enum
Units	Not applicable
Default	NORMAL
Range	NORMAL Normal decimal encoding is used. REVERSED Reversed decimal encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Floating point encoding:

Indicates the type of floating point encoding when native encoding is not enabled.

Data type	Enum
Units	Not applicable
Default	IEEEENORMAL
Range	IEEEENORMAL IEEE normal floating point encoding is used. IEEEEVERSED IEEE reversed floating point encoding is used. S390 S/390 floating point encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Native encoding:

Indicates that the queue destination uses native encoding (appropriate encoding values for the Java platform) when you select this check box.

Data type	Enum
Units	Not applicable
Default	Cleared
Range	<p>Cleared Native encoding is not used, so specify the previous properties for integer, decimal and floating point encoding.</p> <p>Selected Native encoding is used (to provide appropriate encoding values for the Java platform).</p> <p>For more information about encoding properties, see the MQSeries <i>Using Java</i> document.</p>

BrokerDurSubQueue:

The name of the broker queue from which durable subscription messages are retrieved.

The subscriber specifies the name of the queue when it registers a subscription.

Data type	String
Units	En_US ASCII characters
Default	Null
Range	1 through 48 ASCII characters

BrokerCCDurSubQueue:

The name of the broker queue from which durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the Web container.

Data type	String
Units	En_US ASCII characters
Default	Null
Range	1 through 48 ASCII characters

Target Client:

Specifies whether the receiving application is JMS compliant or is a traditional MQSeries application.

Data type	Enum
Units	Not applicable
Default	MQSeries
Range	<p>MQSeries The target is a traditional MQSeries application that does not support JMS.</p> <p>JMS The target is a JMS compliant application.</p>

Custom Properties:

Specifies the name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Generic JMS connection factory settings for application clients

Use this panel to view or change the configuration properties of the selected JMS connection factory for use with the associated JMS provider. These configuration properties control how connections are created to the associated JMS destination.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File > Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **JMS Providers > new_JMS_Provider_instance**. Right click **JMS Connection Factories**, and click **New**. The following fields are displayed on the **General** tab.

A Java Message Service (JMS) connection factory creates connections to JMS destinations. The JMS connection factory is created by the associated JMS provider. A JMS connection factory for a generic JMS provider (other than the internal WebSphere product JMS provider or the MQSeries product JMS provider) has the following properties:

Name:

The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the associated JMS provider.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

Default Null

JNDI Name:

The application client run time uses this field to retrieve configuration information. The name must match the value of the **Name** field on the General tab in the Application Client Resource Reference section of the Application Assembly Tool.

User:

Indicates the user ID used with the **Password** property, for authentication if the calling application does not provide a userid and password explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a userid and password explicitly; for example, if the calling application uses the method `createQueueConnection()`. The JMS client flows the userid and password to the JMS server.

Data type String

Password:

The password used with the **User ID** property for authentication if the calling application does not provide a userid and password explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type	String
Default	Null

Re-Enter Password:

Confirms the password entered in the **Password** field.

External JNDI Name:

The JNDI name that is used to bind the queue into the application server name space.

As a convention, use the fully qualified JNDI name, for example, *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI API by the platform.

Data type	String
------------------	--------

Connection Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for pub/sub).

Select one of the following options:

Queue

A JMS queue destination for point-to-point messaging.

Topic A JMS topic destination for publish subscribe messaging.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Generic JMS destination settings for application clients

Use this panel to view or change the configuration properties of the selected JMS destination for use with the associated JMS provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File > Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **JMS Providers > new JMS Provider instance**. Right-click **JMS Destinations**, and click **New**. The following fields are displayed on the **General** tab.

A JMS destination is used to configure the properties of a JMS destination for the associated generic JMS provider. Connections to the JMS destination are created by the associated JMS connection factory. A JMS destination for use with a generic JMS provider (not the internal WebSphere product JMS provider or MQSeries product JMS provider) has the following properties.

Name:

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

Data type String

Description:

A description of the queue, for administrative purposes

JNDI Name:

The JNDI name of the actual (physical) name of the JMS destination bound into JNDI.

External JNDI Name:

The JNDI name that is used to bind the queue into the application server name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Destination Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publishing and subscribing).

Select one of the following options:

Queue

A JMS queue destination for point-to-point messaging.

Topic A JMS topic destination for pub/sub messaging.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring JMS provider, JMS connection factory and JMS destination settings for application clients

The purpose of this article is to help you to configure JMS Provider, JMS Connection Factory and JMS Destination settings.

- Required fields:
 - JMS Provider Properties page: name, and at least one protocol provider
 - JMS Connection Factory Properties page: name, jndiName, destination type
 - JMS Destination Properties page: name, jndiName, destination type
- Special cases:
 - The destination type must be QUEUE, or TOPIC.
- Example:

```

<resources.jms:JMSProvider xmi:id="JMSProvider_3" name="genericJMSProvider:name"
description="genericJMSProvider:description"
externalInitialContextFactory="genericJMSProvider:contextFactoryClass"
externalProviderURL="genericJMSProvider:providerUrl">
<classpath>genericJMSProvider:classpath</classpath>
<factories xmi:type="resources.jms:GenericJMSDestination"
xmi:id="GenericJMSDestination_1" name="jmsDestination:name"
jndiName="jmsDestination:jndiName" description="jmsDestination:description"
externalJNDIName="jmsDestination:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_15">
<resourceProperties xmi:id="J2EEResourceProperty_17" name="jmsDestination:customName"
value="jmsDestination:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms:GenericJMSConnectionFactory"
xmi:id="GenericJMSConnectionFactory_1" name="jmsCF:name" jndiName="jmsCF:jndiName"
description="jmsCF:description" userID="jmsCF:user" password="{xor}NTIsHB11MT4y0g=="
externalJNDIName="jmsCF:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_16">
<resourceProperties xmi:id="J2EEResourceProperty_18" name="jmsCF:customName"
value="jmsCF:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_17">
<resourceProperties xmi:id="J2EEResourceProperty_19"
name="genericJMSProvider:customName" value="genericJMSProvider:customValue"/>
</propertySet>
</resources.jms:JMSProvider>

```

Configuring new connection factories for application clients

During this task, you create a new Java Messaging Service (JMS) connection factory configuration for your application client.

1. Click the JMS provider for which you want to create a connection factory in the tree. Complete one of the following actions:
 - Configure a new JMS provider.
 - Click an existing JMS provider.
2. Expand the JMS provider to view its **JMS Connection Factories** folder.
3. Click the connection factory folder, and complete one of the following actions:
 - Right-click the folder and select **New Factory**.
 - Click **Edit > New** on the menu bar.
4. Configure the JMS connection factory properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Configuring new Java Message Service destinations for application clients

During this task, you create a new Java Message Service (JMS) destination configuration for your application client.

1. Click the JMS provider in the tree for which you want to create a destination. Complete one of the following actions:
 - Configure a new JMS provider.
 - Click an existing JMS provider.
2. Expand the JMS provider to view its **JMS Destinations** folder.
3. Click the provider folder, and complete one of the following actions:
 - Right-click the folder and select **New Factory**.

- Click **Edit > New** on the menu bar.
- 4. Configure the JMS destination properties in the displayed fields.
- 5. Click **OK** when you finish.
- 6. Click **File > Save** on the menu bar to save your changes.

Example: Configuring MQ Queue and Topic connection factories and destination factories for application clients

The purpose of this article is to help you configure MQ Queue connection factory, MQ Topic connection factory, MQ Queue destination factory, and MQ Topic destination factory settings.

- Required fields:
 - MQ Queue Connection Factory Properties page: name, jndiName and transport type
 - MQ Topic Connection Factory Properties page: name, jndiName and broker Version
 - MQ Queue Factory Properties page: name, jndiName, persistence, priority, expiry, baseQueueName and targetClient
 - MQ Topic Factory Properties page: name, jndiName, persistence, priority, expiry, baseQueueName and targetClient
- Special cases:
 - The transport type must be CLIENT, or BINDINGS.
 - The Broker Version must be MA0C, or MQSI.
 - The port must be a numerical value between -2417483648 and 2417483647.
 - The CCSID must be a numerical value between -2417483648 and 2417483647.
 - The persistence value must be APPLICATION_DEFINED, QUEUE_DEFINED, PERSISTENT or, NONPERSISTENT.
 - The priority must be APPLICATION_DEFINED, QUEUE_DEFINED, or SPECIFIED.
 - The expiry must be APPLICATION_DEFINED, UNLIMITED, or SPECIFIED.
 - The integer encoding must be Normal, or Reversed.
 - The decimal encoding must be Normal, or Reversed.
 - The floating encoding must be IEEENormal, IEEEReversed or S390.
 - The target client must be JMS or MQ.
 - On the MQ Queue Connection Factory Properties page, only set the queueManager, host, and port values. These are required fields if the transport type is CLIENT.
 - On the MQ Topic Connection Factory Properties page, only set the queueManager, host, and port (required) fields if the transport type is CLIENT.
 - On the MQ Topic Factory Properties, and the MQ Queue Factory Properties pages, only set the Integer encoding, decimal encoding, and floating point encoding (required) fields if you do not set the nativeEncoding value.
 - On the MQ Topic Factory Properties and the MQ Queue Factory Properties pages, the specified priority entry field must be an integer between 0 and 9 if priority is set to SPECIFIED .
 - On the MQ Topic Factory Properties and the MQ Queue Factory Properties pages, the specified expiry entry field must be a value greater than 0 if the expiry value is set to SPECIFIED.
- Example:

```
<resources.jms:JMSProvider xmi:id="JMSProvider_1" name="MQ JMS Provider"
description="mqJMSProvider:description"
externalInitialContextFactory="mqJMSProvider:contextFactoryClass"
externalProviderURL="mqJMSProvider:providerUrl">
<classpath>mqJMSProvider:classpath</classpath>
<factories xmi:type="resources.jms.mqseries:MQQueueConnectionFactory"
xmi:id="MQQueueConnectionFactory_1" name="mqQCF:name" jndiName="mqQCF:jndiName"
description="mqQCF:description" userID="mqQCF:user" password="{xor}Mi40HB1lMT4y0g=="
queueManager="mqQCF:queueManager" host="mqQCF:host" port="1" channel="mqQCF:channel"
transportType="CLIENT" clientID="mqQCF:clientId" CCSID="2">
<propertySet xmi:id="J2EEResourcePropertySet_3">
<resourceProperties xmi:id="J2EEResourceProperty_3" name="mqQCF:customName"
value="mqQCF:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms.mqseries:MQTopicConnectionFactory"
xmi:id="MQTopicConnectionFactory_1" name="mqTCF:name" jndiName="mqTCF:jndiName">
```

```

description="mqTCF:description" userID="mqTCF:user"
password="{xor}Mi4LHB1lNTE7NhE+Mjo=" host="mqTCF:host" port="1"
transportType="CLIENT" channel="mqTCF:channel" queueManager="mqTCF:queueManager"
brokerControlQueue="mqTCF:brokerControlQueue"
brokerQueueManager="mqTCF:brokerQueueManager" brokerPubQueue="mqTCF:brokerPubQueue"
brokerSubQueue="mqTCF:brokerSubQueue" brokerCCSubQ="mqTCF:brokerCCSubQ"
brokerVersion="MAQC" clientID="mqTCF:clientId" CCSID="2">
<propertySet xmi:id="J2EEResourcePropertySet_4">
<resourceProperties xmi:id="J2EEResourceProperty_4" name="mqTCF:customName"
value="mqTCF:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms.mqseries:MQQueue" xmi:id="MQQueue_1" name="mqQ:name"
jndiName="mqQ:jndiName" description="mqQ:description" persistence="APPLICATION_DEFINED"
priority="SPECIFIED" specifiedPriority="1" expiry="SPECIFIED" specifiedExpiry="1"
baseQueueName="mqQ:baseQueueName" baseQueueManagerName="mqQ:baseQueueManagerName"
CCSID="1" integerEncoding="Normal" decimalEncoding="Normal"
floatingPointEncoding="IEEENormal" targetClient="JMS">
<propertySet xmi:id="J2EEResourcePropertySet_5">
<resourceProperties xmi:id="J2EEResourceProperty_5" name="mqQ:customName"
value="mqQ:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms.mqseries:MQTopic" xmi:id="MQTopic_1"
name="mqT:name" jndiName="mqT:jndiName" description="mqT:description"
persistence="APPLICATION_DEFINED" priority="SPECIFIED" specifiedPriority="1"
expiry="SPECIFIED" specifiedExpiry="2" baseTopicName="mqT:baseTopicName" CCSID="3"
integerEncoding="Normal" decimalEncoding="Normal" floatingPointEncoding="IEEENormal"
targetClient="JMS" brokerDurSubQueue="mqT:brokerDurSubQueue"
brokerCCDurSubQueue="mqT:brokerCCDurSubQueue">
<propertySet xmi:id="J2EEResourcePropertySet_6">
<resourceProperties xmi:id="J2EEResourceProperty_6" name="mqT:customName"
value="mqT:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_7">
<resourceProperties xmi:id="J2EEResourceProperty_7" name="mqJMSProvider:customName"
value="mqJMSProvider:customValue"/>
</propertySet>
</resources.jms:JMSProvider>

```

Example: Configuring WAS Queue and Topic connection factories and destination factories for application clients

The purpose of this article is to help you configure WAS Queue connection factory, WAS Topic connection factory, WAS Queue destination factory, and WAS Topic destination factory settings.

- Required fields:
 - JMS Provider Properties page: name
 - WAS Queue Connection Factory Properties page: name, jndiName and node
 - WAS Topic Connection Factory Properties page: name, jndiName, node and port
 - WAS Queue Factory Properties page: name, jndiName, node, persistence, priority and expiry
 - WAS Topic Factory Properties page: name, jndiName, topic name, persistence, priority and expiry
- Special cases:
 - The port value must be QUEUED or DIRECT.
 - The CCSID must be a numerical value between -2417483648 and 2417483647.
 - The persistence value must be APPLICATION_DEFINED, PERSISTENT, or NONPERSISTENT.
 - The priority value must be APPLICATION_DEFINED, or SPECIFIED.
 - The expiry value must be APPLICATION_DEFINED, UNLIMITED, or SPECIFIED.
 - On the WAS Topic Factory Properties, and the WAS Queue Factory Properties pages, the specified priority entry field must be an integer between 0 and 9, if the priority value is set to SPECIFIED .
 - On the WAS Topic Factory Properties, and the WAS Queue Factory Properties pages, the specified expiry entry field must be a value greater than 0 if expiry is set to SPECIFIED.
- Example:

```

<resources.jms:JMSProvider xmi:id="JMSProvider_2" name="WebSphere JMS Provider"
description="wasJMSProvider:description"
externalInitialContextFactory="wasJMSProvider:contextfactoryclass"
externalProviderURL="wasJMSProvider:providerURL">
<classpath>wasJMSProvider:classpath</classpath>
<factories xmi:type="resources.jms.internalmessaging:WASQueueConnectionFactory"
xmi:id="WASQueueConnectionFactory_1" name="wasQCF:name" jndiName="wasQCF:jndiName"
description="wasQCF:description" userID="wasQCF:user" password="{xor}KD4sDhwZZSos0i0="
node="wasQCF:Node">
<propertySet xmi:id="J2EEResourcePropertySet_8">

</propertySet>
</resources.jms:JMSProvider>

```

Configuring new resource environment providers for application clients

During this task, you create new resource environment provider configurations for your application client.

To configure a new resource environment provider, perform the following steps:

1. Start the tool and open the EAR file for which you want to configure the new Java Message Service (JMS) provider. The EAR file contents display in a tree view.
2. Select from the tree the JAR file in which you want to configure the new JMS provider.
3. Expand the JAR file to view its contents.
4. Click the **Resource Environment Providers** folder. Take one of the following actions:
 - Right-click the provider folder, and click **New Provider**.
 - Click **Edit > New** on the menu bar.
5. Configure the JMS provider properties in the displayed fields.

6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

Resource environment provider settings for application clients

Use this page to specify resource environment entry properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File > Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right-click **Resource Environment Providers**, and click **New**. The following fields are displayed on the **General** tab:

Name:

Specifies the administrative name for the resource environment provider.

Description:

Specifies a description of the resource environment provider for your administrative records.

Class Path:

Specifies the path to the JAR file that contains the implementation classes for the resource environment provider.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring new resource environment entries for application clients

During this task, you create new resource environment entries for your client application.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new resource environment entry. The EAR file contents are in the displayed tree view.
3. Click the desired resource environment provider, and complete the following action to configure new providers:
 - Configure a new resource environment provider.
4. Expand the resource environment provider to view the **resource environment entries** folder.
5. Click the provider folder, and complete one of the following actions:
 - Right-click the folder and select **New Factory**.
 - Click **Edit > New** on the menu bar.
6. Configure the data source properties in the displayed fields.
7. Click **OK**.
8. Click **File > Save** on the menu bar to save your changes.

Resource environment entry settings for application clients

Use this page to specify resource environment entry properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File > Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Environment Providers > resource environment instance**. Right-click **Resource environment entry**, and click **New**. The following fields appear on the **General** tab:

Name:

Specifies the administrative name for the resource environment entry.

Description:

Specifies a description of the URL for your administrative records.

JNDI Name:

Specifies the Java Naming and Directory Interface (JNDI) name for the resource, including any naming subcontexts.

Use this name to link to the binding information of the platform. The binding associates the resources defined in the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Managing application clients

Perform the following tasks after deploying application clients. This task only applies to J2EE application clients.

1. Update data source and data source provider configurations.
2. Update URLs and URL provider configurations.
3. Update mail session configurations.
4. Update JMS provider, connection factories, and destination configurations.
5. Update MQ JMS provider, MQ connection factories, and MQ destination configurations.
6. Update Resource Environment Entry and Resource Environment Provider configurations.
7. (Optional) Remove application client resources.

Updating data source and data source provider configurations with the Application Client Resource Configuration Tool

During this task, you update the configuration of an existing data source or data source provider.

1. Start the tool and open the Enterprise Archive (EAR) file containing the data source or data source provider. The EAR file contents display in a tree view.
2. Select Java Archive (JAR) file from the navigation tree containing the data source or data source provider to update.

3. Expand the JAR file to view its contents until you locate the particular data source or data source provider to update. Take one of the following actions:
 - Right-click the data source object and click **Properties**.
 - Click **Edit > Properties** on the menu bar.
4. Update the properties in the displayed fields. For detailed field help, go to:
 - Data source provider properties
 - Data source properties
5. Click **OK** when finished.
6. Click **File > Save** on the menu bar to save your changes.

Updating URLs and URL provider configurations for application clients

1. Start the tool and open the Enterprise Archive (EAR) file containing the URL or URL provider. The EAR file contents are displayed in a tree view.
2. Select from the tree the Java Archive (JAR) file containing the URL or URL provider to update.
3. Expand the JAR file to view its contents.
4. Keep expanding the JAR file contents until you locate the particular URL or URL provider to update. Take one of the following actions:
 - a. Right-click the URL object and click **Properties**.
 - b. Click **Edit > Properties** on the menu bar.
5. Update the properties in the displayed fields.
6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

Updating mail session configurations for application clients

During this task, you update the configuration of an existing JavaMail session. You cannot update the name of the default JavaMail provider, and you cannot delete the default JavaMail provider from the navigation tree.

1. Start the tool and open the Enterprise Archive (EAR) file containing the JavaMail session. The EAR file contents are displayed in the navigation tree view.
2. Select the Java Archive (JAR) file containing the JavaMail session to update from the navigation tree.
3. Expand the JAR file to view its contents.
4. Keep expanding the JAR file contents until you locate the particular JavaMail session to update. Take one of the following actions:
 - a. Right-click the object and click **Properties**
 - b. Click **Edit > Properties** from the menu bar.
5. Update the properties in the displayed fields.
6. Click **OK** when you finish.
7. Select **File > Save** from the menu bar to save your changes.

Updating Java Message Service provider, connection factories, and destination configurations for application clients

During this task, you update the configuration of an existing Java Message Service (JMS) provider, connection factory or destination.

1. Start the tool and open the Enterprise Archive (EAR) file containing the Java Message Service (JMS) provider, connection factory, or destination. The EAR file contents display in a tree view.
2. Select the Java Archive (JAR) file containing the JMS provider, connection factory, or destination to update from the navigation tree.

3. Expand the JAR file to view its contents until you locate the particular JMS provider, connection factory, or destination to update. When you find it, do one of the following actions:
 - Right-click the provider, and click **Properties**.
 - Click **Edit > Properties** on the menu bar.
4. Update the properties in the displayed fields. For detailed field help, see:
 - JMS provider properties
 - WAS Queue connection factory properties
 - WAS Topic connection factory properties
 - WAS Queue destination properties
 - WAS Topic destination properties
5. Click **OK**.
6. Click **File > Save** to save your changes.

Updating MQ Java Message Service provider, MQ connection factories, and MQ destination configurations for application clients

During this task, you update the configuration of an existing MQ JMS provider, MQ connection factory, or MQ destination.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the Enterprise Archive (EAR) file containing the MQ JMS provider, MQ connection factory, or MQ destination. The EAR file contents are displayed in the navigation tree view.
3. Select the Java Archive (JAR) file containing the MQ JMS provider, MQ connection factory, or MQ destination to update.
4. Expand the JAR file to view its contents until you locate the particular MQ product JMS provider, MQ connection factory or MQ destination that you want to update. Complete one of the following actions:
 - Right-click the appropriate object and click **Properties**.
 - Click **Edit > Properties** on the menu bar.
5. Update the properties in the displayed fields. For detailed field help, see:
 - JMS provider properties
 - MQ Queue connection factory properties
 - MQ Topic connection factory properties
 - MQ Queue destination properties
 - MQ Topic destination properties
6. Click **OK**.
7. Click **File > Save** to save your changes.

Updating resource environment entry and resource environment provider configurations for application clients

During this task, you update the configuration of an existing resource environment entry or resource environment provider.

1. Start the tool and open the Enterprise Archive (EAR) file containing the resource environment entry or resource environment provider. The EAR file contents display in a navigation tree view.
2. Select from the tree the Java Archive (JAR) file containing the resource environment entry or resource environment provider to update.
3. Expand the JAR file to view its contents until you locate the resource environment entry or resource environment provider to update. Take one of the following actions:
 - Right-click the resource environment object, and click **Properties**.
 - Click **Edit > Properties** on the menu bar.
4. Update the properties in the displayed fields. For detailed field help, see:
 - Resource environment provider properties

- Resource environment entry properties
5. Click **OK** when you finish.
 6. Click **File > Save** on the menu bar to save your changes.

Example: Configuring Resource Environment settings

The purpose of this topic is to help you configure Resource Environment settings.

- Required fields:
 - Resource Environment Provider page: name
 - Resource Environment Entry page: name, jndiName
- Example:

```
<resources.env:ResourceEnvironmentProvider xmi:id="ResourceEnvironmentProvider_1"
name="resourceEnvProvider:name" description="resourceEnvProvider:description">
<classpath>resourceEnvProvider:classpath</classpath>
<factories xmi:type="resources.env:ResourceEnvEntry" xmi:id="ResourceEnvEntry_1"
name="resourceEnvEntry:name" jndiName="resourceEnvEntry:jndiName"
description="resourceEnvEntry:description">
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_21">
<resourceProperties xmi:id="J2EEResourceProperty_23"
name="resourceEnvProvider:customName" value="resourceEnvProvider:customValue"/>
</propertySet>
</resources.env:ResourceEnvironmentProvider>
```

Example: Configuring resource environment custom settings for application clients

The purpose of this topic is to help you configure resource environment custom settings.

- The custom page applies to every resource type. You can specify as many custom names and values as you need.
- Example:

```
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
```

Removing application client resources

The option to delete an item does not offer a confirmation dialog. As a safeguard, consider saving your work right before you begin this task. If you change your mind after removing an item, you can close the EAR file without saving your changes, canceling your deletion. Remember to close the EAR file immediately after the deletion, or you also lose any unsaved work that you performed since the deletion.

This task only applies to J2EE application clients.

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the Enterprise Archive (EAR) file from which you want to remove an object. The EAR file contents display in the navigation tree view. If you already have an EAR file open and have made some changes, click **File > Save** to save your work before proceeding to delete an object.
2. Locate the object that you want to remove in the tree.
3. Right-click the object, and click **Delete**.
4. Click **File > Save**.

Running application clients

The J2EE specification requires support for a client container that runs stand-alone Java applications (known as J2EE application clients) and provides J2EE services to the applications. J2EE services include naming, security, and resource connections.

You are ready to run your application client using this tool after you have:

1. Written the application client program.
2. Assembled and installed an application module (.ear file) in the application server run time.
3. Deployed the application using the Application Client Resource Configuration Tool (ACRCT).

This task only applies to J2EE application clients.

1. Open a command window and invoke the following script to launch J2EE application clients using the `launchClient` shell:

```
install_root/bin/launchClient.bat
```

The `launchClient` batch command starts the application client run time, which:

- Initializes the client run time.
- Loads the class that you designated as the main class with the Assembly Toolkit.
- Runs the main method of the application client program.

When your program terminates, the application client run time cleans up the environment and the Java virtual machine (JVM) code ends.

2. Pass parameters to the `launchClient` command or to your application client program as well. The `launchClient` command allows you to do both. The `launchClient` command requires that the first parameter is either:

- An EAR file specifying the application client to launch.
- A request for `launchClient` usage information.

All other parameters intended for the `launchClient` command must begin with the `-CC` prefix.

Parameters that are not EAR files, or usage requests, or that do not begin with the `-CC` prefix, are ignored by the application client run time, and are passed directly to the application client program.

The `launchClient` command retrieves parameters from three places:

- The command line
- A properties file
- System properties

The parameters are resolved in the order listed above, with command line values having the highest priority and system properties the lowest. Using this prioritization you can set and override default values.

3. Specify the server name. By default, the **launchClient** command uses the environment variable `COMPUTERNAME` for the `BootstrapHost` property value. This setting is effective for testing your application client when it is installed on the same computer as the server. However, in other cases override this value with the name of your server.

You can override the `BootstrapHost` value by invoking `launchClient` command with the following parameters:

```
launchClient myapp.ear -CCBootstrapHost=abc.midwest.mycompany.com
```

You can also override the default by specifying the value in a properties file and passing the file name to the `launchClient` shell.

Security is controlled by the server. You do not need to configure security on the client because the client assumes that security is enabled. If security is not enabled, the server ignores the security request, and the application client works as expected.

You can store `launchClient` values in a properties file, which is a good method for distributing default values. You can then override one or more values on the command line. The format of the file is one `launchClient -CC` parameter per line without the `-CC` prefix. For example:

```
verbose=true classpath=c:\mydir\util.jar;c:\mydir\harness.jar;c:\production\G19
\global.jar BootstrapHost=abc.westcoast.mycompany.com tracefile=c:\WebSphere\mylog.txt
```

launchClient tool

This section describes the Java 2 Platform Enterprise Edition (J2EE) command line syntax for the launchClient tool for WebSphere Application Server.

The following example illustrates the command line invocation syntax for the launchClient tool:

```
launchClient [<userapp.ear>] [-help|-?] [-CCname=value] [app args]
```

where

- *userapp.ear* is the path and the name of the EAR file that contains the application client
- *name* is the name of the parameter
- *value* is the value to which the parameter ID is set
- *app args* are arguments that pass to the application client

To print the usage information, the first parameter must be a path and a name to an Enterprise Archive (EAR) file, -help, or -?. All other parameters are optional and can appear in any order. The application client run time ignores any optional parameters that do not begin with a -CC prefix, and passes them to the application client.

Parameters

Supported arguments include:

-CCsoapConnectorPort

The Simple Object Access Protocol (SOAP) connector port. If you do not specify this argument, the WebSphere Application Server default value is used.

-CCverbose

This option displays additional information messages. The default is false.

-CCclasspath

A class path value. When you launch an application, the system class path is not used. If you want to access classes that are not in the EAR file or part of the resource class paths, specify the appropriate class path here. Multiple paths can be concatenated.

-CCjar

The name of the client Java Archive (JAR) file that resides within the EAR file for the application you wish to launch. Use this argument when you have multiple client JAR files in the EAR file.

-CCadminConnectorHost

Specifies the host name of the server from which configuration information is retrieved. The default is the value of the -CCBootstrapHost parameter or the value of the local host if the -CCBootstrapHost parameter is not specified.

-CCadminConnectorPort

Indicates the port number for the administrative client function to use. The default value is 8880 for SOAP connections and 2809 for Remote Method Invocation (RMI) connections.

-CCadminConnectorType

Specifies how the administrative client connects to the server. Specify RMI to use the RMI connection type, or specify SOAP to use the SOAP connection type. The default value is SOAP.

-CCadminConnectorUser

Administrative clients use this user name when a server requires authentication. If the connection type is SOAP, and security is enabled on the server, this parameter is required. The SOAP connector does not prompt for authentication.

-CCadminConnectorPassword

The password for the user name that the `-CCadminConnectorUser` parameter specifies.

-CCaltDD

The name of an alternate deployment descriptor file. This parameter is used with the `-CCjar` parameter to specify the deployment descriptor to use. Use this argument when a client JAR file is configured with more than one deployment descriptor. Set the value to `null` to use the client JAR file standard deployment descriptor.

-CCbootstrapHost

The name of the host server you want to connect to initially. The format is:

your_server_of_choice.com

-CCbootstrapPort

The server port number. If you do not specify this argument, the WebSphere Application Server default value is used.

-CCproviderURL

Provides bootstrap server information that the initial context factory can use to obtain an initial context. WebSphere Application Server initial context factory can use either a Common Object Request Broker Architecture (CORBA) object URL or an Internet Inter-ORB Protocol (IIOP) URL. CORBA object URLs are more flexible than IIOP URLs and are the recommended URL format to use. This value can contain more than one bootstrap server address. This feature can be used when attempting to obtain an initial context from a server cluster. You can specify bootstrap server addresses, for all servers in the cluster, in the URL. The operation will succeed if at least one of the servers is running, eliminating a single point of failure. The address list does not process in a particular order. For naming operations, this value overrides the `-CCbootstrapHost` and `-CCbootstrapPort` parameters. A CORBA object URL specifying multiple systems is illustrated in the following example:

```
-CCproviderURL=corbaloc:iiop:myserver.mycompany.com:9810,:mybackupserver.mycompany.com:2809
```

This value is mapped to the `java.naming.provider.url` system property.

-CCinitonly

Use this option to initialize application client run time for ActiveX application clients without launching the client application. The default is `false`.

-CCtrace

Use this option to obtain debug trace information. You might need this information when reporting a problem to IBM customer support. The default is `false`.

-CCtracefile

Indicates the name of the file to which trace information is written. The default is to write output to the console.

-CCpropfile

Indicates the name of a properties file that contains `launchClient` properties. Specify the properties without the `-CC` prefix in the file. For example: `verbose=true`.

-CCsecurityManager

Enables and runs the WebSphere Application Server with a security manager. The default is `disable`.

-CCsecurityMgrClass

Indicates the fully qualified name of a class that implements a security manager. Only use this argument if the `-CCsecurityManager` parameter is set to `enable`. The default is `java.lang.SecurityManager`.

-CCsecurityMgrPolicy

Indicates the name of a security manager policy file. Only use this argument if the `-CCsecurityManager` parameter is set to `enable`. When you enable this parameter, the `java.security.policy` system property is set. The default is `<install_root>/properties/client.policy`.

-CCD

Use this option to have the WebSphere Application Server set the specified system property during initialization. Do not use the equals (=) character after the -CCD. For example:

-CCDcom.ibm.test.property=testvalue. You can specify multiple -CCD parameters. The general format of this parameter is -CCD<property key>=<property value>.

-CCexitVM

Use this option to have the WebSphere Application Server call the System.exit() method after the client application completes. The default is false.

-CCdumpJavaNameSpace

Prints out the Java portion of the Java Naming and Directory Interface (JNDI) name space for WebSphere Application Server. The true value uses the short format that prints out the binding name and the type of the object bound at that location. The long value uses the long format that prints out the binding name, bound object type, local object, type and string representation of the local object, for example, IORs and string values. The default value is false.

-CCtraceMode

Specifies the trace format to use for tracing. If the valid value, basic, is not specified the default is advanced. Basic tracing format is a more compact form of tracing.

The following examples demonstrate correct syntax.

On the Windows operating system:

```
launchClient c:\earfiles\myapp.ear -CCBootstrapHost=myWASServer -CCverbose=true  
app_parm1 app_parm2
```

On the UNIX operating system:

```
./launchClient.sh /usr/earfiles/myapp.ear -CCBootstrapHost=myWASServer -CCverbose=true  
app_parm1 app_parm2
```

Specifying the directory for an expanded EAR file

Each time the launchClient tool is called, it extracts the Enterprise Archive (EAR) file to a random directory name in the temporary directory on your hard drive. Then the tool sets up the thread ClassLoader to use the extracted EAR file directory and JAR files included in the Manifest.mf client Java Archive (JAR) file. In a normal J2EE Java client, these files are automatically cleaned up after the application exits. This cleanup occurs when the client container shutdown hook is called. To avoid extracting the EAR file (and removing the temporary directory) each time the launchClient tool is called, complete the following steps:

1. Specify a directory to extract the EAR file by setting the com.ibm.websphere.client.applicationclient.archivedir Java system property. If the directory does not exist or is empty, the EAR file is extracted normally. If the EAR file was previously extracted, the launchClient tool reuses the directory.
2. Delete the directory before running the launchClient tool again, if you need to update your EAR file. When you call the launchClient command, it extracts the new EAR file to the directory. If you do not delete the directory or change the system property value to point to a different directory, the launchClient tool reuses the currently extracted EAR file and does not use your changed EAR file. When specifying the com.ibm.websphere.client.applicationclient.archivedir property, make sure that the directory you specify is unique for each EAR file you use. For example, do not point the MyEar1.ear and the MyEar2.ear files to the same directory.

Example: Using a Java 2 security manager with a J2EE application client

The launchClient command provides several parameters to control the Java 2 security manager. By default the launchClient command does not enable nor run with a Java 2 security manager. To enable the Java 2 security manager, add the following parameter to your launchClient command:

```
-CCsecurityManager=enable
```

For example:

```
launchClient myear.ear -CCsecurityManager=enable
```

- When the security manager is enabled, the `launchClient` command uses by default the `java.lang.SecurityManager` class and the `<install_root>/properties/client.policy` policy file. This policy file is configured to provide the standard permissions as described in the J2EE specification for J2EE application clients and applets. If your application receives a `java.security.AccessControlException` exception, you must add additional permissions to the `client.policy` file. For more information on adding permissions, see "Configuring client.policy files" and "AccessControlException" in the Information Center.
- You can override the default security manager class by specifying the `-CCsecurityMgrClass` parameter and the default policy file using the `-CCsecurityMgrPolicy` parameter. For more information, see `launchClient` tool.
- If you invoke Java code to start the `launchClient` class, it is recommended that you do not use the `-Djava.security.manager` parameter to enable the Java 2 security manager. Using this parameter causes the Java 2 security manager to be enabled prior to initialization of the J2EE application client run-time environment. The necessary permissions are not granted and your application might receive the `java.security.AccessControlExceptions` exception.
- When the J2EE application client run time is initialized, the Enterprise Archive (EAR) file that you specified is extracted to a random subdirectory in your users temporary directory location.

Note: If the EAR file is a set of directories and subdirectories, then it is used in place and not expanded.

The J2EE application client run time sets the

`com.ibm.websphere.client.applicationclient.archivedir` system property to the directory location of the EAR file. The `client.policy` file uses this system property to inform the security manager of the location of your application client code base and to assign the configured permissions to that code base. This activity occurs when the security manager is enabled. If the security manager is enabled at the time the Java code is started, then this system property is not set, the code base is unknown, and the permissions are not granted.

- It is recommended that you enable the security manager with the J2EE application client run time. Use the following parameter: `-CCsecurityManager=enable`.

Example: Enabling Java 2 security prior to J2EE application client run time initialization

To enable the Java 2 security prior to the Java 2 Platform Enterprise Edition (J2EE) application client run time initialization, set the `com.ibm.websphere.client.applicationclient.archivedir` system property.

Perform the following steps:

1. Set the system property to the directory where the Enterprise Archive (EAR) file is expanded, for example:

```
-Dcom.ibm.websphere.client.applicationclient.archivedir=c:\myear1 (Windows systems)
```

```
-Dcom.ibm.websphere.client.applicationclient.archivedir=/usr/mrear1 (UNIX systems)
```

2. Set the `java.security.policy` system property to use the `<WAS_HOME>/properties/client.policy` file, for example:

```
-Djava.security.policy=%WAS_HOME%\properties\client.policy (Windows systems)
```

```
-Djava.security.policy=$WAS_HOME/properties/client.policy (UNIX systems)
```

- Setting the `com.ibm.websphere.client.applicationclient.archivedir` property has the following effects:

- If the directory does not exist or if it is empty, the EAR file is extracted to that directory.
- The EAR file is reused if it was previously extracted. This reuse occurs even if the EAR file specified on the command line is different.
- The security manager grants the permissions from the `client.policy` file to that directory and all its subdirectories.

- There are two types of EAR files. The first type of EAR file is a single file that contains all the enterprise application files. The second type is a set of directories and subdirectories. The following items only apply if you are using the single file form:
 - If you need to update your EAR file, delete the directory first.
 - The new EAR file is extracted to the directory the next time you run. If you do not delete the directory or change the system property value to point to a different temporary directory, the currently extracted EAR file is reused, and your changed EAR file is not used.
- When specifying the `com.ibm.websphere.client.applicationclient.archivedir` property, verify that the directory you specify is unique for each EAR file that you use. For example, do not point `MyEar1.ear` and `MyEar2.ear` files to the same directory. You must also create all directories up to, but not including, the last directory. For example, if you set the following property:
`com.ibm.websphere.client.applicationclient.archivedir=/usr/myears/myear1`

then `usr` and `myears` must exist, but `myear1` need not exist prior to running the `launchClient` class.

Application client troubleshooting tips

This section provides some debugging tips for resolving common Java 2 Platform Enterprise Edition (J2EE) application client problems. To use this troubleshooting guide, review the trace entries for one of the J2EE application client exceptions, and then locate the exception in the guide. Some of the errors in the guide are samples, and the actual error you receive can be different than what is shown here. You might find it useful to rerun the `launchClient` command specifying the `-CCverbose=true` option. This option provides additional information when the J2EE application client run time is initializing

Error: `java.lang.NoClassDefFoundError`

Explanation	This exception is thrown when Java code cannot load the specified class.
Possible causes	<ul style="list-style-type: none">• Invalid or non-existent class• Class path problem• Manifest problem

Recommended response

Check to determine if the specified class exists in a Java Archive (JAR) file within your Enterprise Archive (EAR) file. If it does, make sure the path for the class is correct. For example, if you get the exception:

```
java.lang.NoClassDefFoundError:  
WebSphereSamples.HelloEJB.HelloHome
```

verify that the HelloHome class exists in one of the JAR files in your EAR file. If it exists, verify that the path for the class is WebSphereSamples.HelloEJB.

If both the class and path are correct, then it is a class path issue. Most likely, you do not have the failing class JAR file specified in the client JAR file manifest. To verify this situation, perform the following steps:

1. Open your EAR file with the Application Assembly Tool Assembly Toolkit and click the Application Client.
2. Add the names of the other JAR files in the EAR file to the Classpath field.

This exception is generally caused by a missing Enterprise Java Beans (EJB) module name from the Classpath field.

If you have multiple JAR files to enter in the Classpath field, be sure to separate the JAR names with spaces.

If you still have the problem, you have a situation where a class is loaded from the file system instead of the EAR file. This error is difficult to debug because the offending class is not the one specified in the exception. Instead, another class is loaded from the file system before the one specified in the exception. To correct this error, review the class paths specified with the -CClasspath option and the class paths configured with the Application Client Resource Configuration Tool. Look for classes that also exist in the EAR file. You must resolve the situation where one of the classes is found on the file system instead of in the .ear file. Remove entries from the classpaths, or include the .jar files and classes in the .ear file instead of referencing them from the file system.

If you use the -CClasspath parameter or resource classpaths in the Application Client Resource Configuration Tool, and you have configured multiple JAR files or classes, verify they are separated with the correct character for your operating system. Unlike the Classpath field in the Application Assembly Tool Assembly Toolkit, these class path fields use platform-specific separator characters, usually a colon (on UNIX platforms) or a semi-colon (on Windows systems).

Note: The system class path is not used by the Application Client run time if you use the launchClient batch or shell files. In this case, the system class path would not cause this problem. However, if you load the launchClient class directly, you do have to search through the system class path as well.

Error: com.ibm.websphere.naming.CannotInstantiateObjectException: Exception occurred while attempting to get an instance of the object for the specified reference object. [Root exception is javax.naming.NameNotFoundException: xxxxxxxxxx]

Explanation

This exception occurs when you perform a lookup on an object that is not installed on the host server. Your program can look up the name in the local client Java Naming and Directory Interface (JNDI) name space, but received a NameNotFoundException exception because it is not located on the host server. One typical example is looking up an EJB component that is not installed on the host server that you access. This exception might also occur if the JNDI name you configured in your Application Client module does not match the actual JNDI name of the resource on the host server.

Possible causes

- Incorrect host server invoked
- Resource is not defined
- Resource is not installed
- Application server is not started
- Invalid JNDI configuration

Recommended response

If you are accessing the wrong host server, run the `launchClient` command again with the `-CCBootstrapHost` parameter specifying the correct host server name. If you are accessing the correct host server, use the product `dumpnamespace` command line tool to see a listing of the host server JNDI name space. If you do not see the failing object name, the resource is either not installed on the host server or the appropriate application server is not started. If you determine the resource is already installed and started, your JNDI name in your client application does not match the global JNDI name on the host server. Use the Assembly Tool to compare the JNDI bindings value of the failing object name in the client application to the JNDI bindings value of the object in the host server application. The values must match.

Error: javax.naming.ServiceUnavailableException: A communication failure occurred while attempting to obtain an initial context using the provider url: "iiop://[invalidhostname]". Make sure that the host and port information is correct and that the server identified by the provider URL is a running name server. If no port number is specified, the default port number 2809 is used. Other possible causes include the network environment or workstation network configuration. Root exception is org.omg.CORBA.INTERNAL: JORB0050E: In Profile.getAddress(), InetAddress.getByAddress[invalidhostname] threw an UnknownHostException. minor code: 4942F5B6 completed: Maybe

Explanation

This exception occurs when you specify an invalid host server name.

Possible causes

- Incorrect host server invoked
- Invalid host server name

Recommended response

Run the `launchClient` command again and specify the correct name of your host server with the `-CCBootstrapHost` parameter.

Error: javax.naming.CommunicationException: Could not obtain an initial context due to a communication failure. Since no provider URL was specified, either the bootstrap host and port of an existing ORB was used, or a new ORB instance was created and initialized with the default bootstrap host of "localhost" and the default bootstrap port of 2809. Make sure the ORB bootstrap host and port resolve to a running name server. Root exception is org.omg.CORBA.COMM_FAILURE: WRITE_ERROR_SEND_1 minor code: 49421050 completed: No

Explanation

This exception occurs when you run the `launchClient` command to a host server that does not have the Application Server started. You also receive this exception when you specify an invalid host server name. This situation might occur if you do not specify a host server name when you run the `launchClient` tool. The default behavior is for the `launchClient` tool to run to the local host, because WebSphere Application Server does not know the name of your host server. This default behavior only works when you are running the client on the same machine with WebSphere Application Server is installed.

Possible causes

- Incorrect host server invoked
- Invalid host server name
- Invalid reference to localhost
- Application server is not started
- Invalid bootstrap port

Recommended response

If you are not running to the correct host server, run the `launchClient` command again and specify the name of your host server with the `-CCBootstrapHost` parameter. Otherwise, start the Application Server on the host server and run the `launchClient` command again.

Error: javax.naming.NameNotFoundException: Name comp/env/ejb not found in context "java:"**Explanation**

This exception is thrown when the Java code cannot locate the specified name in the local JNDI name space.

Possible causes

- No binding information for the specified name
- Binding information for the specified name is incorrect
- Wrong class loader was used to load one of the program classes
- A resource reference does not include any client configuration information
- A client container on the deployment manager is trying to use enterprise extensions (not supported)

Recommended response

Open the EAR file with the Assembly Tool, and check the bindings for the failing name. Ensure this information is correct. If you are using Resource References, open the EAR file with the Application Client Resource Configuration Tool, and verify that the Resource Reference has client configuration information and the name of the Resource Reference exactly matches the JNDI name of the client configuration. If the values are correct, you might have a class loader error.

Error: java.lang.ClassCastException: Unable to load class: org.omg.stub.WebSphereSamples.HelloEJB._HelloHome_Stub at com.ibm.rmi.javax.rmi.PortableRemoteObject.narrow(portableRemoteObject.java:269)**Explanation**

This exception occurs when the application program attempts to narrow to the EJB home class and the class loaders cannot find the EJB client side bindings.

Possible causes

- The files, `*_Stub.class` and `_Tie.class`, are not in the EJB `.jar` file
- Class loader could not find the classes

Recommended response

Look at the EJB `.jar` file located in the `.ear` file and verify the class contains the Enterprise Java Beans (EJB) client side bindings. These are class files with file names that end in `_Stub` and `_Tie`. If these files are not present, then use the Application Assembly Tool Assembly Toolkit to generate the binding classes. For more information, see article [Generating deployment code for modules](#). If the binding classes are in the EJB `.jar` file, then you might have a class loader error.

**Error: WSCL0210E: The Enterprise archive file [EAR file name] could not be found.
com.ibm.websphere.client.applicationclient.ClientContainerException:
com.ibm.etools.archive.exception.OpenFailureException**

Explanation

This error occurs when the application client run time cannot read the Enterprise Archive (EAR) file.

Possible causes

The most likely cause of this error is that the system cannot find the EAR file cannot be found in the path specified on the `launchClient` command.

Recommended response

Verify that the path and file name specified on the `launchClient` command are correct. If you are running on the Windows operating system and the path and file name are correct, use a short version of the path and file name (8 character file name and 3 character extension).

The `launchClient` command appears to hang and does not return to the command line when the client application has finished.

Explanation

When running your application client using the `launchClient` command the WebSphere Application Server run time might need to display the security login dialog. To display this dialog, WebSphere Application Server run time creates an Abstract Window Toolkit (AWT) thread. When your application returns from its main method to the application client run time, the application client run time attempts to return to the operating system and end the Java virtual machine (JVM) code. However, since there is an AWT thread, the JVM code will not end until `System.exit` is called.

Possible causes

The JVM code does not end because there is an AWT thread. Java code requires that `System.exit()` be called to end AWT threads.

Recommended response

- Modify your application to call `System.exit(0)` as the last statement.
- Use the `-CCexitVM=true` parameter when you call the `launchClient` command.

For current information available from IBM Support on known problems and their resolution, see the IBM customer support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM customer support page.

Chapter 8. Using Web services based on Web Services for J2EE

Decide if a Web service implementation benefits your business process.

This topic introduces you to using Web services that are based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) specification. WebSphere Application Server supports Web services that are developed and implemented based on Web Services for J2EE.

Use Web services when operating across a variety of platforms, including the J2EE 1.3 and non-J2EE platforms. Web services benefit your e-business solution by integrating these enterprise systems, especially systems that have developed over a long period of time.

Using Web services makes most sense if your application's clients are non-J2EE applications, unless you have J2EE applications spread across the Web. It is recommended that you use J2EE technologies if all your clients are J2EE applications because performance can decrease when you use a Web service in a J2EE exclusive environment.

Because Web services are easily applied to existing applications and information technology assets, new solutions can be deployed quickly and recomposed to address new opportunities. As Web services become more popular, the pool of services grows, promoting development of more robust models of just-in-time application and business integration over the Internet.

To use Web services applications with WebSphere Application Server:

1. Plan to use Web services. Review the Universal Description, Discovery, and Integration (UDDI), Web services gateway and Web Services Invocation Framework concepts to learn how these components can make your Web services plan more robust.
2. (Optional) Migrate existing Web services.
3. Develop Web services.
4. Assemble Web services.
5. Deploy Web services.
6. Secure Web services.
7. Tune Web services.
8. Troubleshoot Web services.

The following is an example of how a business might use Web services.

The owner of a flower shop wants to start receiving orders from customers through the Web. She starts her venture by finding wholesale flower suppliers, pricing their product, and completing contracts for future flower orders.

Using Web services, the flower shop owner can find wholesale flower suppliers. One way she finds new suppliers is to use a UDDI registry to search for potential suppliers. She chooses the suppliers and the registry sends back information on how to contact the flower distributors that meet her criteria.

The flower shop owner can request price lists from each of the suppliers by obtaining a Web Services Description Language (WSDL) file for each potential supplier. The WSDL can be downloaded from the supplier's Web page, received through email, or retrieved from the supplier's UDDI registry entry.

The WSDL describes the procedure call. When using WebSphere Application Server, the procedure call is a Java API for XML-based remote procedure call (JAX-RPC), which helps her get price lists. The WSDL file also specifies the Universal Resource Locator (URL) where the request is to be sent.

The flower shop owner now has to compare the prices she received back from each supplier, decide which suppliers she is going to do business with, and make arrangements for future orders to be filled. The ground work has been laid for the flower shop to sell merchandise through the Web by using Web services to communicate with suppliers for the best prices and complete the ordering processes. The merchandise price lists need to be published to her Web site and she needs to provide a mechanism for customers to order flowers.

The flower supplier's Web services clients are deployed on the flower shop server. When a customer makes a transaction to purchase flowers through the Web, the order is sent to the supplier through JAX-RPC. The supplier responds by sending a confirmation with the order number and shipping date. The suppliers maintain the inventory and the flower shop owner handles billing and customer order management.

Similarly, the flower shop catalog can be composed automatically from the catalogs of all the suppliers. If the supplier ships directly to the customer, the order tracking inquiries can pass directly to the supplier's order tracking system. Web services can also be used by the supplier to send invoices for orders and by the flower shop to pay the supplier's invoices. Processes that previously required forms to be filled out manually, and faxed or mailed, can now be done automatically, saving labor costs for both the flower shop and the supplier.

Using Web services is beneficial because a much larger inventory is made available to the flower shop. There is no merchandise maintenance overhead, but the flower shop can offer their customers products that they otherwise might not have. Selling flowers through the Web increases capital for the flower shop without overhead of another store or money invested into additional product.

5.1 + For a more detailed scenario, see [Web services scenario: Overview](#) which tells the story of a fictional online garden supply retailer named Plants by WebSphere and how they incorporated the Web services concept.

Web services

Web services are self-contained, modular applications that you can describe, publish, locate, and invoke over a network.

WebSphere Application Server supports Web services that are developed and implemented based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) specification.

A typical Web services scenario is a business application requesting a service from a given URL using SOAP messages over a Hypertext Transport Protocol (HTTP) or Java Messaging Service (JMS) transport. The service receives the request, processes it, and returns a response. Examples of a simple Web service include weather reports or getting stock quotes. The method call is synchronous, that is, it waits until the result is available. Transaction Web services, supporting quotes, business-to-business (B2B) or business-to-client (B2C) operations include airline reservations or purchase orders.

A Web service can be the service itself or the client that accesses the service.

Web services reflect a new, service-oriented architecture approach to programming. This approach is based on the idea of building applications by discovering and implementing network-available services, or by invoking available applications to accomplish some task. Web services deliver interoperability, for example, the ability for components created in different programming languages to work together as if they were created using the same language. Web services rely on existing transport technologies, such as HTTP, and standard data encoding techniques, such as Extensible Markup Language (XML), for invoking the implementation.

The key components of a Web service are:

- Web Services Description Language (WSDL)
WSDL is the XML-based file that describes the Web service and allows the Web service request to bind to the service.
- SOAP
SOAP is the XML-based protocol that allows the Web service request to invoke the service.
- Universal Description, Discovery and Integration Protocol (UDDI)
UDDI is the registry that hosts the service broker. UDDI is similar to the Yellow Pages in a phone book.

Web services are Web applications that allow you to be more flexible in your business processes by integrating with applications that otherwise would not communicate. The inner-library loan program at your local library is a good example of the Web services concept and its evolution. The Web service concept existed even before the term; the concept exploded with the birth of the Internet. Before, you would visit your library, search the collections and check out your books. If you didn't find the book you wanted, the librarian did a search for you by computer or phone and located the book at a nearby library. The librarian ordered the book for you and you picked it up after it was delivered to your local library. By incorporating Web services applications, you can streamline your library visit. Now, you can search the local library collection and other local libraries at the same time. When other libraries provide your library with a Web service to search their collection (the service could have been provided through UDDI), your results yield their resources. Another Web service application might enable you to check the book out and get it sent to your home. Using Web services applications saves time and creates a convenience for you, as well as freeing the librarian to do other business tasks. For a more detailed scenario, see *Web services scenario: Overview* which tells the story of a fictional online garden supply retailer named Plants by WebSphere and how they incorporated the Web services concept.

Web Services for J2EE

The *Web services for Java 2 platform, Enterprise Edition (J2EE)* specification defines the programming model and run-time architecture for implementing Web services based on the Java language. Another name for Web Services for J2EE is the Java Specification Requirements (JSR) 109. The specification includes open standards for developing and implementing Web services.

WebSphere Application Server Versions 5.0.2 and 5.1 use Web Services for J2EE 1.0 as the standard for developing and implementing Web services. Web Services for J2EE 1.0 is an API include in J2EE 1.3. Before Version 5.0.2, WebSphere Application Server developed and implemented Web services based on Apache SOAP.

Web Services for J2EE focuses on eXtensible Markup Language (XML) remote procedure call (RPC) and the Java language, including representing XML-based interface definitions in the Java language; Java language definitions in XML-based definition languages, such as SOAP, and assembling.

Web Services for J2EE is the preferred platform for Web-based programming because it provides open standards allowing different types of languages, operating systems and software to communicate seamlessly through the Internet.

In order to achieve the benefits of using Web Services for J2EE, the Web services that you want to communicate with (provided by other sources), must also be based on the Java language. These other Web services can use other operating systems and languages, but the Web service itself must be based on the Java language.

For a Java application to act as Web service client, a mapping between the Web Services Description Language (WSDL) file and the Java application must exist. The mapping is defined by the Java API for XML-based RPC (JAX-RPC) specification. You can use a Java component to implement a Web service by specifying the component's interface and binding information in the WSDL file and designing the application server infrastructure to accept the service request. This entire process encompassed is based on the Web Services for J2EE specification.

Using Web Services for J2EE in WebSphere Application Server is based on J2EE 1.3. The same standards are included in J2EE 1.4.

To review the entire Web Services for J2EE specification, see [Web services: Resources for learning](#).

Java API for XML-based remote procedure call (JAX-RPC)

The *Java API for XML-based RPC (JAX-RPC)* specification enables Java language developers to develop SOAP-based interoperable and portable Web services. JAX-RPC provides core APIs for developing and deploying Web services on a Java platform and is a required part of the J2EE 1.4 platform. JAX-RPC Web services can also be developed and deployed on J2EE 1.3 containers.

WebSphere Application Server Versions 5.0.2 and 5.1 use JAX-RPC 1.0.

The JAX-RPC standard covers the programming model and bindings for using Web Services Description Language (WSDL) for Web services in the Java language.

JAX-RPC defines the mappings between the WSDL port types and the Java interfaces, as well as between Java language and eXtensible Markup Language (XML) schema types.

To learn more about JAX-RPC see [Web services: Resources for learning](#).

SOAP

SOAP is a specification for exchange of structured information in a decentralized, distributed environment. As such, it represents the main way of communication between the three key actors in a service oriented architecture (SOA): service provider, service requestor and service broker. Then main goal of its design is to be simple and extensible. A SOAP message is used to request a Web service.

WebSphere Application Server Versions 5.0.2 and 5.1 follow the standards outlined in SOAP 1.1.

SOAP was submitted to the World Wide Web Consortium (W3C) as the basis of the eXtensible Markup Language (XML) Protocol Working Group by several companies, including IBM and Lotus.

SOAP is an XML-based protocol that consists of three parts: an *envelope* that defines a framework for describing message content and process instructions, a set of *encoding rules* for expressing instances of application-defined data types, and a *convention* for representing remote procedure calls and responses.

SOAP is transport protocol-independent and can be used in combination with a variety of protocols. In Web services that are developed and implemented for use with WebSphere Application Server, SOAP is used in combination with HyperText Transport Protocol (HTTP), HTTP extension framework, and Java Messaging Service (JMS). SOAP is also operating system independent and not tied to any programming language or component technology.

Due to these characteristics, it does not matter what technology is used to implement the client, as long as the client can issue XML messages. Similarly, the service can be implemented in any language, as long as it can process XML messages. Also, both server and client sides can reside on any suitable platform.

For more information about SOAP, see [Web services: Resources for learning](#).

SOAP with Attachments API for Java

SOAP with Attachments API for Java (SAAJ) is used for SOAP messaging that works behind the scenes in the Java API for XML-based RPC (JAX-RPC) implementation. You can also use this API to directly write SOAP messaging applications rather than using JAX-RPC. SAAJ allows you to do XML messaging from the Java platform by making method calls by creating, sending and consuming XML messages over the Internet.

WebSphere Application Server Version 5.0.2 and 5.1 uses SAAJ Version 1.1.

Messages created using SAAJ follow SOAP standards. Many of the SAAJ classes and interfaces represent XML elements in a SOAP message and have the word `element` or `SOAP`, or both, in their names.

The two main types of SOAP messages are messages with attachments and messages without attachments. SAAJ provides the `SOAPMessage` class to represent a SOAP message; the `SOAPPart` class to represent the SOAP part; and the `SOAPEnvelope` interface to represent the SOAP envelope. A SOAP message can also include one or more attachment parts in addition to the SOAP part. The SOAP part must only contain XML content. If any of the message content is not in XML format, it must occur in an attachment part. SAAJ provides the `AttachmentPart` class to represent the attachment part of a SOAP message.

All SOAP messages are sent and received over a connection. When using SAAJ, the connection is represented by a `SOAPConnection` object, which goes directly from a sender to its destination. Messages sent using SAAJ are called request-response messages. The messages are sent over a `SOAPConnection` object with the method call, which sends a message (request) and blocks the request until it receives the reply (a response).

To review the entire SAAJ API, see [Web services: Resources for learning](#).

Planning to use Web services based on Web Services for J2EE

This topic discusses how to plan your use of Web services that are developed and implemented based on the Web Services for Java 2, Enterprise Edition (J2EE) specification. Read the [Web services scenario: Overview](#) which tells the story of a fictional online garden supply retailer named *Plants by WebSphere* and how they incorporated the Web services concept.

To plan to use Web services based on Web Services for J2EE:

1. Design Web services to fit your e-business solution. Consider what you want to accomplish by using Web services, how Web services fit into your current topology, applications and programming model. Decide how the Web services will process requests on the server and how the clients will manage and use the Web service.

Design your Web services for reliability, availability, manageability and security. For example, you want your Web services to process a transaction in a reasonable time at all hours of the day and provide users with good security characteristics, such as authentication for buyers. Planning to use Web services to work with WebSphere Application Server helps to meet these requirements.

To support Web services, extend WebSphere Application Server to support Web services standards. For interoperable Web services running on platforms supplied by multiple vendors, standards are essential. WebSphere Application Server uses Web services standards developed for the Java language under the Java Community Process (JCP). These standards include the Web Services for J2EE and JAX-RPC specifications.

2. Decide what development and implementation tools to use. You can use a variety of manual development and implementation tasks. Whether you have an existing Web service to implement or you want to develop your own from a Java bean or enterprise JavaBean (EJB), you can choose

different tasks respective to your resources. You can also use the WebSphere Studio Application Developer to complete development and implementation tasks.

See *Developing Web services based on Web Services for J2EE* for information about developing Web services based on the Java language through WebSphere Application Server. To read more about the WebSphere Studio Application Developer see the WebSphere Studio Application Developer Information Center.

3. Install WebSphere Application Server. (See "Installing WebSphere Application Server products" in the WebSphere Application Server Information Center.)
4. Review Web services Samples. (See "Samples Gallery" in the WebSphere Application Server Information Center.)

Develop a Web service.

Service-oriented architecture

A *service-oriented architecture (SOA)* is a collection of services that communicate with each other, for example, passing data from one service to another or coordinating an activity between one or more services.

Companies have longed to integrate existing systems in order to implement Information Technology (IT) support for business processes that cover the entire business value chain. A variety of designs are used, ranging from rigid point-to-point electronic data interchange (EDI) interactions to Web auctions. By using the Internet, companies make their IT systems available to internal departments or external customers, but the interactions are not flexible and are without standardized architecture.

Because of this increasing demand for technologies that support connecting and sharing of resources and data, there is a need for a flexible, standardized architecture. SOA is a flexible architecture that unifies business processes by structuring large applications into building blocks, or small modular functional units or services, to be used by different groups of people in and outside the company. The building blocks can be one of three roles: service provider, service broker, or service requestor. See *Web services approach to a service-oriented architecture* to learn more about these roles.

Requirements for a SOA

In order to efficiently use a SOA, you must abide by the following requirements:

- **Interoperability between different systems and programming languages .**

The most important basis for a simple integration between applications on different platforms is a communication protocol, which is available for most systems and programming languages.

- **Clear and unambiguous description language.**

To use a service offered by a provider, it is not only necessary to be able to access the provider system, but the syntax of the service interface must also be clearly defined in a platform-independent fashion.

- **Retrieval of the service.**

To allow a convenient integration at design time or even system run time, a search mechanism is required to retrieve suitable services. The services should be classified as computer-accessible, hierarchical or taxonomies based on what the services in each category do and how they can be invoked.

Web services approach to a service-oriented architecture

Web services implement a service-oriented architecture (SOA). A major focus of Web services is to make functional building blocks accessible over standard Internet protocols that are independent from platforms and programming languages. These services can be new applications or just wrapped around existing legacy systems to make them network-enabled. A service can rely on another service to achieve its goals.

Each SOA building block can play one or more of three roles:

- **Service provider**

The service provider creates a Web service and possibly publishes its interface and access information to the service registry. Each provider must decide which services to expose, how to make trade-offs between security and easy availability, how to price the services, or, if they are free, how to exploit them for other value. The provider also has to decide what category the service should be listed in for a given broker service and what sort of trading partner agreements are required to use the service.

- **Service broker**

The service broker, also known as service registry, is responsible for making the Web service interface and implementation access information available to any potential service requestor. The implementer of the broker decides about the scope of the broker. Public brokers are available through the Internet, while private brokers are only accessible to a limited audience, for example, users of a company intranet. Furthermore, the amount of the offered information has to be decided. Some brokers specialize in many listings. Others offer high levels of trust in the listed services. Some cover a broad landscape of services and others focus within an industry. There are also brokers that catalog other brokers. Depending on the business model, brokers can attempt to maximize look-up requests, number of listings or accuracy of the listings. The Universal Description, Discovery, and Integration (UDDI) specification defines a way to publish and discover information about Web services.

- **Service requestor**

The service requestor or Web service client locates entries in the broker registry using various find operations and then binds to the service provider in order to invoke one of its Web services.

Characteristics of the Web service architecture

The presented SOA employs a loose coupling between the participants, which provides greater flexibility in the following ways:

- A client is not coupled to a server, but to a service. Therefore, the integration of the server takes place outside the scope of the client application programs.
- Old and new functional blocks, or applications and systems, are encapsulated into components that work as services.
- Functional components and their interfaces are separate, allowing new interfaces to be plugged in more easily.

- Within complex applications, the control of business processes can be isolated. A business rule engine can be incorporated to control the workflow of a defined business process. Depending on the state of the workflow, the engine calls the respective services.
- Services can be incorporated dynamically during run time.
- Bindings are specified using configuration files and can be easily adapted to new needs.

Properties of a service-oriented architecture

The service-oriented architecture offers the following properties:

- **Web services are self-contained.**

On the client side, no additional software is required. A programming language with extensible markup language (XML) and Hyper Text Transport Protocol (HTTP) client support is enough to get you started. On the server side, a Web server and a SOAP server are required. It is possible to Web services-enable an existing application without writing a single line of code.

- **Web services are self-describing.**

Neither the client nor the server knows or cares about anything besides the format and content of request and response messages (loosely coupled application integration). The definition of the message format travels with the message; no external metadata repositories or code generation tool are required.

- **Web services can be published, located, and invoked across the Internet.**

This technology uses established lightweight Internet standards such as HTTP. It leverages the existing infrastructure. Some additional standards that are required to do so include SOAP, WSDL, and UDDI.

- **Web services are language-independent and interoperable.**

Client and server can be implemented in different environments. Existing code does not have to be changed in order to be Web service enabled.

- **Web services are inherently open and standard-based.**

XML and HTTP are the major technical foundation for Web services. A large part of the Web service technology has been built using open-source projects. Therefore, vendor independence and interoperability are realistic goals this time.

- **Web services are dynamic.**

Dynamic e-business can become reality using Web services because, with UDDI and WSDL, the Web service description and discovery can be automated.

- **Web services are composable.**

Simple Web services can be aggregated to more complex ones, either using workflow techniques or by calling lower-layer Web services from a Web service implementation. Web services can be chained together to perform higher-level business functions. This shortens development time and enables best-of-breed implementations.

- **Web services build on proven mature technology.**

There are a lot of commonalities, as well as a few fundamental differences to other distributed computing frameworks. For example, the transport protocol is text based and not binary.

- **Web services are loosely coupled.**

Traditionally, application design has depended on tight interconnections at both ends. Web services require a simpler level of coordination that allows a more flexible re-configuration for an integration of the services in question.

- **Web services provide programmatic access.**

The approach provides no graphical user interface; it operates at the code level. Service consumers need to know the interfaces to Web services but do not need to know the implementation details of services.

- **Web services provide the ability to wrap existing applications.**

Already existing stand-alone applications can easily be integrated into the service-oriented architecture by implementing a Web service as an interface.

Web services business models supported

The properties and benefits of using a service-oriented architecture (SOA) such as Web services is well suited for binding small modules that perform independent tasks within a highly heterogeneous e-business model. Web services can be easily wrapped around existing applications in your business model and plugged into different business processes.

For connecting to a large monolithic system that does not allow the implementation of different flexible business processes, other approaches might be better suited, for example, to satisfy specialized features, such as performance or security.

The following business models are easily implemented by using an architecture including Web services:

- **Business information**

Sharing of information with consumers or other businesses. Web services can be used to expand the reach through such services as news streams, local weather reports, integrated travel planning, and intelligent agents.

- **Business integration**

Providing transactional, fee-based services for customers. A global network of suppliers can be easily created. Web services can be implemented in auctions, e-marketplaces, and reservation systems.

- **Business process externalization**

Web services can be used to model value chains by dynamically integrating processes to a new solution within an organizational unit or even with those of other e-businesses. This can be achieved by dynamically linking internal applications to new partners and suppliers, to offer their services to complement internal services.

5.1 + To see how these models are implemented using all aspects of Web services, see Web services scenario: Overview which tells the story of a fictional online garden supply retailer named Plants by WebSphere and how they incorporate the Web services concept.

Migrating Apache SOAP Web services to Web Services for J2EE

If you have used Web services based on Apache SOAP in WebSphere Application Server Version 4.0.x through Version 5.0.2, and now want to develop and implement Web services based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) specification, you need to migrate your Version 4.0 and 5.0 client applications.

To migrate these client applications according to the Web Services for J2EE standards:

1. Plan your migration strategy. There are two ways you can port an Apache SOAP client to Java API for XML-based RPC (JAX-RPC) Web services client:
 - If you have, or can create, a Web Services Description Language (WSDL) document for the service, consider using the **WSDL2Java** command tool to generate bindings for the Web service. It is more work to adapt an Apache SOAP client to use the generated JAX-RPC bindings, but the resulting client code is more robust and easier to maintain. To follow this path, see Develop a Web services client based on Web Services for J2EE.
 - If you do not have a WSDL document for the service, do not expect the service to change, and you want to port the Apache SOAP client with a minimal work, you can convert the code to use the JAX-RPC dynamic invocation interface (DII), which is similar to the Apache SOAP APIs. The DII APIs do not use WSDL or generated bindings.

You should be aware that since JAX-RPC does not specify a framework for user-written serializers, the JAX-RPC does not support the use of custom serializers. If your application cannot conform to the

default mapping between Java, WSDL, and XML supported by WebSphere Application Server, you should not attempt to migrate the application. The remainder of this topic assumes that you have decided to use the JAX-RPC DII APIs.

2. Review the GetQuote sample. (See "Samples Gallery" in the Information Center.) There is a Web services migration sample in the Samples Gallery. This sample is located in the GetQuote.java file, originally written for Apache SOAP, and includes an explanation about the changes needed to migrate to the JAX-RPC DII interfaces.
3. Convert the client application from Apache SOAP to JAX-RPC DII The Apache SOAP API and JAX-RPC DII API structures are similar. You can instantiate and configure a call object, set up the parameters, invoke the operation, and process the result in both. You can create a generic instance of a Service object with

```
javax.xml.rpc.Service service = ServiceFactory.newInstance().createService(new QName(""));
```

in JAX-RPC.

- a. Create the call object. An instance of the call object is created by

```
org.apache.soap.rpc.Call call = new org.apache.soap.rpc.Call ()
```

in Apache SOAP.

An instance of the call object is created by

```
java.xml.rpc.Call call = service.createCall();
```

in JAX-RPC.

- b. Set the endpoint URI. The target URI for the operation is passed as a parameter to

```
call.invoke: call.invoke("http://...", "");
```

in Apache SOAP.

The setTargetEndpointAddress method is used as a parameter to

```
call.setTargetEndpointAddress("http://...");
```

in JAX-RPC.

Apache SOAP has a setTargetObjectURI method on the call object that contains routing information for the request. JAX-RPC has no equivalent method. The information in the targetObjectURI is included in the targetEndpoint URI for JAX-RPC.

- c. Set the operation name. The operation name is configured on the call object by

```
call.setMethodName("opName");
```

in Apache SOAP.

The setOperationName method, which accepts a QName instead of a String parameter, is used in JAX-RPC as follows:

```
call.setOperationName(new javax.xml.namespace.Qname("namespace", "opName"));
```

- d. Set the encoding style. The encoding style is configured on the call object by

```
call.setEncodingStyleURI(org.apache.soap.Constants.NS_URI_SOAP_ENC);
```

in Apache SOAP.

The encoding style is set by a property of the call object

```
call.setProperty(javax.xml.rpc.Call.ENCODINGSTYLE_URI_PROPERTY, "http://schemas.xmlsoap.org/soap/encoding/");
```

in JAX-RPC.

- e. Declare the parameters and set the parameter values. Apache SOAP parameter types and values are described by parameter instances, which are collected into a Vector and set on the call object before the call, for example:

```

Vector params = new Vector ();
params.addElement (new org.apache.soap.rpc.Parameter(name, type, value, encodingURI));
// repeat for additional parameters...
call.setParams (params);

```

For JAX-RPC, the call object is configured with parameter names and types without providing their values, for example:

```

call.addParameter(name, xmlType, mode);
// repeat for additional parameters
call.setReturnType(type);

```

Where

- *name* (type `java.lang.String`) is the name of the parameter
- *xmlType* (type `javax.xml.namespace.QName`) is the XML type of the parameter
- *mode* (type `javax.xml.rpc.ParameterMode`) the mode of the parameter, for example, IN, OUT, or INOUT

- f. Make the call. The operation is invoked on the call object by
- ```

org.apache.soap.Response resp = call.invoke(endpointURI, "");

```

in Apache SOAP.

The parameter values are collected into an array and passed to `call.invoke` as follows:

```

Object resp = call.invoke(new Object[] {parm1, parm2,...});

```

in JAX-RPC.

- g. Check for faults. You can check for a SOAP fault on the invocation by checking the response:

```

if resp.generatedFault then {
org.apache.soap.Fault f = resp.getFault();
f.getFaultCode();
f.getFaultString();
}

```

in Apache SOAP.

A `java.rmi.RemoteException` is thrown in JAX-RPC if a SOAP fault occurs on the invocation.

```

try {
... call.invoke(...)
} catch (java.rmi.RemoteException) ...

```

- h. Retrieve the result. In Apache SOAP, if the invocation was successful and returns a result, it can be retrieved from the Response object:

```

Parameter result = resp.getReturnValue(); return result.getValue();

```

In JAX-RPC, the result of `invoke` is the returned object when no exception is thrown:

```

Object result = call.invoke(...);
...
return result;

```

Developing a Web services client based on Web Services for J2EE.

Test the Web services-enabled clients.

---

## Developing Web services based on Web Services for J2EE

This topic explains how to develop a Web service using the Web Services for Java 2, Enterprise Edition (J2EE) specification. Web services are structured in a service-oriented architecture (SOA) that makes integrating your business and e-commerce systems more flexible.

For more information about when and how you should to use Web services see Using Web services based on Web Services for J2EE. You can read about several concepts, including what is Web services,

SOAP, WSDL, Web Services for J2EE and Java API for XML-based remote procedure call (JAX-RPC). If you would like to review a scenario where Web services are used, see [Web services scenario: Overview](#).

WebSphere Application Server uses Web services standards developed for the Java language under the Java Community Process (JCP). WebSphere Application Server Versions 5.0.2 and 5.1 follow these standards:

- SOAP Version 1.1
- WSDL Version 1.1
- Web Services for J2EE (JSR-109) Version 1.0
- JAX-RPC Version 1.0
- SOAP with attachments API for Java (SAAJ) Version 1.1

You can also use the WebSphere Studio Application Developer development tools to develop Web services that integrate with WebSphere Application Server.

Before you develop a Web service you need to Set up a Web services development and unmanaged client execution environment .

Follow the [Example: Developing Web services based on Web Services for J2EE](#) for a step-by-step look at this task.

You can develop a Web service based on Web Services for J2EE in one of four ways:

1. Develop a Web service using a Java bean.
2. Develop a Web service using a stateless session enterprise bean.
3. Develop a Web service with an existing WSDL file using a Java bean.
4. Develop a Web service with an existing WSDL file using a stateless session enterprise bean.

Assemble the Web service.

## **Example: Developing Web services based on Web Services for J2EE**

This example takes you through the steps to develop a Web service from an enterprise JavaBean (EJB) implementation. The development process is based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) specification.

### **1. Select the EJB or Java bean implementation that you want to enable as a Web service.**

The implementation must meet the following Web Services for J2EE specification requirements:

- It must have methods that can be mapped to a Service Endpoint Interface. See step 2 for more information.
- It must be a stateless session EJB or a Java bean without client-specific state, since the implementation bean might be selected to process a request from any client. If a client-specific state is required, a client identifier must be passed as a parameter of the Web service operation.

The selected methods of an EJB must not have a transaction attribute of Mandatory, because there is no standard for Web services transactions at this time.

A Java bean in a Web container requires the following:

- A public default constructor
- Exposed public methods
- It must not save a client-specific state between method calls
- It must be a public, non-final, and non-abstract class
- It must not define a `finalize()` method

### **2. Develop a Service Endpoint Interface.**

Developing a Web service requires a Service Endpoint Interface.

If you are using an EJB implementation, develop a Service Endpoint Interface from an EJB remote interface.

If you are using a Java bean implementation, develop a Service Endpoint Interface for a Java bean implementation.

3. Develop a WSDL file.

4. **Develop deployment descriptor templates.**

If you are using an EJB implementation, develop Web services deployment descriptor templates from an EJB implementation.

If you are using a Java bean implementation, develop Web services deployment descriptor templates for a Java bean implementation.

5. **Configure the deployment descriptors.**

By setting the `ejb-link` or `servlet-link` values of the `service-impl-bean` elements you can link to the EJB or Java bean that implements the service.

Configure the `webservices.xml` deployment descriptor.

Configure the `ibm-webservices-bnd.xmi` deployment descriptor.

6. Assemble a JAR file or Assemble a WAR file.

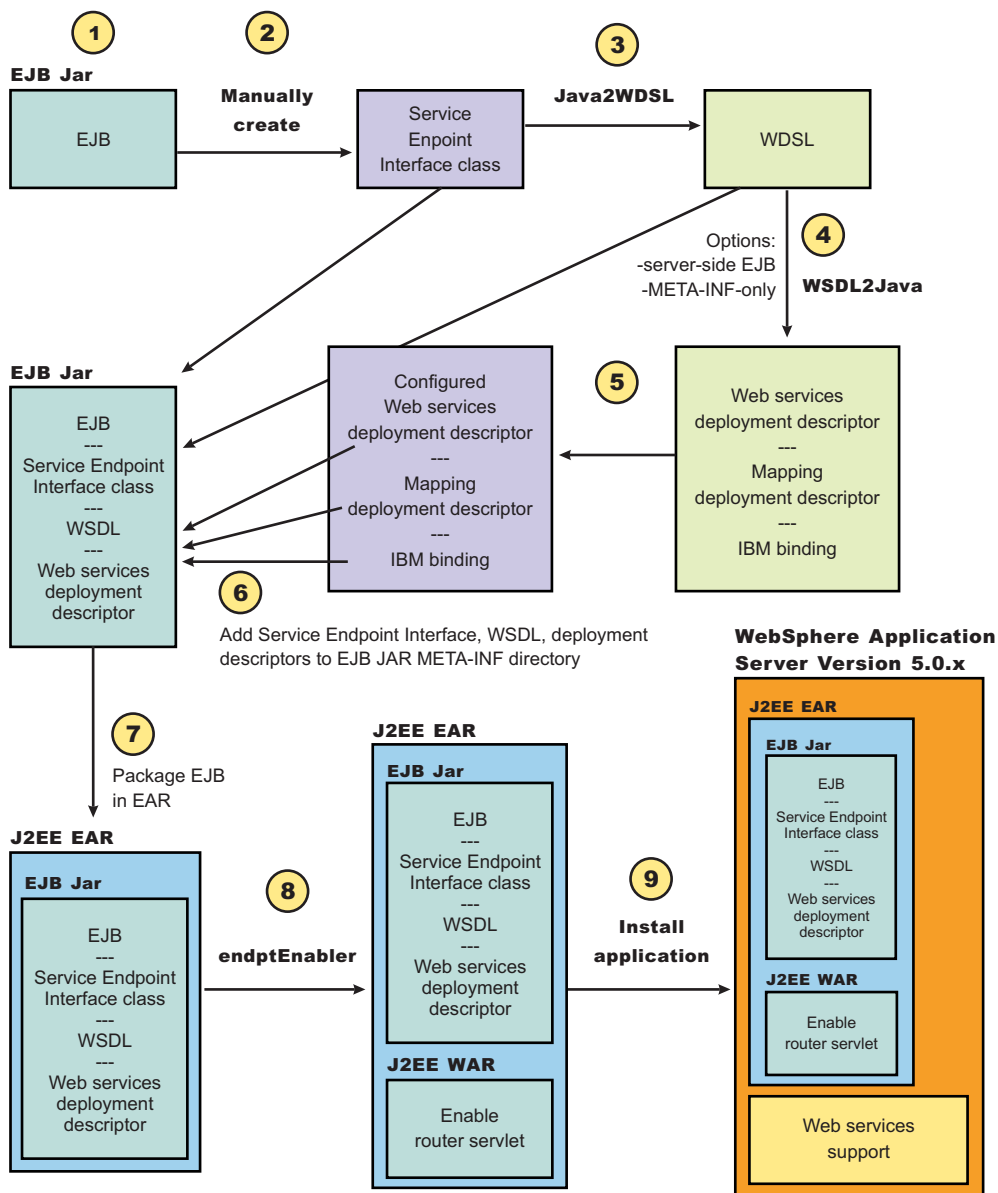

7. Assemble an EAR file from a Jar file or Assemble an EAR file from a WAR file.

8. Enable the Web service-enabled EAR file.

This step only applies if you are using an EJB implementation.

9. Deploy the Web service application.

10. Publish the WSDL file.

## Artifacts used to develop Web services based on Web Services for J2EE

*Development artifacts* enable an enterprise bean or a Java bean module to be a Web service. This topic describes artifacts used to develop Web services that are based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) specification.

To create a Web service from an enterprise bean or a Java bean module, the following files are added to the respective Java archive (JAR) or Web archive (WAR) modules at assembly time:

- **Web Services Description Language (WSDL) eXtensible Markup Language (XML) file**

The WSDL XML file describes the Web service being implemented.

- **Service Endpoint Interface**

A Service Endpoint Interface is the Java interface corresponding to the Web service port type implemented. The Service Endpoint Interface is defined by the WSDL 1.1 W3C Note.

- **webservices.xml**

The `webservices.xml` file contains the J2EE Web service deployment descriptor specifying how the Web service is implemented. The `webservices.xml` file is defined in the Web Services for J2EE specification available through Web services: Resources for learning

- **ibm-webservices-bnd.xmi**

This file contains WebSphere product-specific deployment information and is defined in `ibm-webservices-bnd.xmi` assembly properties.

- **Java API for XML-based remote procedure call (JAX-RPC) mapping file**

The JAX-RPC mapping deployment descriptor specifies how Java elements are mapped to and from WSDL file elements.

The following files are added to an application client, enterprise JavaBean (EJB), or Web module to permit J2EE client access to Web services:

- **WSDL file**

The WSDL file is provided by the Web service implementer.

- **Java interfaces for the Web service**

The Java interfaces are generated from the WSDL file as specified by the JAX-RPC specification. These bindings are the Service Endpoint Interface based on the WSDL port type, or the service interface, which is based on the WSDL service.

- **webservicesclient.xml**

The `webservicesclient.xml` file is the client-side deployment descriptor describing the services being accessed. The `webservicesclient.xml` file is defined in the Web Services for J2EE specification, available through Web services: Resources for learning.

- **ibm-webservicesclient-bnd.xmi**

This file contains WebSphere product-specific deployment information such as security information.

- **Other JAX-RPC binding files**

Additional JAX-RPC binding files that support the client application in mapping SOAP to Java language are generated from WSDL by the **WSDL2Java** command tool.

## Mapping between Java language, WSDL and XML

This topic contains the mappings between the Java language and eXtensible Markup Language (XML) technologies, including XML Schema, Web Services Description Language (WSDL) and SOAP, supported by WebSphere Application Server. Most of these mappings are specified by the Java API for XML-based remote procedure call (JAX-RPC) specification. Some mappings that are optional or unspecified in JAX-RPC are also supported.

There are references to the JAX-RPC specification through this topic. You can review the JAX-RPC specification through Web services: Resources for learning.

### Notational conventions

The following table specifies the namespace prefixes and corresponding namespaces used.

| Namespace prefix | Namespace                                                                                         |
|------------------|---------------------------------------------------------------------------------------------------|
| xsd              | <a href="http://www.w3.org/2001/XMLSchema">http://www.w3.org/2001/XMLSchema</a>                   |
| xsi              | <a href="http://www.w3.org/2001/XMLSchema-instance">http://www.w3.org/2001/XMLSchema-instance</a> |
| soapenc          | <a href="http://schemas.xmlsoap.org/soap/encoding/">http://schemas.xmlsoap.org/soap/encoding/</a> |
| wSDL             | <a href="http://schemas.xmlsoap.org/wSDL/">http://schemas.xmlsoap.org/wSDL/</a>                   |
| wSDL soap        | <a href="http://schemas.xmlsoap.org/wSDL/soap/">http://schemas.xmlsoap.org/wSDL/soap/</a>         |
| ns               | user defined namespace                                                                            |
| apache           | <a href="http://xml.apache.org/xml-soap">http://xml.apache.org/xml-soap</a>                       |
| wasws            | <a href="http://websphere.ibm.com/webservices/">http://websphere.ibm.com/webservices/</a>         |

## Detailed mapping information

The following sections identify the supported mappings, including:

- Java-to-WSDL mapping
- WSDL-to-Java mapping
- Mapping between WSDL and SOAP messages

### Java-to-WSDL mapping

This section summarizes the Java-to-WSDL mapping rules. The Java-to-WSDL mapping rules are used by the **Java2WSDL** command tool for bottom-up processing. In bottom-up processing, an existing Java service implementation is used to create a WSDL file defining the Web service. The generated WSDL file can require additional manual editing for the following reasons:

- Not all Java classes and constructs have mappings to WSDL. For example, Java classes that do not comply with the Java bean specification rules might not map to a WSDL construct.
- Some Java classes and constructs have multiple mappings to WSDL. For example, a `java.lang.String` class can be mapped to either an `xsd:string` or `soapenc:string`. The **Java2WSDL** command chooses one of these mappings, but the WSDL file must be edited if a different mapping is desired.
- There are multiple ways to generate WSDL constructs. For example, the `part` element in the `wsdl:message` can be generated with a `type` or `element` attribute. The **Java2WSDL** command makes an informed choice based on the settings of the `-style` and `-use` options.
- The WSDL file describes the instance data elements sent in the SOAP message. If you want to modify the names or format used in the message, the WSDL file must be edited. For example, write a bean property value as an attribute instead of an element.
- The WSDL file requires editing if header or attachment support is desired.
- The WSDL file requires editing if a multipart WSDL, one using `wsdl:import`, is desired.

For simple services, the generated WSDL file is sufficient. For complicated services, the generated WSDL file is a good starting point.

### General issues

#### • Package to namespace mapping

The JAX-RPC specification does not specify the default mapping of Java package names to XML namespaces. The JAX-RPC specification does specify that each Java package must map to a single XML namespace. Likewise, each XML namespace must map to a single Java package. A default mapping algorithm is provided that constructs the namespace by reversing the names of the Java package and adding an `http://` prefix. For example, a package named, `com.ibm.webservice`, is mapped to the namespace `http://webservice.ibm.com`.

The default mapping between XML namespaces and Java package names can be overridden using the `-NstoPkg` and `-PkgtoNS` options of the **WSDL2Java** and **Java2WSDL** commands.

#### • Identifier mapping

Java identifiers are mapped directly to WSDL file and XML identifiers.

Java bean property names are mapped to the WSDL file and XML identifiers. For example, a Java bean, with `getInfo` and `setInfo` methods, maps to an XML construct with the name, `info`.

The Service Endpoint Interface method parameter names, if available, are mapped directly to the XML identifiers. See the **WSDL2Java** command `-implClass` option for more details.

#### • WSDL construction summary

The following table summarizes the mapping from a Java construct to the related WSDL and XML construct.

| Java construct             | WSDL and XML construct     |
|----------------------------|----------------------------|
| Service Endpoint Interface | <code>wsdl:portType</code> |

|                         |                                          |
|-------------------------|------------------------------------------|
| Method                  | wsdl:operation                           |
| Parameters              | wsdl:input, wsdl:message, wsdl:part (1)  |
| Return                  | wsdl:output, wsdl:message, wsdl:part (1) |
| Throws                  | wsdl:fault, wsdl:message, wsdl:part (1)  |
| Primitive types         | xsd and soapenc simple types             |
| Java beans              | xsd:complexType                          |
| Java bean properties    | Nested xsd:elements of xsd:complexType   |
| Arrays                  | JAX-RPC defined array xsd:complexType    |
| User defined exceptions | xsd:complexType                          |

**Note:** The generated WSDL file is affected by the `-style` and `-use` options. A `wsdl:binding` that conforms to the generated `wsdl:portType` is generated. The style and use constructs of the `wsdl:binding` are determined from the `-style` and `-use` options. A `wsdl:service` containing a port that references the generated `wsdl:binding` is generated. The names and values of the `wsdl:service` are controlled by the **Java2WSDL** command options.

- **Style and use**

Use the `-style` and `-use` options to generate different kinds of WSDL files. The four supported combinations are:

- `-style RPC -use ENCODED`
- `-style DOCUMENT -use LITERAL`
- `-style RPC -use LITERAL`
- `-style DOCUMENT -use LITERAL -wrapped false`

The `-use LITERAL` option affects the generated WSDL file in the following ways:

- The `soap:body` elements in the `wsdl:binding` are specified as `use="literal"`.
- The `soap:fault` elements in the `wsdl:binding` are specified as `use="literal"`.
- The soap encoded types are not used.
- The soap encoded array style is not used. The `maxOccurs` attribute is used to indicate arrays.

The `-use ENCODED` option affects the generated WSDL file in the following ways:

- The `soap:body` elements in the `wsdl:binding` are specified as `use="encoded"` and the `encodingStyle` is set.
- The `soap:fault` elements in the `wsdl:binding` are specified as `use="encoded"` and the `encodingStyle` is set.

The `-style RPC` option affects the generated WSDL file in the following ways:

- The `wsdl:part` elements use the `type` attribute to reference XML types.
- The `wsdl:binding` is specified as `style="rpc"`.

The `-style DOCUMENT -wrapped false` option affects the generated WSDL file in the following ways:

- The `wsdl:part` elements use the `type` attribute to reference simple types. The `element` attribute is used to reference the root `xsd:elements` for everything that is not a simple type.
- The `wsdl:binding` is specified as `style="document"`.

The `-style DOCUMENT -wrapped true` option generates a WSDL file that conforms to the .NET WSDL file format:

- A request `xsd:element` is generated for each method in the Service Endpoint Interface as follows:
  - The name of the `xsd:element` is the same as the name of the `wsdl:operation`.
  - The `xsd:element` contains an `xsd:sequence` that contains `xsd:elements` defining each parameter.
  - The request `wsdl:message` references the wrapper `xsd:element` using a single part:
    - The name of the part is `parameters`.
    - The `element` attribute is used to reference the wrapper `xsd:element`.
- A response `xsd:element` is generated for each method in the Service Endpoint Interface as follows:
  - The name of the `xsd:element` is the same as the name of the `wsdl:operation` appended with `Response`
  - The `xsd:element` contains an `xsd:sequence` that contains `xsd:elements` defining the return value.

- The request wsdl:message references this wrapper xsd:element using a single part.
  - The element attribute is used to reference the wrapper xsd:element.
- The wsdl:binding is specified as style="document".

## Mapping of standard XML types from Java types

Some Java types map directly to standard XML types. These types do not require additional XML definitions in the wsdl:types section.

### • JAX-RPC Java primitive type mapping

The following table describes the mapping from the Java primitive and standard types to XML standard types. For more information see the JAX-RPC specification.

| Java type                                                | XML type                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| int                                                      | xsd:int                                                                                                                                                                                                                                                                                                                                                                      |
| long                                                     | xsd:long                                                                                                                                                                                                                                                                                                                                                                     |
| short                                                    | xsd:short                                                                                                                                                                                                                                                                                                                                                                    |
| float                                                    | xsd:float                                                                                                                                                                                                                                                                                                                                                                    |
| double                                                   | xsd:double                                                                                                                                                                                                                                                                                                                                                                   |
| boolean                                                  | xsd:boolean                                                                                                                                                                                                                                                                                                                                                                  |
| byte                                                     | xsd:byte                                                                                                                                                                                                                                                                                                                                                                     |
| byte[]                                                   | xsd:base64Binary<br><b>Note:</b> The default mapping for byte[] is xsd:base64Binary. The data in byte[] is passed over the wire as a text string encoded in the base64 format. An alternative format is xsd:hexBinary. To use the xsd:hexBinary format: <ul style="list-style-type: none"> <li>• Edit the WSDL file and change xsd:base64Binary to xsd:hexBinary.</li> </ul> |
| java.lang.String                                         | xsd:string                                                                                                                                                                                                                                                                                                                                                                   |

| java.lang.Integer                                        | xsd:int xsi:nillable=true                                                                                                                                                                                                                                                                                                                                                    |
| java.lang.Short                                          | xsd:short xsi:nillable=true                                                                                                                                                                                                                                                                                                                                                  |
| java.lang.Byte                                           | xsd:byte xsi:nillable=true                                                                                                                                                                                                                                                                                                                                                   |

**Note:** The java.lang wrapper classes in the last seven lines of the table map to the same XML construct as the corresponding Java primitive type. In addition, the xsi:nillable attribute is generated to indicate that such elements can be null.

### • Additional Java class mappings

In addition to the standard JAX-RPC mapping, the following classes are mapped directly to XML types:

| Java type | XML type |
|-----------|----------|
|-----------|----------|

|                                                                                                                                                                              |                    |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| java.util.Map<br><b>Note:</b> Any classes that implement java.util.Map are also mapped to apache:Map.                                                                        | apache:Map         |
| java.util.Collection<br><b>Note:</b> Each Java array, except byte[], and every class that implements java.util.Collection is mapped to a JAX-RPC defined soapenc:Array type. | soapenc:Array      |
| org.w3c.dom.Element                                                                                                                                                          | apache:Element     |
| java.util.Vector                                                                                                                                                             | apache:Vector      |
| java.awt.Image<br><b>Note:</b> Used for attachment support.                                                                                                                  | apache:Image       |
| javax.mail.internet.MimeMultiPart<br><b>Note:</b> Used for attachment support.                                                                                               | apache:Multipart   |
| javax.xml.transform.Source<br><b>Note:</b> Used for attachment support.                                                                                                      | apache:Source      |
| javax.activation.DataHandler<br><b>Note:</b> Used for attachment support.                                                                                                    | apache:DataHandler |

## Generation of wsdl:types

Java types that cannot be mapped directly to standard XML types are generated in the wsdl:types section.

- **Java arrays**

Java arrays for the -use ENCODED option, with the exception of byte[], are generated using the following format. See the JAX-RPC specification for more details. Alternative mappings can be found in Table 18.1 of the JAX-RPC specification.

**Java:**

```
Item[]
```

**Mapped to:**

```
<xsd:complexType name="ArrayOfItem">
 <xsd:complexContent>
 <xsd:restriction base="soapenc:Array">
 <xsd:attribute ref="soapenc:arrayType" wsdl:arrayType="ns:Item"/>
 </xsd:restriction>
 </xsd:complexContent>
</xsd:complexType>
```

- **JAX-RPC value type and bean mapping**

A Java class that matches the Java value type or bean pattern is mapped to an xsd:complexType. In order for a Java class to be mapped to XML, follow these conditions:

- The class must have a public default constructor.
- The class must not implement, directly or indirectly, java.rmi.Remote.
- Public, non-static, non-final, non-transient fields are mapped. The class can contain other fields and methods, but they are not mapped.
- If the class follows the Java bean pattern and has public getter and setter methods, the property is mapped.

Additional mapping rules can be found in the JAX-RPC specification. The following example indicates the mapping for sample base and derived Java classes:

**Java:**

```

public abstract class Base {
 public Base() {}
 public int a; // mapped
 private int b; // mapped via setter/getter
 private int c; // not mapped
 private int[] d; // mapped via indexed setter/getter

 public int getB() { return b;} // map property b
 public void setB(int b) {this.b = b;}

 public int[] getD() { return d;} // map indexed property d
 public void setD(int[] d) {this.d = d;}
 public int getD(int index) { return d[index];}
 public void setB(int index, int value) {this.d[index] = value;}

 public void someMethod() {...} // not mapped
}

public class Derived extends Base {
 public int x; // mapped
 private int y; // not mapped
}

```

#### Mapped to:

```

<xsd:complexType name="Base" abstract="true">
 <xsd:sequence>
 <xsd:element name="a" type="xsd:int"/>
 <xsd:element name="b" type="xsd:int"/>
 <xsd:element name="d" minOccurs="0" maxOccurs="unbounded" type="xsd:int"/>
 </xsd:sequence>
</xsd:complexType>

<xsd:complexType name="Derived">
 <xsd:complexContent>
 <xsd:extension base="ns:Base">
 <xsd:sequence>
 <xsd:element name="x" type="xsd:int"/>
 </xsd:sequence>
 </xsd:extension>
 </xsd:complexContent>
</xsd:complexType>

```

#### ***Inheritance and abstract classes***

The example contains two optional JAX-RPC features that are supported by WebSphere Application Server:

1. An abstract class is mapped to an `xsd:complexType` with `abstract="true"`.
2. An indexed bean property (see the methods for `d` in `Base`) are mapped to a nested element specified with `maxOccurs="unbounded"`. This format is similar to an XML array, but the SOAP message is different. An XML array defines an element for the array and nested elements for each item in the array. An element defined with `maxOccurs` indicates a series of items without the surrounding array wrapper element. Both formats are popular.

- **JAX-RPC enumeration class mapping**

Section 4.2.4 of the JAX-RPC specification defines the mapping from an XML enumeration to a Java class. Though not specifically required by the JAX-RPC, the **Java2WSDL** command performs the reverse mapping. If you have a class that has the same format as a JAX-RPC enumeration class, it is mapped to an XML enumeration.

- **Holder classes**

The JAX-RPC specification defines Holder classes in section 4.3.5. A Holder class is used to support in and out parameter passing. Every Holder class implements the `javax.xml.rpc.holders.Holder` interface. The **Java2WSDL** command maps Holder classes to the same XML type as the held type. In addition, references to Holder classes affect the generation of `wsdl:messages`.

- **Exception classes**

If a class extends the exception, `java.lang.Exception`, it is mapped to an `xsd:complexType` similar to the Java bean mapping. The getter methods of the exception are mapped as nested `xsd:elements` of the `xsd:complexType`. See section 5.5.5 of the JAX-RPC specification for more details.

**Note:** You need to generate implementation specific exception classes by invoking the **WSDL2Java** command on the resulting WSDL file.

- **Unsupported classes**

If a class cannot be mapped to an XML type, the **Java2WSDL** command issues a message and an `xsd:anyType` reference is generated in the WSDL file. In these situations, modify the Web service implementation to use the JAX-RPC compliant classes.

- **Generation of root elements**

If the **Java2WSDL** command generates an `xsd:complexType` or `xsd:simpleType` for a parameter reference, a corresponding `xsd:element` is also generated. The `xsd:element` has the same name as the `xsd:complexType/xsd:simpleType` and uses the `type` attribute to reference the `xsd:complexType/xsd:simpleType`. The `wsdl:message` part can use the `element` attribute or the `type` attribute to reference the `xsd:element` or `type`. This choice is determined by the `-style` and `-use` options.

## Generation from the interface or implementation class

The class passed to the **Java2WSDL** command represents the interface of the `wsdl:service`. The `wsdl:portType` and `wsdl:message` elements generate from this interface or implementation class.

- **Generation of the `wsdl:portType`**

The name of the `wsdl:portType` is the name of the class unless overridden by the `-portTypeName` option.

- **Generation of `wsdl:operation`**

A `wsdl:operation` generates for each public method in the interface that throws the exception, `java.rmi.RemoteException`.

- The name of the `wsdl:operation` is the name of the method.
- The `wsdl:operation` has a `parameterOrder` attribute, which defines the order of the parameters in the signature. Specifically, the `parameterOrder` lists the order of the parts of the request or response `wsdl:messages`.
- The `wsdl:operation` has a nested `wsdl:input` element that references the request `wsdl:message` using the `message` attribute.
- The `wsdl:operation` has a nested `wsdl:output` element that references the response `wsdl:message` using the `message` attribute.
- The `wsdl:operation` has a nested `wsdl:fault` element that references the default `wsdl:message` using the `message` attribute.

See sections 5.5.4 and 5.5.5 of the JAX-RPC specification for more information.

- **Generation of `wsdl:message`**

Generating the `wsdl:message` is directly related to the `-style` and `-use` options. The following is the default mapping (`-style RPC -use ENCODED`):

- A `wsdl:message` is created to represent the request.
  - A `wsdl:part` representing each parameter is added to the `wsdl:message`.
    - The `wsdl:part` has the same name as the parameter.
    - The `wsdl:part` uses the `type` attribute to locate the XML type of the parameter.
- A `wsdl:message` is created to represent the response:
  - A `wsdl:part` representing the method return is created.
    - The `wsdl:part` has the same name as the method with `Return` appended.

**Note:**

The name of the part is not specified by the JAX-RPC and is typically not checked by SOAP engines.

- The `wsdl:part` has the same name as the parameter.
- The `wsdl:part` uses the `type` attribute to locate the XML type of the parameter.

- A `wsdl:part` is created for each parameter that is a Holder.
- The `wsdl:part` has the same name as the parameter.
- A `wsdl:message` is created to represent the fault if the operation has a `wsdl:fault`.
- A `wsdl:part` representing the fault is created.
- The `wsdl:part` has the same name as the exception.
- The `wsdl:part` uses the `type` attribute to locate the `complexType` representing the exception.

The same mapping is used as described if you use the `-style RPC` and `-use LITERAL` options. It is also valid to use the `wsdl:part` element attribute instead of the `type` attribute to reference the XML schema. If you use the `-style DOCUMENT -wrapped false` and `-use LITERAL` options, the same mapping is used as described except the `wsdl:part` element attribute is used to reference the XML schema. If the XML schema is a primitive type, like `xsd:string`, the `type` attribute is used to reference the XML type. The `-style DOCUMENT, -wrapped true` and `-use LITERAL` options result in completely different mappings for the request and response messages. For example:

- A request `xsd:element` is generated for each method in the Service Endpoint Interface.
  - The name of the `xsd:element` is the same as the name of the `wsdl:operation`.
  - The `xsd:element` contains an `xsd:sequence` that contains `xsd:elements` defining each parameter.
  - The request `wsdl:message` references the wrapper `xsd:element` using a single part.
    - The name of the part is `parameters`.
    - The `element` attribute is used to reference the wrapper `xsd:element`.
- A response `xsd:element` is generated for each method in the Service Endpoint Interface.
  - The name of the `xsd:element` is the same as the name of the `wsdl:operation` appended with `Response`.
  - The `xsd:element` contains an `xsd:sequence` that contains `xsd:elements` defining the return value.
  - The request `wsdl:message` references this wrapper `xsd:element` using a single part.
    - The `element` attribute is used to reference the wrapper `xsd:element`.

- **Generation of `wsdl:binding`**

Generate a `wsdl:binding` with a name defined by the **Java2WSDL -bindingName** command.

- The `wsdlsoap:binding` style attribute is set to `rpc` if you use the `-style RPC` option; otherwise it is set to `document`.
- A `wsdl:operation` generates for each `wsdl:operation` defined in the `wsdl:portType`.
- Each `wsdl:operation` has corresponding `wsdl:input`, `wsdl:output` and `wsdl:fault` elements.
- The `wsdl:input`, `wsdl:output` and `wsdl:fault` elements each contain a `wsdlsoap:body` element.
- The `wsdlsoap:body` use attribute is set to `literal` or `encoded` according to the **-use** argument. Set the `encodingStyle` attribute to `http://schemas.xmlsoap.org/soap/encoding/` when **use** is `encoded`.

- **Generation of the `wsdl:service`**

Generate a `wsdl:service` with a name defined by the **Java2WSDL -serviceElement** command. For example:

- The `wsdl:service` contains a port with a name defined by the **Java2WSDL -servicePortName** command.
- The port references the generated `wsdl:binding` with the `binding` attribute.
- The port contains a `wsdlsoap:address` element with a
- The `location` attribute is set to the value of the **Java2WSDL -location** command.

## WSDL-to-Java mapping

The **WSDL2Java** command tool uses the following rules to generate Java classes when developing your Web services client and server. In addition, implementation specific Java classes are generated that assist in the serialization and deserialization, and invocation of the Web service.

### General issues

- **Mapping of namespace to package**

The JAX-RPC does not specify the mapping of XML namespaces to Java package names. The JAX-RPC does specify that each Java package map to a single XML namespace. Likewise, each XML namespace must map to a single Java package. A default mapping algorithm omits any protocol from

the XML namespace and reverses the names. For example, an XML namespace `http://websphere.ibm.com` becomes a Java package with the name `com.ibm.websphere`.

The default mapping of XML namespace to Java package disregards the context-root. If two namespaces are the same up until the first slash, they map to the same Java package. For example, the XML namespaces `http://websphere.ibm.com/foo` and `http://websphere.ibm.com/bar` map to the Java package `com.ibm.websphere`. The default mapping between XML namespaces and Java package names can be overridden using the `-NStoPkg` and `-PkgtoNS` options of **WSDL2Java** and **Java2WSDL** commands.

- **Identifier mapping**

XML names are much richer than Java identifiers. They can include characters that are not permitted in Java identifiers. See section 20 of the JAX-RPC specification for the rules to map an XML name to a Java identifier.

The mapping rules attempt to follow accepted Java coding conventions. Class names always begin with an uppercase letter. Method names begin with a lowercase letter. The **WSDL2Java** command generates metadata in the `_Helper` class so that the values are serialized or deserialized using the XML names specified in the WSDL file.

- **Java construction summary**

| WSDL and XML                                                                                                                                                                                                                                                             | Java                                                                                                                                                                                                                     |

### Mapping standard XML types

- **JAX-RPC simple XML types mapping**

The following mappings are XML types to Java types. For more information about these mappings, see section 4.2.1 of the JAX-RPC specification.

| XML type                                                                                                                                                           | Java type            |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|
| xsd:string                                                                                                                                                         | java.lang.String     |
| xsd:integer                                                                                                                                                        | java.math.BigInteger |
| xsd:int<br><b>Note:</b> If an element with this type has the xsi:nillable attribute set to true, it is mapped to the Java wrapper class of the primitive type.     | int                  |
| xsd:long<br><b>Note:</b> If an element with this type has the xsi:nillable attribute set to true, it is mapped to the Java wrapper class of the primitive type.    | long                 |
| xsd:short<br><b>Note:</b> If an element with this type has the xsi:nillable attribute set to true, it is mapped to the Java wrapper class of the primitive type.   | short                |
| xsd:decimal                                                                                                                                                        | java.math.BigDecimal |
| xsd:float<br><b>Note:</b> If an element with this type has the xsi:nillable attribute set to true, it is mapped to the Java wrapper class of the primitive type.   | float                |
| xsd:double<br><b>Note:</b> If an element with this type has the xsi:nillable attribute set to true, it is mapped to the Java wrapper class of the primitive type.  | double               |
| xsd:boolean<br><b>Note:</b> If an element with this type has the xsi:nillable attribute set to true, it is mapped to the Java wrapper class of the primitive type. | boolean              |
| xsd:byte<br><b>Note:</b> If an element with this type has the xsi:nillable attribute set to true, it is mapped to the Java wrapper class of the primitive type.    | byte                 |
| xsd:dateTime                                                                                                                                                       | java.util.Calendar   |
| xsd:date<br><b>Note:</b> This mapping is not supported by the JAX-RPC.                                                                                             | java.util.Date       |
| xsd:base64Binary                                                                                                                                                   | byte[]               |
| xsd:hexBinary                                                                                                                                                      | byte[]               |
| --                                                                                                                                                                 | --                   |
| soapenc:base64                                                                                                                                                     | byte[]               |
| soapenc:base64Binary                                                                                                                                               | byte[]               |
| soapenc:string                                                                                                                                                     | java.lang.String     |
| soapenc:boolean                                                                                                                                                    | java.lang.Boolean    |
| soapenc:float                                                                                                                                                      | java.lang.Float      |
| soapenc:double                                                                                                                                                     | java.lang.Double     |
| soapenc:decimal                                                                                                                                                    | java.math.BigDecimal |
| soapenc:int                                                                                                                                                        | java.lang.Integer    |
| soapenc:integer<br><b>Note:</b> This mapping is not supported by the JAX-RPC.                                                                                      | java.math.BigInteger |
| soapenc:short                                                                                                                                                      | java.lang.Short      |

|                                                            |                |
|------------------------------------------------------------|----------------|
| soapenc:long                                               | java.lang.Long |
| <b>Note:</b> This mapping is not supported by the JAX-RPC. |                |
| soapenc:byte                                               | java.lang.Byte |

- **JAX-RPC optional simple XML type mapping**

The **WSDL2Java** command supports the following JAX-RPC optional simple XML types.

| XML type  | Java type                 |
|-----------|---------------------------|
| xsd:qname | javax.xml.namespace.QName |

- **JAX-RPC xsd:anyType mapping**

The **WSDL2Java** command maps an `xsd:anyType` to a `java.lang.Object`. This is an optional feature of the JAX-RPC specification. The `xsd:anyType` can be used to store any XML type other than the XML primitive type. An `xsd:anyType` is always serialized along with an `xsi:type` that specifies the actual type.

- **Additional supported mappings**

The following mappings are also supported by the **WSDL2Java** command. These mappings are not defined by the JAX-RPC specification.

| XML type                           | Java type                         |
|------------------------------------|-----------------------------------|
| apache:PlainText                   | java.lang.String                  |
| <b>Note:</b> For MIME attachments. |                                   |
| apache:Map                         | java.util.Map                     |
| apache:Element                     | org.w3c.dom.Element               |
| apache:Vector                      | java.util.Vector                  |
| apache:Image                       | java.awt.Image                    |
| <b>Note:</b> For MIME attachments. |                                   |
| apache:Multipart                   | javax.mail.internet.MimeMultipart |
| <b>Note:</b> For MIME attachments. |                                   |
| apache:Source                      | javax.xml.transform.Source        |
| <b>Note:</b> For MIME attachments. |                                   |
| apache:octetStream                 | javax.activation.DataHandler      |
| <b>Note:</b> For MIME attachments. |                                   |
| apache:DataHandler                 | javax.activation.DataHandler      |
| <b>Note:</b> For MIME attachments. |                                   |

## Mapping XML defined in the `wsdl:types` section

The **WSDL2Java** command generates Java types for the XML schema constructs defined in the `wsdl:types` section. The XML schema language is broader than the required or optional subset defined by the JAX-RPC specification. The **WSDL2Java** command supports all required mappings and most optional mappings. In addition, the command supports some XML schema mappings that are outside the JAX-RPC specification. In general, the **WSDL2Java** command ignores constructs that it does not support. For example, the **WSDL2Java** command does not support the `default` attribute. If an `xsd:element` is defined with the `default` attribute, the `default` attribute is ignored. In some cases it maps unsupported constructs to `wasws:SOAPElement`.

- **Mapping of `xsd:complexType` to Java bean**

The most common mapping is from an `xsd:complexType` to a Java bean class.

- **Standard Java bean mapping**

The standard Java bean mapping is defined in section 4.2.3 of the JAX-RPC specification. The `xsd:complexType` defines the type. The nested `xsd:elements` within the `xsd:sequence` or `xsd:all` groups are mapped to Java bean properties. For example:

**XML:**

```
<xsd:complexType name="Sample">
 <xsd:sequence>
 <xsd:element name="a" type="xsd:string"/>
 <xsd:element name="b" maxOccurs="unbounded" type="xsd:string"/>
 </xsd:sequence>
</xsd:complexType>
```

**Java:**

```
public class Sample {
 // ..
 public Sample() {}

 // Bean Property a
 public String getA() {...}
 public void setA(String value) {...}

 // Indexed Bean Property b
 public String[] getB() {...}
 public String getB(int index) {...}
 public void setB(String[] values) {...}
 public void setB(int index, String value) {...}
}
}
```

– **Methods equals() and hashCode()**

The generated Java bean classes contain an implementation of the equals() method. The generation of this method is outside the JAX-RPC specification. The equals() method returns true if equals() is true for each contained bean property. The implementation accounts for self-referencing loops. This version of the equals() method is typically more useful than the "identity" equals provided by java.lang.Object.

A corresponding hashCode() method is also generated in the Java bean class.

– **Properties and indexed properties**

In the standard Java bean mapping example, the nested xsd:element for property a is mapped to a Java bean property. In addition, the **WSDL2Java** command maps a nested xsd:element with maxOccurs > 1 to a Java bean indexed property.

– **Attributes**

The **WSDL2Java** command also supports the xsd:attribute element, as shown in the following example.

Attribute a is mapped as a Java bean property, which is exactly the same mapping as a nested xsd:element. Implementation specific metadata is generated in the Sample2\_Helper class to ensure that property a is serialized and deserialized as an attribute, and not as a nested element. For example:

**XML:**

```
<xsd:complexType name="Sample2">
 <xsd:sequence>
 <xsd:attribute name="a" type="xsd:string"/>
 </xsd:sequence>
</xsd:complexType>
```

**Java:**

```
public class Sample2 {
 // ..
 public Sample2() {}
}
```

```

 // Bean Property a
 public String getA() {...}
 public void setA(String value) {...}
}

```

– **Qualified versus unqualified names**

The **WSDL2Java** command supports the `elementForm` and `attributeForm` schema attributes.

This support is not specified in the JAX-RPC specification. These attributes are used to indicate whether an element or attribute is serialized and deserialized with a qualified or unqualified name. The default setting for `elementForm` is `qualified` and the default setting for `attributeForm` is `unqualified`. These settings do not affect the Java bean class that is generated, but the information is captured in the `_Helper` class metadata.

– **Extension and the abstract attribute**

The **WSDL2Java** command supports extension of an `xsd:complexType` through the `xsd:extension` element. This support is required by the JAX-RPC specification.

The **WSDL2Java** command supports the `abstract` attribute. This feature is listed as optional by the JAX-RPC specification.

The following example shows the accepted use of the extension and abstract constructs. WebSphere Application Server uses the extension and abstract constructs to support polymorphism.

**XML:**

```

<xsd:complexType name="Base" abstract="true">
 <xsd:sequence>
 <xsd:element name="a" type="xsd:int"/>
 </xsd:sequence>
</xsd:complexType>

<xsd:complexType name="Derived">
 <xsd:complexContent>
 <xsd:extension base="ns:Base">
 <xsd:sequence>
 <xsd:element name="b" type="xsd:int"/>
 </xsd:sequence>
 </xsd:extension>
 </xsd:complexContent>
</xsd:complexType>

```

**Java:**

```

public abstract class Base {
 // ...
 public Base() {}

 public int getA() {...}
 public void setA(int a) {...}
}

public class Derived extends Base {
 // ...
 public Derived() {}

 public int getB() {...}
 public void setB(int b) {...}
}

```

– **Support for `xsd:any`**

The **WSDL2Java** command supports `xsd:anyElement`, which is different than `xsd:anyType`. This feature is not defined within the JAX-RPC specification and is subject to change.

If an `<xsd:any/>` element is defined within `xsd:sequence` or `xsd:all` group, SOAP values that do match one of the `xsd:elements` are stored in the Java bean. Values can be accessed from the Java bean using the `get_any()` and `set_any()` methods.

- **Mapping of `xsd:element`**

An `xsd:element` is a construct that has a name or name attribute, and a type defined by a `complexType` or primitive type. There are two different kinds of `xsd:elements`:

- **Root:** Defined directly underneath the schema elements and referenced by other constructs.
- **Nested:** Nested underneath group elements and are not referenced by other constructs.

Root elements are referenced by the WSDL file constructs, especially if the WSDL file is used to describe a literal service. Typically, root elements and types have the same names, which is allowed in the schema language. Under most circumstances the **WSDL2Java** command can produce Java artifacts without name collisions.

- **Four ways to reference a type**

There are four ways that a nested or root `xsd:element` can reference a type:

- **Use the type attribute:**

This is the most common way to reference a type, for example:

```
<xsd:element name="one" type="ns:myType"/>
```

The **WSDL2Java** command recognizes the type attribute as a reference to a `complexType` or `simpleTypeName`, `myType`. The **WSDL2Java** command generates a Java type based on the characteristics of `myType`. Support for the type attribute is required by the JAX-RPC specification.

- **Use the ref attribute:** For example:

```
<xsd:element ref="ns:myElement"/>
```

The **WSDL2Java** command recognizes the `ref` attribute as a reference to another root element named `myElement`. The name of the element is obtained from the referenced element, such as `myElement`. The type of the element is the type of the referenced element. The **WSDL2Java** command generates a Java type based on the characteristics of the referenced type. The `ref` attribute is an optional feature of the JAX-RPC specification.

- **Use no attribute:**

For example:

```
<xsd:element name="three"/>
```

When you do not use an attribute, the **WSDL2Java** command recognizes a reference to the `xsd:anyType` as defined by the XML schema specification. The `xsd:anyType` is an optional type of the JAX-RPC specification.

- **Use an anonymous type:**

For example:

```
<xsd:element name="four">
 <xsd:complexType>
 <xsd:sequence>
 <xsd:element name="foo" type="xsd:string"/>
 </xsd:sequence>
 </xsd:complexType>
</xsd:element>
```

When you use an anonymous type, the **WSDL2Java** command recognizes a reference to the type defined within the element.

**Note:** The `complexType` does not have a name.

The **WSDL2Java** command generates a Java type based on the characteristics of this type. Since the anonymous type does not have a name, the **WSDL2Java** command uses the name of the container element, which can result in collisions with defined types and other anonymous types.

The **WSDL2Java** command automatically detects and renames classes to avoid collisions.

Support for anonymous types is not defined by the JAX-RPC specification, however using anonymous types is common.

**Note:** An `xsd:attribute` is like an `xsd:element`; it contains a name and refers to a type. An `xsd:attribute` can refer to its type with the `typeattribute` or using an anonymous type.

– **Element specific attributes**

Some attributes can be applied to `xsd:elements` and not to XML types.

The `maxOccurs` attribute indicates the maximum number of occurrences of the element in the SOAP message. The default value is 1. If the value is greater than 1, or unbounded, the **WSDL2Java** command maps the construct to a Java array or bean indexed property. Metadata is also generated to properly serialize and deserialize a series of elements versus a normal XML array. The `maxOccurs` attribute is an optional feature of the JAX-RPC specification.

The `minOccurs` attribute indicates the minimum number of occurrences of the element in the SOAP message. The default value is 1. The `xsi:nillable` attribute indicates whether the element can have a `nil` value. The `minOccurs` and `xsi:nillable` settings affect how a `null` value is serialized in a SOAP message. If `minOccurs=0`, the `null` value is not serialized. If `xsi:nillable=true`, the value is serialized with the `xsi:nil=true` attribute.

• **Mapping of `xsd:complexType` to Java array**

The **WSDL2Java** command maps the following three kinds of XML formats to Java arrays:

**XML:**

```
<xsd:element name="array1" type="soapenc:Array"/>
```

**Java:**

```
Object[] array1;
```

**XML:**

```
<xsd:complexType name="arrayOfInt">
 <xsd:complexContent>
 <xsd:restriction base="soapenc:Array">
 <xsd:attribute ref="soapenc:arrayType" wsdl:arrayType="xsd:int[]"/>
 </xsd:restriction>
 </xsd:complexContent>
</xsd:complexType>

<xsd:element name="array2" type="ns:arrayOfInt"/>
```

**Java:**

```
int[] array2;
```

**XML:**

```
<xsd:complexType name="arrayOfInt">
 <xsd:complexContent>
 <xsd:restriction base="soapenc:Array">
 <xsd:sequence>
 <xsd:element name="item" type="xsd:int" maxOccurs="unbounded"/>
 </xsd:sequence>
 </xsd:restriction>
 </xsd:complexContent>
</xsd:complexType>

<xsd:element name="array3" type="ns:arrayOfInt"/>
```

**Java:**

```
int[] array3;
```

• **Mapping of `xsd:simpleType enumeration`**

The **WSDL2Java** command maps the following XML enumeration to a JAX-RPC specified enumeration class. See section 4.2.4 of the JAX-RPC specification for more details.

```

<xsd:simpleType name="EyeColorType">
 <xsd:restriction base="xsd:string">
 <xsd:enumeration value="brown"/>
 <xsd:enumeration value="green"/>
 <xsd:enumeration value="blue"/>
 </xsd:restriction>
</xsd:simpleType>

```

- **Mapping of xsd:complexType to exception class**

If a complexType is referenced in a wsdl:message for a wsdl:fault, the complexType is mapped to a class that extends the exception, java.lang.Exception. This mapping is similar to the mapping of a complexType to a Java bean class, except a full constructor is generated, and only getter methods are generated. See section 4.3.6 of the JAX-RPC specification for more details.

- **Other mappings**

The **WSDL2Java** command supports the mapping of xsd:simpleType and xsd:complexTypes that extend xsd:simpleTypes. These constructs are mapped to Java bean classes. The simple value is mapped to a Java bean property named, value. This is an optional feature of the JAX-RPC specification.

## Mapping of wsdl:portType

The wsdl:portType construct is mapped to the Service Endpoint Interface. The name of the wsdl:portType is mapped to the name of the class of the Service Endpoint Interface.

## Mapping of wsdl:operation

A wsdl:operation within a wsdl:portType is mapped to a method of the Service Endpoint Interface. The name of the wsdl:operation is mapped to the name of the method. The wsdl:operation contains wsdl:input and wsdl:output elements that reference the request and response wsdl:message constructs using the message attribute. The wsdl:operation can contain a wsdl:fault element that references a wsdl:message describing the fault. These faults are mapped to Java classes that extend the exception, java.lang.Exception as discussed in section 4.3.6 of the JAX-RPC specification.

- **Effect of document literal wrapped format**

If the WSDL file uses the .NET document and literal wrapped format, the method parameters are mapped from the wrapper xsd:element. The .NET document and literal format is automatically detected by the **WSDL2Java** command. The following criteria must be met:

- The WSDL file must have style="document" in its wsdl:binding constructs.
- The WSDL file must have use="literal" in its wsdl:binding constructs.
- The wsdl:message referenced by the wsdl:operation input construct must have a single part.
- The part must use the element attribute to reference an xsd:element.
- The referenced xsd:element, or wrapper element, must have the same name as the wsdl:operation.
- The wrapper element must not contain any xsd:attributes.

In such cases, each parameter name is mapped from a nested xsd:element contained within wrapper element. The type of the parameter is mapped from the type of the nested xsd:element. For example:

**XML:**

```

<xsd:element name="myMethod">
 <xsd:complexType>
 <xsd:sequence>
 <xsd:element name="param1" type="xsd:string"/>
 <xsd:element name="param2" type="xsd:int"/>
 </xsd:sequence>
 </xsd:complexType>
</xsd:element>
...
<wsdl:message name="response"/>
 <part name="parameters" element="ns:myMethod"/>
</wsdl:message name="response"/>

<wsdl:message name="response"/>

```

```

...
<wsdl:operation name="myMethod">
 <input name="input" message="request"/>
 <output name="output" message="response"/>
</wsdl:operation>

```

**Java:**

```
void myMethod(String param1, int param2) ...
```

- **Parameter mapping**

If the document and literal wrapped format is not detected, the parameter mapping follows the normal JAX-RPC mapping rules set in section 4.3.4 of the JAX-RPC specification.

Each parameter is defined by a `wsdl:message` part referenced from the input and output elements.

- A `wsdl:part` in the request `wsdl:message` is mapped to an input parameter.
- A `wsdl:part` in the response `wsdl:message` is mapped to the return value. If there are multiple `wsdl:parts` in the response message, they are mapped to output parameters.
  - A Holder class is generated for each output parameter as discussed in section 4.3.5 of the JAX-RPC specification.
- A `wsdl:part` that is both the request and response `wsdl:message` is mapped to an inout parameter.
  - A Holder class is generated for each inout parameter as discussed in section 4.3.5 of the JAX-RPC specification.
  - The `wsdl:operation parameterOrder` attribute defines the order of the parameters.

The **WSDL2Java** command supports overloaded methods, but confirm that the part names of the overloaded methods are unique. For example:

**XML:**

```

<wsdl:message name="request">
 <part name="param1" type="xsd:string"/>
 <part name="param2" type="xsd:int"/>
</wsdl:message name="request"/>

<wsdl:message name="response"/>

...
<wsdl:operation name="myMethod" parameterOrder="param1, param2">
 <input name="input" message="request"/>
 <output name="output" message="response"/>
</wsdl:operation>

```

**Java:**

```
void myMethod(String param1, int param2) ...
```

## Mapping of `wsdl:binding`

The **WSDL2Java** command uses the `wsdl:binding` information to generate an implementation specific client side stub. WebSphere Application Server uses the `wsdl:binding` information on the server side to properly deserialize the request, invoke the Web service, and serialize the response. The information in the `wsdl:binding` should not affect the generation of the Service Endpoint Interface, but it can when the document and literal wrapped format is used or when there are MIME attachments.

- **MIME attachments**

For a WSDL 1.1 compliant WSDL file, a part of an operation message, which is defined in the binding to be a MIME attachment, becomes a parameter of the type of the attachment regardless of the part declared. For example:

**XML:**

```

<wsdl:types>
 <schema ...>
 <complexType name="ArrayOfBinary">
 <restriction base="soapenc:Array">
 <attribute ref="soapenc:arrayType" wsdl:arrayType="xsd:binary[]" />
 </restriction>
 </complexType>
 </schema>
</wsdl:types>

```

```

 </restriction>
 </complexType>
</schema>
</wsdl:types>

<wsdl:message name="request">
 <part name="param1" type="ns:ArrayOfBinary"/>
</wsdl:message name="response"/>

<wsdl:message name="response"/>
 ...

<wsdl:operation name="myMethod">
 <input name="input" message="request"/>
 <output name="output" message="response"/>
</wsdl:operation>
 ...

<binding ...
<wsdl:operation name="myMethod">
 <input>
 <mime:multipartRelated>
 <mime:part>
 <mime:content part="param1" type="image/jpeg"/>
 </mime:part>
 </mime:multipartRelated>
 </input>
 ...
</wsdl:operation>

```

**Java:**

```
void myMethod(java.awt.Image param1) ...
```

The JAX-RPC requires support for the following MIME types:

| MIME type       | Java type                         |
|-----------------|-----------------------------------|
| image/gif       | java.awt.Image                    |
| image/jpeg      | java.awt.Image                    |
| text/plain      | java.lang.String                  |
| multipart/*     | javax.mail.internet.MimeMultipart |
| text/xml        | javax.xml.transform.Source        |
| application/xml | javax.xml.transform.Source        |

There are a number of problems with MIME attachments as they are defined in WSDL 1.1, including:

- The semantics of the mime:multipartRelated clause are not fully defined
- The semantics do not allow for arrays of MIME attachments

Because of these problems, several types are not specified by the JAX-RPC for MIME attachments.

These types are defined in the supported mappings previously discussed.

• **Headers**

A wsdl:binding can also define SOAP headers, for example:

**XML:**

```

<wsdl:message name="request">
 <part name="param1" type="xsd:string"/>
</wsdl:message/>

 ...

 <wsdl:message name="response"/>
 ...

 <wsdl:operation name="myMethod">

```

```

 <input name="input" message="request"/>
 <output name="output" message="response"/>
 </wsdl:operation>
 ...
<binding ...
 <wsdl:operation name="myMethod">
 <input>
 <soap:header message="request" part="param1" use="literal"/>
 </input>
 ...
 </wsdl:operation>

```

#### Java:

```
void myMethod(String param1) ...
```

This is an example of an explicit header or a header with a value determined from a method parameter. Instead of appearing in the `soap:body` SOAP message, the value of `param1` now appears in the `soap:header` SOAP message. The **WSDL2Java** command supports explicit headers and does not support implicit headers. Implicit headers have a value not determined by a parameter. For example, you could replace the `soap:header` clause in the example with:

```
<soap:header message="someOtherMsgNotAppearingInThePortType" part="someOtherPart"
use="literal"/>
```

**Note:** The **WSDL2Java** command supports explicit headers, but it is not considered good programming practice to use them. Headers are typically used for middleware logic, not business logic. Explicit headers place parameters used in business logic into the header.

### Mapping of `wsdl:service`

The `wsdl:service` element is mapped to a Generated Service interface. The Generated Service interface contains methods to access each of the ports in the `wsdl:service`. The Generated Service interface is discussed in sections 4.3.9, 4.3.10, and 4.3.11 of the JAX-RPC specification.

In addition, the `wsdl:service` element is mapped to the implementation-specific `ServiceLocator` class, which is an implementation of the Generated Service interface.

### Mapping between WSDL and SOAP messages

The WSDL file defines the format of the SOAP message that is sent over the wire. The **WSDL2Java** command and the WebSphere Application Server run time use the information in the WSDL file to confirm that the SOAP message is properly serialized and deserialized.

### Document versus RPC, literal versus encoded

If a `wsdl:binding` indicates a message is sent using an RPC format, the SOAP message contains an element defining the operation. If a `wsdl:binding` indicates the message is sent using a document format, the SOAP message does not contain the operation element.

If the `wsdl:part` is defined using the `type` attribute, the name and type of the part are used in the message. If the `wsdl:part` is defined using the `element` attribute, the name and type of the element are used in the message. The `element` attribute is not allowed by the JAX-RPC specification when `use="encoded"`.

If a `wsdl:binding` indicates a message is encoded, the values in the message are sent with `xsi:type` information. If a `wsdl:binding` indicates that a message is literal, the values in the message are typically not sent with `xsi:type` information. For example:

**WSDL:**

```

<xsd:element name="c" type="xsd:int"/>
...
<wsdl:message name="request">
 <part name="a" type="xsd:string"/>
 <part name="b" element="ns:c"/>
</wsdl:message>
...
<wsdl:operation name="method">
 <input message="request"/>
...

```

**RPC/ENCODED:**

```

<soap:body>
 <ns:method>
 <a xsi:type="xsd:string">ABC
 <element attribute is not allowed in rpc/encoded mode>
 </ns:method>
</soap:body>

```

**DOCUMENT/LITERAL:**

```

<soap:body>
 <a>ABC
 <c>123
</soap:body>

```

**DOCUMENT/LITERAL wrapped:**

```

<soap:body>
 <ns:method_wrapper>
 <a>ABC
 <c>123
 </ns:method_wrapper>
</soap:body>

```

The document and literal wrapped mode is the same as the document and literal mode. However, in the document and literal wrapped mode, there is only a single element within the body, and the element has the same name as the operation.

**Multi-ref processing**

If use=encoded, XML types that are not simpleTypes are passed in the SOAP message using the multi-ref attributes, href and id. The following example assumes that parameters one and two reference the same Java bean named, info containing fields a and b:

**Note:**

Deserialization produces a single instance of the info class for the encoded case and two instances are created for the literal case.

**RPC/ENCODED:**

```

<soap:body>
 <ns:method>
 <param1 href="#id1"/>
 <param2 href="#id2"/>
 </ns:method>
 <multiref id="id1" xsi:type="ns:info">
 <a xsi:type="xsi:string">hello<a>
 <b xsi:type="xsi:string">world
 </multiref>
</soap:body>

```

**RPC/LITERAL:**

```

<soap:body>
 <ns:method>
 <param1>
 <a>hello

```

```

 world
 </param1>
 <param2>
 <a>hello
 world
 </param2>
</ns:method>
</soap:body>

```

## XML arrays and the maxOccurs attribute

A SOAP message is affected by whether the element is defined by an XML array or using the maxOccurs attribute.

### WSDL:

```
<element name="foo" type="ns:ArrayOfString"/>
```

### Literal Instance:

```

<foo>
 <item>A</item>
 <item>B</item>
 <item>C</item>
</foo>

```

### WSDL:

```
<element name="foo" maxOccurs="unbounded" type="xsd:string"/>
```

### Literal Instance:

```

<foo>A</foo>
<foo>B</foo>
<foo>C</foo>

```

## minOccurs and nillable attributes

An element specified with minOccurs=0 that has a null value is not serialized in the SOAP message. An element specifying nillable="true" has a null value and is serialized into a SOAP message with the xsi:nil=true attribute. For example:

```
<a xsi:nil="true"/>
```

## Qualified versus unqualified

The XML schema attributeForm and elementForm attributes indicate whether the attributes and nested elements are serialized with qualified or unqualified names. If a part name is serialized, it is always serialized as an unqualified name.

## Java2WSDL command

The **Java2WSDL** command maps a Java class to a Web Services Description Language (WSDL) file by following the Java API for XML-based remote procedure call (JAX-RPC) specification. The **Java2WSDL** command accepts a Java class as input and produces a WSDL file representing the input class. If there is an existing file at the output location, it is overwritten. The WSDL file generated by the **Java2WSDL** command contains WSDL and XML schema constructs that are automatically derived from the input class. You can override these default values with command-line arguments.

### Command line syntax and arguments

The command line syntax is:

```
Java2WSDL [argument...] class
```

The following command-line arguments are supported:

## Required arguments

- **class**

Represents the fully qualified name of one of the following Java classes:

- Stateless session EJB remote interface that extends the javax.ejb.EJBObject class
- Service Endpoint Interface that extends the java.rmi.Remote class
- Java bean

The **Java2WSDL** command locates the class in CLASSPATH.

## Important arguments

- **-bindingName *name***

Specifies the name to use for the binding element. If not specified, the binding name is the portTypeName.

- **-help**

Displays the help message.

- **-helpX**

Displays the help message for extended options.

- **HelpOptions**

- **-debug**

Displays debug messages.

- **-outputImpl *impl-wsdl***

Specifies if you want an interface and implementation WSDL file emitted.

- **-locationImport *location-uri***

Specifies the location of the interface WSDL file if you use the -outputImpl argument specified.

- **-MIMEStyle**

Specifies a style representing Multipurpose Internet Mail Extensions (MIME) information. Valid arguments are:

- **Axis**
- **WSDL11** (default)

- **-soapAction**

Valid arguments are:

- **DEFAULT**

Sets the soapAction field according to deployment information.

- **NONE**

Sets the soapAction field to "".

- **OPERATION**

Sets the soapAction field to the operation name.

- **-stopClasses *parent* [, *parent*]**

If the -all argument is specified, the **Java2WSDL** command searches inherited classes and interfaces to construct the list of methods for WSDL file operations. The **Java2WSDL** command searches inherited classes and interfaces when generating extended complexTypes. The search stops when a class or interface is found within a package that begins with java or javax. The -stopClasses argument can be used to define additional classes that cause the search to stop.

- **-namespaceImpl *namespace***

Specifies the target namespace for the implementation WSDL if -outputImpl specified.

- **-voidReturn**

Valid arguments are:

- **ONEWAY**

Methods with void returns are one-way. This is the default for JMS transport.

- **TOWAY**

Methods with void returns are two-way. This the default for HTTP transport.

- **-wrapped *boolean***

Specifies if the WSDL file should be generated according to wrapped rules. This is only valid if use is literal. The option defaults to true.

- **-extraClasses *classes***

Specifies other classes that should be represented in the WSDL file.

- **-input *wsdl-uri***

Specifies the input WSDL file used to build an output WSDL file. Information from an existing WSDL file, whose name is specified in this option, is used with the input Java class to generate the desired output.

- **-implClass *impl-class***

The **Java2WSDL** command uses method parameter names to construct the WSDL file message part names. The command automatically obtains the message names from the debug information in the class. If the class is compiled without debug information, or if the class is an interface, the method parameter names are not available. In this case, you can use the **-implClass** argument to provide an alternative class from which to obtain method parameter names. The **impl-class** does not need to implement the class if the class is an interface, but it must implement the same methods as class.

- **-location *location***

Provides the location or Uniform Resource Locator (URL) of the service. Typically, this value fills automatically when the Web service deploys. Use this argument to specify the location if you want to generate a WSDL file containing a location URL without deploying. A warning displays to remind you that the generated WSDL file should not be published if the final location is not yet been determined. The name after the last slash or backslash is the name of the service port, unless the name is overridden by the **-servicePortName** argument. The service port address location attribute is assigned the specified value.

- **-namespace *targetNamespace***

Indicates the target namespace for the WSDL file being generated. See Mapping between Java, WSDL and XML for the algorithm used to obtain the default namespace.

- **-output *wsdl-uri***

Indicates the path and file name of the output WSDL file. If not specified, the default file, *class.wsdl*, is written into the current directory.

- **-PkgtoNS *package namespace***

Specifies the mapping of a Java package to a namespace. If there is a package without a namespace, the **Java2WSDL** command generates a namespace name. This argument can be repeated to specify mappings for multiple packages.

- **-portTypeName *name***

Specifies the name to use for the portType element. If not specified, the class name is used.

- **-serviceElementName *name***

Specifies the name of the service element.

- **-servicePortName *name***

Specifies the name of the service. If not specified, the service name is derived from the **-location** argument.

- **-style **RPC | DOCUMENT****

Specifies the WSDL style to use in the generated WSDL file. For more information about styles, see Mapping between Java, WSDL and XML. This argument is used with the **-use** argument.

If **RPC** is specified with **-use ENCODED**, or omitting use, a *style=rpc/use=encoded* WSDL file is generated. If **RPC** is specified with **-use LITERAL**, a *style=rpc/use=literal* WSDL file is generated. If **DOCUMENT** is specified with **-use LITERAL** or omitting use, a *style=document/use=literal* WSDL file is generated.

- **-transport **http | jms****

Generates SOAP bindings for either Hyper Text Transport Protocol (HTTP) (default) or Java Messaging Service (JMS). If **jms** is specified, the characters "jms" are appended to the WSDL file name to prevent overwriting an existing WSDL file for another transport. The transport option can only be specified once.

- **-use **LITERAL | ENCODED****

Specifies which style and use combinations are generated into the WSDL file when used with the `-style` argument. The combinations are `rpc` and `encoded`, `rpc` and `literal`, or `doc` and `literal`. For more information, see the Mapping between Java language, WSDL and XML.

- **-verbose**

Displays verbose messages.

## WSDL2Java command

The **WSDL2Java** command tool creates Java classes and deployment descriptor templates from a Web Services Description Language (WSDL) file using the Java API for XML-based remote procedure call (JAX-RPC) 1.0 specification. See Mapping between Java language, WSDL and XML for more information.

### Classes and files generated

The following kinds of classes and files are generated:

- **For each portType in the WSDL document (<wsdl:portType> element tag):**

- Service Endpoint Interface

- **For each service in the WSDL document (<wsdl:service> element tag):**

- Service Interface when the `-role develop-client` argument is specified.

- ServiceLocator when the `-role deploy-client` argument is specified.

This class is a WebSphere product-specific implementation of the service interface, and is not used directly.

- `webservices.xml` deployment descriptor template when the `-role develop-server` argument is specified

- `ibm-webservices-bnd.xmi` deployment descriptor template when the `-role develop-server` argument is specified.

- `ibm-webservices-ext.xmi` deployment descriptor template when the `-role develop-server` argument is specified.

- `wsdlfile_mapping.xml` JAX-RPC mapping file when the `-role develop-client` or `-role develop-server` is specified.

- `webservicesclient.xml` deployment descriptor template when the `-role develop-client` argument is specified.

- `ibm-webservicesclient-bnd.xmi` deployment descriptor template when the `-role develop-client` argument is specified.

- `ibm-webservicesclient-ext.xmi` deployment descriptor template when the `-role develop-client` argument is specified.

When the role is a server role, the container argument specifies which J2EE container the implementation uses. When the `-role develop-server -container ejb` arguments are specified, the `webservices.xml`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-ext.xmi` and the mapping file are generated into the META-INF subdirectory. When the `-role develop-server -container web` arguments are specified, the files are generated into the WEB-INF directory.

- **For each binding in the WSDL file (<wsdl:binding> element tag):**

- A stub that implements the Service Endpoint Interface (deploy-client role)

- An implementation template for an enterprise bean and templates for the EJB remote interface and home interface generate when the `-role develop-server` and `-container-ejb` arguments are specified.

- An implementation template for the Java bean when the `-role develop-server` and `-container-web` arguments are specified.

- **Other classes and files:**

- A Java bean representing the structure of the type when the `-role develop-server` or `-role develop-client` arguments are specified for each `complexType` or `simpleType`.

- Three classes, `*_Ser.java`, `*_Deser.java`, and `*_Helper.java`, generate for each `complexType` to assist in converting the bean to SOAP and back when the `-role deploy-server` or `-role deploy-client` argument is specified.

- A `*Holder.java` class generates when the `-role develop-server` or `-role develop-client` arguments are specified for each out and inout parameter.

## Command line syntax

The command line syntax is:

```
WSDL2Java [arguments] WSDL-URI
```

## Required arguments

- **WSDL-URI**

Specifies the location of the input WSDL document using a Universal Resource Identifier (URI). You can also use a regular file path if the WSDL file is on the local file system.

## Important arguments

- **-container** *j2ee-container*

Indicates the J2EE container to be used. Valid arguments are:

- **client**  
Indicates client container.
- **ejb**  
Indicates enterprise JavaBean (EJB) container.
- **none**  
Indicates no container.
- **web**  
Indicates Web container.

If client is role, the default argument is **none**. If server is role, the container must be **ejb** or **web**. The same container option must be used for both development and deployment.

- **-deployScope** *argument*

Indicates how to deploy the server implementation. Valid arguments are:

- **Application**  
Uses one instance of the implementation class for all requests.
- **Request**  
Creates a new instance of the implementation class for each request.
- **Session**  
Creates a new instance of the implementation class for each session.

- **-genResolver**

Generates an `absolute-import resolver` class. The purpose of this class is to record the contents of the imported WSDL files used by the WSDL URI. This class is used by the runtime. It can also be used for future **WSDL2Java** command runs. This is desirable when the imported WSDL files are remote and can be inaccessible or slow to access. It also eliminates the possibility that a remote WSDL file might have different contents at run time than it did at development time. The generated class is named `_AbsoluteImportResolver.java`. You should compile and package this class with the other Java classes generated by the **WSDL2Java** command.

- **-help**

Displays a help message and exits.

- **-helpX**

Displays a help message for extended options and exits. The options are:

- **-all**  
Generates Java files for all types, even those that are not referenced.
- **-debug**  
Prints debugging information.
- **-fileNStoPkg** *filename*  
Specifies the file of namespace to package mappings. The default is `NStoPKG.properties`.
- **-genJava** *argument*  
Generates Java files. Valid arguments are:

- **IfNotExists**, default
- **Overwrite**
- **No**
- **-genXML** *argument*  
Generates the .xml and .xmi files. Valid arguments are:
  - **IfNotExists**, default
  - **Overwrite**
  - **No**
- **-password** *password*  
Specifies the login user password to access the WSDL URI.
- **-testCase**  
Generates the template for a JUnit test case for testing a Web service.
- **-user** *id*  
Specifies the login user name to access the WSDL URI.
- **-inputMappingFile** *mapping file*  
Specifies the file name of the Java to WSDL mapping file.
- **-NStoPkg** *namespace=package*  
By default, package names are automatically derived from the namespace strings in the WSDL file. For example, if the namespace is of the form *http://x.y.com* or *urn:x.y.com*, the corresponding package is *com.y.x*.  
You can provide your own mapping by using the **-NStoPkg** argument, which you can repeat as often as necessary, once for each unique namespace mapping. For example, if there is a namespace in the WSDL file called *urn:AddressFetcher2*, and you want files generated from the objects in this namespace to reside in the package *samples.addr*, provide the **-NStoPkg** *urn:AddressFetcher2=samples.addr* argument to the **WSDL2Java** command.
- **-output** *directory*  
Sets the root directory for emitted files.
- **-role** *j2ee role*  
Specifies the J2EE development role that identifies which files to generate. Valid arguments are:
  - **client**  
Combination of *develop-client* and *deploy-client*.
  - **deploy-client**  
Generates binding files for client deployment.
  - **deploy-server**  
Generates binding files for server deployment.
  - **develop-client** (default)  
Generates files for client development.
  - **develop-server**  
Generates files for server development.
  - **server**  
Combination of *develop-server* and *deploy-server*.
- **-timeout** *seconds*  
Specifies how long the **WSDL2Java** command should wait, in seconds, for the WSDL-URI to respond before giving up. The default is 45 seconds, -1 disables the timeout.
- **-useResolver** *resolver-class*  
Specifies an *absolute-import* resolver class to use during parsing. This class must have been created during a previous execution of the **WSDL2Java** command using the **-genResolver** option. The class must be available in CLASSPATH.
- **-verbose**  
Displays processing information, including the names of the generated files.

## Setting up a development and unmanaged client execution environment for Web services based on Web Services for J2EE

WebSphere Application Server provides command-line tools to develop Web services clients and implementations that are based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) specification. WebSphere Application Server also includes the Assembly Toolkit that can be downloaded from the Web site [http://www-1.ibm.com/support/docview.wss?rs=180&context=SSEQTP&q=ASTK&uid=swg24005125&loc=en\\_US&cs=utf-8&lang=en+en](http://www-1.ibm.com/support/docview.wss?rs=180&context=SSEQTP&q=ASTK&uid=swg24005125&loc=en_US&cs=utf-8&lang=en+en). The Assembly Toolkit replaces the Application Assembly Tool (AAT). It is one of the tools available with the Application Server Toolkit product.

WebSphere Studio Application Developer also has GUI-based development tools to develop Web services that integrate with WebSphere Application Server.

Before you can set up a Web services development and unmanaged client execution environment within WebSphere Application Server, you must install WebSphere Application Server. (See "Installing WebSphere Application Server products" in the Information center.)

To set up a Web services development and unmanaged client execution environment:

1. Develop thin application client code on a server machine and run the `setupCmdLine` script.
2. Configure the path. You can add the WebSphere and Java `bin` directories to your path by typing:

On Windows platforms:

```
set PATH=%WAS_PATH%;%PATH%
```

On UNIX:

```
export PATH=$WAS_PATH:$PATH
```

Develop Web services based on Web Services for J2EE.

## Using the Java Messaging Service to transport Web services requests

WebSphere Application Server supports the use of the Java Messaging Service (JMS) to transport Web services requests, as an alternate to using HyperText Transport Protocol (HTTP). Using the JMS transport allows your Web service clients and servers to communicate through JMS queues and topics instead of HTTP connections. One-way and synchronous two-way requests are supported.

**Note:** A Web service must be implemented as an enterprise JavaBean (EJB) to be accessed through the JMS transport.

The benefits of using JMS include:

- Request and response messages are sent through reliable messaging.
- One-way requests allow clients and servers to be more loosely-coupled. For example, the server does not have to be active when the client sends the one-way request.
- One-way requests can be sent to multiple servers simultaneously through the use of a topic.

To use JMS as a transport for Web services requests:

1. Add a JMS binding and a SOAP address to the Web Services Description Language (WSDL) file. The WSDL file of a Web service must include a JMS binding and a SOAP address, which specifies a JMS endpoint URL string, in order to be accessible on the JMS transport. A JMS binding is a `wsdl:binding` element containing a `wsdlsoap:binding` element whose `transport` attribute ends in `soap/jms`, rather than the typical `soap/http` value.

In addition to the JMS binding, a `wsdl:port` element referencing the JMS binding must be included in the `wsdl:service` element within the WSDL file. The `wsdl:port` element should contain a `wsdlsoap:address` element whose `location` attribute specifies a JMS endpoint URL string.

**Note:** When you develop the Web service, a placeholder such as `file:/unspecified_location` can be used for the endpoint URL string.

2. Decide on the names and types of JMS objects that your application uses. Before your application can be installed, you need to:
  - a. Decide whether your Web service receives its requests from a queue or a topic.
  - b. Decide whether to use a secure destination (queue or topic) or a nonsecure destination.
  - c. Decide on the names for your destination, connection factory and listener port. The following list provides examples of the names that might be used for the mythical StockQuote Web service:
    - **Queue:** StockQuote\_Q (JNDI name: `jms/StockQuote_Q`)
    - **Connection factory:** StockQuote\_CF (JNDI name: `jms/StockQuote_CF`)
    - **Listener port:** StockQuoteEJB\_ListenerPort
3. Define the JMS administered objects. Once you have decided on the names and types of the JMS objects, use the administrative console or the **wsadmin** scripting interface to define the JMS objects.
4. Add the JMS endpoints to your EAR file using the **endptEnabler** command tool. You must run the **endptEnabler** command to add a JMS endpoint or router module for each Web service-enabled EJB JAR file contained in the EAR file. By default, the **endptEnabler** command adds only HTTP endpoints, but the `-transport jms` option can be used to request the addition of JMS endpoints.
5. Deploy the Web services application. During the install process you are prompted for two types of information for each Web service-enabled EJB JAR contained in your EAR file:
  - The Java Naming and Directory Interface (JNDI) name of the connection factory to be used by the EJB JAR file message driven bean (MDB) listener for sending reply messages.

If your Web service contains two-way operations, the MDB listener, defined inside the JMS endpoint added by **endptEnabler** command, needs to access a queue connection factory in order to add a reply message to the reply queue.

The MDB listener uses a resource environment reference of `java:comp/env/jms/WebServicesReplyQCF`. Therefore, during the application install process, you must provide the actual JNDI name of the queue connection factory that should be used by the MDB listener for that Web service. You might want to use the same connection factory that you defined for use by clients in step 2.

- The name of the listener port to be used by the MDB listener.

A listener port is an object used to associate a JMS connection factory with a JMS destination (queue or topic). When deployed, an MDB is configured with the correct listener port so that messages from the desired queue or topic are properly delivered to the MDB. During deployment, you can modify the name of the listener port associated with each MDB listener. The listener port name contained in the input EAR file displays as a default value. If you specify the correct listener port name to the **endptEnabler** command, perhaps through the use of properties, during step 3, you can accept the default value. Otherwise, enter the correct listener port name.

**Hint:** By default, the **endptEnabler** command produces listener port names of the form `<ejb-jar-name>_ListenerPort`. To simplify this step, define the listener ports that follow this naming convention during step 2.

## Java Messaging Service endpoint URL syntax

A Java Messaging Service (JMS) endpoint URL is used to access a Web service with the JMS transport. This URL specifies the JMS destination and connection factory, as well as the port component name for the Web service request. This is similar to the HTTP endpoint URL, which specifies the host and port, as well as the context root and port component name.

A JMS endpoint URL has the following general form:

```
jms:[queue|topic]?<property>=<value>&<property>=<value>&...
```

The URL consists of the transport type, `jms:`, followed by either `/queue` or `/topic` to indicate the JMS destination type, followed by the query string containing a list of property and value pairs used to specify the JMS endpoint information.

The properties supported in the URL string are described as follows:

#### Destination-related properties (required)

Property name	Description
destination	Specifies the Java Naming and Directory Interface (JNDI) name of the destination queue or topic.
connectionFactory	Specifies the JNDI name of the connection factory.
targetService	Specifies the name of the port component to which the request is dispatched.

#### JNDI-related properties (optional)

Property name	Description
initialContextFactory	Specifies the name of the initial context factory to use which is mapped to the <code>java.naming.factory.initial</code> property.
jndiProviderURL	Specifies the JNDI provider URL which is mapped to the <code>java.naming.provider.url</code> property.

#### JMS-related properties (optional)

Property name	Description
deliveryMode	Indicates whether the request message should be persistent or not. The valid values are 1 for nonpersistent and 2 for persistent. The default value is 1.
timeToLive	Specifies the lifetime, in milliseconds, of the request message. A value of 0 indicates an infinite lifetime.
priority	Specifies the JMS priority associated with the request message. Valid values are between 0 to 9. The default value is 4.

The required properties, `destination`, `connectionFactory`, and `targetService`, must appear in the JMS endpoint URL string. The rest of the properties are optional.

You can set any of the properties on the client Stub object. This means that the various properties can be specified by including them as part of the endpoint URL or they can be set programmatically by the client on the Stub object. Properties specified on the client Stub object take precedence over properties specified as part of a JMS endpoint URL string.

## Developing a Web service from a Java bean

Set up a Web services development and unmanaged client execution environment.

To develop a Web service from a Java bean:

1. Access an existing Java bean Web archive (WAR) file.
2. Develop a Java bean Service Endpoint Interface.
3. Develop a Web Services Description Language (WSDL) file.
4. Develop Web services deployment descriptor templates for a Java bean implementation.
5. Configure the `webservices.xml` deployment descriptor.

6. Configure the `ibm-webservices-bnd.xml` deployment descriptor.
7. Assemble a Web services-enabled WAR file when starting from Java.
8. Assemble a Web services-enabled WAR into an EAR file.
9. Deploy the EAR file into WebSphere Application Server.

Test the Web service.

## Developing a WSDL file

Develop a Service Endpoint Interface.

You need a Web Services Description Language (WSDL) file to use Web services. You can develop your own WSDL file or get one from a Web service provider through E-mail, downloading or through a Uniform Resource Locator (URL). This documentation assumes you are creating your own.

To develop a WSDL file:

1. Configure the Service Endpoint Interface class and referenced classes into your CLASSPATH.
  - On Windows, set `CLASSPATH=%CLASSPATH%;<list your application JAR files and classes>`.
  - On UNIX, export `CLASSPATH=%CLASSPATH:<list your application JAR files and classes>`.
2. Run the **Java2WSDL *seiInterface*** command. A WSDL file named `seiInterface.wsdl` is created.
  - Move the WSDL file to the `META-INF/wsdl` subdirectory if you are using an enterprise JavaBean (EJB).
  - Move the WSDL file to the `WEB-INF/wsdl` subdirectory if you are using a Java bean.
3. Edit the generated WSDL file and inspect the part names. The WSDL parts have names like `arg_0_0`. Modify the WSDL file to use the actual names of the Java parameters.
4. (Optional) Use the **Java2WSDL** command tool to generate the correct part names of WSDL file. You can automatically generate and set the correct part names by using the **Java2WSDL** command tool. Generating and setting the part names is done by providing additional information to the **Java2WSDL** command tool in the form of a Java implementation class that implements the same methods as the Service Endpoint Interface and is compiled with debug information on (**javac -g**). Parameter names are stored in the `.class` file with the debug information. If your implementation class was compiled with debug on, you can use the **Java2WSDL -implClass *seiImpl seiInterface*** command to generate a WSDL file having the proper part names.

A WSDL file that defines the Web service described by the Service Endpoint Interface.

This example uses a JAR file named `AddressBook.jar` containing a class named `AddressBook.class` file.

You must add the `AddressBook.jar` file to your CLASSPATH to create the WSDL file. The JAR file contains an EJB implementation class that was compiled with debugging information on. Run the **Java2WSDL -implClass *addr.AddressBookBean addr.AddressBook*** command to create a WSDL file named `AddressBook.wsdl`.

Develop Web services deployment descriptor templates from a WSDL file.

### **WSDL:**

*Web Services Description Language (WSDL)* is an eXtensible Markup Language (XML)-based description language that has been submitted to the World Wide Web Consortium (W3C) as the industry standard for describing Web services. The power of WSDL is derived from two main architectural principles: the ability to describe a set of business operations and the ability to separate the description into two basic units, a description of the operations and the details of how the operation and the information associated with it are packaged.

The WSDL document is the engine of a Java 2 platform, Enterprise Edition (J2EE) Web service; without it there is no service. The information within a WSDL file maps to the Java application to create a Web service. WebSphere Application Server Versions 5.0.2 and 5.1 use standards based on WSDL 1.1.

A WSDL document allows a service provider to specify the name and address of the Web service; protocol and encoding style used when accessing the public operations of the Web service; and the type information, including name, operations, parameters and data comprising the interface of the Web service.

A WSDL document defines services as collections of network endpoints, or ports. In WSDL, the abstract definition of endpoints and messages is separated from their concrete network deployment or data format bindings. This allows the reuse of abstract definitions: messages, which are abstract descriptions of the data being exchanged, and port types which are abstract collections of operations. The concrete protocol and data format specifications for a particular port type constitutes a reusable binding. A port is defined by associating a network address with a reusable binding, and a collection of ports define a service. Therefore, a WSDL document is composed of several elements. See WSDL anatomy for more information and examples of the WSDL elements.

When creating a Web service for WebSphere Application Server, you must first have an implementation bean that includes a Service Endpoint Interface. Then, you use the **Java2WSDL** command-line tool to create a WSDL that defines the Web service. To learn more about how the WSDL file is used in the development process, see *Developing Web services based on Web Services for J2EE*.

#### ***Publishing WSDL files:***

To publish a Web Services Description Language (WSDL) file you need an enterprise application, also known as an enterprise archive (EAR) file, that contains a Web services-enabled module and has been deployed into WebSphere Application Server. See *Deploying Web services based on Web Services for Java 2 platform, Enterprise Edition (J2EE)*.

The WSDL files for each Web services-enabled module are published to the file system location you specify. You can provide these WSDL files to clients that want to invoke your Web services.

By publishing your WSDL files, you are enabling users to generate and export WSDL files with endpoint information for Web services ports. If you are a client developer or a system administrator, you can use WSDL files to enable clients to connect to a Web service. Server configuration allows you to specify URL fragments to enable full URL specification of WSDL file ports.

You can publish WSDL files for the deployed EAR file in one of three ways:

1. Publish a WSDL file with the administrative console.
2. Publish a WSDL file with the **wsadmin** command tool.
3. Publish a WSDL file through a URL.

#### ***Publishing WSDL files with the administrative console:***

**5.1** You can specify default or custom HTTP URL prefixes when using the administrative console to publish Web Services Description Language (WSDL) files. You can also specify Java Messaging Service (JMS) URL prefixes.

To publish a WSDL file with the administrative console:

1. Open the administrative console.
2. Click **Applications > Enterprise Applications > *application\_instance***. Under Additional Properties, click **Publish WSDL files** which brings you to the **Publish WSDL zip files** panel.
3. **5.1** Specify the default URL prefixes for the Web service.

- a. Select **HTTP URL prefix**.
  - b. Select an entry from the drop down list. If you have multiple application modules, select the application module's check box on the module table.
  - c. Click **Apply**. The URL prefix is copied to the selected module HTTP URL prefix field.
  - d. Click **OK**.
  - e. Click the exported *WSDL\_zip\_file* listed on the **Export WSDL Zip file** panel.
  - f. Download the zip file. Follow your browser's instructions to download the zip file.
4. **5.1** Specify custom URL prefixes for the Web service.
- a. Select **Custom HTTP URL prefix**.
  - b. Type the name of the URL prefix in the **Custom HTTP URL prefix** field. The entry must be of the form `http|https://<host_name>:<port_number>`. For example:  
`http://myHost:999`  
 If you have multiple application modules, select the application module's checkbox on the module table.
  - c. Click **Apply**. The URL prefix is copied to the selected module HTTP URL prefix field.
  - d. Click **OK**.
  - e. Click the exported *WSDL\_zip\_file* listed on the **Export WSDL Zip file** panel.
  - f. Download the zip file. Follow your browser's instructions to download the zip file.
5. **5.1** Specify a JMS URL prefix.
- a. Select the application module.
  - b. Type the JMS URL prefix into the **JMS URL prefix** field. The entry must be of the form:  
`jms:[<queue|topic>?destination=<queue or topic_jndi_name>&connectionFactory=<connection_factory_jndi_name>`. For example:  
`jms:/queue?destination=jms/Q1&connectionFactory=jms/QCF1`
  - c. Click **OK**.
  - d. Click the exported *WSDL\_zip\_file* listed on the **Export WSDL Zip file** panel.
  - e. Download the zip file. Follow your browser's instructions to download the zip file.

*Publish WSDL zip files:*

Use this page to publish Web Services Description Language (WSDL) files.

**5.1** To view this administrative console page, click **Applications >Enterprise Applications > application\_instance > Publish WSDL**.

**5.1** When you click **OK**, a zip file of all the Web services-enabled modules in the application is produced. The name of the published zip file is `application_name_WSDLFiles.zip`. In the published zip file, the directory structure is `application_name/module_name/[META-INF|WEB-INF]/wsdl/wsd_file_name`.

**5.1** In a published WSDL file, the location attribute of a service `soap:address` stanza contains the URL through which the Web service is accessed. You can specify the portion of the URL to be used for the Web services in each module. You can access the Web services in a module through a HTTP transport or JMS transport, or both. You can specify URL information for both types of transports.

*Specify URL prefixes for Web Services:*

Specifies the *protocol* (either `http` or `https`), *host\_name*, and *port\_number* to be used in the URL.

The URL prefix format is `protocol://host_name:port_number`, for example, `http://myHost:9045`. The actual URL that appears in a published WSDL file consists of the prefix prepended to the module's context-root and the Web service url-pattern, for example, `http://myHost:9045/services/myService`.

#### *Select HTTP URL prefix:*

Specifies the drop down list associated with a default list of URL prefixes. This list is the intersection of the set of ports for the module's virtual host and the set of ports for the module's application server. Use items from this list if the Web services application server is accessed directly.

To set an HTTP prefix, select either the **HTTP URL prefix** or **Custom HTTP URL prefix**, enter the value, select the check box of the modules that are to use the prefix, and click **Apply**. When you click **Apply**, the entry in the **Select HTTP URL prefix** or **Custom HTTP URL prefix** fields, depending on which is selected, is copied into the **HTTP URL prefix** field of any module whose check box (in the leftmost column) is selected. The HTTP prefix is not applied to the fields in the JMS URL prefix column.

#### *Custom HTTP URL prefix:*

Specifies the *protocol*, *host*, and *port\_number* of the intermediate service if the Web services in a module are accessed through an intermediate node, for example the Web services gateway or an IHS server.

To set an HTTP prefix, select either the **HTTP URL prefix** or **Custom HTTP URL prefix**, enter the value, select the check box of the modules that are to use the prefix, and click **Apply**. When you click **Apply**, the entry in the **Select HTTP URL prefix** or **Custom HTTP URL prefix** fields, depending on which is selected, is copied into the **HTTP URL prefix** field of any module whose check box (in the leftmost column) is selected. The HTTP prefix is not applied to the fields in the JMS URL prefix column.

#### *JMS URL prefix:*

Specifies the JMS URL prefix string used for each module.

The URL prefix specified must contain the destination and connectionFactory properties. It can contain other property-value pairs, but it must not contain the targetService property, which is added by the system when the published WSDL files are created. The format of the JMS URL prefix is `jms:[queue&topic]?destination=target_queue_or_topic_jndi_name&connectionFactory=factory_jndi_name`, for example,

`jms:/queue?destination=jms/Q1&connectionFactory=jms/QCF`. The actual URL that appears in a published WSDL file consists of the prefix prepended to the Web service targetService, for example, `jms:/queue?destination=jms/Q1&connectionFactory=jms/QCF&targetService=StockQuote`.

#### *Web services client bindings:*

Use this page to specify the Web Service Description Language (WSDL) file name and port type mappings for the Web services in a module.

To view this page, click **Applications >Enterprise Applications > application\_instance > Web Modules > module\_instance>Web Services Client Bindings**.

For EJB modules, click **Applications >Enterprise Applications > application\_instance > EJB Modules > module\_instance>Web Services Client Bindings**

#### *Web Service:*

Specifies the name of this Web service. A module can contain one or more Web services.

*URI:*

Specifies the Uniform Resource Identifier (URI) of the binding file that defines the scope. The URI is relative to the module.

*WSDL Filename:*

Specifies the WSDL file name, which is relative to the module.

A Web service can specify the relative path within the module of a compatible WSDL file containing the actual URL to be used for requests. This is needed only if the original WSDL file does not contain a URL or when a different URL is needed. For a service endpoint with multiple ports defined, a default port mapping specifies the port to use for a port type.

*Default Port Mappings:*

Specifies and manages the default port type mapping for a Web service when a particular port type is requested.

*Web services implementation scope:*

Use this page to view and manage the scope of the ports of a Web Service.

To view this administrative console page, click **Applications >Enterprise Applications > application\_instance > Web Modules > module\_instance>Web Services Implementation Scope**.

*Port:*

Specifies a port name for a Web service. A module can contain one or more Web services, each of which can contain one or more ports.

*Web Service:*

Specifies the name of the Web service. A module can contain one or more Web services.

*URI:*

Specifies the Uniform Resource Identifier (URI) of the binding file that defines the scope. The URI is relative to the Web module.

*Scope:*

Specifies the scope of a port.

The scope determines when a new instance of a service implementation is created for the Web service ports in a module. An application scope causes the same instance of the implementation to be used for all requests on the application. A session scope causes the same instance to be used for all requests on each session. A request scope causes a new instance to be used on every request.

*Publishing WSDL files using the wsadmin command:*

The Web Services Description Language (WSDL) files in each Web services-enabled module are published to the file system location you specify. You can provide these WSDL files to the clients that want to invoke your Web services.

The scripting client, **wsadmin**, can publish the WSDL files in either local, for example, -conntype NONE, or remote mode. However, in local mode, the target application should be located at the same node where the **wsadmin** command is invoked.

The steps below assume that the application has been deployed and that the application server is running.

To publish a WSDL file with the **wsadmin** command:

1. From a command prompt, start `install_root\bin\wsadmin` if you are using Windows or `install_root/bin/wsadmin` if you are using UNIX.
2. At the **wsadmin** command prompt, enter one of the two commands:
  - **\$AdminApp publishWSDL *app\_Name path\_Name***
  - **\$AdminApp publishWSDL *app\_Name path\_Name* {{module {{*binding url-prefix*}}}}**

Where

- *app\_Name* is the application name
- *path\_Name* is the absolute path to the zip file that will contain the published WSDL files. The zip file is saved on the machine running WebSphere Application Server, therefore, if the server is running on a different machine, you need to obtain the zip file from that machine. The directory structure of the resulting zip file is based on the following information:

```
Application file name
 module file name
 META-INF/ or WEB-INF/
 wsdl/
 WSDL file name
```

See the usage scenario for an example of this directory structure.

- *binding* is either http or jms (both are in lower case)
- *url-prefix* is the partial SOAP address for the associated SOAP binding. For an HTTP binding the form is `http://host:port/` or `https://host:port`.

For Java Message Service (JMS) bindings, the form is  
`jms:/queue?destination=dest&connectionFactory=cf` or  
`jms:/topic?destination=dest&connectionFactory=cf`

The **\$AdminApp publishWSDL *app\_Name path\_Name*** command updates the WSDL SOAP address prefixes using the default values. If you do not want to update the WSDL SOAP address prefixes, use the other command, instead of the default values.

The **\$AdminApp publishWSDL *app\_Name path\_Name* {{module {{*binding url-prefix*}}}}** command allows you to customize the WSDL SOAP address for each module. You can specify a different address prefix for each SOAP binding.

The WSDL files from Web services are published to a specified zip file. You can hand the zip file to the client and the client can use the published WSDL files to create a Web services client that accesses the deployed service.

The command to publish WSDL files for a Web service named `WebServicesSamples` could be  
**\$AdminApp publishWSDL WebServicesSamples c:/temp/samplesWSDL.zip**

or

**\$AdminApp publishWSDL WebServicesSamples c:/temp/samplesWSDL.zip { {AddressBookJ2WB.war  
{{http http://localhost:9080}} {StockQuote.jar {{http https://localhost:9443}} } }**

The directory structure for this created zip files is

WebServicesSamples.ear/StockQuote.jar/META-INF/wsdl/StockQuoteFetcher.wsdl  
WebServicesSamples.ear/AddressBookW2JE.jar/META-INF/wsdl/AddressBookW2JE.wsdl  
WebServicesSamples.ear/AddressBookJ2WE.jar/META-INF/wsdl/AddressBookJ2WE.wsdl  
WebServicesSamples.ear/AddressBookJ2WB.war/WEB-INF/wsdl/AddressBookJ2WB.wsdl  
WebServicesSamples.ear/AddressBookW2JB.war/WEB-INF/wsdl/AddressBookW2JB.wsdl

### *Publishing WSDL files using a URL:*

Before you can publish a Web Services Description Language (WSDL) file using a URL, the Web services-enabled application should be installed and running.

The files referenced by the `<wsdl-file>` element in the `webservices.xml` deployment descriptor file can or cannot import other WSDL or XML schema definition (XSD) files. Typically, all WSDL or XSD files are originally placed into the `META-INF/wsdl` directory when using enterprise JavaBeans (EJBs) or the `WEB-INF/wsdl` directory when using Java beans. If your WSDL or XSD files are not placed in one of these directories, the file referenced by the `<wsdl-file>` element and its imported files are located at the same directory and copied to the `wsdl/` directory for publishing purposes.

**Note:** **5.1** EJB-based Web service applications must have an HTTP router or a Web module. Only HTTP URLs are supported for publishing.

To publish a WSDL file using a URL:

1. Retrieve the outer-most WSDL file. The outer-most WSDL file is the WSDL file defined by the `<wsdl-file>` element in the `webservices.xml` deployment descriptor file.  
Each Web service has an endpoint address, for example, `http://example.com/services/stockquote`. You can retrieve the outer-most WSDL file by appending the string with `/wsdl` or `/wsdl/` to the endpoint address, for example, `http://example.com/services/stockquote/wsdl`. **5.1+** You get a WSDL back that supports all protocols, including HTTP, Java Messaging Service and capabilities to directly access EJB bindings.
2. Retrieve the imported WSDL files. When the outer-most WSDL file imports other WSDL or XSD files, these imported files can be retrieved by appending the relative path to the URL, which is used to retrieve the outer-most WSDL file. This is also true for WSDL files that import other files. This process is similar to the use of relative hyperlinks in Hypertext Markup Language (HTML) documents. If an HTML document contains a hyperlink to other documents, the relative path is appended to create the URL to access the hyperlinked documents.

Suppose you have an application with the following directory structure:

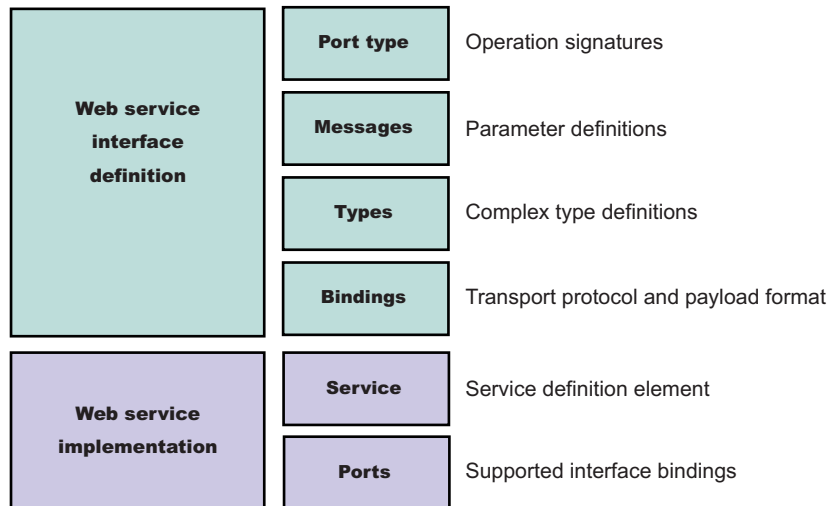

```
<module-root>/
META-INF/
WEB-INF/
webservices.xml/* define Foo service, the <wsdl-file> element points to "/wsdl/fooImpl.wsdl"
*/ web.xml
ibm-webservices-bnd.xml
<jaxrpc-mapping-file>
wsdl/
fooImpl.wsdl/* importing foo.wsdl which is an interface wsdl */
foo.wsdl /* importing type definition for the interface */
fooTypes.xsd
```

If the SOAP address for the foo service is `http://examples.com:9080/services/foo`, the simple way to retrieve the foo service's outer-most WSDL is with the following form:

`http://examples.com:9090/services/foo/wsdl` or `http://examples.com:9090/services/foo/wsdl/`. The URL is redirected to `http://examples.com:9090/services/foo/wsdl/fooImpl.wsdl`, where `fooImpl.wsdl` is the name of the outer-most WSDL file.

Since the `fooImpl.wsdl` file has the import `<import namespace="http://examples.com/foo" location="a/b/foo.wsdl">`, use the URL `http://examples.com:9090/services/foo/wsdl/a/b/foo.wsdl` to obtain the `foo.wsdl` file.

**WSDL anatomy:** Web Services Description Language (WSDL) files are written in eXtensible Markup Language (XML). To learn more about XML, see [Web services: Resources for learning](#).

A WSDL contains the following parts:

- **Web service interface definition**  
This is where the elements are contained, as well as the namespaces.
- **Web service implementation**  
This is where you find the definition of the service and ports.

A WSDL file describes a Web service with the following elements:

### portType

The description of the operations and their associated messages. PortTypes define abstract operations.

```
<portType name="EightBall">
 <operation name="getAnswer">
 <input message="ebs:IngetAnswerRequest"/>
 <output message="ebs:OutgetAnswerResponse"/>
 </operation>
</portType>
```

### message

The description of parameters (input and output) and return values.

```
<message name="IngetAnswerRequest">
 <part name="meth1_inType" type="ebs:questionType"/>
</message>
<message name="OutgetAnswerResponse">
 <part name="meth1_outType" type="ebs:answerType"/>
</message>
```

## types

The schema for describing XML complex types used in the messages.

```
<types>
 <xsd:schema targetNamespace="...">
 <xsd:complexType name="questionType">
 <xsd:element name="question" type="string"/>
 </xsd:complexType>
 <xsd:complexType name="answerType">
 ...
 </xsd:complexType>
 </types>
```

## binding

Bindings describe the protocol used to access a service, as well as the data formats for the messages defined by a particular portType.

```
<binding name="EightBallBinding" type="ebs:EightBall">
 <soap:binding style="rpc" transport="schemas.xmlsoap.org/soap/http">
 <operation name="ebs:getAnswer">
 <soap:operation soapAction="urn:EightBall"/>
 <input>
 <soap:body namespace="urn:EightBall" ... />
 </input>
 ...
</binding>
```

The remaining parts, services and ports, indicate where you can find the WSDL.

## Service

Contains the Web service name and a list of the ports.

## Ports

Contains the location of the Web service and the binding to be used to access the service.

```
<service name="EightBall">
 <port binding="ebs:EightBallBinding" name="EightBallPort">
 <soap:address location="localhost:8080/axis/EightBall"/>
 </port>
</service>
```

**Multipart WSDL best practices:** WebSphere Application Server supports deployment of Web services using a multipart Web Services Description Language (WSDL) file. That is, WSDL files import other WSDL files when the WSDL file listed in the `<wsdl-file>` element of the `webservices.xml` deployment descriptor contains all `<wsdl:service>` and `<wsdl:port>` elements. The WSDL file is divided into an implementation WSDL and an interface WSDL.

The `<wsdl:import>` element indicates a reference to another WSDL file. If the `<wsdl:import>` element location attribute does not contain a URL, that is, it contains only a file name, and does not begin with `http://`, `https://` or `file://`, the imported file must be located in the same directory and must not contain a relative path component. For example, if `META-INF/wsdl/A_Impl.wsdl` is in your module and contains the import statement `<wsdl:import="A.wsdl" namespace="...">`, the file, `A.wsdl` must also be located in the module `META-INF/wsdl` directory.

It is recommended that all WSDL files be placed in either the `META-INF/wsdl` directory, if you are using enterprise JavaBeans (EJBs), or the `WEB-INF/wsdl` directory, if you are using Java beans, even if there are relative imports within the WSDL files. Otherwise, there are implications with the WSDL publication when you use a path like the following `<location=" ../interfaces/A_Interface.wsdl" namespace="...">`. Using a path like this fails because the presence of the relative path, regardless of whether the file is located at that path or not. If the location is a URL, it must be readable at both deployment and server startup.

## WSDL publication

The files located in the META-INF/wsdl or WEB-INF/wsdl directory can be published through either a URL or file, including WSDL or XSD files. For example, if the file referenced in the `<wsdl:file>` element of the `webservices.xml` deployment descriptor is located in the META-INF/wsdl or WEB-INF/wsdl directory, it is publishable. If the files imported by the `<wsdl:file>` are located in the `wsdl/` directory or its subdirectory, they are publishable.

If the WSDL file referenced by the `<wsdl:file>` element is located in a directory other than `wsdl/`, or its subdirectories, the file and its imported files, either WSDL or XSD files, which are in the same directory, are copied to the `wsdl` directory without modification when the application is installed. These types of files can also be published.

If the `<wsdl:file>` imports a file located in a different directory, the file is not copied to the `wsdl` directory and not available for publishing.

## Developing a Service Endpoint Interface for a Java bean implementation

Access an existing Java bean WAR file.

Set up a Web services development and unmanaged client execution environment.

The Service Endpoint Interface defines the methods for a particular Web service. The Java bean implementation must implement methods having the same signature as the methods on the Service Endpoint Interface. There are a number of restrictions on which types to use as parameters and results of Service Endpoint Interface methods. These restrictions are documented in the Java API for XML-based remote procedure call (JAX-RPC) specification, which is available through Web services: Resources for learning.

You can also create a Service Endpoint Interface by using the Assembly Toolkit, which is a component of the Application Assembly Toolkit. The steps are similar except the Assembly Toolkit automatically compiles the interface when you save it.

To develop a Service Endpoint Interface for a Java bean implementation:

1. Create a Java interface containing the methods to include in the Service Endpoint Interface. The interface should extend the `java.rmi.Remote` interface. Each method throws the exception, `java.rmi.RemoteException`. If you start with an existing Java interface, remove any methods that do not conform to JAX-RPC. See the example that follows this tasks steps.
2. Compile the interface. Use the **javac** commands for Windows and UNIX platforms listed in the topic Developing thin application client code to compile the interface. In the **javac** command, use the name of the Service Endpoint Interface class for the class to be compiled.

A Service Endpoint Interface which you can use to develop a Web service.

This example uses a Java interface called `AddressBook`. The following example depicts the `AddressBook` interface:

```
package addr;
public interface AddressBook {
 /**
 * Retrieve an entry from the AddressBook.
 *
 * @param name the name of the entry to look up.
 * @return the AddressBook entry matching name or null if none.
 * @throws java.rmi.RemoteException if communications failure.
 */
 public addr.Address getAddressFromName(java.lang.String name);
}
```

You use the AddressBook Java interface to create the Service Endpoint Interface:

1. Begin with the remote interface, AddressBook.java.
2. Make a copy of the remote interface named AddressBook\_SEI.java and use it as a template for the Service Endpoint Interface.
3. Change the interface to extend the java.rmi.Remote interface.
4. Modify each method declaration to add a throws clause for java.rmi.RemoteException.
5. Compile the interface.

Use the Service Endpoint Interface to Develop a Web Services Description Language (WSDL) file.

## Developing Web services deployment descriptor templates for a Java bean implementation

To develop the deployment descriptor templates from a Web Services Description Language (WSDL) file, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use.

If it is a local file and you are running the Windows platform, the URL looks like this:

*file:drive:\path\file\_name.wsdl*. If you are using the UNIX platform, the URL looks like this:

*file:/path/file\_name.wsdl*. You can also specify local files using the absolute or relative file system path.

When the Web service implementation is a Java bean in a Web module, the webservices.xml, ibm-webservices-bnd.xmi and ibm-webservices-ext.xmi deployment descriptors and the Java API for XML-based remote procedure call (JAX-RPC) mapping file are generated in the WEB-INF subdirectory.

To develop deployment descriptor templates:

Run the **WSDL2Java -verbose -role develop-server -container web -genJava no wsdlURL** command to generate the server deployment descriptor templates and mapping file into the WEB-INF subdirectory. If the **-verbose** option is specified, a list of all generated files displays when the command runs.

Deployment descriptor templates that are required to implement or use a Web service.

The following example uses a WSDL file named AddressBookJ2WB.wsdl:

1. Generate the template files:
  - `WSDL2Java -verbose -role develop-server -container web -genJava no AddressBookJ2WB.wsdl`

The deployment descriptor templates and mapping file are generated into the WEB-INF subdirectory as follows:

```
Parsing XML file: AddressBookJ2WB.wsdl
Generating: WEB-INF\webservices.xml
Generating: WEB-INF\ibm-webservices-bnd.xmi
Generating: WEB-INF\ibm-webservices-ext.xmi
Generating: WEB-INF\AddressBookJ2WB_mapping.xml
```

## Developing a Web service using a stateless session enterprise bean

Set up a Web services development and unmanaged client execution environment.

To use an enterprise bean as the basis for a Web service implementation, follow these requirements:

- The enterprise bean must be a stateless session bean.
- Web service method parameters must be serializable and cannot be object references.
- Web service method parameters must be one of the supported Java API for XML-based remote procedure call (JAX-RPC) types.

These requirements are documented in the JAX-RPC specification available through Web services: Resources for learning.

Create the artifacts that enable the enterprise bean to be a Web service and assemble the artifacts into the enterprise application as follows:

1. Access an existing Java archive (JAR) file to be used as a Web service. Make sure that the enterprise bean meets the requirements.
2. Develop an EJB Service Endpoint Interface. The Service Endpoint Interface defines which enterprise bean methods should be made available as a Web service.
3. Develop a Web Services Description Language (WSDL) file.
4. Develop Web services deployment descriptor templates from an EJB implementation.
5. Assemble a Web services-enabled JAR file.
6. Configure the `webservices.xml` deployment descriptor.
7. Configure the `ibm-webservices-bnd.xmi` deployment descriptor.
8. Assemble a Web services-enabled enterprise archive (EAR) file.
9. Enable the EAR file. When the EAR file contains EJB modules, it must have the Web services endpoint Web archive (WAR) file added with the `endptEnabler` tool before it is deployed.
10. Deploy the EAR file into WebSphere Application Server.

A Web service from a stateless session enterprise bean.

## Developing a Service Endpoint Interface from an EJB remote interface

Set up a Web services development and unmanaged client execution environment.

The Service Endpoint Interface defines the Web services methods. The enterprise JavaBean (EJB) that implements the Web service must implement methods having the same signature as the methods of the Service Endpoint Interface. There are a number of restrictions on which types to use as parameters and results of Service Endpoint Interface methods. These restrictions are documented in the Java API for XML-based remote procedure call (JAX-RPC) specification, which is available through Web services: Resources for learning.

The easiest method for creating the Service Endpoint Interface for an EJB Web service implementation is from the EJB remote interface.

You can also create a Service Endpoint Interface by using the Assembly Toolkit, which is a component of the Application Server Toolkit. The steps are similar except the Assembly Toolkit automatically compiles the interface when you save it.

To develop a Service Endpoint Interface:

1. Create a Java interface containing the methods to include in the Service Endpoint Interface. The interface should extend the `java.rmi.Remote` interface. Each method throws the exception, `java.rmi.RemoteException`. If you start with an existing Java interface, remove any methods that do not conform to JAX-RPC.
2. Compile the interface. Use the **javac** commands for Windows and UNIX platforms listed in the topic Developing thin application client code to compile the interface. In the **javac** command, use the name of the Service Endpoint Interface class for the class to be compiled.

A Service Endpoint Interface which you can use to develop a Web service.

This example uses an EJB remote interface called `AddressBook_RI`.

```
package addr;
public interface AddressBook_RI extends javax.ejb.EJBObject {
 /**
 * Retrieve an entry from the AddressBook.
 *
 * @param name the name of the entry to look up.
 */
}
```

```

 *@return the AddressBook entry matching name or null if none.
 *@throws java.rmi.RemoteException if communications failure.
 */
 public addr.Address getAddressFromName(java.lang.String name)
 throws java.rmi.RemoteException;
}

```

You use the AddressBook\_RI remote interface to create the Service Endpoint Interface:

1. Begin with the remote interface, AddressBook\_RI.java:
2. Make a copy of the remote interface named AddressBook.java and use it as a template for the Service Endpoint Interface.
3. Change the interface to extend the java.rmi.Remote interface, instead of the javax.ejb.EJBObject Service Endpoint Interface.
4. Compile the AddressBook.java Service Endpoint Interface.

Use the Service Endpoint Interface to Develop a WSDL file.

## Developing Web services deployment descriptor templates for an EJB implementation

To develop the deployment descriptor templates from a Web Services Description Language (WSDL) file, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use.

If it is a local file and you are running the Windows platform, the URL looks like this:  
*file:drive:\path\file\_name.wsdl*. If you are using the UNIX platform, the URL looks like this:  
*file:/path/file\_name.wsdl*. You can also specify local files using the absolute or relative file system path.

When the Web service implementation is an enterprise Java bean (EJB) in an EJB module, the webservices.xml, ibm-webservices-bnd.xmi and ibm-webservices-ext.xmi deployment descriptors, and the Java API for XML-based remote procedure call (JAX-RPC) mapping file are generated in the META-INF subdirectory.

To develop deployment descriptor templates:

Run the **WSDL2Java -verbose -role develop-server -container ejb -genJava no wsdIURL** command to generate the server deployment descriptor templates and mapping file into the META-INF subdirectory. If the **-verbose** option is specified, a list of all generated files displays when the command runs.

Deployment descriptor templates that are required to implement a Web service.

The following example uses a WSDL file named AddressBookJ2WE.wsdl:

1. Generate the template files:
  - WSDL2Java -verbose -role develop-server -container ejb -genJava no AddressBookJ2WE.wsdl

The deployment descriptor templates are generated into the META-INF subdirectory as follows:

```

Parsing XML file: AddressBookJ2WE.wsdl
Generating: META-INF\webservices.xml
Generating: META-INF\ibm-webservices-bnd.xmi
Generating: META-INF\ibm-webservices-ext.xmi
Generating: META-INF\AddressBookJ2WE_mapping.xml

```

## Completing the EJB implementation

Develop EJB implementation templates and bindings from a Web Services Description (WSDL) file.

To complete the EJB implementation:

1. Inspect the enterprise EJB remote interface template, *portType\_RI.java*. If necessary, modify the template. *portType* is the name of the <wsdl:portType> element in the WSDL file.
2. Inspect the EJB home interface template, *portTypeHome.java*. If necessary, modify the template.

3. Edit the EJB implementation template, *bindingImpl.java*. *binding* is the name of the <wsdl:binding> element in the WSDL file.
  - a. Complete the implementation of the methods in the template.
  - b. (Optional) Make changes if necessary.
  - c. (Optional) Change the class name if the binding name is not acceptable.
4. Compile all the Java classes.
5. Assemble an EJB Java archive (JAR) file. Assemble all the Java classes into an EJB JAR file using the typical EJB assembly tools. Include all of the classes generated from running the **WSDL2Java** command tool when developing implementation templates and bindings from a WSDL file.

An EJB JAR file containing an EJB and supporting classes created from a WSDL file.

Configure the webservices.xml deployment descriptor .

## Developing a new Web service with an existing WSDL file using a Java bean

Locate the Web Services Description Language (WSDL) file that defines the Web service to be implemented. You can develop a WSDL or obtain one from an existing Web service through e-mail, downloading or a Uniform Resource Locator (URL).

To develop a new Web service with an existing WSDL file using a Java bean:

1. Develop Java bean implementation templates and bindings from a WSDL file.
2. Complete the Java bean implementation.
3. Assemble a Web services-enabled Web archive (WAR) file when starting from a WSDL file.
4. Configure the webservices.xml deployment descriptor.
5. Configure the ibm-webservices-bnd.xmi deployment descriptor.
6. Assemble a Web services-enabled WAR into an EAR file.
7. Deploy the EAR file into WebSphere Application Server.

Develop Web services deployment descriptor templates from a WSDL file.

You can either develop Web services deployment descriptor templates for a Java bean implementation or develop Web services deployment descriptor templates for an EJB implementation.

## Developing Web services deployment descriptor templates for a Java bean implementation

To develop the Java bean implementation templates and bindings from a Web Services Description (WSDL) file, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use.

If it is a local file and you are running the Windows platform, the URL looks like this: `file:drive:\path\file_name.wsdl`. If you are using the UNIX platform, the URL looks like this: `file:/path/file_name.wsdl`. You can also specify local files using the absolute or relative file system path.

Implementation templates are generated using the `-role develop-server` option of the **WSDL2Java** command. The **WSDL2Java** command also generates bindings and deployment descriptors.

To develop Java bean implementation templates and bindings from a WSDL file: Run the **WSDL2Java -verbose -role develop-server -container web wsdIURL** command. Since the **verbose** option is specified, a list of all generated files is displayed when the command runs.

Templates for the implementation and deployment descriptors required to implement a Web service, as well as bindings files. These templates are partially filled with information from the WSDL file.

The following example uses an Java bean named `AddressBook` and a WSDL file named `AddressBook.wsdl`. After generating the template files from the **WSDL2Java -verbose -role develop-server -container web AddressBook.wsdl** command, the following files are generated:

```
Parsing XML file: file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file: AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookSoapBindingImpl.java..
WSWS3282I: Info: Generating WEB-INF\webservices.xml.
WSWS3282I: Info: Generating WEB-INF\ibm-webservices-bnd.xmi.
WSWS3282I: Info: Generating WEB-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating WEB-INF\ibm-webservices-ext.xmi.
```

The generated file named `AddressBookSOAPBindingImpl.java` is the template for the implementation bean. It is named after the port in the WSDL file. Generally, this class is renamed to a more meaningful name.

Complete the Java bean implementation.

## Completing the Java bean implementation

Develop Java bean implementation templates and bindings from a Web Services Description Language (WSDL) file.

1. Edit the Java bean implementation template, `bindingImpl.java`. *binding* is the name of the `<wsdl:binding>` element in the WSDL file.
  - a. Complete the implementation of the methods in the template.
  - b. (Optional) Make changes if necessary.
  - c. (Optional) Change the class name if the binding name is not acceptable.
2. Compile all the Java classes.
3. Assemble a Web archive (WAR) file. Assemble all the Java classes into a WAR file using typical Web module assembly tools. Include all of the classes generated from running the **WSDL2Java** command tool when developing implementation templates and bindings from a WSDL file.

A Java archive (JAR) file containing a Java bean and supported classes created from the WSDL file.

Configure the `webservices.xml` deployment descriptor.

## Developing a new Web service from an existing WSDL file using a stateless session enterprise bean

Set up a Web services development and unmanaged client execution environment.

Locate the Web Services Description Language (WSDL) file that defines the Web service to implement. The SOAP address URI is not required because it is updated when your new implementation is deployed.

Create the enterprise bean and artifacts that enable the enterprise bean to be a Web service and assemble those artifacts into the enterprise application as follows:

1. Develop implementation templates and bindings from a WSDL file.
2. Complete the enterprise bean implementation.
3. Assemble a Web services-enabled enterprise EJB Java archive (JAR) file.
4. Configure the `webservices.xml` deployment descriptor.

5. Configure the `ibm-webservices-bnd.xmi` deployment descriptor.
6. Assemble a Web services-enabled EJB JAR into an EAR file.
7. Enable the EAR file. When the EAR file contains EJB modules, it must have the Web services endpoint Web archive (WAR) file added with the **endptEnabler** command or Assembly Toolkit before deployment.
8. Deploy the EAR file into WebSphere Application Server.

An EJB implementation of a Web service defined in the WSDL file.

## Developing EJB implementation templates and bindings from a WSDL file

To develop enterprise JavaBean (EJB) implementation templates and bindings from a Web Services Description (WSDL) file, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use.

If it is a local file and you are running the Windows platform, the URL looks like this: `file:drive:\path\file_name.wsdl`. If you are using the UNIX platform, the URL looks like this: `file:/path/file_name.wsdl`. You can also specify local files using the absolute or relative file system path.

Implementation templates are generated using the `-role develop-server` option of the **WSDL2Java** command.

Templates are generated for an EJB implementation for the following:

- EJB
- EJB remote interface
- EJB Home

The **WSDL2Java** command also generates bindings and deployment descriptors.

To develop implementation templates and bindings from a WSDL file: Run the **WSDL2Java -verbose -role develop-server -container ejb wsdIURL** command. Since the **verbose** option is specified, a list of all generated files is displayed when the command runs.

Templates for the implementation and deployment descriptors required to implement a Web service, as well as bindings files. These templates are partially filled with information from the WSDL file.

The following example uses an enterprise bean named `AddressBook` and a WSDL file named `AddressBook.wsdl`. After generating the template files from the **WSDL2Java -verbose -role develop-server -container EJB AddressBook.wsdl** command, the following files are generated:

```
Parsing XML file: file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file: AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookSoapBindingImpl.java.
WSWS3282I: Info: Generating addr\AddressBook_RI.java.
WSWS3282I: Info: Generating addr\AddressBookHome.java.
WSWS3282I: Info: Generating META-INF\webservices.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservices-bnd.xmi.
WSWS3282I: Info: Generating META-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservices-ext.xmi.
```

Complete the EJB implementation.

---

## Developing Web services clients based on Web Services for J2EE

This topic explains how to develop a Web services client based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) specification.

For a Java application to act as Web service client, a mapping between the Web Services Description Language (WSDL) file and the Java application must exist. The mapping is defined by the Java API for XML-based RPC (JAX-RPC) specification. You can use a Java component to implement a Web service by specifying the component's interface and binding information in the WSDL file and designing the application server infrastructure to accept the service request. This entire process encompassed is based on the Web Services for J2EE specification.

Before you begin this task, locate the Web Services Description Language (WSDL) file that defines the Web service to access.

To create the client code and artifacts that enable the application client to access a Web service:

1. Develop client bindings from a WSDL file. The client-side bindings and deployment descriptors are generated.
2. Complete the client implementation.
3. (Optional) Assemble a Web services-enabled client Java archive (JAR) file. Complete this step if you are developing a managed client that runs in the J2EE client container.
4. (Optional) Assemble a Web services-enabled client Web archive (WAR) file. Complete this step if you are developing a managed client that runs in the J2EE client container.
5. (Optional) Configure the `webservicesclient.xml` deployment descriptor. Complete this step if you are developing a managed client that runs in the J2EE client container.
6. (Optional) Configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor. Complete this step if you are deploying a managed client that runs in the J2EE client container and you want to override the default client settings. See `ibm-webservicesclient-bnd.xmi` assembly properties for more information about the `ibm-webservicesclient-bnd.xmi` deployment descriptor.
7. Test the Web services-enabled client application.

You have created and tested a Web services client application. For step-by-step information see Example: Developing Web services clients based on Web Services for J2EE.

### Example: Developing Web services clients based on Web Services for J2EE

This example takes you through the steps to develop a Web service client. The development process is based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) and the Java API for XML-based remote procedure call (JAX-RPC) specification. For a Java or J2EE application to act as a client of a Web service, you must map the WSDL file to the Java code. The JAX-RPC specification defines the mapping between a WSDL file, Java code and XML Schema types.

#### Steps for this example task

1. Obtain the Web Services Description Language (WSDL) document for the Web service that you want to access.

You can obtain the WSDL document from the service provider by e-mail or by looking it up in a Universal Description, Discovery and Integration (UDDI) registry.

2. Develop client bindings from your WSDL file.

The WSDL document is used to generate all the information needed to invoke the Web service, including the Service Endpoint Interface and implementations; generated service interface; `webservicesclient.xml` and `ibm-webservicesclient-bnd.xmi` and `ibm-webservicesclient-ext.xmi` deployment descriptors.

The **WSDL2Java** command-line tool is run against your WSDL file to develop client bindings.

3. Implement the client.

See Chapter 4 of the JSR-109 specification. You can access the specification through Web services: Resources for learning.

You can also review the GetQuote sample available in the Samples Gallery. (See "Samples Gallery" in the Information Center.)

4. Assemble the module.

Assemble the client JAR file into an EAR file or assemble the client WAR file into an EAR file.

5. Configure the deployment descriptors.

Configure the `webservicesclient.xml` deployment descriptor.

Configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor.

6.

7. Test the Web services client.

You should test the client to make sure it correctly operates and binds to the Web service.

## Developing client bindings from a WSDL file

To develop the client bindings from a Web Services Description (WSDL) file, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use.

If it is a local file and you are running the Windows platform, the URL looks like this:

`file:drive:\path\file_name.wsdl`. If you are using the UNIX platform, the URL looks like this:

`file:/path/file_name.wsdl`. You can also specify local files using the absolute or relative file system path.

Client bindings are generated using the `-role develop-client` option in combination with the `-container` option of the `WSDL2Java` command. The `-container` option takes the following parameters:

- **-container client**

Generates bindings and deployment descriptors for a client residing the application client container.

- **-container ejb**

Generates bindings and deployment descriptors for a client that is an EJB in the EJB module.

- **-container web**

Generates bindings and deployment descriptors for a client residing in the Web container.

To develop client bindings from a WSDL file:

Run the **WSDL2Java -verbose -role develop-client -container *type* *wsdlURL*** command.

Where *type* is **ejb** for an enterprise JavaBean (EJB) client, **web** for a Java bean client, or **client** for an application client.

**Note:** You can have:

- `-container web`
- `-container ejb`
- `-container client`

Since the **verbose** option is specified, a list of all generated files is displayed when the command runs.

The bindings and deployment descriptors needed by a client to use a Web service.

The following example uses an enterprise bean named `AddressBook` and a WSDL file named `AddressBook.wsdl`. After generating the bindings from the **WSDL2Java -verbose -role develop-client -container client AddressBook.wsdl** command, the following files are generated:

```
Parsing XML file: file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file: AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookService.java.
WSWS3282I: Info: Generating META-INF\webservicesclient.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservicesclient-bnd.xmi.
WSWS3282I: Info: Generating META-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservicesclient-ext.xmi.
```

Complete the client implementation.

Assemble a Web services-enabled client JAR and EAR file.

## Assembling a Web services-enabled client JAR file into an EAR file

You need the following artifacts:

- Assembled client module, containing the implementation, all classes generated by the **WSDL2Java** command-line tool, MANIFEST.MF and deployment descriptor. This module can be:
  - An application client module containing META-INF/application-client.xml
  - An enterprise JavaBean (EJB) module containing META-INF/ejb-jar.xml
- Web Services Description Language (WSDL) file used to develop the client
- Templates for webservicesclient.xml and ibm-webservicesclient-ext.xmi deployment descriptors, if used.
- Generated JAX-RPC mapping deployment descriptor

You can use the Assembly Toolkit to assemble Web service-enabled client applications.

To assemble the client code and artifacts that enable the application client to access a Web service:

1. Start the Assembly Toolkit.
2. Click **File > Import** to import the EJB JAR file, App Client JAR file, or WAR file into the Assembly Toolkit.
3. Open the J2EE perspective by clicking **Windows > Open Perspective > Other > J2EE**.
4. Switch to the **Project Navigator** pane by clicking the **Project Navigator** tab.
5. Locate the project for the file you just imported in the **Project Navigator** pane.
6. Expand the `ejbModule` (for an EJB JAR file) or the `appClientModule` (for the application client JAR file) entry so the META-INF directory is displayed. Expand the META-INF directory.
7. Right-click the META-INF directory and select **New > Folder**. Create a subfolder named `wsdl` in the META-INF directory.
  - a. Copy the WSDL file to the META-INF\wsdl directory by right-clicking on the `wsdl` directory and click **File > Import > File system**. Browse the WSDL file for this Web service and click **Finish**.
  - b. Copy the `webservicesclient.xml` and the JAX-RPC mapping file in the META-INF subdirectory in the same manner you copied the WSDL file. The JAX-RPC mapping file is indicated by the `<jaxrpc-mapping-file>` element in the `webservicesclient.xml` file.
  - c. (Optional) Place the `ibm-webservicesclient-ext.xmi` and the `ibm-webservicesclient-bnd.xmi` file in the META-INF subdirectory, if used.
8. Assemble the JAR file into an EAR file using typical assembly techniques if the client runs in a container.
9. Right-click on the WEB-INF directory and select **New > Folder**. Create a subfolder named `wsdl` in the WEB-INF directory.
  - a. Copy the WSDL file to the WEB-INF\wsdl directory by right-clicking on the `wsdl` directory and click **File > Import > File system**. Browse the WSDL file for this Web service and click **Finish**.

- b. Copy the `webservicesclient.xml` and the JAX-RPC mapping file in the WEB-INF subdirectory in the same manner you copied the WSDL file. The JAX-RPC mapping file is indicated by the `<jaxrpc-mapping-file>` element in the `webservicesclient.xml` file.
- c. (Optional) Place the `ibm-webservicesclient-ext.xmi` and `ibm-webservicesclient-bnd.xmi` file in the WEB-INF subdirectory, if used.

The artifacts required to enable the client module to use Web services are added to the module.

This example uses a JAR file named `AddressBookClient.jar` and an EAR file named `AddressBookClient.ear`:

```

META-INF/MANIFEST.MF
META-INF/application-client.xml
META-INF/wsdl/AddressBook.wsdl
META-INF/webservicesclient.xml
META-INF/AddressBook_mapping.xml
com/ibm/websphere/samples/webservices/addr/Address.class
com/ibm/websphere/samples/webservices/addr/AddressBook.class
com/ibm/websphere/samples/webservices/addr/AddressBookClient.class
com/ibm/websphere/samples/webservices/addr/AddressBookService.class
...other generated classes...

```

After assembling the `AddressBookClient.jar` file into the `AddressBookClient.ear` file, the `AddressBookClient.ear` file contains the following files:

```

META-INF/MANIFEST.MF
AddressBookClient.jar
META-INF/application.xml

```

Configure the `webservicesclient.xml` deployment descriptor .

## Assembling a Web services-enabled client WAR file into an EAR file

You need the following artifacts:

- Assembled client Web archive (WAR) module, containing the implementation, all classes generated by the **WSDL2Java** command-line tool, `MANIFEST.MF` and deployment descriptor.
- Web Services Description Language (WSDL) file used to develop the client
- Templates for `webservicesclient.xml`, `ibm-webservicesclient-bnd.xmi` and `ibm-webservicesclient-ext.xmi` deployment descriptors, if used.
- Generated JAX-RPC mapping deployment descriptor

You can use the Assembly Toolkit to assemble Web service-enabled client applications.

To assemble the client code and artifacts that enable the application client to access a Web service:

1. Start the Assembly Toolkit.
2. Click **File > Import** to import the WAR file into the Assembly Toolkit.
3. Open the J2EE perspective by clicking **Windows > Open Perspective > Other > J2EE**.
4. Switch to the **Project Navigator** pane by clicking the **Project Navigator** tab.
5. Locate the project for the file you just imported in the **Project Navigator** pane.
6. Expand the `webContent` entry so the WEB-INF directory is displayed. Expand the WEB-INF directory.
7. Right-click on the WEB-INF directory and select **New > Folder**. Create a subfolder named `wsdl` in the WEB-INF directory.
  - a. Copy the WSDL file to the `WEB-INF\wsdl` directory by right-clicking on the `wsdl` directory and click **File > Import > File system**. Browse the WSDL file for this Web service and click **Finish**.
  - b. Copy the `webservicesclient.xml` and the JAX-RPC mapping file in the WEB-INF subdirectory in the same manner you copied the WSDL file. The JAX-RPC mapping file is indicated by the `<jaxrpc-mapping-file>` element in the `webservicesclient.xml` file.

- c. (Optional) Place the `ibm-webservicesclient-ext.xml` and `ibm-webservicesclient-bnd.xml` file in the `WEB-INF` subdirectory, if used.
8. Assemble the WAR file into an EAR file using typical assembly techniques.

The artifacts required to enable the client module to use Web services are added to the module.

This example uses a WAR file named `AddressBookWeb.war` and an EAR file named `AddressBook.ear`:

```
WEB-INF/MANIFEST.MF
WEB-INF/web.xml
WEB-INF/wsd1/AddressBook.wsdl
WEB-INF/webservicesclient.xml
WEB-INF/AddressBook_mapping.xml
WEB-INF/ibm-webservicesclient-ext.xml (optional)
WEB-INF/ibm-webservicesclient-bnd.xml
com/ibm/websphere/samples/webservices/addr/Address.class
com/ibm/websphere/samples/webservices/addr/AddressBook.class
com/ibm/websphere/samples/webservices/addr/AddressBookClient.class
com/ibm/websphere/samples/webservices/addr/AddressBookService.class
...other generated classes...
```

After assembling the `AddressBookWeb.war` file into the `AddressBook.ear` file, the `AddressBook.ear` file contains the following files:

```
WEB-INF/MANIFEST.MF
AddressBookWeb.war
WEB-INF/application.xml
```

Configure the `webservicesclient.xml` deployment descriptor .

## Configuring the `ibm-webservicesclient-bnd.xml` deployment descriptor

This topic explains how to configure the `ibm-webservicesclient-bnd.xml` deployment descriptor file using the Assembly Toolkit, which replaces the Application Assembly Tool (AAT). It is one of the tools available with the Application Server Toolkit product.

To configure the `ibm-webservicesclient-bnd.xml` deployment descriptor file:

1. Start the Assembly Toolkit
2. Locate the `webservicesclient.xml` file in the module.
3. Double-click the `webservices.xml` file to open the **Web Services Client** editor.
4. Access the **Web Services Client Bindings** editor through the **Client Binding** tab at the bottom of the editor pane.
5. Verify the `componentNameLink` element settings.
  - a. Open the **Web Services Client Bindings** editor.
  - b. Expand the **Component scoped references** section.
  - c. Click **Add**.
  - d. Select the component scoped references defined in the `webservicesclient.xml` file from the list.
6. Verify the `serviceRefLink` element settings.
  - a. Open the **Web Services Client Bindings** editor.
  - b. Click the **Services References** tab.
  - c. Click **Add**.
  - d. Select the service references defined in the `webservicesclient.xml` file from the list.
7. Verify the `deployWSDLFile` element settings.
  - a. Open the **Web Services Client Bindings** editor.
  - b. Select the service references or component scoped reference desired.

- c. Expand the **Service reference details** section.
- d. Click **Browse** on the **Deployed WSDL file** field.
- e. Select the new WSDL file.
- f. Click **OK**.

The `deployedWSDLFile` element of a deployed Web service can also be changed using the administrative console. Using application management, navigate to the Web module or EJB module of the Web service application and select **Web Services Client Bindings**.

8. Verify the `defaultMappings` element settings.
  - a. Open the **Web Services Client Bindings** editor.
  - b. Click **Default Mappings**.
  - c. Click **Add**.
  - d. Edit the entries in the newly added row to establish a mapping between a *portType* and *port* in the WSDL file. There can only be one entry for each *portType*.
  - e. Select the new WSDL file.
  - f. Click **OK**.

The `defaultMappings` of a deployed Web service can also be changed using the administrative console. Using application management, navigate to the Web module or EJB module of the Web service application and select **Web Services Client Bindings**.

9. Access the **Web Services Client Port Bindings** editor through the **Port Bindings** tab at the bottom of the editor pane.
10. Verify the `syncTimeout` element settings.
  - a. Create a **Port Qualified Name Bindings** for the port.
  - b. Open the **Web Services Client Bindings** editor.
  - c. Confirm that a service reference is selected in either the **Component scoped references** or **Service references** section.
  - d. Expand the **Port qualified name bindings** section.
  - e. Click **Add**. A new entry is now added to the **Port qualified name bindings** list.
  - f. Click the new **Port qualified name bindings** entry. The **Web Services Client Port Bindings** editor opens.
  - g. Expand the **Port qualified name bindings details** section.
  - h. Type the *namespace* of the WSDL file port you want to configure, in the **Port Namespace Link** field.
  - i. Type the *local\_name* of the WSDL file port you want to configure in the **Port Local Name Link** field. The name displayed in the **Port qualified name bindings** list is the local name of the WSDL file port.
  - j. Click **OK**.
  - a. Configure the `syncTimeout` property by locating the **Synchronization timeout** field and enter the desired value.
11. Verify the `basicAuth` element settings.
  - a. Open the **Web Services Client Bindings** editor.
  - b. Expand the **Basic authentication** section.
  - c. Type the desired value in the **User ID** and **Password** fields.
  - d. Click **OK**.
12. Verify the `sslConfig` element settings.
  - a. Open the **Web Services Client Bindings** editor.
  - b. Expand the **SSL Configuration** section.
  - c. Type the desired value in the **Name** field.

d. Click **OK**.

13. After editing the properties, type **ctrl-s** on your keyboard to save the changes.

## **ibm-webservicesclient-bnd.xmi assembly properties**

The `ibm-webservicesclient-bnd.xmi` file contains information for the Web services runtime that is WebSphere product-specific.

You can edit these properties using the Assembly Toolkit. See *Configuring the ibm-webservicesclient-bnd.xmi deployment descriptor* for instructions.

### **Assembly properties**

The following user-definable assembly properties are supported:

- **componentNameLink**

Attribute of the `componentScopedRefs` element that specifies the link to the corresponding `<component-scoped-refs>` element in `webservicesclient.xml` file. This property is used only when the Web service client is an EJB.

- **serviceRefLink**

Attribute of the `serviceRefs` element that specifies the link to the `<service-ref-name>` in the `webservicesclient.xml` file.

You can edit this property in the Assembly Toolkit:

- **deployedWSDLFile**

Attribute of the `serviceRefs` element is optional and permits an alternate WSDL file to be used other than that specified in the `<wsdl-file>` element of `webservicesclient.xml` file. If this attribute is specified, the alternate WSDL file must be packaged in the same module and must be compatible with the development WSDL file. The `deployedWSDLFile` property is used to supply a new WSDL file containing a different endpoint URL than the original WSDL file.

- **defaultMappings** element

Identifies which port should be used for a given `portType` when none is explicitly selected by the client. This element has the following attributes: `portTypeNamespace`, `portTypeLocalName`, `portNamespace`, `portLocalName`. These attributes identify which `wsdl:port` should be used for a `wsdl:portType`.

- **syncTimeout**

Attribute of the `portQnameBindings` element that specifies how long, in seconds, to wait for a response from a synchronous call.

- **basicAuth**

Element of the `portQnameBindings` element that can be used to authenticate a service client to the service endpoint, independent of the underlying transport that includes, HTTP, HTTPS, and JMS. Set the user ID and password attributes as needed.

- **sslConfig**

Element of the `portQnameBindings` element that specifies the Secure Sockets Layer (SSL) configuration of an HTTPS outbound request. The name attribute is the name of a SSL configuration entry or alias defined in the SSL Configuration Repertoire.

**Note:** This attribute is only used when the client is running in the WebSphere Application Server.

### **Example bindings file**

The following examples demonstrate the spelling and position of the various attributes. You cannot cut and paste these examples because they do not contain the required ID attributes. If you add elements to a binding file template generated by the **WSDL2Java** command, you must confirm that each element has an ID attribute whose value is a unique string. Review the template `xmi` files generated by the **WSDL2Java** command for examples of ID strings.

```

<com.ibm.etools.webservice.wscbnd:ClientBinding xmi:version="2.0"
xmlns:xmi="http://www.omg.org/XMI" xmlns:com.ibm.etools.webservice.wscbnd=
"http://www.ibm.com/websphere/appserver/schemas/5.0.2/wscbnd.xmi">

 <componentScopedRefs componentNameLink="myComponent ref"/>

 <serviceRefs serviceRefLink="myService ref"
 deployedWSDLFile="META-INF/wsdl/alternate.wsdl">
 <defaultMappings portTypeLocalName="AddressBook"
 portTypeNamespace="http://www.com.ibm"
portLocalName="AddressBookPort" portNamespace="http://www.com.ibm"/>
 <portQnameBindings portQnameNamespaceLink="http://www.com.ibm"
portQnameLocalNameLink="AddressBookPort" syncTimeout="99">
 <basicAuth userid="myId" password="myPassword"/>
 <sslConfig name="mynode/DefaultSSLSettings"/>
 </portQnameBindings>
 </serviceRefs>
</com.ibm.etools.webservice.wscbnd:ClientBinding>

```

## Configuring the webservicescient.xml deployment descriptor

You should have an enterprise JavaBean (EJB) Java archive (JAR) file, Web archive (WAR) file or an application client file that you can import into the Assembly Toolkit.

This topic explains how to configure the webservicescient.xml deployment descriptor with the Assembly Toolkit. It is one of the tools available with the Application Server Toolkit product. For more information about completing tasks with the Assembly Toolkit, click **Help > Help** in the Assembly Toolkit graphical user interface (GUI).

To configure the webservicescient.xml deployment descriptor with the Assembly Toolkit:

1. Start the Assembly Toolkit.
2. Click **File > Import** to import the EJB JAR file, WAR file or application client file into the Assembly Toolkit.
3. Open the J2EE perspective by clicking **Windows > Open Perspective > J2EE**.
4. Switch to the **Project Navigator** pane by clicking the **Project Navigator** tab.
5. Locate the project containing the webservicescient.xml file in the **Project Navigator** pane.
6. Expand the directories under the project until the META-INF or WEB-INF directory and its contents appear.
7. Right-click on the webservicescient.xml file.
8. Select **Open. The Web Services Client** editor opens.
9. Expand the **Service references** section.
10. Select the *service\_reference* that you want to configure.
11. Expand the **Service reference overview** section.
12. Type the name of the service for which the client accesses in the **Description** field.
13. Expand the **Service reference implementation details** section.
  - a. Type the name that the Java Naming Directory Interface (JNDI) uses to locate the service in the **Service references name** field. The JNDI lookup string for this service is `java:comp/env/service-ref-name`. By convention, the service reference name always begins with `service/`.
  - b. Type the class name, including package, of the generated Java interface that is the Service Interface for this Web service in the **Service interface name** field.
  - c. Type the WSDL file name used by the client, relative to the root of the module, in the **WSDL file** field.

- d. Type the file name of the Java mapping file, relative to the root of the module, in the **JAX RPC mapping file** field.
14. Click **ctrl-s** to save the changes.

The `webservicesclient.xml` deployment descriptor is configured.

## Configuring the `webservicesclient.xml` deployment descriptor for Handler classes

This topic explains how to use the Assembly Toolkit to configure the `webservicesclient.xml` deployment descriptor for user-provided Handler classes. The Assembly Toolkit is a component of the Application Server Toolkit. For more information about completing tasks with the Assembly Toolkit, click **Help > Help** in the Assembly Toolkit graphical user interface (GUI).

You should have an Enterprise archive (EAR) file for the applications you want to configure. For some handler use, such as logging or tracing, only the server or client application needs to be configured. For other handler use, including sending information in SOAP headers, the client and server applications must be configured with symmetrical handlers.

The modules in the EAR file should contain the handler classes being configured. These classes implement the `javax.xml.rpc.handler.Handler` interface. For more information on writing handler classes, see Chapter 6 of the Web Services for Java 2 platform, Enterprise Edition (J2EE) 1.0 specification and chapter 12 of the Java API for XML-based remote procedure call (JAX-RPC) 1.0 specification available through Web services: Resources for learning. The application modules must contain the `webservices.xml` (for server) and `webservicesclient.xml` (for client) deployment descriptors.

To configure a handler in the `webservicesclient.xml` deployment descriptor:

1. Start the Assembly Toolkit.
2. Click **File > Import** and import the EAR file into the Assembly Toolkit.
3. Open the J2EE perspective by clicking **Windows > Open Perspective > Other > J2EE**.
4. Click the **Project Navigator** tab to switch to the **Project Navigator** pane.
5. Locate the project that contains the `webservicesclient.xml` deployment descriptor. Expand the directories under the project until the `META-INF` or `WEB-INF` directory and its contents, including the `webservicesclient.xml` file, are visible.
6. Right-click the `webservicesclient.xml` file.
7. Click **Open**. The **Service References** pane of the **Web Services Client** editor opens.
8. Expand the **Service references** section.
  - a. Select the *service\_reference* for which you want to configure the handler.
9. Expand the **Handlers** section.
10. Click **Add** at the bottom of the **Handlers** section. A **Class browser** opens.
11. Browse for the name of the Handler class in the module. When it displays in the **Matching types** field, select the class and click **OK**. The Class browser window closes after you click OK and the **Handlers** pane of the **Web Services Editor** opens.
12. (Optional) Configure properties in the **Handlers** pane. See Handler class properties for a list of the properties you can configure in this step.
13. Type **ctrl-s** to save the changes.

### Handler class properties

You can configure the following Handler class properties through the Assembly Toolkit. See Configuring the `webservices.xml` deployment descriptor for Handler classes or Configuring the `webservicesclient.xml` deployment descriptors for Handler classes for instructions on how to configure the properties.

**Description**

Standard Java 2 platform, Enterprise Edition (J2EE) technology descriptor field.

**Display name**

Standard J2EE technology descriptor field.

**Small icon**

Standard J2EE technology descriptor field.

**Large icon**

Standard J2EE technology descriptor field.

**Handler name**

The name of the handler. This name must be unique within the module.

**Handler class**

The fully qualified name of the Handler class. Initially, it is set by the Assembly Toolkit's class browser.

**Initial parameters**

Property names and values to be made available to the handler.

**SOAP headers**

Qnames of the SOAP headers that are processed by this handler. See section 12.2.2 of the Java API for XML-based remote procedure call (JAX-RPC) 1.0 specification, available through Web services: Resources for learning, for more information about setting this property.

**SOAP roles**

URIs containing the SOAP actor names for which the handler acts in the role of. See section 12.2.2 of the Java API for XML-based remote procedure call (JAX-RPC) 1.0 specification, available through Web services: Resources for learning, for more information about setting this property.

**Example: Configuring Handler classes for Web services deployment descriptors**

This scenario explains how to add trivial client and server Handler classes to a sample application named `WebServicesSamples.ear`. The Handler classes display messages when given a request or response to handle.

The code for the client Handler class is:

```
package samples;

public class ClientHandler implements javax.xml.rpc.handler.Handler {
 public ClientHandler() { }

 public boolean handleRequest(javax.xml.rpc.handler.MessageContext
 context) {
 System.out.println("ClientHandler: In handleRequest");
 return true; }

 public boolean handleResponse(javax.xml.rpc.handler.MessageContext
 context) {
```

```

 System.out.println("ClientHandler: In handleResponse");
 return true; }

public boolean handleFault(javax.xml.rpc.handler.MessageContext
context) {
 System.out.println("ClientHandler: In handleFault");
 return true; }

public void init(javax.xml.rpc.handler.HandlerInfo config) { }

public void destroy() {
}

public javax.xml.namespace.QName[] getHeaders() {
 return null; }
}

```

The code for the server Handler class is:

```

package sample;
public class ServerHandler implements javax.xml.rpc.handler.Handler {
 public ServerHandler() { }

public boolean handleRequest(javax.xml.rpc.handler.MessageContext
context) {
 System.out.println("ServerHandler: In handleRequest");
 return true; }

public boolean handleResponse(javax.xml.rpc.handler.MessageContext
context) {
 System.out.println("ServerHandler: In handleResponse");
 return true; }

public boolean handleFault(javax.xml.rpc.handler.MessageContext
context) {
 System.out.println("ServerHandler: In handleFault");
 return true; }

public void init(javax.xml.rpc.handler.HandlerInfo config) { }

public void destroy() { }

public javax.xml.namespace.QName[] getHeaders() {
 return null; }
}

```

1. Compile these classes using
  - %JAVA\_HOME%\bin\java -extdirs %WAS\_EXT\_DIRS% ClientHandler.java ServerHandler.java (on Windows)
  - \$JAVA\_HOME/bin/java -extdirs \$WAS\_EXT\_DIRS ClientHandler.java ServerHandler.java (on Unix)
2. Open the Assembly Toolkit and import the two sample EAR files:
  - %WAS\_HOME%\samples\lib\WebServicesSamples\WebServicesSamples.ear on Windows or \$WAS\_HOME/samples/lib/WebServicesSamples/WebServicesSamples.ear on Unix.
  - %WAS\_HOME%\samples\lib\WebServicesSamples\ApplicationClients.ear on Windows or \$WAS\_HOME/samples/lib/WebServicesSamples/ApplicationClients.ear on Unix..
3. Import the compiled handler classes into the projects for the sample modules:
  - Import sample.ClientHandler into the **appClientModule** directory of the **AddressBookClient** project.
  - Import sample.ServerHandler into the **ejbModule** directory of the **AddressBookW2JE** project.
4. Configure the webservicessclient.xml deployment descriptor for Handler classes.
5. Configure the webservicess.xml deployment descriptor for Handler classes.
6. Save your changes and export the EAR files.

7. Uninstall the WebServicesSamples.ear application from your server if it is already installed.
8. Install the new WebServicesSamples.ear application.
9. Start the server.
10. Run the client:

**launchClient ApplicationClients.ear -CCjar=AddressBookClient.jar**

When the client executes, the console output is as shown below. The messages from the handlers are shown in bold.

```
IBM WebSphere Application Server, Release 5.1
J2EE Application Client Tool
Copyright IBM Corp., 1997-2003
WSCL0012I: Processing command line arguments.
WSCL0013I: Initializing the J2EE Application Client
Environment.
WSCL0035I: Initialization of the J2EE Application Client
Environment has completed.
WSCL0014I: Invoking the Application Client class
com.ibm.websphere.samples.webservices.addr.AddressBookClient
>> Querying address for 'Purdue Boilermaker' using port
AddressBookW2JE
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
 1 University Drive
 West Lafayette, IN 47907
 Phone: (765) 555-4900
>> Querying address for 'Purdue Boilermaker' using port
AddressBookJ2WE
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
 2 University Drive
 West Lafayette, IN 47907
 Phone: (765) 555-4900
>> Querying address for 'Purdue Boilermaker' using port
AddressBookJ2WB
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
 3 University Drive
 West Lafayette, IN 47907
 Phone: (765) 555-4900
>> Querying address for 'Purdue Boilermaker' using port AddressBookW2JB
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
 4 University Drive
 West Lafayette, IN 47907
 Phone: (765) 555-4900
```

For the client, the Handler class is configured for each service reference, not for each port. The AddressBook sample has four ports, but only one service reference, therefore the ClientHandler handles requests and responses on all ports.

When the server log file is examined, it contains:

```
[9/24/03 16:39:22:661 CDT] 4deec1c6 WebGroup I SRVE0180I:
[HTTP router for AddressBookW2JE.jar] [/AddressBookW2JE] [Servlet.LOG]:
AddressBook: init
[9/24/03 16:39:23:161 CDT] 4deec1c6 SystemOut 0 ServerHandler: In handleRequest
[9/24/03 16:39:23:211 CDT] 4deec1c6 SystemOut 0 ServerHandler: In handleResponse
```

## What to do next

Install and test the application.

## Testing Web services-enabled clients

Before testing your Java client, confirm that the server endpoint specified in the client Web Services Description Language (WSDL) file is running and available.

The following steps and examples assume that you are testing a system that has WebSphere Application Server installed, and that you have configured your environment as described in Setting up a Web services development and unmanaged client execution environment.

Tests are run differently depending on whether the client module has client container deployment information, which consists of the `application-client.xml` and `webservicesclient.xml` files, as well as the JAX-RPC mapping file and WSDL file. The client enterprise archive (EAR) files discussed in this topic are referred to as managed because they contain the deployment information. The client Java archive (JAR) files discussed are referred to as unmanaged because they that do not contain the deployment information.

To test Web services-enabled clients:

1. Test an unmanaged client JAR file.

- a. Execute your application with the **java** command. On Windows platforms:

```
%JAVA_HOME%\bin\java" "-Xbootclasspath/p:%WAS_BOOTCLASSPATH%"
-Djava.security.auth.login.config="%WAS_HOME%\properties\wsjaas_client.conf"
-Djava.ext.dirs="%WAS_EXT_DIRS%"
-classpath "%WAS_CLASSPATH%;<list your application JAR files and classes>"
<fully qualified class name to run><your application parameters>
```

On UNIX:

```
`${JAVA_HOME}/bin/java" "-Xbootclasspath/p:$WAS_BOOTCLASSPATH"
-Djava.security.auth.login.config="$WAS_HOME/properties/wsjaas_client.conf"
-Djava.ext.dirs="$WAS_EXT_DIRS"
-classpath "$WAS_CLASSPATH;<list of your application JAR files and classes>"
<fully qualified class name to run><your application parameters>
```

The unmanaged client application runs.

2. Test a managed client EAR file.

- a. Execute your client application with the **launchClient** command. An example of using the command is as follows:

```
launchClient clientEar
```

Web services-enabled clients that have been tested.

Troubleshoot your Web services application.

---

## Assembling Web services applications based on Web Services for J2EE

This topic explains how to assemble a Web services application that is based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) specification.

You can assemble Web Services for J2EE modules with the Assembly Toolkit which replaces the Application Assembly Tool (AAT). The Assembly Toolkit is one of the tools available with the Application Server Toolkit product. .

To assemble Web services applications:

1. Start the Assembly Toolkit.
2. Assemble a Web services-enabled EJB JAR file.
3. Assemble a Web services-enabled EJB JAR file into an EAR file.
4. (Optional) Enable the EAR file. When the EAR file contains EJB modules, it must have the Web services endpoint WAR file added with the **endptEnabler** command-line tool or Assembly Toolkit before deployment.
5. Assemble a Web services-enabled WAR file.
6. Assemble a Web services-enabled WAR file into an EAR file.

A Web services-enabled EAR file that you can deploy into WebSphere Application Server.

Deploy the Web services-enabled EAR file into WebSphere Application Server.

## Assembling a Web services-enabled EJB JAR file

You can assemble a Web services-enabled enterprise JavaBean (EJB) Java archive (JAR) file in one of two ways:

1. Assemble a Web services-enabled EJB JAR file when starting from Java code.
2. Assemble a Web services-enabled EJB JAR file when starting from Web Services Description Language (WSDL).

An assembled Web services-enabled EJB JAR file.

Configure the webservices.xml deployment descriptor .

## Assembling a Web services-enabled EJB JAR file when starting from Java code

You need the following artifacts:

- Assembled Enterprise JavaBean (EJB) Java archive (JAR) file (not enabled for Web services)
- Compiled Java class for the Service Endpoint Interface
- Web Services Description Language (WSDL) file
- Complete `webservices.xml`, `ibm-webservices-bnd.xmi`, `ibm-webservices-ext.xmi` and Java API for XML-based remote procedure call (JAX-RPC) mapping deployment descriptors.

This topic explains how to assemble a Web service-enabled EJB JAR file with the Assembly Toolkit. The Assembly Toolkit replaces the Application Assembly Tool (AAT) and is one of the tools available with the Application Server Toolkit product.

To assemble an Web services-enabled EJB JAR file when starting from Java code:

1. Start the Assembly Toolkit.
2. Click **File > Import** to import the EJB JAR file into the Assembly Toolkit.
3. Open the J2EE perspective by clicking **Windows > Open Perspective > Other > J2EE**.
4. Switch to the **Project Navigator** pane by clicking the **Project Navigator** tab.
5. Locate the project containing the JAR file you just imported in the **Project Navigator** pane.
6. Expand the `ejbModule` entry until the `META-INF` directory displays. Expand the `META-INF` directory.
7. Right-click the `META-INF` directory and click **New > Folder**. Create a subfolder named `wsdl` in the `META-INF` directory.
8. Copy the WSDL file to the `META-INF\wsdl` directory by right-clicking on the `wsdl` directory and click **File > Import > File system**. Browse the WSDL file for this Web service and click **Finish**.
9. Copy the JAX-RPC mapping file, `webservices.xml`, `ibm-webservices-bnd.xmi`, and `ibm-webservices-ext.xmi` files into the `META-INF` directory.

10. Import the Service Endpoint Interface class so its package begins in the `ejbModule` directory. You can import either the source file or compiled class file. If you import the source file it automatically compiles.

The artifacts required to Web service-enable an EJB module for Web services are added to the JAR file.

After assembling a JAR file named `AddressBook.jar`, the JAR file contains the following files. The files added in this task are in bold:

```
META-INF/MANIFEST.MF
META-INF/ejb-jar.xml
addr/Address.class
addr/AddressBook_RI.class
addr/AddressBookBean.class
addr/AddressBookHome.class
addr/Phone.class
addr/StateType.class
addr/AddressBook.class
META-INF/wsd1/AddressBook.wsd1
META-INF/ibm-webservices-bnd.xmi
META-INF/ibm-webservices-ext.xmi
META-INF/webservices.xml
META-INF/AddressBook_mapping.xml
```

Configure the `webservices.xml` deployment descriptor .

## Assembling Web services-enabled EJB JAR file when starting from WSDL

You need the following artifacts:

- An assembled Enterprise JavaBean (EJB) Java archive (JAR) file containing the EJB implementation and all classes generated by the **WSDL2Java** command tool when the **role** argument is `develop-server` and the **container** argument is `EJB`.
- A Web Services Description Language (WSDL) file
- Complete `webservices.xml`, `ibm-webservices-bnd.xmi`, `ibm-webservices-ext.xmi`, and Java API for XML-based remote procedure call (JAX-RPC) mapping deployment descriptors.

You can use the Assembly Toolkit to assemble Web services-enabled JAR files. The Assembly Toolkit replaces the Application Assembly Tool (AAT). It is one of the tools available with the Application Server Toolkit product.

To assemble a Web services-enabled EJB JAR file when starting from WSDL:

1. Start the Assembly Toolkit.
2. Click **File > Import** to import the EJB JAR file into the Assembly Toolkit.
3. Open the J2EE perspective by clicking **Windows > Open Perspective > Other > J2EE**.
4. Switch to the **Project Navigator** pane by clicking the **Project Navigator** tab.
5. Locate the project for the JAR file you just imported in the **Project Navigator** pane.
6. Expand the `ejbModule` entry so the `META-INF` directory is displayed. Expand the `META-INF` directory.
7. Right-click the `META-INF` directory and select **New > Folder**. Create a subfolder named `wsdl` in the `META-INF` directory.
8. Copy the WSDL file to the `META-INF\wsdl` directory by right-clicking on the `wsdl` directory and click **File > Import > File system**. Browse the WSDL file for this Web service and click **Finish**.
9. Copy the JAX-RPC mapping file as specified by the deployment descriptor `<jaxrpc-mapping-file>` element of `webservices.xml`.
10. Copy `webservices.xml`, `ibm-webservices-bnd.xmi` and `ibm-webservices-ext.xmi` into the `META-INF` subdirectory in the same manner.

The artifacts required to enable an EJB module for Web services are added to the JAR file.

After assembling a JAR file named `AddressBook.jar` contains the following files. The files added in this task are in bold:

```
META-INF/MANIFEST.MF
META-INF/ejb-jar.xml
addr/Address.class
addr/AddressBook_RI.class
addr/AddressBookSoapBindingImpl.class
addr/AddressBookHome.class
addr/Phone.class
addr/StateType.class
addr/AddressBook.class
META-INF/wsdl/AddressBook.wsdl
META-INF/ibm-webservices-bnd.xmi
META-INF/ibm-webservices-ext.xmi
META-INF/webservices.xml
META-INF/AddressBook_mapping.xml
```

Configure the `webservices.xml` deployment descriptor .

## Assembling a Web services-enabled WAR file

You can assemble a Web services-enabled Web archive (WAR) file in one of two ways:

1. Assemble a Web services-enabled WAR file when starting from Java code.
2. Assemble a Web services-enabled WAR file when starting from WSDL.

A Web services-enabled WAR file is assembled.

### Assembling a Web services-enabled WAR file when starting from Java code

You need the following artifacts:

- An assembled Web archive (WAR) file containing `web.xml`, but not Web services-enabled
- The Java class for the Service Endpoint Interface
- A Web Services Description Language (WSDL) file
- Complete `webservices.xml`, `ibm-webservices-bnd.xmi`, `ibm-webservices-ext.xmi`, and Java API for XML-based remote procedure call (JAX-RPC) mapping deployment descriptors.

You can use the Assembly Toolkit to assemble a Web services-enabled WAR file. The Assembly Toolkit replaces the Application Assembly Tool (AAT). It is one of the tools available with the Application Server Toolkit product.

To assemble a Web services-enabled WAR file when starting from Java code:

1. Start the Assembly Toolkit.
2. Click **File > Import** to import the WAR file into the Assembly Toolkit.
3. Open the J2EE perspective by clicking **Windows > Open Perspective > Other > J2EE**.
4. Switch to the **Project Navigator** pane by clicking the **Project Navigator** tab.
5. Locate the project for the WAR file you just imported in the **Project Navigator** pane.
6. Expand the `WebContent` directory so the `WEB-INF` directory is displayed. Expand the `WEB-INF` directory
7. Confirm that the `WEB-INF/web.xml` descriptor for the Web module contains a `<servlet-class>` element indicating the Java bean class that is implementing the service. Confirm by:
  - a. Double-click **Web Deployment Descriptor**.
  - b. In the **Web Deployment Descriptor** editor, click the **Servlets**.
  - c. Enter the full path name of the Java bean class implementing the Web service in the **Servlet class** field.
  - d. Close the editor window to save your changes.

8. Right-click the WEB-INF directory and click **New > Folder**. Create a subfolder named wsd1 in the WEB-INF directory.
9. Copy the WSDL file to the WEB-INF\wsd1 directory by right-clicking on the wsd1 directory and click **File > Import > File system**. Browse the WSDL file for this Web service and click **Finish**.
10. Copy the JAX-RPC mapping file as specified by the deployment descriptor <jaxrpc-mapping-file> element of webservices.xml.
11. Copy webservices.xml,ibm-webservices-bnd.xmi and ibm-webservices-ext.xmi into the WEB-INF subdirectory in the same manner.
12. Import the Service Endpoint Interface class so that its package begins in the JavaSource directory. When you import the source file it is automatically compiled.

The artifacts required to Web service-enable the Web module are added to the WAR file.

Assemble a Web services-enabled WAR into an EAR file.

## Assembling a Web services-enabled WAR file when starting from WSDL

You need the following artifacts:

- Assembled Web archive (WAR) file containing the enterprise JavaBean (EJB) implementation, all classes generated by the **WSDL2Java** command tool and a Web deployment descriptor, web.xml.
- A Web Services Description Language (WSDL) file
- Complete webservices.xml, ibm-webservices-bnd.xmi, ibm-webservices-ext.xmi, and Java API for XML-based remote procedure call (JAX-RPC) mapping deployment descriptors.

You can use the Assembly Toolkit to assemble Web services-enabled WAR files. The Assembly Toolkit replaces the Application Assembly Tool (AAT). It is one of the tools available with the Application Server Toolkit product.

To assemble a Web services-enabled WAR file when starting from WSDL:

1. Start the Assembly Toolkit.
2. Click **File > Import** to import the WAR file into the Assembly Toolkit.
3. Open the J2EE perspective by clicking **Windows > Open Perspective > Other > J2EE**.
4. Switch to the **Project Navigator** pane by clicking the **Project Navigator** tab.
5. Locate the project for the WAR file you just imported in the **Project Navigator** pane.
6. Expand the WebContent directory so the WEB-INF directory is displayed. Expand the WEB-INF directory
7. Confirm that the WEB-INF/web.xml deployment descriptor for the Web module contains a <servlet> element including the <servlet-name> element. To confirm:
  - a. Double-click **Web Deployment Descriptor**.
  - b. In the **Web Deployment Descriptor** editor click the **Servlets** tab.
  - c. Enter the full path name of the Java bean class implementing the Web service in the **Servlet class** field.
  - d. Close the editor window to save your change.
8. Right-click the WEB-INF directory and select **New > Folder**. Create a subfolder named wsd1 in the WEB-INF directory.
9. Copy the WSDL file to the WEB-INF\wsd1 directory by right-clicking on the wsd1 directory and click **File > Import > File system**. Browse the WSDL file for this Web service and click **Finish**.
10. Copy the JAX-RPC mapping file as specified by the deployment descriptor <jaxrpc-mapping-file> element of webservices.xml.
11. Copy the webservices.xml, ibm-webservices-ext.xmi, ibm-webservices-bnd.xmi deployment descriptors in the WEB-INF subdirectory.

The artifacts required to Web service-enable the Web module is added to the WAR file.

Assemble a Web services-enabled WAR into an EAR file.

## Assembling a Web services-enabled EJB JAR into an EAR file

Before assembling a Web services-enabled enterprise archive (EAR) file Assemble a Web services-enabled EJB Java archive (JAR) file.

You can assemble a Web services-enabled EAR file with the Assembly Toolkit. The Assembly Toolkit replaces the Application Assembly Tool (AAT). It is one of the tools available with the Application Server Toolkit product.

To assemble a Web services-enabled EAR file:

1. Start the Assembly Toolkit.
2. Assemble the Web services-enabled JAR file into an EAR file. The EAR file can contain an enterprise bean or application client JAR files, WAR files, Web applications, and metadata describing the applications or `application.xml` files.

A Web services-enabled EAR file.

In the following example, there is an `application.xml` deployment descriptor packaged with a Web services-enabled JAR file called `AddressBook.jar` that is packaged into an EAR file called `AddressBook.ear`. The EAR file contains:

```
META-INF/MANIFEST.MF
META-INF/application.xml
AddressBook.jar
```

An example of the `application.xml` deployment descriptor is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE application PUBLIC "-//Sun Microsystems, Inc.//DTD J2EE Application 1.3//EN"
"http://java.sun.com/dtd/application_1_3.dtd">
<application id="Application_ID">
 <display-name>AddressBookJ2WEE</display-name>
 <description>AddressBook EJB Example from Java</description>
 <module id="EjbModule_1">
 <ejb>AddressBook.jar</ejb>
 </module>
</application>
```

Enable the EAR file. Then, deploy the EAR file into WebSphere Application Server.

## Assembling a Web services-enabled WAR into an EAR file

Before assembling a Web services-enabled enterprise archive (EAR) file Assemble a Web services-enabled Web archive (WAR) file.

This topic explains how to assemble a Web services-enabled WAR file into and EAR file using the Assembly Toolkit. The Assembly Toolkit replaces the Application Assembly Tool (AAT) and is one of the tools available with the Application Server Toolkit product.

To assemble a Web services-enabled WAR file into an EAR file:

1. Start the Assembly Toolkit.

2. Assemble the Web services-enabled WAR file into an EAR file. Now assemble the EAR file that contains the JAR or WAR files. The EAR file can contain an enterprise bean or application client JAR files; Web applications or WAR files; and metadata describing the applications or application.xml files.

A Web services-enabled EAR file.

In the following example, there is an application.xml deployment descriptor packaged with a Web services-enabled JAR file called AddressBook.jar that is packaged into an EAR file called AddressBook.ear. The EAR file contains:

```
META-INF/MANIFEST.MF
META-INF/application.xml
AddressBook.war
```

An example of the application.xml deployment descriptor is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE application PUBLIC "-//Sun Microsystems, Inc.//DTD J2EE Application 1.3//EN"
"http://java.sun.com/dtd/application_1_3.dtd">
<application id="Application_ID">
 <display-name>AddressBook</display-name>
 <description>AddressBook Example from Java bean</description>
 <module id="WebModule_1">
 <web>
 <web-uri>AddressBook.war</web-uri>
 <context-root>/AddressBook</context-root>
 </web>
 </module>
</application>
```

Deploy Web services based on Web Services for J2EE.

## Enabling a Web services-enabled EAR file

Before doing this task, you need to Assemble a Web services-enabled EJB JAR into an enterprise archive (EAR) file.

You can add router modules to your Web services-enabled application, also known as an EAR file with the **endptEnabler** command or the Assembly Toolkit. The Assembly Toolkit replaces the Application Assembly Toolkit (AAT) and is a component of the Application Server Toolkit (ASTK) product.

These tools add one or more router modules to the EAR file for each EJB JAR module within the EAR file. A router module provides an endpoint for the Web services in a particular enterprise JavaBean (EJB) Java archive (JAR) module.

Each router module supports a specific transport such as HyperText Transport Protocol (HTTP) or Java Messaging Service (JMS). If there are no EJB JAR modules in the EAR file, it is not necessary to use these tools.

1. Enable an EAR file with the **endptEnabler** command-line tool.
2. Enable an EAR file with the Assembly Toolkit.

Deploy the EAR file into WebSphere Application Server.

## Enabling a Web services-enabled EAR file with the endptEnabler command

Before doing this task, you need to assemble a Web services-enabled EJB JAR into an enterprise archive (EAR) file.

The **endptEnabler** command-line tool adds one or more router modules to the EAR file for each EJB JAR module within the EAR file. A router module provides an endpoint for the Web services in a particular Enterprise JavaBean (EJB) Java archive (JAR) module.

Each router module supports a specific transport such as HyperText Transport Protocol (HTTP) or Java Messaging Service (JMS). If there are no EJB JAR modules in the EAR file, it is not necessary to use these tools.

To enable an EAR file with the **endptEnabler** command:

1. Invoke the **endptEnabler** command from the *install\_root*\bin directory. If you are using UNIX, invoke the command from the *install\_root*/bin directory.
2. Enter the name of the EAR file, when prompted.
3. Enter various input values as they are requested by the **endptEnabler** command. You are prompted for various input values for each Web services-enabled EJB JAR module in the EAR file. Typically, you should accept the defaults for each prompt. See **endptEnabler** prompts and commands for more information about **endptEnabler** command prompts.

An HTTP or JMS router module is added to the EAR file for each Web services-enabled EJB JAR module contained in the EAR file. For HTTP, a context-root is configured for the application so the Web service can be invoked through a URL. The URL used to invoke the Web service is:

```
http://host[:port]/context-root/services/port-component-name
```

Deploy the EAR file into WebSphere Application Server.

**endptEnabler command:** The **endptEnabler** command enables a set of Web services within an enterprise archive (EAR) file. You can add one or more router modules to the EAR file that include a Web service-enabled EJB JAR file.

Each router module provides a Web service endpoint for a particular transport. For example, an HyperText Transport Protocol (HTTP) router module can be added so that the Web service can receive requests over the HTTP transport, and a Java Messaging Service (JMS) router module can be added so that the Web service can receive requests from a JMS queue or topic.

In its interactive mode, the **endptEnabler** command guides you through the required steps to enable one or more services within an application. The **endptEnabler** command makes a backup copy of your original EAR file in the event that you need to remove or add services at a later time. If your EAR file contains a Web service-enabled EJB JAR file, you must run the **endptEnabler** command before the EAR file is deployed. Otherwise, you do not need to run the command.

### **endptEnabler usage syntax**

Invoke the **endptEnabler** command from the WebSphere Application Server bin directory. The command syntax is as follows:

```
endptEnabler
 [-verbose|-v]
 [-quiet|-q]
 [-help|-h|-?]
 [-properties|-p properties-filename]
 [-transport|-t default-transport]
 [-enableHttpRouterSecurity]
 [ear-filename]
```

All parameters are optional and described as follows:

- **-verbose, -v**

Detailed progress messages are displayed as the tool processes the EAR file. This command-line option is mapped to the verbose global property.

- **-quiet, -q**

No per-module progress messages are displayed as the tool processes the EAR file. This command-line option is mapped to the quiet global property.

- **-help, -h, -?**

A brief help message is displayed explaining the various options.

- **-properties, -p <properties-filename>**

Properties from the file *properties-filename* are read and used to control the behavior of the tool.

- **-transport, -t <default-transport>**

Specifies the default list of transports for which router modules should be created for each EJB JAR file contained in the EAR file. This command-line option is mapped to the defaultTransports global property.

Examples are:

```
-transport http (the default)
-transport jms
-t http,jms
```

- **-enableHttpRouterSecurity**

Enables you to add a security policy for all authenticated users to protect the HTTP router module if all the EJB's are secured in the EJB JAR file. This command-line option is mapped to the http.enableRouterSecurity global property.

- **<ear-filename>**

Specifies the name of the EAR file to be processed.

If the *ear-filename* parameter is not entered on the command line, the interactive mode is used. In interactive mode, you are prompted for the EAR file name, router module names and other important values as the processing occurs. The following dialog is an example of the endptEnabler interactive mode:

**Note:** In this dialog, user input is in fixed width font, and endptEnabler output is in bold.

```
endptEnabler<enter>
WSWS2004I: IBM WebSphere Application Server Release 5
WSWS2005I: Web Services Enterprise Archive Endpoint Enabler Tool.
WSWS2007I: (C) COPYRIGHT International Business Machines Corp. 1997, 2003
WSWS2006I: Please enter the name of your EAR file: AddressBook.ear<enter>

WSWS2003I: Backing up EAR file to: AddressBook.ear~

WSWS2016I: Loading EAR file: AddressBook.ear
WSWS2017I: Found EJB Module: AddressBookEJB.jar

WSWS2029I: Enter http router name for EJB Module AddressBookEJB
[AddressBookEJB_HTTPRouter.war]:<enter>
WSWS2030I: Enter http context root for EJB Module AddressBookEJB
[/AddressBookEJB]:<enter>
WSWS2024I: Adding http router for EJB Module AddressBookEJB.jar.
WSWS2036I: Saving EAR file AddressBook.ear...
WSWS2037I: Finished saving the EAR file.
WSWS2018I: Finished processing EAR file AddressBook.ear.
```

If the *ear-filename* parameter is entered on the command line, the non-interactive mode is used. In non-interactive mode, router module names and other important values are determined from user-specified properties or default values.

## endptEnabler properties

The **endptEnabler** command allows you to control its run time behavior by specifying a set of properties with the **-properties** command-line option. These properties fall into two categories: global and per-module. Global properties affect the overall behavior of the tool as it processes multiple EJB JAR modules within the EAR file. Per-module properties affect the processing of a particular EJB JAR module.

## Global properties

The following table describes the global properties supported by the **endptEnabler** command:

Property name	Description	Default value
verbose	Displays detailed progress messages.	False
quiet	Displays only brief progress messages.	False
http.enableRouter Security	Enables you to add a security policy for all authenticated users to protect the HTTP router module if all the EJB's are secured in the EJB JAR file.	False
http.router ModuleNameSuffix	Specifies the suffix used to construct default HTTP router module names. The .war extension is added by the <b>endptEnabler</b> command.	_HTTPRouter
jms.routerModule NameSuffix	Specifies the suffix used to construct default JMS router module names. The .jar extension is added by the <b>endptEnabler</b> command.	_JMSRouter
jms.listenerInput PortNameSuffix	Specifies the suffix used to construct default Listener Input Port names.	_ListenerPort
jms.default DestinationType	Specifies the default destination type to use for all JMS router modules added to the EAR file. This should be either queue or topic.	queue
defaultTransports	Specifies the default list of transports for which router modules should be created. The list can contain the values http and jms. Multiple values are separated by a comma. Examples are: http, jms and http,jms.	http

### Per-module properties

The following table describes the per-module properties supported by the **endptEnabler** command. *ejbJarName* refers to the name of an EJB JAR module within the EAR file, without the .jar extension.

Property name	Description	Default value
<ejbJarName> .transports	Lists the transports for which router modules should be created for a particular EJB JAR file. The list can contain the values http and jms. Multiple values are separated by a comma. Examples are: http, jms and http,jms.	http
<ejbJarName>.http.skip	Specifies the flag which bypasses the addition of an HTTP router module even if it would otherwise be added (based on other properties). Valid values are true and false.	False
<ejbJarName> .http.routerModuleName	Specifies the name of the HTTP router module for a particular EJB JAR file.	<i>ejbJarName</i> _HTTPRouter

<ejbJarName>.http.contextRoot	Specifies the context root associated with the HTTP router module for a particular EJB JAR file.	<i>/ejbJarName</i>
<ejbJarName>.jms.skip	Specifies the Flag which bypasses the addition of an HTTP router module even if it would otherwise be added (based on other properties). Valid values are true and false.	false
<ejbJarName>.jms.routerModuleName	Specifies the name of the JMS router module for a particular EJB JAR file.	<i>ejbJarName_JMSRouter</i>
<ejbJarName>.jms.listenerInputPortName	Specifies the name of the Listener Input Port to be associated with the JMS router module.	<i>ejbJarName_ListenerPort</i>
<ejbJarName>.ejb JarName>.jms.destinationType	Specifies the JMS destination type associated with the JMS router. Valid values are queue and topic.	queue

### Properties example

Suppose an EAR file contains an EJB JAR file named, StockQuoteEJB.jar that contains Web services. The following set of properties might be used to control the **endptEnabler** command runtime behavior as it processes the EAR file:

```
StockQuoteEJB.transports=http,jms
```

```
StockQuoteEJB.http.routerModuleName=StockQuoteEJB_HTTP
```

```
StockQuoteEJB.http.contextRoot=/StockQuote
```

```
StockQuoteEJB.jms.routerModuleName=StockQuoteEJB_JMS
```

```
StockQuoteEJB.jms.listenerInputPortName=StockQuote_LP
```

```
StockQuoteEJB.jms.destinationType=queue
```

### endptEnabler examples

The following commands are examples of how the **endptEnabler** command can be used:

```
endptEnabler MyApp.ear
```

```
endptEnabler -t jms,http MyApp.ear
```

```
endptEnabler -v -properties MyApp.props MyApp.ear
```

```
endptEnabler -q -t jms MyApp.ear
```

### Enabling a Web services-enabled EAR file with the Assembly Toolkit

Before doing this task, you need to Assemble a Web services-enabled EJB JAR into an enterprise archive (EAR) file.

You can add one or more router modules to your Web services-enabled application, also known as an EAR file with the Assembly Toolkit. The Assembly Toolkit replaces the Application Assembly Toolkit (AAT) and is a component of the Application Server Toolkit (ASTK) product.

A router module provides an endpoint for the Web services in a particular Enterprise JavaBean (EJB) Java archive (JAR) module.

Each router module supports a specific transport such as HyperText Transport Protocol (HTTP) or Java Messaging Service (JMS). If there are no EJB JAR modules in the EAR file, it is not necessary to use these tools.

To enable a Web services-enabled EAR file with the Assembly Toolkit:

1. Start the Assembly Toolkit.
2. Right-click on the EJB project to be enabled.
3. Click **Web Services > Endpoint Enabler**.
4. Specify the transport and router module names in the corresponding fields.
5. Click **OK**.

An HTTP or JMS router module is added to the EAR file for each Web services-enabled EJB JAR module contained in the EAR file. For HTTP, a context-root is configured for the application so the Web service can be invoked through a URL. The URL used to invoke the Web service is:

```
http://host[:port]/context-root/services/port-component-name
```

Deploy the EAR file into WebSphere Application Server.

---

## Configuring the webservices.xml deployment descriptor

Create an enterprise JavaBean (EJB) Java archive (JAR) file or Web archive (WAR) file containing `webservices.xml`:

- Assemble a Web services-enabled EJB JAR file when starting from Java code.
- Assemble a Web services-enabled EJB JAR file from WSDL.
- Assemble a Web services-enabled WAR file when starting from Java code.
- Assemble a Web services-enabled WAR file when starting from WSDL.

Do one of the following based on whether your implementation is an EJB JAR file or Web module WAR file:

- Develop Web services Java bean deployment descriptor templates from a WSDL file.
- Develop Web services EJB deployment descriptor templates from a WSDL file.

This topic explains how to configure the `webservices.xml` deployment descriptor with the Assembly Toolkit. It is one of the tools available with the Application Server Toolkit product. For more information about completing tasks with the Assembly Toolkit, click **Help > Help** in the Assembly Toolkit graphical user interface (GUI).

To configure the `webservices.xml` deployment descriptor:

1. Start the Assembly Toolkit.
2. Click **File > Import** to import the EJB JAR file or WAR file into the Assembly Toolkit.
3. Open the J2EE perspective by clicking **Windows > Open Perspective > J2EE**.
4. Switch to the **Project Navigator** pane by clicking the **Project Navigator** tab.
5. Locate the project containing the `webservicesclient.xml` file in the **Project Navigator** pane.
6. Expand the directories under the project until the META-INF or WEB-INF directory and its contents appear.
7. Right-click the `webservices.xml` file.
8. Select **Open**. The **Web Services** editor opens.
9. Expand the **Web service descriptions** section.
  - a. Select the service you want to configure.
10. Expand the **Web service description implementation details** section.

- a. Verify the **Web service description name** field is unique among all the Web service descriptions in the editor.
  - b. Verify that the **WSDL file** field indicates there is an existing WSDL file in the module. This file, by convention, should be located in the META-INF/wsdl directory for an enterprise bean JAR file and in the WEB-INF/wsdl directory for a WAR file.
  - c. Verify the **JAX-RPC mapping file** field indicates an existing mapping file within the module. This file, by convention, should be located in the META-INF directory for an enterprise bean JAR file and in the WEB-INF directory for a WAR file.
11. Expand the **Port components** section.
    - a. Verify there are port component entries corresponding to the used WSDL ports in the **Port components** section.
  12. Select a *port\_component* to open the editor for that port component. The **Port Components** editor opens.
  13. Expand the **Port component implementation details** section.
    - a. Verify the **WSDL Port Namespace URL** and **WSDL Port Local part** fields are set to the namespace and local name of the corresponding port in the WSDL file. These fields are configured by the **WSDL2Java** command tool when the webservices.xml file is generated.
  14. Verify the **Service endpoint interface** field names the fully qualified Service Endpoint Interface class. This field is configured by the **WSDL2Java** command when the webservices.xml file is generated.
  15. Locate the **Service implementation bean** field.
    - a. Configure this field to indicate the EJB or servlet that implements the Web service. Configure by selecting **EJB link** for an enterprise bean module or **Servlet link** for a Web module. Use the drop down list in the **Service implementation bean** field to select the enterprise bean or servlet used to implement the Web service. The choices in the drop down menu come from the enterprise beans defined in the ejb-jar.xml file for an enterprise bean module or the servlets defined in the web.xml file for a Web module.

---

## Configuring the ibm-webservices-bnd.xmi deployment descriptor

Develop implementation templates and bindings for the `ibm-webservices-bnd.xmi` from the Web Services Description Language (WSDL) file.

Do one of the following based on whether your implementation is an EJB Java archive (JAR) file or Web module Web archive (WAR) file:

- Assemble a Web services-enabled JAR file when starting from Java code.
- Assemble a Web services-enabled WAR file when starting from Java code.
- Assemble a Web services-enabled JAR file when starting from WSDL.
- Assemble a Web services-enabled WAR file when starting from WSDL.

This topic explains how to configure bindings using the Assembly Toolkit which replaces the Application Assembly Tool (AAT). It is one of the tools available with the Application Server Toolkit product. For more information about completing tasks with the Assembly Toolkit, click **Help > Help** in the Assembly Toolkit graphical user interface. .

To configure the `ibm-webservices-bnd.xmi` deployment descriptor with the Assembly Toolkit:

1. Start the Assembly Toolkit.
2. Click **File > Import** to import the EJB JAR file or WAR file into the Assembly Toolkit.
3. Open the J2EE perspective by clicking **Windows > Open Perspective > Other > J2EE**.
4. Switch to the **Project Navigator** pane by clicking the **Project Navigator** tab.
5. Locate the project containing the `webservices.xml` file in the **Project Navigator** pane.

6. Expand the directories under the project until the META-INF or WEB-INF directory and its contents appear.
7. Right-click the `webservices.xml` file.
8. Select **Open**. The **Web Services** editor opens.
9. Click the **Bindings** tab located at the bottom of the editor pane. The **Web Services Bindings** editor opens.
10. Verify the `wsdescNameLink` element settings.
  - a. Expand the **Web services description bindings** section. Verify that the value of the `<webservice-description-name>` element in the `webservices.xml` deployment descriptor is listed in the section. If the value is not listed:
  - b. (Optional) Click **Add**, choose the correct Web services name and click **OK**. You do not need to complete this step if you have verified that the correct Web services name is listed in the **Web Services Description Bindings** tab.
11. Verify the `pcnameLink` attribute settings.
  - a. Expand the **Web Service Description Bindings** section. Verify that the correct service is selected. If the correct service is not listed:
  - b. (Optional) Expand **Port Component Binding**. Verify the correct Web services name is selected in the **Web Service Description Bindings** section.  
This selection is a prerequisite to creating a `pcnameLink` attribute.
  - c. In the **Port Component Binding** section, click **Add**. You need to make a selection in the **Web Service Description Bindings** section before you can create the port component binding in the **Port Component Binding** section. The **Port Component Bindings Dialog** opens.
  - d. Select the desired port from the drop down list in the **PC Name Link** field.
  - e. Click **OK**.
  - f. Click the **Binding Configurations** tab to view the bindings for your port.
  - g. **Save** the bindings file.
12. Click **File > Export** to export the JAR file, or continue using the Assembly Toolkit for configuration and assembly tasks.
13. Click **ctrl-s** to save your changes.

The `ibm-webservices-bnd.xmi` deployment descriptor is configured for the Web service implementation module.

## ibm-webservices-bnd.xmi assembly properties

### ibm-webservices-bnd.xmi properties

The `ibm-webservices-bnd.xmi` file is a deployment descriptor for a Web Services-enabled Web module or enterprise JavaBean (EJB) module. It contains information for the Web services runtime that is either WebSphere product-specific or was not specified by the Web Services for Java 2 platform, Enterprise Edition (J2EE) specification.

You can edit these properties using the Assembly Toolkit. See *Configuring the `ibm-webservices-bnd.xmi` deployment descriptor* for instructions.

The following user-definable assembly properties are supported:

- **wsDescNameLink**  
Attribute of the `wsdescBindings` element that specifies the link to the corresponding `<webservice-description-name>` in `webservices.xml`.
- **pc-name-link**  
Attribute of the `pcBindings` element that specifies the link to the `<port-component-name>` in the `webservices.xml` file.

- **scope**

Attribute of the `pcBindings` element that specifies when new instances of implementation beans are created. Possible values are Request, Session, and Application.

The value of `scope` for a deployed Web service can be changed using the administrative console. Using application management, navigate to the Web module of the Web service application and select Web Services Implementation Scope.

### Example bindings file

The following examples demonstrate the spelling and position of the various attributes. You cannot cut and paste these examples because they do not contain the required ID attributes. If you add elements to a binding file template generated by the **WSDL2Java** command, you must confirm that each element has an ID attribute whose value is a unique string. Review the template xmi files generated by the **WSDL2Java** command for examples of ID strings.

```
<com.ibm.etools.webservice.wsbind:WSBinding xmi:version="2.0" xmlns:xmi="http://www.omg.org/XMI" xmlns:com.ibm.etools.webservice.wsbind="http://www.ibm.com/websphere/appserver/schemas/5.0.2/wsbind.xmi">
 <wsdescBindings wsDescNameLink="AddressBookService">
 <pcBindings pcNameLink="AddressBook" scope="Application"/>
 </wsdescBindings>
</com.ibm.etools.webservice.wsbind:WSBinding>
```

---

## Configuring the `webservices.xml` deployment descriptor for Handler classes

This topic explains how to use the Assembly Toolkit to configure the `webservices.xml` deployment descriptor for user-provided Handler classes. The Assembly Toolkit is a component of the Application Server Toolkit. For more information about completing tasks with the Assembly Toolkit, click **Help > Help** in the Assembly Toolkit graphical user interface (GUI).

You should have an enterprise archive (EAR) file for the applications you want to configure. For some handler use, such as logging or tracing, only the server or client application needs to be configured. For other handler use, including sending information in SOAP headers, the client and server applications must be configured with symmetrical handlers.

The modules in the EAR file should contain the handler classes being configured. These classes implement the `javax.xml.rpc.handler.Handler` interface. For more information on writing handler classes, see Chapter 6 of the Web Services for J2EE 1.0 specification and chapter 12 of the JAX-RPC 1.0 specification available through Web services: Resources for learning. The application modules must contain the `webservices.xml` (for server) and `webservicesclient.xml` (for client) deployment descriptors.

To configure a handler in the `webservices.xml` deployment descriptor:

1. Start the Assembly Toolkit.
2. Click **File > Import** and import the EAR file into the Assembly Toolkit.
3. Open the J2EE perspective by clicking **Windows > Open Perspective > Other > J2EE**.
4. Click the **Project Navigator** tab to switch to the **Project Navigator** pane.
5. Locate the project that contains the `webservices.xml` deployment descriptor. Expand the directories under the project until the META-INF or WEB-INF directory and its contents, including the `webservices.xml` file, are visible.
6. Right-click the `webservices.xml` file.
7. Click **Open**. The **Web Services** editor opens.
8. Expand the **Web services descriptions** section.

- a. Select the *service* for which you want to configure the handler.
9. Expand the **Port components** section.
10. Select a *port\_component* for which you want the editor to open. The **Port Components** editor opens.
11. Expand the **Port component handlers** section.
12. Click **Add** at the bottom of the **Port component handlers** section. A **Class browser** opens.
13. Browse for the name of the Handler class in the module. When it displays in the **Matching types** field, select the class and click **OK**. The Class browser window closes after you click OK and the **Handlers** pane of the **Web Services Editor** opens.
14. (Optional) Configure properties in the **Handlers** pane. See Handler class properties for a list of the properties you can configure in this step.
15. Type **ctrl-s** to save the changes.

---

## Deploying Web services based on Web Services for J2EE

To deploy Web services that are based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) specification, you need an enterprise application, also known as an enterprise archive (EAR) file that has been configured and enabled for Web services. You can use either the administrative console or the **wsadmin** scripting interface to deploy an EAR file.

If you are installing an application containing Web services by using the **wsadmin** command, specify the **-deployws** option. If you are installing an application containing Web services by using the administrative console, select **Deploy WebServices** during step 1 of the Install New Application wizard. For more information about installing applications using the administrative console see Installing a new application.

### Note:

If the Web services in the application is previously deployed with the **wsdeploy** command, it is not necessary to specify Web services deployment during installation.

Use the following steps to deploy the EAR file with the **wsadmin** command:

1. Start `install_root\bin\wsadmin` from a command prompt. If you are using UNIX start `install_root/bin/wsadmin`.
2. Enter the **\$AdminApp install EARfile "-usedefaultbindings -deployws"** command at the **wsadmin** prompt.

The Web service is installed into the application server.

Secure Web services.

## wsdeploy command

This topic explains how to use the **wsdeploy** command-line tool with Web services that are based on the Web Services for J2EE specification. The **wsdeploy** command adds WebSphere product-specific deployment classes to a Web services compatible enterprise application enterprise archive (EAR) file or an application client Java archive (JAR) file. These classes include:

- Stubs
- Serializers and deserializers
- Implementations of service interfaces

This deployment step must be performed at least once, and can be performed more than once. Deployment can be performed separately using the **wsdeploy** command, the Assembly Toolkit, or when the application is installed. The Assembly Toolkit replaces the Application Assembly Tool (AAT). It is one of the tools available with the Application Server Toolkit product. When using the **wsadmin** command for installation, specify the **-deployws** option. When using the administrative console for installation, select the

**Deploy Web services** check box. When using the Assembly Toolkit, **Right-click** the module and select **Web Services >Deploy Web Services** from the pop-up menu. You can download the Assembly Toolkit from the Web site

[http://www-1.ibm.com/support/docview.wss?rs=180&context=SSEQTP&q=ASTK&uid=swg24005125&loc=en\\_US&cs=utf-8&lang=en+en](http://www-1.ibm.com/support/docview.wss?rs=180&context=SSEQTP&q=ASTK&uid=swg24005125&loc=en_US&cs=utf-8&lang=en+en)

The **wsdeploy** command operates as follows:

- Each module in the enterprise application or JAR file is examined
- If the module contains Web services implementations, indicated by the presence of the `webservicexml` deployment descriptor, the associated Web Services Description Language (WSDL) files are located and the **WSDL2Java** command is run with the role `deploy-server`.
- If the module contains Web services clients, indicated by the presence of the `webservicexml` deployment descriptor, the associated WSDL files are located and the **WSDL2Java** command is run with the role `deploy-client`.
- The files generated by the **WSDL2Java** command are compiled and repackaged.

See `WSDL2Java` command for more information about the files that are generated for deployment.

When the generated files are compiled, they can reference application-specific classes outside the EAR or JAR file if the EAR or JAR file is not self-contained. In this case, use either the `-jardir` or `-cp` option to specify additional JAR or zip files to be added to `CLASSPATH` when the generated files are compiled.

### **wsdeploy command syntax**

The command syntax is as follows:

```
wsdeploy Input_filename Output_filename [options]
```

#### **Required options:**

- ***Input\_filename***  
Specifies the path to the EAR or JAR file to be deployed.
- ***Output\_filename***  
Specifies the path of the deployed EAR or JAR file. If *output\_filename* already exists, it is silently overwritten. The *output\_filename* can be the same as the *input\_filename*.

#### **Other options:**

- **`-jardir` *directory***  
Specifies a directory containing JAR or zip files. All JAR and zip files in this directory are added to the `CLASSPATH` used to compile the generated files. This option can be specified zero or more times.
- **`-cp` *entries***  
Specifies entries to be added to `CLASSPATH` when the generated classes are compiled. Multiple entries are separated the same as they would be in the `CLASSPATH` environment variable, with a semicolon on Windows platforms and a colon for UNIX platforms.
- **`-codegen`**  
Specifies that deployment code is to be generated, but not compiled. This option implicitly specifies the `-keep` option.
- **`-debug`**  
Includes debugging information when compiling, that is, use `javac -g` to compile.
- **`-help`**  
Displays a help message and exit.
- **`-ignoreerrors`**  
Do not stop deployment if validation or compilation errors are encountered.
- **`-keep`**  
Do not delete working directories containing generated classes. A message is displayed indicating the name of the working directory that is retained.

- **-novalidate**  
Do not validate the Web services deployment descriptors in the input file.
- **-trace**  
Displays processing information, including the names of the generated files.

### Example

```
wsdeploy x.ear x_deployed.ear -trace -keep
Processing web service module x_client.jar.
Keeping directory: f:\temp\Base53383.tmp for module: x_client.jar.
Parsing XML file:f:\temp\Base53383.tmp\WarDeploy.wsdl
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java.
Done processing module x_client.jar.
```

### Messages

- Flag *-f* is not valid  
Option *f* was not recognized as being a valid option.
- Flag *-c* is ambiguous  
Options may be abbreviated, but the abbreviation must be unique. In this case, the **wsdeploy** command can not determine which option was intended.
- Flag *-c* is missing parameter *-p*  
A required parameter for an option was omitted.
- Missing *p* parameter  
A required option was omitted.

---

## Securing Web services based on WS-Security

Web services security for WebSphere Application Server is based on standards included in the Web services security (WS-Security) specification. These standards address how to provide protection for messages exchanged in a Web service environment. The specification defines the core facilities for protecting the integrity and confidentiality of a message and provides mechanisms for associating security-related claims with the message. Web services security is a message-level standard based on securing Simple Object Access Protocol (SOAP) messages through XML digital signature, confidentiality through XML encryption, and credential propagation through security tokens.

Use the deprecated "Securing Apache SOAP Web services" topics in the WebSphere Application Server, Version 5 documentation if you are still using Apache SOAP Version 2.3.

To secure Web services, you must consider a broad set of security requirements, including authentication, authorization, privacy, trust, integrity, confidentiality, secure communications channels, federation, delegation, and auditing across a spectrum of application and business topologies. One of the key requirements for the security model in today's business environment is the ability to interoperate between formerly incompatible security technologies (such as public key infrastructure, Kerberos and so on.) in heterogeneous environments (such as Microsoft .NET and Java 2 Platform, Enterprise Edition (J2EE)). The complete Web services security protocol stack and technology roadmap is described in Security in a Web Services World: A Proposed Architecture and Roadmap.

Specification: Web Services Security (WS-Security) proposes a standard set of SOAP extensions that you can use to build secure Web services. These standards confirm integrity and confidentiality, which are generally provided with digital signature and encryption technologies. In addition, Web services security provides a general purpose mechanism for associating security tokens with messages. A typical example

of the security token is a user name and password token, in which a user name and password are included as text. Web services security defines how to encode binary security tokens using methods such as X.509 certificates and Kerberos tickets.

To establish a managed environment and to enforce constraints for Web services security, you must perform a Java Naming and Directory Interface (JNDI) lookup on the client to resolve the service reference. For more information on the recommended client programming model, see "Service lookup" in the Java Specification Request (JSR) 109 specification available at: [ftp://www-126.ibm.com/pub/jsr109/spec/1.0/websvcs-1\\_0-fr.pdf](ftp://www-126.ibm.com/pub/jsr109/spec/1.0/websvcs-1_0-fr.pdf).

An administrator can use any of the following methods to integrate message-level security into a WebSphere Application Server environment:

- Secure Web services using XML digital signature
- Secure Web services using XML encryption
- Secure Web services using basicauth authentication
- Secure Web services using identity assertion authentication
- Secure Web services using signature authentication
- Secure Web services using a pluggable token

## Web services security specification- a chronology

This document describes the process used to develop the Web services security specifications.

### Non-OASIS activities

In April 2002, IBM, Microsoft, and VeriSign proposed the *Web Services Security (WS-Security) specification* on their Web sites. This specification included the basic ideas of security token, XML signature, and XML encryption. The specification also defined the format for username tokens and encoded binary security tokens. After some discussion and an interoperability test based on the specification, the following issues were noted:

- The specification requires that the Web services security processors understand the schema correctly so that the processor distinguishes between the ID attribute for XML signature and XML encryption.
- The freshness of the message, which indicates whether the message complies with predefined time constraints, cannot be determined.
- Digested password strings do not strengthen security.

In August 2002, IBM, Microsoft, and VeriSign published the *Web Services Security Addendum*, which attempted to address the previously listed issues. The following solutions were put in the addendum:

- Require a global ID attribute for XML signature and XML encryption
- Use time stamp header elements that indicate the time of the creation, receipt, or expiration of the message
- Use password strings that are digested with a time stamp and nonce (randomly generated token)

### OASIS activities

In June 2002, the Organization for the Advancement of Structured Information Standards (OASIS) received a proposed Web services security specification from IBM, Microsoft, and Verisign. The Web Services Security Technical Committee (WSS TC) was organized at OASIS soon after the submission. The technical committee included many companies including IBM, Microsoft, VeriSign, Sun Microsystems, and BEA Systems.

In September 2002, WSS TC published its first specification, *Web Services Security Core Specification, Working Draft 01*. This specification included the contents of both the original Web services security specification and its addendum.

The coverage of the technical committee became larger as the discussion proceeded. Since the Web Services Security Core Specification allows arbitrary types of security tokens, proposals were published as profiles. The profiles described the method for embedding tokens, including Security Assertion Markup Language (SAML) tokens and Kerberos tokens imbedded into the Web services security messages. Subsequently, the definitions of the usage for user name tokens and X.509 binary security tokens, which were defined in the original Web Services Security Specification, were divided into the profiles.

WebSphere Application Server supports the following specifications:

- Web Services Security: SOAP Message Security Draft 13 (formerly Web Services Security Core Specification)
- Web Services Security: Username Token Profile Draft 2

The following figure shows the various Web services security-related specifications. As indicated in the figure, the current support level for Web services security: SOAP message security is based on Draft 13 from May 2003. The current support level for Web services security User name token profiles, is based on Draft 2 from February 2003.

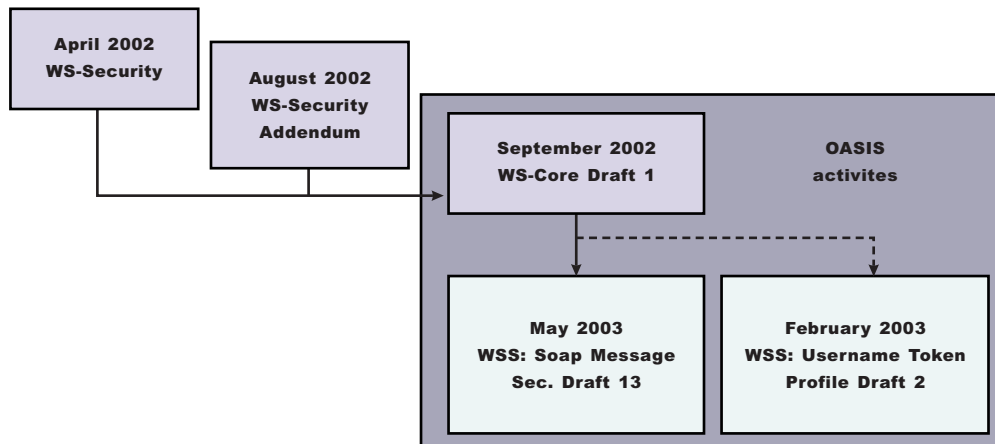

Figure 11. Web services security specification support

## Web services security support

WebSphere Application Server, Versions 4.x, 5, and 5.0.1 support digital signature for Apache Simple Object Access Protocol (SOAP) Version 2.x. Beginning with WebSphere Application Server, Version 5.0.2, IBM supports *Web services security*, which is an extension of the IBM Web services engine to provide a quality of service. The IBM implementation is based on the Web services security specification, "Web Services Security (WS-Security)", originally proposed by IBM, Microsoft, and VeriSign in April 2002. Early versions of the proposed draft specification can be found in Web Services Security (WS-Security) Version 1.0 05 April 2002 and Web Services Security Addendum 18 August 2002. The WebSphere Application Server implementation is based on the Organization for the Advancement of Structured Information Standards (OASIS) working Draft 13 specification. (See the OASIS Web Services Security TC Web site for the latest working specification.) However, not all the features in the OASIS working Draft 13 specification are implemented.

WebSphere Application Server security infrastructure fully integrates Web services security with Java 2 Platform, Enterprise Edition (J2EE) security. When a user ID and password are embedded in a request

message, authentication is performed with the user ID and password. If authentication is successful, a user identity is established and further resource access is authorized based on that identity. After the user ID and password are authenticated by the Web services security run time, a J2EE container performs authorization.

WebSphere Application Server provides an implementation of the key features of Web services security based on the following specifications:

- Specification: Web Services Security (WS-Security) Version 1.0 05 April 2002
- Web Services Security Addendum 18 August 2002
- Web Services Security: SOAP Message Security Working 13 May 2003
- Web Services Security: Username Token Profile Draft

The following table provides a summary of Web services security elements supported by WebSphere Application Server:

*Table 5. Web services security elements*

Element	Notes
UsernameToken	Both the user name and password for the BasicAuth authentication method and the user name for the identity assertion authentication method are supported. WebSphere Application Server, Version 5.1 supports nonce, a randomly generated value.
BinarySecurityToken	X.509 certificates and Lightweight Third Party Authentication (LTPA) can be embedded, but there is no implementation to embed Kerberos tickets. However, the binary token generation and validation are pluggable and are based on the Java Authentication and Authorization Service (JAAS) Application Programming Interfaces (APIs). You can extend this implementation to generate and validate other types of binary security tokens.
Signature	The X.509 certificate is embedded as a binary security token and can be referenced by the SecurityTokenReference. WebSphere Application Server does not support shared, key-based signature.
Encryption	Both the EncryptedKey and ReferenceList XML tags are supported. KeyIdentifier specifies public keys and KeyName identifies the secret keys. WebSphere Application Server has the capability to map an authenticated identity to a key for encryption or use the signer certificate to encrypt the response message.
Timestamp	WebSphere Application Server supports the Created and Expires attributes. The freshness of the message, which indicates whether the message complies with predefined time constraints, is checked only if the Expires attribute is present in the message. WebSphere Application Server does not support the Received attribute, which is defined in the addendum. Instead, WebSphere Application Server uses the TimestampTrace Received attribute, which is defined in the OASIS specification.
XML based token	You can insert and validate an arbitrary format of XML tokens into a message. This format mechanism is based on the JAAS APIs.

Signing and encrypting attachments is not supported by WebSphere Application Server. However, WebSphere Application Server signs and encrypts the following elements for the request message.

Method	Element
XML digital signature	<ul style="list-style-type: none"> <li>• Body</li> <li>• Securitytoken</li> <li>• Timestamp</li> </ul>
XML encryption	<ul style="list-style-type: none"> <li>• Bodycontent</li> <li>• Usenametoken</li> </ul>
AuthMethod	<ul style="list-style-type: none"> <li>• BasicAuth</li> <li>• IDAssertion (From WebSphere Application Server to another WebSphere Application Server)</li> <li>• Signature</li> <li>• Lightweight Third Party Authentication (LTPA) on the server side</li> <li>• Other customer tokens</li> </ul>

WebSphere Application Server signs and encrypts the following elements for the response message:

Method	Element
XML digital signature	<ul style="list-style-type: none"> <li>• Body</li> <li>• Timestamp</li> </ul>
XML encryption	<ul style="list-style-type: none"> <li>• Bodycontent</li> </ul>

The namespaces used for sending a message were published by OASIS in draft 13 (<http://schemas.xmlsoap.org/ws/2003/06/secext>). However, the Web services security run time in WebSphere Application Server can accept any of the following namespaces:

**April 2002 specification**

<http://schemas.xmlsoap.org/ws/2002/04/secext>

**August 2002 addendum**

<http://schemas.xmlsoap.org/ws/2002/07/secext>

<http://schemas.xmlsoap.org/ws/2002/07/utility>

**OASIS draft published on draft 13 May 2003**

<http://schemas.xmlsoap.org/ws/2003/06/secext>

<http://schemas.xmlsoap.org/ws/2003/06/utility>

**Note:** **5.1+** WebSphere Application Server only uses the previously mentioned two name spaces for sending out requests and responses. However, the product can process all other mentioned name spaces for incoming requests and responses.

WebSphere Application Server provides the following capabilities for Web services security:

- Integrity of the message
- Authenticity of the message
- Confidentiality of the message
- Privacy of the message
- Transport level security: provided by Secure Sockets Layer (SSL)
- Security token propagation (pluggable)
- Identity assertion

See the previous table titled, "Web services security elements," for a description of capabilities that are not supported.

## Web services security and Java 2 Platform, Enterprise Edition security relationship

This document describes the relationship between Web services security (message level security) and Java 2 Platform, Enterprise Edition (J2EE) platform security.

WebSphere Application Server supports Java Specification Requests (JSR) 101 and JSR 109 (see Developing Web services for more information). These JSRs define Web services for the Java 2 Platform, Enterprise Edition (J2EE) architecture so that you can develop and run Web services on the J2EE component architecture. "Web services security" refers to the "Web services security: SOAP Message Security" specification (see Web services security support for more information).

### Important

**Note:** "Web services security" refers to the "Web services security: SOAP Message Security" specification (see Web services security support for more information).

### Securing Web services with WebSphere Application Server security (J2EE role-based security)

You can secure Web services using the existing security infrastructure of WebSphere Application Server, J2EE role-based security, and Secure Sockets Layer (SSL) transport level security.

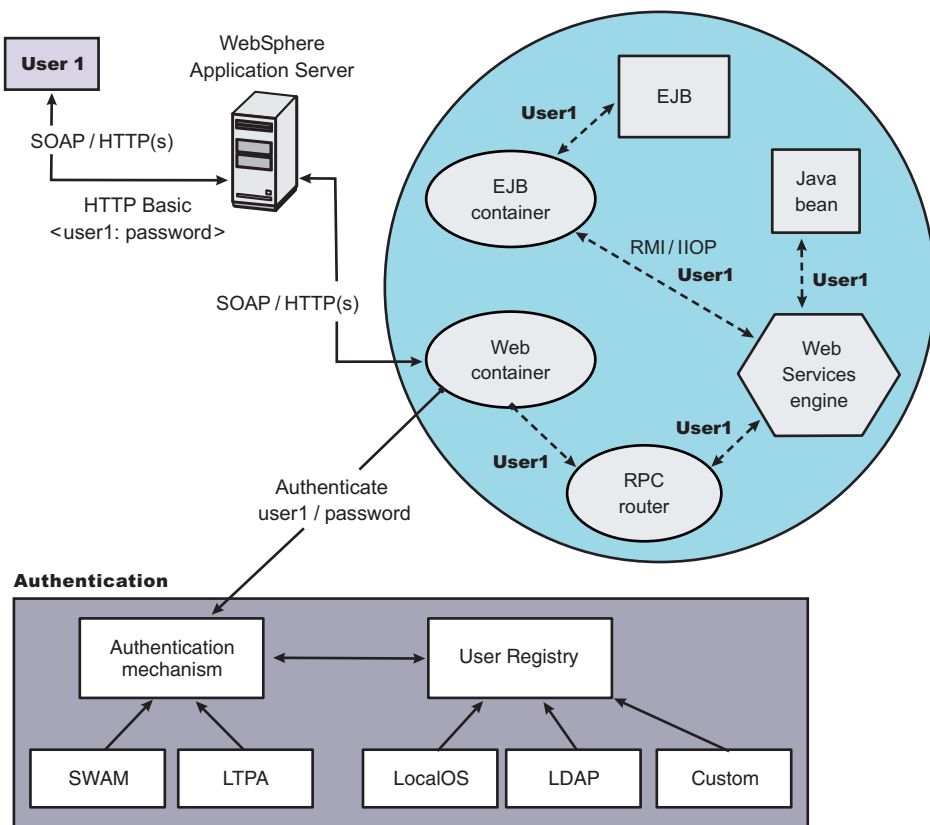

Figure 12. Simple object access protocol message flow using existing security infrastructure of WebSphere Application Server

The Web services endpoint can be secured using J2EE role-based security. The Web services sender sends the basic authentication data using the HTTP header. SSL (HTTPS) can be used to secure the transport. When the WebSphere Application Server receives the SOAP message, the Web container authenticates the user (in this example, user1) and sets the security context for the call. After the security context is set, the SOAP router servlet sends the request to the implementation of the Web services (the implementation can be JavaBeans or enterprise bean files). For enterprise bean implementations, the EJB container performs an authorization check against the identity of user1.

The Web services endpoint also can be secured using the J2EE role. Then, authorization is performed by the Web container before the SOAP request is dispatched to the Web services implementation.

### Securing Web services with Web services security at the message level

You can also secure Web services using Web services security at the message level. In this case, you can digitally sign or encrypt a certain part of the message. Web services security also supports security token propagation within the SOAP message. The following scenario assumes that the Web services endpoint is not secured with J2EE role-based security and the enterprise bean is secured with J2EE role-based security.

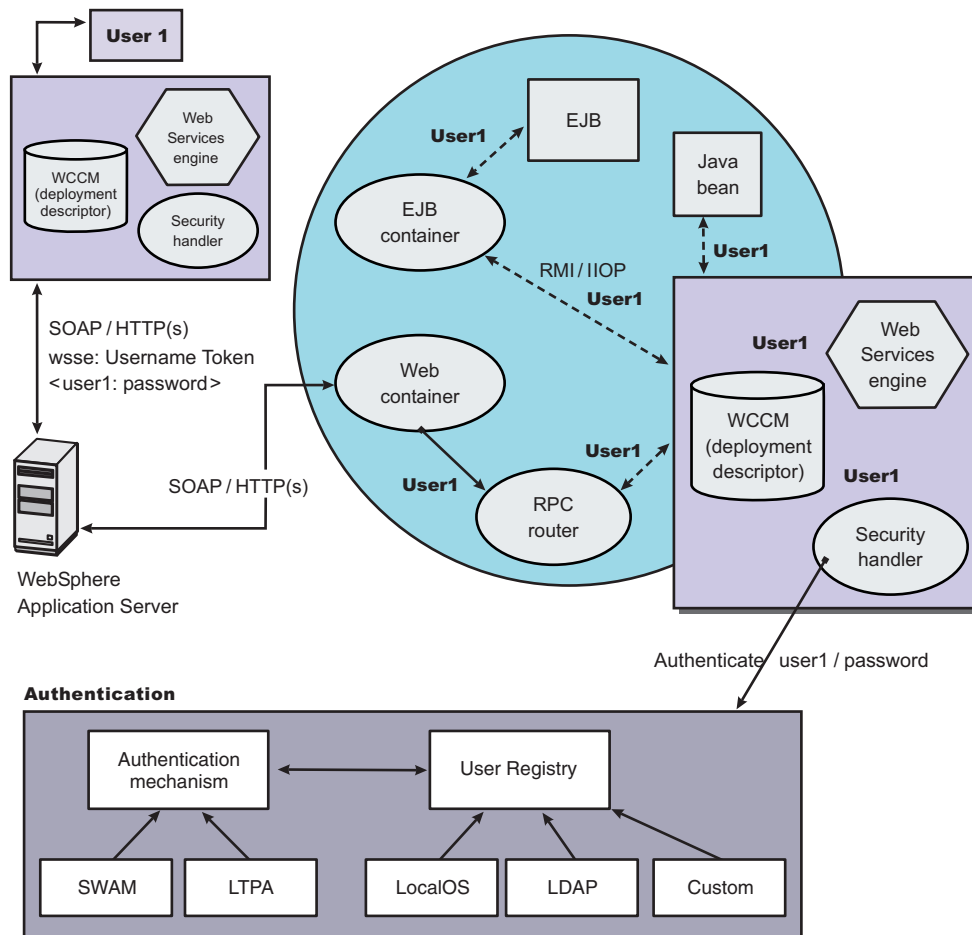

Figure 13. Simple Object Access Protocol message flow using Web services security

In this case, the Web services endpoint is not secured with J2EE role-based security. The Web services engine processes the SOAP message before the client sends the message to the Web services endpoint.

The Web services security run time acts on the security constraints, such as digitally signing, encrypting, or generating (and inserting) a security token in the SOAP header. In this case `<wsse:UsernameToken>` is generated using `user1` and the password. On the server-side (receiving), the Web services process the incoming message and Web services security enforces security constraints. This enforcement includes making sure that messages are properly signed, properly encrypted, and decrypted, authenticating the security token, and setting up the security context with the authenticated identity. (In this case, `user1` is the authenticated identity.) Finally, the SOAP message is dispatched to the Web services implementation (if the implementation is an enterprise beans file, the EJB container performs an authorization check against `user1`). SSL also might be used in this scenario.

### **Mixing the two**

The second scenario shows that Web services security can complement J2EE role-based security. For example, SSL can be enabled at the transport level to provide a secure channel. Furthermore, if the Web services implementation is an enterprise beans file, you can leverage the EJB role-based authorization by performing authorization checks. Web services security run time leverages the security infrastructure to set the authenticated identity in the security context. The authenticated identity can be used in the downstream call to J2EE resources (or other resource types).

There are subtle consequences of combining the two scenarios. For example, if the HTTP transport is sending basic authentication data with `user1` and password in the HTTP header, but `<wsse:UsernameToken>` with `user99` and `letmein` also is inserted into the SOAP header. In the previous scenarios, there are two authentications performed. One authentication is performed by the Web container for authenticating `user1`, and the other is performed by Web services security for authenticating `user99`. The Web services security run time runs after the Web container runs and `user99` is the authenticated identity that is set in the security context.

Web services security can also propagate security tokens from the sender to the receiver for SOAP over a Java Message Service (JMS) transport.

## **Web services security model in WebSphere Application Server**

The Web services security model used by WebSphere Application Server is the declarative model. WebSphere Application Server does not include any application programming interfaces (APIs) for programmatically interacting with Web services security. However, a few Server Provider Interfaces (SPIs) are available for extending some security-related behaviors.

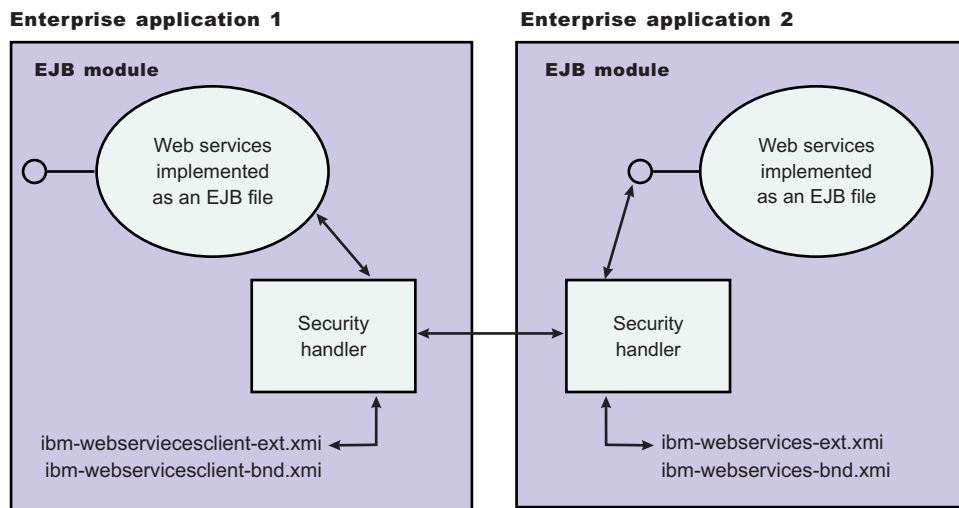

Figure 14. Web services security model

The security constraints for Web services security are specified in IBM deployment descriptor extensions for Web services. The Web services security run time acts on the constraints to enforce Web services security for the Simple Object Access Protocol (SOAP) message. The scope of the IBM deployment descriptor extension is at the enterprise bean (EJB) or Web module level. Bindings are associated with each of the following IBM deployment descriptor extensions:

**Client (Might be either a J2EE Client (Application Client Container) or Web services acting as a client)**

`ibm-webservicesclient-ext.xmi`  
`ibm-webservicesclient-bnd.xmi`

**Server**

`ibm-webservices-ext.xmi`  
`ibm-webservices-bnd.xmi`

It is recommended that you use the tools provided by IBM (the Assembly Toolkit and WebSphere Studio Application Developer) to create the IBM deployment descriptor extension and bindings. After the bindings are created, you can use the administrative console, the Assembly Toolkit, or the WebSphere Studio Application Developer to specify the bindings.

**Important**

**Note:** The binding information is collected after application deployment rather than during application deployment. The alternative is to specify the required binding information before deploying your application.

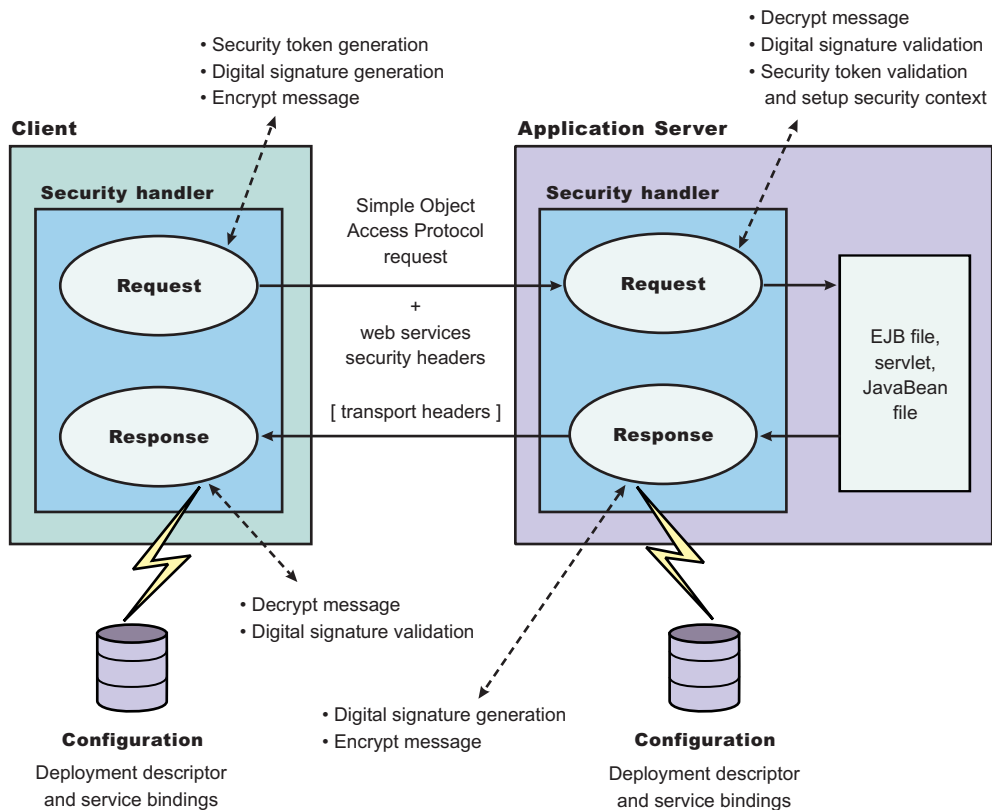

Figure 15. Web services security message interpretation

The Web services security run time enforces Web services security based on the defined security constraints in the deployment descriptor and binding files. Web services security has the following four points where it intercepts the message and acts on the security constraints defined:

Message points	Description
Request sender (defined in the <code>ibm-webservicesclient-ext.xmi</code> and <code>ibm-webservicesclient-bnd.xmi</code> files)	<ul style="list-style-type: none"> <li>Applies the appropriate security constraints to the SOAP message (such as signing or encryption) before the message is sent, generating the time stamp or the required security token.</li> </ul>
Request receiver (defined in the <code>ibm-webservices-ext.xmi</code> and <code>ibm-webservices-bnd.xmi</code> files)	<ul style="list-style-type: none"> <li>Verifies that the Web services security constraints are met.</li> <li>Verifies the freshness of the message based on the time stamp. The freshness of the message indicates whether the message complies with predefined time constraints.</li> <li>Verifies the required signature.</li> <li>Verifies that the message is encrypted and decrypts the message if encrypted.</li> <li>Validates the security tokens and sets up the security context for the downstream call.</li> </ul>
Response sender (defined in the <code>ibm-webservices-ext.xmi</code> and <code>ibm-webservices-bnd.xmi</code> files)	<ul style="list-style-type: none"> <li>Applies the appropriate security constraints to the SOAP message response, like signing the message, encrypting the message, or generating the time stamp.</li> </ul>

Message points	Description
Response receiver (defined in the <code>ibm-webservicesclient-ext.xmi</code> or <code>ibm-webservicesclient-bnd.xmi</code> files)	<ul style="list-style-type: none"> <li>• Verifies that the Web services security constraints are met.</li> <li>• Verifies the freshness of the message based on the time stamp. The freshness of the message indicates whether the message complies with predefined time constraints.</li> <li>• Verifies the required signature.</li> <li>• Verifies that the message is encrypted and decrypts the message, if encrypted.</li> </ul>

## Web services security property collection

Use this page to view a list of additional properties for the configuration.

There are several ways to view a Web services security property collection panel. Complete the following steps to view one of these administrative console pages:

1. Click **Servers > Application Servers > *server\_name***.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Key Locators > *key\_locator\_name***.
3. Under Additional Properties, click **Properties**.
4. Click **New** to create a new property.
5. Click **Delete** to delete a property that you specified previously.

### Name

Specifies the name of the property.

### Value

Specifies the value for the property.

## Web services security property configuration settings

Use this page to configure additional properties.

There are several ways to view a Web services security property configuration settings panel. Complete the following steps to view one of these administrative console pages:

1. Click **Servers > Application Servers > *server\_name***.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Key Locators > *key\_locator\_name***.
3. Under Additional Properties, click **Properties > New**.

### Property Name

Specifies the name of the property.

**Data type:** String

### Property Value

Specifies the value for the property.

**Data type:** String

# Usage scenario for propagating security tokens

## A sample scenario

This document describes a usage scenario for Web services security.

In scenario 1, Client 1 invokes Web services 1. Then Web services 1 calls EJB file 2. EJB file 2 calls Web services 3 and Web services 3 calls Web services 4.

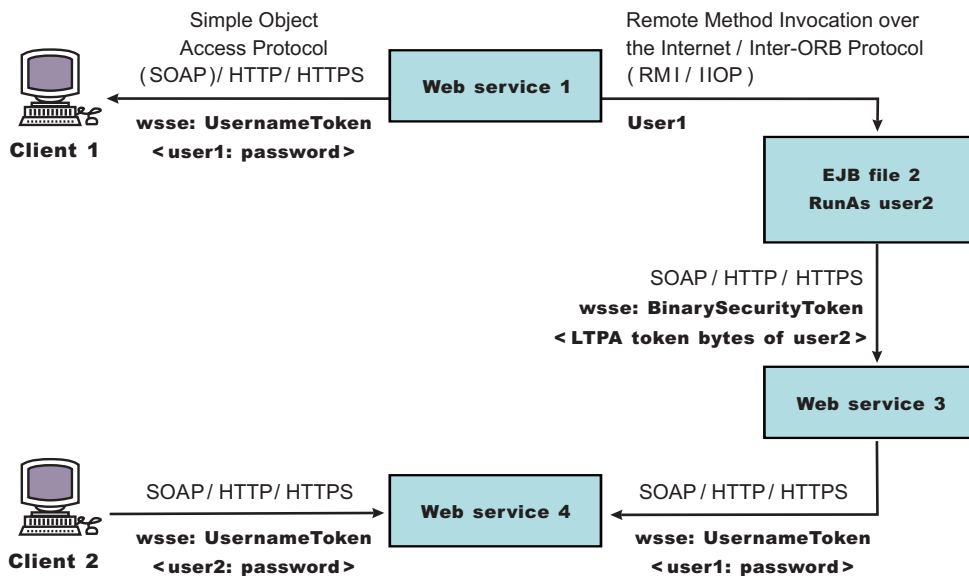

Figure 16. Propagating security tokens

The previous scenario shows how to propagate security tokens using Web services security, the security infrastructure of the WebSphere Application Server, and Java 2 Platform, Enterprise Edition (J2EE) security. Web services 1 is configured to accept `<wsse:UsernameToken>` only and use the BasicAuth authentication method. However, Web services 4 is configured to accept either `<wsse:UsernameToken>` using the BasicAuth authentication method or Lightweight Third Party Authentication (LTPA) as `<wsse:BinarySecurityToken>`. The following steps describe the scenario shown in the previous figure:

1. Client 1 sends a SOAP message to Web services 1 with user1 and password in the `<wsse:UsernameToken>` element.
2. The user1 and password values are authenticated by the Web services security run time and set in the current security context as the Java Authentication and Authorization Service (JAAS) Subject.
3. Web services 1 invokes EJB file 2 using the Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP) protocol.
4. The user1 identity is propagated to the downstream call.
5. The EJB container of EJB file 2 performs an authorization check against user1.
6. EJB file 2 calls Web services 3 and Web services 3 is configured to accept LTPA tokens.
7. The RunAs role of EJB file 2 is set to user2.
8. The LTPA CallbackHandler implementation extracts the LTPA token from the current JAAS Subject in the security context and Web services security run time inserts the token as `<wsse: BinarySecurityToken>` in the SOAP header.
9. The Web services security run time in Web services 3 calls the JAAS login configuration to validate the LTPA token and set it in the current security context as the JAAS Subject.

10. Web services 3 is configured to send LTPA security to Web services 4. In this case, assume that the RunAs role is not configured for Web services 3. The LTPA token of user2 is propagated to Web services 4.
11. Client 2 uses the <wsse:UsernameToken> element to propagate the basic authentication data to Web services 4.

Web services security complements the WebSphere Application Server security run time and the J2EE role-based security. This scenario demonstrates how to propagate security tokens across multiple resources such as Web services and EJB files.

## Configurations

The Web services security model used by WebSphere Application Server is the declarative model.

No Application Programming Interfaces (APIs) exist in WebSphere Application Server for programmatically interacting with Web services security. However, Service Provider Programming Interfaces (SPIs) are available for extending some security run-time behaviors. You can secure an application with Web services security by defining security constraints in the IBM extension deployment descriptors and in IBM extension bindings.

The development life cycle of a Web services security-enabled application is similar to the Java 2 Platform, Enterprise Edition (J2EE) model. See the following figure for more details.

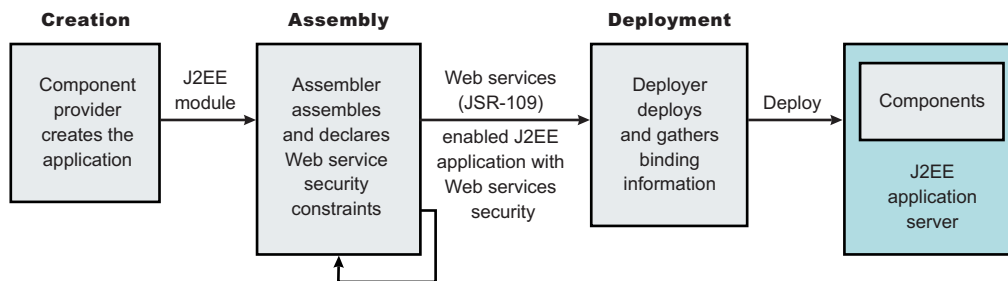

Figure 17. Application development life cycle

The Web services security constraints are defined by the assembler during the application assembly phase if the J2EE application is Web services-enabled. Create, define, and edit the Web services security constraints with the Assembly Toolkit, which can be downloaded from the following location:[http://www-1.ibm.com/support/docview.wss?rs=180&context=SSEQTP&q=ASTK&uid=swg24005125&loc=en\\_US&cs=utf-8&lang=en+en](http://www-1.ibm.com/support/docview.wss?rs=180&context=SSEQTP&q=ASTK&uid=swg24005125&loc=en_US&cs=utf-8&lang=en+en)

### Web services security constraints

The security constraints for Web services security are specified in the IBM deployment descriptor extension for Web services. The assembler defines these constraints during the application assembly phase, if the J2EE application is Web services enabled. Define the Web services security constraints using the Assembly Toolkit.

The Web services security run time acts on the constraints to enforce Web services security for the SOAP message. The scope of the IBM deployment descriptor extension is at the EJB module or Web module level. There also are bindings associated with each of the following IBM deployment descriptor extensions:

**Client** (might be either a J2EE client (application client container) or Web services acting as a client)

- ibm-webservicesclient-ext.xmi
- ibm-webservicesclient-bnd.xmi

**Server**

- ibm-webservices-ext.xmi
- ibm-webservices-bnd.xmi

The IBM extension deployment descriptor and bindings are associated with each EJB module or Web module. See Figure 2 for more information. If Web services is acting as a client, then it contains the client IBM extension deployment descriptors and bindings in the EJB module or Web module.

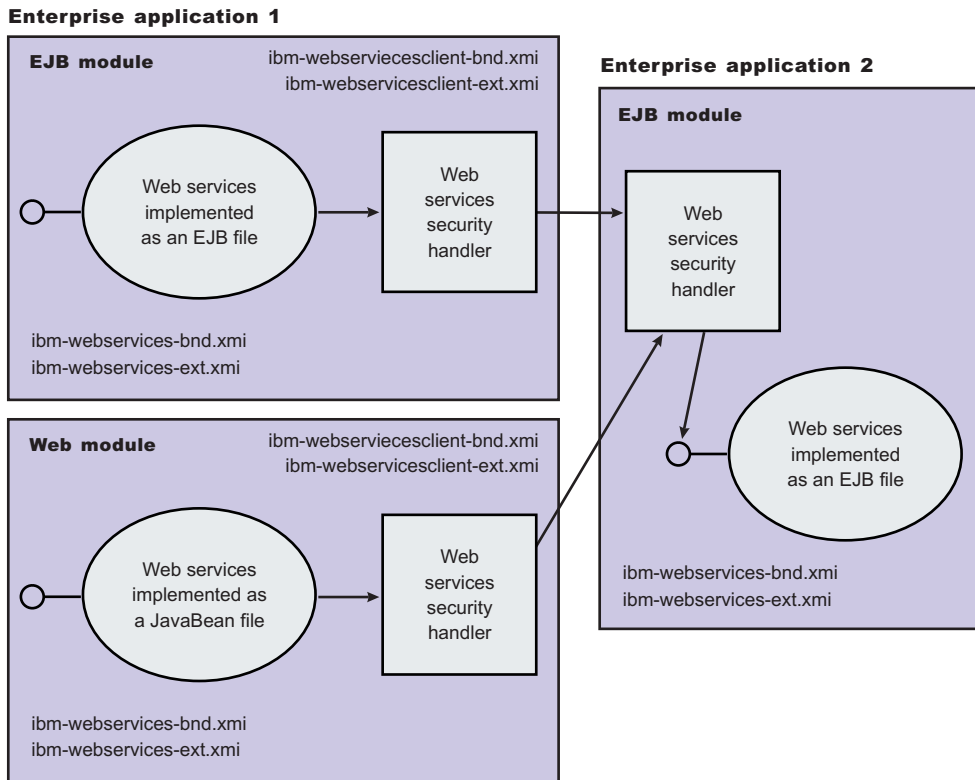

Figure 18. IBM extension deployment descriptors and bindings

The Web services security handler acts on the security constraints defined in the IBM extension deployment descriptor and enforces the security constraints accordingly. There are outbound and inbound configurations in both the client and server security constraints.

In a SOAP request, the following message points exist:

- Sender outbound
- Receiver inbound
- Receiver outbound
- Sender inbound

These message points correspond to the following four security constraints:

- Request sender (sender outbound)
- Request receiver (receiver inbound)

- Response sender (receiver outbound)
- Response receiver (sender inbound)

The security constraints of request sender and request receiver must match. Also, the security constraints of the response sender and response receiver must match. For example, if you specify integrity as a constraint in the request receiver, then you must configure the request sender to have integrity applied to the SOAP message. Otherwise, the request is denied because the SOAP message does not include the integrity specified in the request constraint.

The four security constraints are shown in the following figure of Web services security constraints.

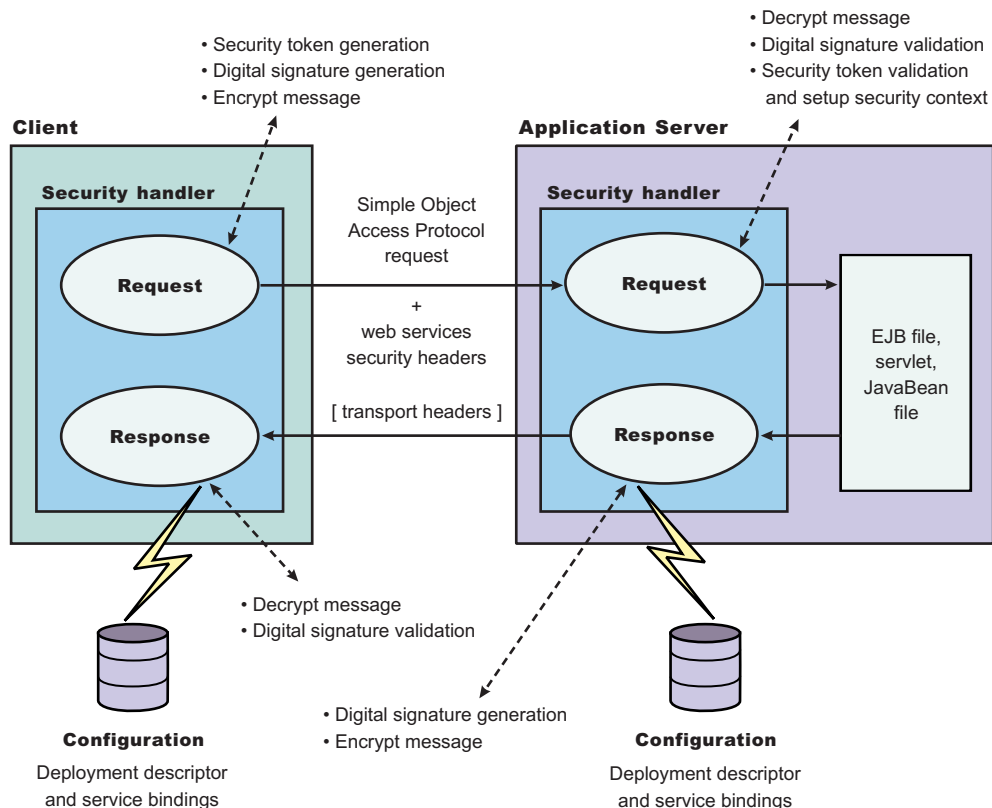

Figure 19. Web services security constraints

## Sample configuration

WebSphere Application Server provides the following sample key stores for sample configurations. These sample key stores are for testing and sample purposes only. Do not use them in a production environment.

- {USER\_INSTALL\_ROOT}/etc/ws-security/samples/dsig-sender.ks
  - The keystore password is client
  - Trusted certificate with alias name, soapca
  - Personal certificate with alias name, soaprequester and key password client issued by intermediary certificate authority Int CA2, which is, in turn, issued by soapca
- {USER\_INSTALL\_ROOT}/etc/ws-security/samples/dsig-receiver.ks
  - The keystore password is server
  - Trusted certificate with alias name, soapca

- Personal certificate with alias name, soapprovider and key password server, issued by intermediary certificate authority Int CA2, which is, in turn, issued by soapca
- {USER\_INSTALL\_ROOT}/etc/ws-security/samples/enc-sender.jceks
  - The keystore password is storepass
  - Secret key CN=Group1, alias name Group1, and key password keypass
  - Public key CN=Bob, O=IBM, C=US, alias name bob, and key password keypass
  - Private key CN=Alice, O=IBM, C=US, alias name alice, and key password keypass
- {USER\_INSTALL\_ROOT}/etc/ws-security/samples/enc-receiver.jceks
  - The keystore password is storepass
  - Secret key CN=Group1, alias name Group1, and key password keypass
  - Private key CN=Bob, O=IBM, C=US, alias name bob, and key password keypass
  - Public key CN=Alice, O=IBM, C=US, alias name alice, and key password keypass
- {USER\_INSTALL\_ROOT}/etc/ws-security/samples/intca2.cer
  - The intermediary certificate authority is Int CA2.

### Default binding (cell and server level)

WebSphere Application Server provides the following default binding information:

#### Trust anchors

Used to validate the trust of the signer certificate.

- SampleClientTrustAnchor is used by the response receiver to validate the signer certificate.
- SampleServerTrustAnchor is used by the request receiver to validate the signer certificate.

#### Collection Certificate Store

Used to validate the certificate path.

- SampleCollectionCertStore is used by the response receiver and the request receiver to validate the signer certificate path.

#### Key Locators

Used to locate the key for signature, encryption, and decryption.

- SampleClientSignerKey is used by the requesting sender to sign the SOAP message. The signing key name is clientsignerkey, which can be referenced in the signing information as the signing key name.
- SampleServerSignerKey is used by the responding sender to sign the SOAP message. The signing key name is serversignerkey, which can be referenced in the signing information as the signing key name.
- SampleSenderEncryptionKeyLocator is used by the sender to encrypt the SOAP message. It is configured to use the {USER\_INSTALL\_ROOT}/etc/ws-security/samples/enc-sender.jceks keystore and the com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator keystore key locator.
- SampleReceiverEncryptionKeyLocator is used by the receiver to decrypt the encrypted SOAP message. The implementation is configured to use the {USER\_INSTALL\_ROOT}/etc/ws-security/samples/enc-receiver.jceks keystore and the com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator keystore key locator. The implementation is configured for symmetric encryption (DES or TRIPLEDES). However, to use it for asymmetric encryption (RSA), you must add the private key CN=Bob, O=IBM, C=US, alias name bob, and key password keypass.
- SampleResponseSenderEncryptionKeyLocator is used by the response sender to encrypt the SOAP response message. It is configured to use the {USER\_INSTALL\_ROOT}/etc/ws-security/samples/enc-receiver.jceks keystore and the com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator key locator. This key locator maps an authenticated identity (of the current thread) to a public key for encryption. By default,

WebSphere Application Server is configured to map to public key `alice`, and you must change WebSphere Application Server to the appropriate user. The `SampleResponseSenderEncryptionKeyLocator` key locator also can set a default key for encryption. By default, this key locator is configured to use public key `alice`.

### Trusted ID Evaluator

Used to establish trust before asserting to the identity in identity assertion.

`SampleTrustedIDEvaluator` is configured to use the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl` implementation. The default implementation of `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` contains a list of trusted identities. The list is defined as properties with `trustedId_*` as the key and the value as the trusted identity. Define this information for the server level in the administration console by completing the following steps:

1. Click **Servers > Application Servers > *server1***.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Trusted ID Evaluators > *SampleTrustedIDEvaluator***

### Login Mapping

Used to authenticate the incoming security token in the Web services security SOAP header of a SOAP message.

- The `BasicAuth` authentication method is used to authenticate user name security token (user name and password).
- The signature authentication method is used to map a distinguished name (DN) into a WebSphere Application Server Java Authentication and Authorization Server (JAAS) Subject.
- The `IDAssertion` authentication method is used to map a trusted identity into a WebSphere Application Server JAAS Subject for identity assertion.
- The Lightweight Third Party Authentication (LTPA) authentication method is used to validate a LTPA security token.

The previous default bindings for trust anchors, collection certificate stores, and key locators are for testing or sample purpose only. Do not use them for production.

### A sample configuration

The following examples demonstrate what IBM deployment descriptor extensions and bindings can do. The unnecessary information was removed from the examples to improve clarity. Do not copy and paste these examples into your application deployment descriptors or bindings. These examples serve as reference only and are not representative of the recommended configuration.

Use the following tools to create or edit IBM deployment descriptor extensions and bindings:

- Use the Assembly Toolkit to create or edit the IBM deployment descriptor extensions.
- Use the Assembly Toolkit or the administrative console to create or edit the bindings file.

The following example illustrates a scenario that:

- Signs the SOAP body, time stamp, and security token.
- Encrypts the body content and user name token.
- Sends the user name token (basic authentication data).
- Generates the time stamp for the request.

For the response, the SOAP body and time stamp are signed, the body content is encrypted, and the SOAP message freshness is checked using the time stamp. The freshness of the message indicates whether the message complies with predefined time constraints.

The request sender and the request receiver are a pair. Similarly, the response sender and the response receiver are a pair.

**Tip:** It is recommended that you use the WebSphere Application Server variables for specifying the path to the key stores. In the administrative console, click **Environment > Manage WebSphere Variables**. These variables often help with platform differences such as file system naming conventions. In the following examples, `${USER_INSTALL_ROOT}` is used for specifying the path to the key stores.

### Client-side IBM deployment descriptor extension

The client-side IBM deployment descriptor extension describes the following constraints:

#### Request Sender

- Signs the SOAP body, time stamp and security token
- Encrypts the body content and user name token
- Sends the basic authentication token (user name and password)
- Generates the time stamp to expire in three minutes

#### Response Receiver

- Verifies that the SOAP body and time stamp are signed
- Verifies that the SOAP body content is encrypted
- Verifies that the time stamp is present (also check for message freshness)

### Example 1: Sample client IBM deployment descriptor extension

The `xmi:id` statements are removed for readability. These statements must be added for this example to work.

**Important:** In the following code sample, lines 2 through 4 were split into three lines due to the width of the printed page.

```
<?xml version="1.0" encoding="UTF-8"?>

```

## Client-side IBM extension bindings

Example 2 shows the client-side IBM extension binding for the security constraints described previously in the discussion on client-side IBM deployment descriptor extensions.

The signer key and encryption (decryption) key for the message can be obtained from the keystore key locator implementation (`com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator`). The signer key is used for encrypting the response. The sample is configured to use the Java Certification Path API to validate the certificate path of the signer of the digital signature. The user name token (basic authentication) data is collected from the standard in (stdin) prompts using one of the default Java Authentication and Authorization Service (JAAS) implementations: `javax.security.auth.callback.CallbackHandler` implementation (`com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler`).

### Example 2: Sample client IBM extension binding

**Important:** In the following code sample, several lines were split into multiple lines due to the width of the printed page. See the close bracket for an indication of where each line of code ends.

## Server-side IBM deployment descriptor extension

The client-side IBM deployment descriptor extension describes the following constraints:

Request Receiver (ibm-webservices-ext.xmi and ibm-webservices-bnd.xmi)

- Verifies that the SOAP body, time stamp, and security token are signed.
- Verifies that the SOAP body content and user name token are encrypted.
- Verifies that the basic authentication token (user name and password) is in the Web services security SOAP header.
- Verifies that the time stamp is present (also check for message freshness). The freshness of the message indicates whether the message complies with predefined time constraints.

Response Sender (ibm-webservices-ext.xmi and ibm-webservices-bnd.xmi)

- Signs the SOAP body and time stamp
- Encrypts the SOAP body content
- Generates the time stamp to expire in 3 minutes

### Example 3: Sample server IBM deployment descriptor extension

**Important:** In the following code sample, several lines were split into multiple lines due to the width of the printed page. See the close bracket for an indication of where each line of code ends.

```

<?xml version="1.0" encoding="UTF-8"?>
<com.ibm.etools.webservice.wsext:WsExtension xmi:version="2.0"
 xmlns:xmi="http://www.omg.org/XMI"
 xmlns:com.ibm.etools.webservice.wsext=
http://www.ibm.com/websphere/appserver/schemas/5.0.2/wsext.xmi">

</securityResponseSenderServiceConfig>
</serverServiceConfig>
</pcBinding>
</wsDescExt>
</com.ibm.etools.webservice.wsExt:WsExtension>

```

## Server-side IBM extension bindings

The following binding information reuses some of the default binding information defined either at the server level or the cell level, which depends upon the installation. For example, request receiver is referencing the `SampleCollectionCertStore` certification store and the `SampleServerTrustAnchor` trust store is defined in the default binding. However, the encryption information in the request receiver is referencing a `SampleReceiverEncryptionKeyLocator` key locator defined in the application-level binding (the same `ibm-webservices-bnd.xmi` file). The response sender is configured to use the signer key of the digital signature of the request to encrypt the response using one of the default key locator (`com.ibm.wsspi.wssecurity.config.CertInRequestKeyLocator`) implementations.

### Example 4: Sample server IBM extension binding

```

## View Web services client deployment descriptor

Use this page to view your client deployment descriptor.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise Applications** > *application\_name*.
2. Under Related Items, click **Web Modules > URI\_file\_name > View Web Services Client Deployment Descriptor**.

The information in the following implementation descriptions indicates how to configure your application-level bindings. If the Web server is acting as a client, the default bindings are used. To configure the server-level bindings, which are the defaults, complete the following steps:

1. Click **Servers > Application Servers** > *server\_name*.
2. Under Related Items, click **Web Services: Default bindings for Web Services Security**.

If you are using any of the following configurations, verify that the deployment descriptor is configured properly:

- Request signing
- Request encryption
- BasicAuth authentication
- Identity (ID) Assertion authentication
- Identity (ID) Assertion authentication with the signature TrustMode
- Response digital signature verification
- Response decryption

## Request signing

If the integrity constraints (digital signature) are specified, verify that you configured the signing information in the binding files.

To configure the signing parameters, complete the following steps:

1. Click **Applications > Enterprise Applications** > *application\_name*.

2. Under Related Items, click **Web Modules** >*URI\_file\_name* **Web Services: Client Security Bindings** .
3. In the Response Receiver Binding column, click **Edit** > **Signing Information** > **New**.

To configure the key locators, complete the following steps:

1. Click **Servers** > **Application Servers** > *server\_name*.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security** > **Key Locators**.

### Request encryption

If the confidentiality constraints (encryption) are specified, verify that you configured the encryption information in the binding files.

To configure the encryption parameters, complete the following steps:

1. Click **Applications** > **Enterprise Applications** >*application\_name*.
2. Under Related Items, click **Web Modules** >*URI\_file\_name* > **Web Services: Client Security Bindings** .
3. In the Response Receiver Binding column, click **Edit** > **Encryption Information** > **New**.

To configure the key locators, complete the following steps:

1. Click **Servers** > **Application Servers** > *server\_name*.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security** > **Key Locators**.

### BasicAuth authentication

If BasicAuth authentication is configured as the required security token, specify the CallbackHandler in the binding file to collect the basic authentication data. The following list contains the Callback support implementations:

#### **com.ibm.wsspi.wssecurity.auth.callback.GuiPromptCallbackHandler**

This implementation prompts for BasicAuth information (user name and password) in an interface.

#### **com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler**

This implementation reads the BasicAuth information from the binding file.

#### **com.ibm.wsspi.wssecurity.auth.callback.StdPromptCallbackHandler**

This implementation prompts for a user name and password using the standard in (stdin) prompt.

To configure the login binding information, complete the following steps:

1. Click **Applications** > **Enterprise Applications** >*application\_name*.
2. Under Related Items, click **Web Module** >*URI\_file\_name* > **Web Services: Client Security Bindings**.
3. Under Request Sender Bindings, click **Edit** > **Login Binding**.

### Identity (ID) Assertion authentication with BasicAuth TrustMode

Configure a login binding in the bindings file with a `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler` implementation. Specify a BasicAuth user ID and password that a TrustedIDEvaluator on a downstream server trusts.

To configure the login binding information, complete the following steps:

1. Click **Applications** > **Enterprise Applications** >*application\_name*.
2. Under Related Items, click **Web Module** >*URI\_file\_name*> **Web Services: Client Security Bindings**.
3. Under **Request Sender Bindings**, click **Edit** > **Login Binding**.

## Identity (ID) Assertion authentication with the Signature TrustMode

Configure the signing information in the bindings file with a signing key pointing to a key locator. The key locator contains the X.509 certificate that is trusted by the downstream server.

To configure ID assertion, complete the following steps:

1. Click **Servers > Application Servers > *server\_name***.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Login Mappings > IDAssertion**.

To configure the login binding information, complete the following steps:

1. Click **Applications > Enterprise Applications > *application\_name***.
2. Under Related Items, click **Web Module > *URI\_file\_name* > Web Services: Client Security Bindings**.
3. Under Request Sender Bindings, click **Edit > Login Binding**.

## Response digital signature verification

If the integrity constraints (signature required) are defined, verify that you configured the signing information in the binding files.

To configure the signing parameters, complete the following steps:

1. Click **Applications > Enterprise Applications > *application\_name***.
2. Under Related Items, click **Web Modules > *URI\_file\_name* > Web Services: Client Security Bindings**.
3. In the Response Receiver Binding column, click **Edit > Signing Information > New**.

To configure the trust anchors, complete the following steps:

1. Click **Servers > Application Servers > *server\_name***.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Trust Anchors > New**.

To configure the collection certificate store, complete the following steps:

1. Click **Servers > Application Servers > *server\_name***.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Collection Certificate Store > New**.

## Response decryption

If the confidentiality constraints (encryption) are specified, verify that you defined the encryption information.

To configure the encryption information, complete the following steps:

1. Click **Applications > Enterprise Applications > *application\_name***.
2. Under Related Items, click **Web Modules > *URI\_file\_name* > Web Services: Client Security Bindings**.
3. In the Response Receiver Binding column, click **Edit > Encryption Information > New**.

To configure the key locators, complete the following steps:

1. Click **Servers > Application Servers > *server\_name***.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Key Locators**.

## View Web services server deployment descriptor

Use this page to view your server deployment descriptor settings.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise Applications > *application\_name***.
2. Under Related Items, click **Web Modules > *URI\_file\_name* > View Web Services Server Deployment Descriptor**.

The information in the following implementation descriptions indicate how to configure your application-level bindings. To configure the server-level bindings, which are the defaults, complete the following steps:

1. Click **Servers > Application Servers > *server\_name***.
2. Under Related Items, click **Web Services: Default bindings for Web Services Security**.
  - Request digital signature verification
  - Request decryption
  - BasicAuth authentication
  - Identity (ID) Assertion authentication
  - Identity (ID) Assertion authentication with the signature TrustMode
  - Response signing
  - Response encryption

### Request digital signature verification

If the integrity constraints (signature required) are defined, verify that you configured the signing information in the binding files.

To configure the signing parameters, complete the following steps:

1. Click **Applications > Enterprise Applications > *application\_name***.
2. Under Related Items, click **Web Modules > *URI\_file\_name* > Web Services: Server Security Bindings**.
3. In the Request Receiver Binding column, click **Edit > Signing Information**.

To configure the trust anchor, complete the following steps:

1. Click **Servers > Application Servers > *server\_name***.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Trust Anchors**.

To configure the collection certificate store, complete the following steps:

1. Click **Servers > Application Servers > *server\_name***.
2. Under Related Items, click **Web Services: Default bindings for Web Services Security > Collection Certificate Store**.

To configure the key locators, complete the following steps:

1. Click **Servers > Application Servers > *server\_name***.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Key Locators**.

### Request decryption

If the confidentiality constraints (encryption) are specified, verify that the encryption information is defined.

To configure the encryption information parameters, complete the following steps:

1. Click **Enterprise Applications** > *application\_name*.
2. Under Related Items, click **Web Module**.
3. Under Additional Properties, click **Web Services: Server Security Bindings**. Under Request Receiver Binding, click **Edit** > **Encryption Information**.

To configure the key locators, complete the following steps:

1. Click **Servers** > **Application Servers** > *server\_name*.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security** > **Key Locators**.

### BasicAuth authentication

If BasicAuth authentication is configured as the required security token, specify the CallbackHandler in the binding file to collect the basic authentication data. The following list contains Callback support implementations:

#### **com.ibm.wsspi.wssecurity.auth.callback.GuiPromptCallbackHandler**

The implementation prompts for BasicAuth information (user name and password) in an interface panel.

#### **com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler**

This implementation reads the BasicAuth information from the binding file.

#### **com.ibm.wsspi.wssecurity.auth.callback.StdPromptCallbackHandler**

This implementation prompts for a user name and password using the standard in (stdin) prompt.

To configure the login mapping information, complete the following steps:

1. Click **Server** > **Application Servers** > *server\_name*.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security** > **Login Mappings**.

### Identity (ID) Assertion authentication with the BasicAuth TrustMode

Configure a login binding in the bindings file with a `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler` implementation. Specify a BasicAuth user ID and password that a TrustedIDEvaluator on a downstream server trusts.

To configure the login mapping information, complete the following steps:

1. Click **Server** > **Application Servers** > *server\_name*.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security** > **Login Mappings**.

### Identity (ID) Assertion authentication with the Signature TrustMode

Configure the signing information in the bindings file with a signing key pointing to a key locator. The key locator contains the X.509 certificate that is trusted by the downstream server.

To configure the login mapping information, complete the following steps:

1. Click **Server** > **Application Servers** > *server\_name*.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security** > **Login Mappings**.

The Java Authentication and Authorization Service (JAAS) uses `WSLogin` as the name of the login configuration. To configure JAAS, click **Security** > **JAAS Configuration** > **Application Logins**.

The value of the <TrustedIDEvaluatorRef> tag in the binding must match the value of the <TrustedIDEvaluator> name.

To configure the trusted ID evaluators, complete the following steps:

1. Click **Servers > Application Servers > *server\_name***.
2. Under Additional Services, click **Web Services: Default bindings for Web Services Security > Trusted ID Evaluators**.

### Response signing

If the integrity constraints (digital signature) are defined, verify that you have the signing information configured in the binding files.

To specify the signing information, complete the following steps:

1. Click **Applications > Enterprise Applications > *application\_name***.
2. Under Related Items, click **Web Modules > *URI\_file\_name* > Web Services: Server Security Bindings**.
3. In the Request Receiver Binding column, click **Edit > Signing Information**.

To configure the key locators, complete the following steps:

1. Click **Servers > Application Servers > *server\_name***.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Key Locators**.

### Response encryption

If the confidentiality constraints (encryption) are specified, verify that the encryption information is defined.

To specify the encryption information, complete the following steps:

1. Click **Enterprise Applications > *application\_name***.
2. Under Related Items, click **Web Module**.
3. Under Additional Properties, click **Web Services: Server Security Bindings**.
4. Under Request Receiver Binding, click **Edit > Encryption Information**.

To configure the key locators, complete the following steps:

1. Click **Servers > Application Servers > *server\_name***.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Key Locators**.

## Authentication method overview

The Web services security implementation for WebSphere Application Server supports the following authentication methods: BasicAuth, Lightweight Third Party Authentication (LTPA), digital signature, and identity assertion.

When the WebSphere Application Server is configured to use the BasicAuth authentication method, the sender attaches the LTPA token as a BinarySecurityToken from the current security context or from basic authentication data configuration in the binding file in the SOAP message header. The Web services security message receiver authenticates the sender by validating the user name and password against the configured user registry. With the LTPA method, the sender attaches the LTPA BinarySecurityToken it previously received in the SOAP message header. The receiver authenticates the sender by validating the LTPA token and the token expiration time. With the Digital Signature authentication method, the sender attaches a BinarySecurityToken from a X509 certificate to the Web services security message header

along with a digital signature of the message body, time stamp, security token, or any combination of the three. The receiver authenticates the sender by verifying the validity of the X.509 certificate and the digital signature using the public key from the verified certificate.

The identity assertion authentication method is different from the other three authentication methods. This method establishes the security credential of the sender based on the trust relationship. You can use the identity assertion authentication method, for example, when an intermediary server must invoke a service from a downstream server on behalf of the client, but does not have the client authentication information. The intermediary server might establish a trust relationship with the downstream server and then assert the client identity to the same downstream server.

Web Services Security supports the following trust modes:

- BasicAuth
- Digital signature
- Presumed trust

When you use the BasicAuth and digital signature trust modes, the intermediary server passes its own authentication information to the downstream server for authentication. The presumed trust mode establishes a trust relationship using some external mechanism. For example, the intermediary server might pass SOAP messages through a Secure Socket Layers (SSL) connection with the downstream server and transport layer client certificate authentication.

The Web services security implementation for WebSphere Application Server validates the trust relationship by following this procedure:

1. The downstream server validates the authentication information of the intermediary server.
2. The downstream server verifies whether the authenticated intermediary server is authorized for identity assertion. For example, the intermediary server must be in the trust list for the downstream server.

The client identity might be represented by a name string, a distinguished name (DN), or an X.509 certificate. The client identity is attached in the Web services security message in a UsernameToken with just a user name, DN, or in a BinarySecurityToken of a certificate. The following table summarizes the type of security token that is required for each authentication method.

*Table 6. Authentication methods and their security tokens*

Authentication method	Security token
BasicAuth	BasicAuth requires <wsse:UsernameToken> with <wsse:Username> and <wsse:Password>.
Signature	Signature requires <ds:Signature> and <wsse:BinarySecurityToken>.
IDAssertion	IDAssertion requires <wsse:UsernameToken> with <wsse:Username> or <wsse:BinarySecurityToken> with a X.509 certificate for client identity depending on <idType>. This method also requires other security tokens according to the <trustMode>: <ul style="list-style-type: none"> <li>• If the &lt;trustMode&gt; is BasicAuth, IDAssertion requires &lt;wsse:UsernameToken&gt; with &lt;wsse:Username&gt; and &lt;wsse:Password&gt;.</li> <li>• If the &lt;trustMode&gt; is Signature, IDAssertion requires &lt;wsse:BinarySecurityToken&gt;.</li> </ul>
LTPA	LTPA requires <wsse:BinarySecurityToken> with an LTPA token.

A Web service can support multiple authentication methods simultaneously. The receiver side of the Web services deployment descriptor can specify all the authentication methods that are supported in the `ibm-webservices-ext.xml` XML file. The Web services receiver-side, as shown in the following example, is configured to accept all the authentication methods described previously:

```
<loginConfig xmi:id="LoginConfig_1052760331326">
 <authMethods xmi:id="AuthMethod_1052760331326" text="BasicAuth"/>
 <authMethods xmi:id="AuthMethod_1052760331327" text="IDAssertion"/>
 <authMethods xmi:id="AuthMethod_1052760331336" text="Signature"/>
 <authMethods xmi:id="AuthMethod_1052760331337" text="LTPA"/>
</loginConfig>
<idAssertion xmi:id="IDAssertion_1052760331336" idType="Username" trustMode="Signature"/>
```

You can define only one authentication method in the sender-side Web services deployment descriptor. A Web service client can use any of the authentication methods that are supported by the particular Web services application. The following example illustrates an identity assertion authentication method configuration in the `ibm-webservicesclient-ext.xml` deployment descriptor extension of the Web service client:

```
<loginConfig xmi:id="LoginConfig_1051555852697">
 <authMethods xmi:id="AuthMethod_1051555852698" text="IDAssertion"/>
</loginConfig>
<idAssertion xmi:id="IDAssertion_1051555852697" idType="Username" trustMode="Signature"/>
```

As shown in the previous example, the client identity type is Username and the trust mode is digital signature.

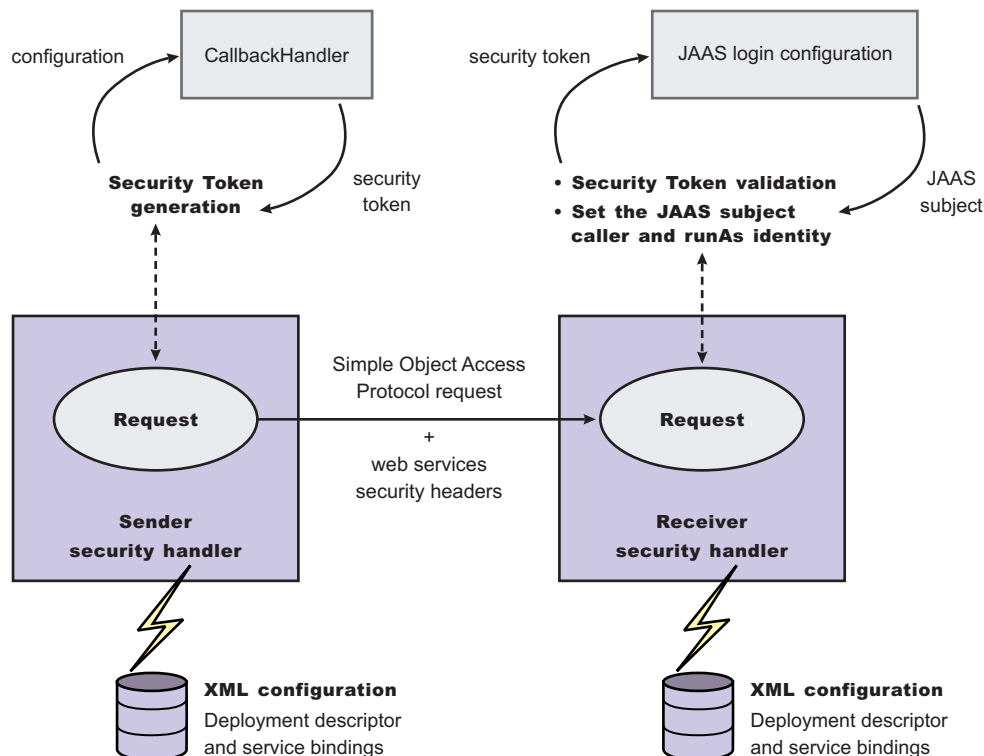

Figure 20. Security token generation and validation

The sender security handler invokes the `handle()` method of an implementation of the `javax.security.auth.callback.CallbackHandler` interface. The `javax.security.auth.callback.CallbackHandler` interface creates the security token and passes it back to

the sender security handler. The sender security handler constructs the security token based on the authentication information in the callback array and inserts the security token into the Web services security message header.

The receiver security handler compares the token type in the message header with the expected token types configured in the deployment descriptor. If none of the expected token types are found in the Web services security header of the SOAP message, the request is rejected with a SOAP fault exception. Otherwise, the token type is used to map to a Java Authentication and Authorization Service (JAAS) login configuration for validating the token. If the authentication is successful, a JAAS Subject is created and associated with the running thread. Otherwise, the request is rejected with a SOAP fault exception.

## XML digital signature

XML-Signature Syntax and Processing (XML signature) is a specification that defines XML syntax and processing rules to sign and verify digital signatures for digital content. The specification was developed jointly by the World Wide Web Consortium (W3C) and the Internet Engineering Task Force (IETF).

XML signature does not introduce new cryptographic algorithms. WebSphere Application Server uses XML signature with existing algorithms such as RSA, HMAC, and SHA1. XML signature defines many methods for describing key information and enables the definition of a new method.

XML canonicalization (c14n) is often needed when you use XML signature. Information can be represented in various ways within serialized XML documents. For example, although their octet representations are different, the following examples are identical:

- `<person first="John" last="Smith"/>`
- `<person last="Smith" first="John"></person>`

C14n is a process used to canonicalize XML information. Select an appropriate c14n algorithm because the information that is canonicalized is dependent upon this algorithm. One of the major c14n algorithms, Exclusive XML Canonicalization, canonicalizes the character encoding scheme, attribute order, namespace declarations, and so on. The algorithm does not canonicalize white space outside tags, namespace prefixes, or data type representation.

### XML signature in the Web Services Security-Core specification

The Web Services Security-Core (WSS-Core) specification defines a standard way for Simple Object Access Protocol (SOAP) messages to incorporate an XML signature. You can use almost all of the XML signature features in WSS-Core except enveloped signature and enveloping signature. However, WSS-Core has some recommendations such as exclusive canonicalization for the c14n algorithm and some additional features such as `SecurityTokenReference` and `KeyIdentifier`. The `KeyIdentifier` is the value of the `SubjectKeyIdentifier` field within the X.509 certificate. For more information on the `KeyIdentifier`, see "Reference to a Subject Key Identifier" within the OASIS Web Services Security X.509 Certificate Token Profile documentation.

By including XML signature in SOAP messages, the following are realized:

#### Message integrity

A message receiver can confirm that attackers or accidents have not altered parts of the message after these parts are signed by a key.

#### Authentication

You can assume that a valid signature is *proof of possession*. A message with a digital certificate issued by a certificate authority and a signature in the message that is validated successfully by a public key in the certificate, is proof that the signer has the corresponding private key. The receiver can authenticate the signer by checking the trustworthiness of the certificate.

## XML signature in the current implementation

XML signature is supported in Web services security, however, an application programming interface (API) is not available. The current implementation has many hardcoded behaviors and has some user-operable configuration items. To configure the client for digital signature, see [Configuring the client for response digital signature verification: Verifying the message parts](#). To configure the server for digital signature, see [Configuring the server for request digital signature verification: Verifying the message parts](#).

## Security considerations

In a replay attack, an attacker taps the lines, receives a signed message, and then returns the message to the receiver. In this case, the receiver receives the same message twice and might process both of them if the signatures are valid. Processing both messages can cause damage to the receiver if the message is a claim for money. If you have the signed generation time stamp and the signed expiration time in a message replay, attacks might be reduced. However, this is not a complete solution. A message must have a nonce value to prevent these attacks and the receiver must reject a message that contains a processed nonce. The current implementation does not provide a standard way to generate and check nonces in messages. In WebSphere Application Server, Version 5.1, nonce is supported in username tokens only. The username token profile contains concrete nonce usage scenarios for username tokens. Applications handle nonces (such as serial numbers) and they need to be signed.

## Signing information collection

Use this page to view a list of signing parameters. Signing information is used to sign and validate parts of a message including the body, time stamp, and user name token. You can also use these parameters for X.509 validation when the authentication method is IDAssertion and the ID type is X509Certificate in the server-level configuration. In such cases, you must fill in the certificate path fields only.

To view this administrative console page, complete the following steps:

1. Click **Applications** > **Enterprise Applications** > *application\_name*.
2. Under Related Items, click **Web Modules** > *URI\_file\_name* > **Web Services: Server Security Bindings**.
3. In the Request Receiver Binding column, click **Edit** > **Signing Information**.
4. Click **New** to create a signing parameter. Click **Delete** to delete a signing parameter.

### **Signature Method:**

Specifies the unique name of the signature method.

## Signing information configuration settings

Use this page to configure new signing parameters.

The specifications listed on this page for the signature method, digest method, and canonicalization method are located in the W3C document entitled, "XMLSignature Syntax and Specification: W3C Recommendation 12 Feb 2002".

To view this administrative console page:

1. Click **Enterprise Applications** > *application\_name*.
2. Under Related Items, click **Web Modules** > *URI\_file\_name* > **Web Services: Server Security Bindings**.
3. In the Request Receiver Binding column, click **Edit** > **Signing Information**.
4. Click **New** to create a signing parameter or click **Delete** to delete a signing parameter.

### **Signature Method:**

Specifies the algorithm Uniform Resource Identifiers (URI) of the signature method. This method contains the actual value of the digital signature encoded using base64.

The following algorithms are supported:

- <http://www.w3.org/2000/09/xmlsig#rsa-sha1>
- <http://www.w3.org/2000/09/xmlsig#dsa-sha1>

#### **Digest Method:**

Specifies the algorithm URI of the digest method.

The <http://www.w3.org/2000/09/xmlsig#sha1> algorithm is supported.

#### **Canonicalization Method:**

Specifies the algorithm URI of the canonicalization method.

The following algorithms are supported:

- <http://www.w3.org/2001/10/xml-exc-c14n#>
- <http://www.w3.org/2001/10/xml-exc-c14n#WithComments>
- <http://www.w3.org/TR/2001/REC-xml-c14n-20010315>
- <http://www.w3.org/TR/2001/REC-xml-c14n-20010315#WithComments>

#### **Signing Key:**

Specifies the key information that is used for signing. These fields are ignored in receiver-side configuration.

If you specify a **Key Name** and a **Key Locator Reference**, select **None** for the Certificate Path.

#### **Certificate Path:**

Specifies the settings for the certificate path validation. When you select **Trust Any**, this validation is skipped and all the incoming certificates are trusted. These fields are ignored in sender-side configuration.

If you click **Trust Any** or select a **Trust Anchor** and a **Certificate Store**, select **None** for the Signing Key in the previous field.

#### **Trust Anchor**

The selections available for Trust Anchor are specified by clicking **Servers > Application Servers > *server\_name***. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Trust Anchors**.

#### **Certificate Store**

The selections available for the Collection Store are specified by clicking **Servers > Application Servers > *server\_name***. Under Related Items, click **Web Services: Default bindings for Web Services Security > Collection Certificate Store**.

### **Signing parameter configuration settings**

Use this page to configure new signing parameters.

The specifications listed on this page for the signature method, digest method, and canonicalization method are located in the World Wide Web Consortium (W3C) document entitled, *XML Signature Syntax and Specification: W3C Recommendation 12 Feb 2002*.

To view this administrative console page, complete the following steps:

1. Click **Enterprise Applications** > *application\_name*.
2. Under Related Items, click **Web Modules** > *URI\_file\_name* > **Web Services: Client Security Bindings**.
3. In the Request Sender Binding column, click **Edit** > **Signing Information**.

If the signing information is not available, select **None**.

If the signing information is available, select **Dedicated Signing Information** and specify the configuration in the following fields:

***Signature Method:***

Specifies the algorithm Uniform Resource Identifiers (URI) of the signature method. This method contains the actual value of the digital signature encoded using base64.

The following algorithms are supported:

- <http://www.w3.org/2000/09/xmlsig#rsa-sha1>
- <http://www.w3.org/2000/09/xmlsig#dsa-sha1>

***Digest Method:***

Specifies the algorithm URI of the digest method.

The <http://www.w3.org/2000/09/xmlsig#sha1> algorithm is supported.

***Canonicalization Method:***

Specifies the algorithm URI of the canonicalization method.

The following algorithms are supported:

- <http://www.w3.org/2001/10/xml-exc-c14n#>
- <http://www.w3.org/2001/10/xml-exc-c14n#WithComments>
- <http://www.w3.org/TR/2001/REC-xml-c14n-20010315>
- <http://www.w3.org/TR/2001/REC-xml-c14n-20010315#WithComments>

***Signing Key:***

Specifies the key information that is used for signing. These fields are ignored in receiver-side configuration.

If the signing key is not available, select **None**.

***Certificate Path:***

Specifies the settings for the certificate path validation. When you select **Trust Any**, this validation is skipped and all the incoming certificates are trusted. These fields are ignored in sender-side configuration.

If there is not a certificate path, select **None**.

If there is a certificate path, select **Trust Any** or select a Trust Anchor and a Certificate Store.

**Trust Anchor**

Specify the selections for the Trust Anchor field by clicking **Servers > Application Servers > *server\_name***. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Trust Anchors**.

### Certificate Store

Specify the selections for the Collection Store field by clicking **Servers > Application Servers *server\_name***. Under Related Items, click **Web Services: Default bindings for Web Services Security > Collection Certificate Store**.

## Securing Web services using XML digital signature

WebSphere Application Server provides several different methods to secure your Web services; Extensible Markup Language (XML) digital signature is one of these methods. You might secure your Web services using any of the following methods:

- XML digital signature
- XML encryption
- Basicauth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

XML digital signature provides both message integrity and authentication capabilities when it is used with SOAP messages. A message receiver can verify that attackers or accidents have not altered parts of the message after the message was signed by a key. If a message has a digital certificate issued by a certificate authority (CA) and a signature in the message is validated successfully by a public key in the certificate, it is proof that the signer has the corresponding private key. To use XML digital signature to secure Web services, complete the following steps:

1. Define the security constraints or extensions. To configure the security constraints, you must use the Application Server Toolkit, which is available at the following Web site:  
[http://www.ibm.com/support/docview.wss?rs=180&context=SSEQTP&q=ASTK&uid=swg24005125&loc=en\\_US&cs=utf-8&lang=en+en](http://www.ibm.com/support/docview.wss?rs=180&context=SSEQTP&q=ASTK&uid=swg24005125&loc=en_US&cs=utf-8&lang=en+en)
  - a. Configure the client to digitally sign a message request. To configure the client, complete the following steps to specify which parts of the SOAP message to digitally sign and define the method used to digitally sign the message. The client in these steps is the request sender.
    - 1) Specify the message parts by following the steps found in Configuring the client for request signing: digitally signing message parts.
    - 2) Select the method used to digitally sign the request message. You can select the digital signature method by following the steps in Configuring the client for request signing: choosing the digital signature method.
  - b. Configure the server to verify the digital signature that is used in the message request. To configure the server, you must specify which parts of the SOAP message, sent by the request sender, contain digitally signed information and which method was used to digitally sign the message. The settings chosen for the request receiver, or the server in this step, must match the settings chosen for the request sender in the previous step.
    - 1) Define the message parts by following the steps found in Configuring the server for request digital signature verification: verifying message parts.
    - 2) Select the same method used by the request sender to digitally sign the message. You can select the digital signature method by following the steps in Configuring the server for request digital signature verification: choosing the verification method

- c. Configure the server to digitally sign a message response. To configure the server, complete the following steps to specify which parts of the SOAP message to digitally sign and define the method used to digitally sign the message. The sender in these steps is the response sender.
    - 1) Specify which message parts to digitally sign by following the steps found in Configuring the server for response signing: digitally signing message parts.
    - 2) Select the method used to digitally sign the response message. You can select the digital signature method by following the steps in Configuring the server for response signing: choosing the digital signature method
  - d. Configure the client to verify the digital signature that is used in the message response. To configure the client, you must specify which parts of the SOAP message sent by the response sender contain digitally signed information and which method was used to digitally sign the message. The settings chosen for the response receiver, or client in this step, must match the settings chosen for the response sender in the previous step.
    - 1) Define the message parts by following the steps found in Configuring the client for response digital signature verification: verifying message parts
    - 2) Select the same method used by the response sender to digitally sign the message. You can select the digital signature method by following the steps in Configuring the client for response digital signature verification: choosing the verification method
2. Define the client security bindings. To configure the client security bindings, complete the steps in either of the following topics:
    - Configuring the client security bindings using the Application Server Toolkit
    - Configuring the client security bindings using the administrative console
  3. Define the server security bindings. To configure the server security bindings, complete the steps in either of the following topics:
    - Configuring the server security bindings using the Application Server Toolkit
    - Configuring the server security bindings using the administrative console

After completing these steps, you have secured your Web services using XML digital signature.

## Transport level security

*Transport level security* is based on Secure Sockets Layer (SSL) or Transport Layer Security (TLS) that runs beneath HTTP.

SSL and TLS provide security features including authentication, data protection, and cryptographic token support for secure HTTP connections. To run with HTTPS, the service endpoint address must be in the form `https://`.

The integrity and confidentiality of transport data, including SOAP messages and HTTP basic authentication, is confirmed when you use SSL and TLS. See "Secure Sockets Layer" in the Information Center. Web services applications can also use Federal Information Processing Standard (FIPS) approved ciphers for more secure TLS connections.

WebSphere Application Server uses the Java Secure Sockets Extension (JSSE) package to support SSL and TLS.

## Configuring HTTP outbound transport level security

The HTTP outbound transport-level security for a Web service is based on the Secure Sockets Layer (SSL) configuration of the WebSphere Application Server Web container. Review "Configuring Secure Sockets Layer" and "HTTP transport collection" in the Information Center.

To configure HTTP outbound transport-level security, complete the following steps:

1. Configure the HTTP outbound transport-level security settings.

- Use either the WebSphere Application Server administrative console or the Assembly Toolkit to configure the HTTP outbound transport-level security for a Web Service acting as a client to another Web service.
  - Before installing the Web services application, use the Assembly Toolkit to configure the HTTP SSL Configuration in the Web Services Client Port Binding page. The Web Services Client Port Binding page is available after double-clicking the `webservicesclient.xml` file.
  - After installing the Web services application, use the administrative console to configure the Web services client security binding collection. To access the collection, complete the following steps:
    - a. Click **Applications > Enterprise Applications**.
    - b. Under Related Items, click either **Web Modules** or **EJB Modules**.
    - c. Click the name of the URI.
    - d. Under Additional Properties, click **Web Services: Client Security Bindings**.

**Attention:** If the HTTP outbound transport-level security settings are not configured, the default Secure Sockets Layer (SSL) settings for the Java Secure Socket Extension (JSSE) file are used.

- Use the properties to configure the HTTP outbound transport-level security for a Web service client.
  - a. Create a property file that includes the following properties:

```
com.ibm.ssl.protocol
com.ibm.ssl.keyStoreType
com.ibm.ssl.keyStore
com.ibm.ssl.keyStorePassword
com.ibm.ssl.trustStoreType
com.ibm.ssl.trustStore
com.ibm.ssl.trustStorePassword
```

- b. Set the `com.ibm.webservices.sslConfigURL` Java system property to the absolute path of the created property file.

**Attention:** If the outbound transport-level security is not configured, the default SSL settings of the JSSE file are used.

2. Optional: Accept the redirection of HTTP request to a different URI in HTTPS. A redirection of the HTTP request to a different URI in HTTPS can occur if the transport guarantee of CONFIDENTIAL or INTEGRAL is configured in the application. To accept the redirection, you can do either of the following tasks:
  - Set the `com.ibm.ws.webservices.HttpRedirectEnabled` Java system property to `true`.
  - Programmatically set the `com.ibm.wsspi.webservices.Constants.HTTP_REDIRECT_ENABLED` property to `true` in the stub or call object before invoking the service.

### **HTTP SSL Configuration collection:**

Use this page to configure transport-level Secure Sockets Layer (SSL) security. You can use this configuration when a Web service is a client to another Web service.

You can use transport-level security to enable HTTP SSL (or HTTPS). Transport-level security can be enabled or disabled independently from message-level security. Because transport-level security provides minimal security, use message-level security when security is essential to the Web service application.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise Applications > *application\_name***.
2. Under Related Items, click **Web Module > *URI\_file\_name* > Web Services: Client Security Bindings**.
3. Under HTTP SSL Configuration, click **Edit**.

### *HTTP SSL Enabled:*

Specifies secure socket communications for the HTTP transport for this port. When enabled, WebSphere Application Server uses the HTTP SSL Configuration setting.

### *HTTP SSL Configuration:*

Specifies which alias of the SSL configuration to use with the HTTP transport for this port.

This option is used if you select **HTTP SSL Enabled**. SSL aliases are defined in the Secure Sockets Layer configuration repertoire, which you can configure by clicking **Security > SSL**.

## **HTTP basic authentication**

*HTTP basic authentication* uses a user name and password to authenticate a service client to a secure endpoint.

WebSphere Application Server can have several resources, including Web services, protected by a Java 2 Platform, Enterprise Edition (J2EE) security model.

A simple way to provide authentication data for the service client is to authenticate to the protected service endpoint to the HTTP basic authentication. The basic authentication is located in the HTTP header that carries the SOAP request. When the application server receives the HTTP request, the user name and password are retrieved and verified using the authentication mechanism specific to the server.

Although the basic authentication data is base64-encoded, sending data over HTTPS is recommended. The integrity and confidentiality of the data can be protected by the Secure Sockets Layer (SSL) protocol.

In some cases, a firewall is present using the pass-thru HTTP proxy server. The HTTP proxy server forwards the basic authentication data into the J2EE application server. The proxy server can also be protected. Applications can specify the proxy data by setting properties in a stub object.

## **Configuring HTTP basic authentication**

To configure HTTP basic authentication, use the WebSphere Application Server tools to modify the binding information or programmatically set properties in a Stub or Call object. The values set programmatically take precedence over the values defined in the binding. However, you only can programmatically configure the HTTP proxy authentication.

1. Use either the Assembly Toolkit or the administrative console to configure the HTTP basic authentication
  - Before installing the Web services application, use Assembly toolkit to configure the HTTP basic authentication in the Web Services Client Port Binding page for a Web service or a Web service client. The Web Services Client Port Binding page is available after double-clicking the `webservicesclient.xml` file.
  - After installing the Web services application, you can use administrative console to configure the Web services client security bindings for a Web service only. To access the collection, complete the following steps:
    - a. Click **Applications > Enterprise Applications**.
    - b. Under Related Items, click either **Web Modules** or **EJB Modules**.
    - c. Click the name of the URI.
    - d. Under Additional Properties, click **Web Services: Client Security Bindings**.
2. Programmatically set the properties in the stub or call object for a Web service or a Web service client  
Programmatically set the following properties:

```
javax.xml.rpc.Call.USERNAME_PROPERTY
javax.xml.rpc.Call.PASSWORD_PROPERTY
javax.xml.rpc.Stub.USERNAME_PROPERTY
javax.xml.rpc.Stub.PASSWORD_PROPERTY
```

3. Programmatically set the properties in the stub or call object to configure the HTTP proxy authentication. Programmatically set the following properties for HTTP:

```
com.ibm.wsspi.webservices.HTTP_PROXYHOST_PROPERTY
com.ibm.wsspi.webservices.HTTP_PROXYPORT_PROPERTY
com.ibm.wsspi.webservices.HTTP_PROXYUSER_PROPERTY
com.ibm.wsspi.webservices.HTTP_PROXYPASSWORD_PROPERTY
```

Programmatically set the following properties for HTTPS:

```
com.ibm.wsspi.webservices.HTTPS_PROXYHOST_PROPERTY
com.ibm.wsspi.webservices.HTTPS_PROXYPORT_PROPERTY
com.ibm.wsspi.webservices.HTTPS_PROXYUSER_PROPERTY
com.ibm.wsspi.webservices.HTTPS_PROXYPASSWORD_PROPERTY
```

### ***HTTP basic authentication collection:***

Use this page to specify a user ID and password for transport-level basic authentication security for this port. You can use this configuration when a Web service is a client to another Web service.

You can use transport-level security to enable basic authentication. Transport-level security can be enabled or disabled independently from message-level security. Because transport-level security provides minimal security, use message-level security when security is essential to the Web service application.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise Applications > application\_name**.
2. Under Related Items, click **Web Module > URI\_file\_name > Web Services: Client Security Bindings**.
3. Under HTTP Basic Authentication, click **Edit**.

#### *Basic Authentication ID:*

Specifies the user ID for the HTTP basic authentication for this port.

#### *Basic Authentication Password:*

Specifies the password for the HTTP basic authentication for this port.

## **Default configuration for WebSphere Application Server**

In the WebSphere Application Server, each application server has a copy of the `ws-security.xml` file, which defines the default binding information for Web services security. The following list contains the defaults defined in the `ws-security.xml` file:

### **Trust anchors**

Identifies the trusted root certificates for signature verification.

### **Collection certificate stores**

Contains certificate revocation lists (CRLs) and nontrusted certificates for verification.

### **Key locators**

Locates the keys for digital signature and encryption.

### Trusted ID evaluators

Evaluates the trust of the received identity before identity assertion.

### Login mappings

Contains the Java Authentication and Authorization Service (JAAS) configurations for AuthMethod token validation.

If the Web services security constraints specified in the deployment descriptors and the required bindings are not defined in the bindings file, the default constraints in the `ws-security.xml` file are used.

When you use the **addNode** command, the `ws-security.xml` file is added with the server configuration to the new cell. The following figure shows the activity when you use the **addNode** command.

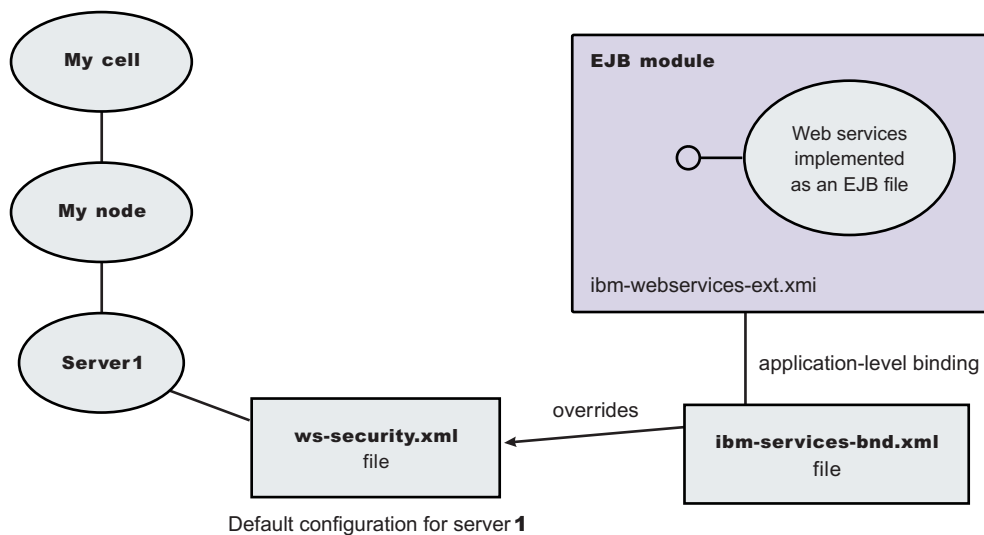

Figure 21. Configuration when using the **addNode** command

### Default binding:

The default binding information is defined in the `ws-security.xml` file and can be administered by either the administrative console or by scripting.

Certain applications can share certain binding information. This information includes truststores, keystores, and authentication methods (token validation). WebSphere Application Server provides support for default binding information. Administrators can define binding information at the server level and applications can refer to this binding information.

You can define the following binding information in the `ws-security.xml` file:

### Trust anchors (truststore)

- *Trust anchors* contain key store configuration information that has the root-trusted certificates. Trust anchors are used for certificate path validation of the incoming X.509-formatted security tokens.
- The Trust Anchor Name is used in the binding file (`ibm-webservices-bnd.xmi` and `ibm-webservicesclient-bnd-xmi` when Web services is running as a client) to refer to the trust anchor defined in the default binding information. The trust anchor name must be unique in the trust anchor collection.

## Collection certificate store

- The *collection certificate store* specifies a list of untrusted, intermediate certificates and is used for certificate path validation of incoming X.509-formatted security tokens. The default provider is IBM CertPath.
- The Certificate Store Name is used in the binding file (`ibm-webservices-bnd.xml` and `ibm-webservicesclient-bnd.xml` when Web services is running as a client) to refer to the certificate store defined in the default binding information. The Certificate Store Name must be unique to the collection certificate store collection.

## Key locators

- *Key locators* specify implementation of the `com.ibm.wsspi.wssecurity.config.KeyLocator` interface. This interface is used to retrieve keys for signature or encryption. Customer implementations can extend the key locator interface to retrieve keys using other methods. WebSphere Application Server provides implementations to retrieve a key from the key store, map an authenticated identity to a key in the key store, or retrieve a key from the signer certificate (mapping and retrieving actions are used for encrypting the response).
- The Key Locator Name is used in the binding file (`ibm-webservices-bnd.xml` and `ibm-webservicesclient-bnd.xml` when Web services is running as a client) to refer to the key locator defined in the default binding information. The Key Locator Name must be unique to the key locators collection in the default binding information.

## Trusted ID evaluators

- *Trusted ID evaluators* are an implementation of the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` interface. This interface is used to make sure the identity (ID)-asserting authority is trusted. Additionally, you can extend the trusted identity evaluator to validate the trust. WebSphere Application Server provides a default implementation for validating trust based on a predefined list of identities.
- The Trusted ID Evaluator Name is used in the binding file (`ibm-webservices-bnd.xml`) to refer to the trusted identity evaluator defined in the default binding information. The Trusted ID Evaluator Name must be unique to the Trusted ID Evaluator collection.

## Login mappings

- *Login mappings* define the mapping of the authentication method to the Java Authentication and Authorization Service (JAAS) login configuration. The mappings are used to authenticate the incoming security token embedded in the Web services security Simple Object Access Protocol (SOAP) message header. The JAAS login configuration is defined in the administrative console under **Security > JAAS Configuration > Application Logins**.
- WebSphere Application Server defines the following authentication methods:

### BasicAuth

Authenticates user name and password.

### Signature

Maps the subject distinguished name (DN) in the certificate to a WebSphere Application Server credential.

### IDAssertion

Maps the identity to a WebSphere Application Server credential.

**LTPA** Authenticates a Lightweight Third Party Authentication (LTPA) token.

After identity authentication, the associated credential is used in the downstream call.

- This method can be extended to authenticate custom security tokens by providing a custom JAAS login configuration and by using the `com.ibm.wsspi.wssecurity.auth.module.WSSecurityMappingModule` to create the principal and credential required by WebSphere Application Server.

- If LoginConfig (AuthMethod) is defined in the IBM extension deployment descriptor (`ibm-webservices-ext.xmi`), but there are no login mapping bindings (`ibm-webservices-bnd.xmi`) defined for the AuthMethod, Web services security run time uses the login mapping defined in the default binding information.

## WebSphere Application Server

In the WebSphere Application Server, each server has a copy of the `ws-security.xml` file (default binding information for Web services security). There is no cell-level copy of the `ws-security.xml` file, which is only available in the WebSphere Application Server Network Deployment installation. To navigate to the server-level default binding in the administrative console, complete the following steps:

1. Click **Servers > Application Servers > server1**.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security**.

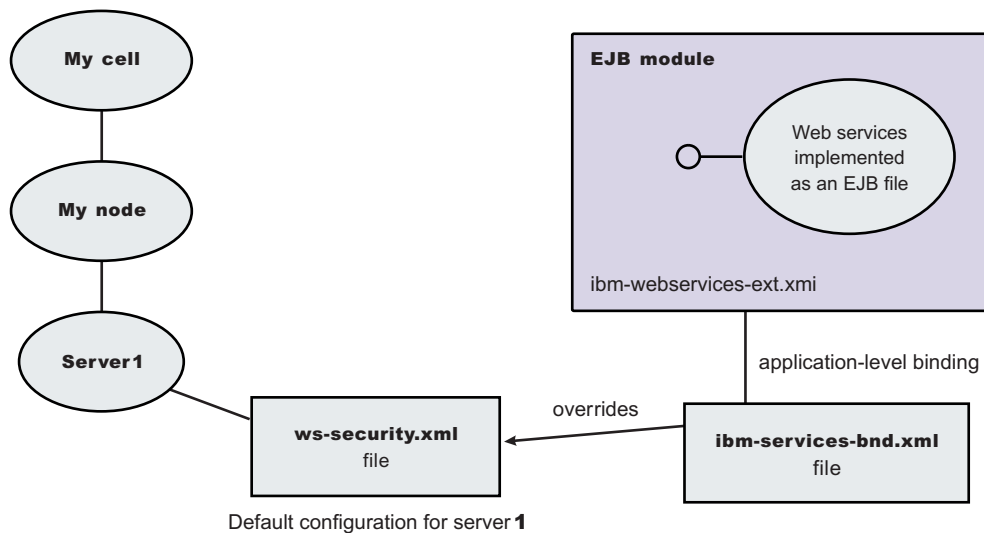

Figure 22. Web services security application-level bindings and server-level default binding information

Web services security run time uses the binding information in the application Enterprise JavaBeans (EJB) or Web module binding file (`ibm-webservices-bnd.xmi` or `ibm-webservicesclient-bnd.xmi` if Web services is acting as a client on the server) if the binding information is defined in the application-level binding file. For example, if key locator K1 is defined in both the application-level binding file and the default binding file (`ws-security.xml`), the K1 in the application-level binding file is used.

*Web services: default bindings for the Web services security collection:*

Use this page to configure the settings for nonce on the server level and to manage the default bindings for trust anchors, the collection certificate store, key locators, trusted ID evaluators, and login mappings.

To view this administrative console page, click **Servers > Application Servers > server\_name**. Under Additional Properties, click **Web Services: Default bindings for Web Services Security**.

Read the Web services documentation before you begin defining the default bindings for Web services security.

To define the server bindings, complete the following steps:

1. Click **Applications > Enterprise Applications > *application\_name***.
2. Under Related Items, click **Web Modules > *URI\_file\_name* > Web Services: Server Security Bindings**.

To define the client bindings, complete the following steps:

1. Click **Applications > Enterprise Applications > *application\_name***.
2. Under Related Items, click **Web Modules > *URI\_file\_name* > Web Services: Client Security Bindings**.

**5.1 +** *Nonce* is a unique cryptographic number embedded in a message to help stop repeat, unauthorized attacks of user name tokens. In a base WebSphere Application Server environment, you must specify values for the **Nonce Cache Timeout**, **Nonce Maximum Age**, and **Nonce Clock Skew** fields for the server-level.

The default binding configuration provides a central location where reusable binding information is defined. The application binding file can reference the information contained in the default binding configuration.

*Nonce Cache Timeout:*

Specifies the timeout value, in seconds, for the nonce cached on the server. Nonce is a randomly generated value.

The Nonce Cache Timeout field is required for the base WebSphere Application Server environment.

If you make changes to the nonce cache timeout value, you must restart WebSphere Application Server for the changes to take effect.

<b>Default</b>	600 seconds
<b>Minimum</b>	300 seconds

*Nonce Maximum Age:*

Specifies the default time, in seconds, before the nonce time stamp expires. Nonce is a randomly generated value.

The maximum value cannot exceed the number of seconds specified in the Nonce Cache Timeout field for the server level. The value set for this server-level Nonce Maximum Age field must not exceed Nonce Maximum Age value set for the cell level, which you can access by clicking **Security > Web Services > Properties**.

The Nonce Maximum Age field is required for the base WebSphere Application Server environment.

<b>Default</b>	300 seconds
<b>Range</b>	300 to Nonce Cache Timeout seconds

*Nonce Clock Skew:*

Specifies the default clock skew value, in seconds, to consider when WebSphere Application Server checks the timeliness of the message. Nonce is a randomly generated value.

The maximum value cannot exceed the number of seconds specified in the Nonce Maximum Age field.

The Nonce Clock Skew field is required for the base WebSphere Application Server environment.

<b>Default</b>	0 seconds
<b>Range</b>	0 to Nonce Maximum Age seconds

*Trust Anchors:*

Specifies a list of keystore objects that contain the trusted root certificates, self-signed or issued by a certificate authority (CA).

The certificate authority authenticates a user and issues a certificate. After the certificate is issued, the keystore objects, which contain these certificates, use the certificate for certificate path or certificate chain validation of incoming X.509-formatted security tokens.

*Collection Certificate Store:*

Specifies a list of the untrusted, intermediate certificate files.

The collection certificate store contains a chain of untrusted, intermediate certificates. The CertPath API attempts to validate these certificates, which are based on the trust anchor.

*Key Locators:*

Specifies a list of key locator objects that retrieves the keys for digital signature and encryption from a keystore file or a repository. The key locator maps a name or logical name to an alias or maps an authenticated identity to a key. This logical name is used to locate a key in a key locator implementation.

*Trusted ID Evaluators:*

Specifies a list of trusted ID evaluators that determines whether to trust the identity-asserting authority or the message sender.

The trusted ID evaluators are used to authenticate additional identities from one server to another server. For example, a client sends the identity of user A to server 1 for authentication. Server 1 calls downstream to server 2, asserts the identity of user A, and includes the user ID and password of server 1. Server 2 attempts to establish trust with server 1 by authenticating its user ID and password and checking the trust based on the TrustedIDEvaluator implementation. If the authentication process and the trust check are successful, server 2 trusts that server 1 authenticated user A and a credential is created for user A on server 2 to invoke the request.

*Login Mappings:*

Specifies a list of configurations for validating tokens within incoming messages.

Login mappings map the authentication method to the Java Authentication and Authorization Service (JAAS) configuration.

To configure JAAS, use the administrative console and click **Security > JAAS Configuration**.

*Web Services: Client security bindings collection:*

Use this page to view a list of client-side binding configurations for Web services security. These bindings are used when a Web service is a client to another Web service.

To view this administrative console page, complete the following steps:

1. Click **Enterprise Applications > application\_name**.

2. Under Related Items, click **Web Module** > *URI\_file\_name* > **Web Services: Client Security Bindings**.

*Port:*

Specifies the port used to send and receive messages from a server.

*Web Service:*

Specifies the name of the Web service.

*Request Sender Binding:*

Specifies the binding configuration used to send request messages to the request receiver.

Click **Edit** to configure the signing information, encryption information, and the login bindings for the request sender and to view a listing of key locators in the key store.

The binding information for the request sender that is specified for the client must match the binding information for the request receiver that is specified for the server.

*Response Receiver Binding:*

Specifies the binding configuration used to receive response messages from the response sender.

Click **Edit** to configure the signing and encryption information, and to view a list of trust anchors, intermediate certificates found in the collection certificate store, and the key locator objects for the response receiver.

The binding information for the response receiver that is specified for the client must match the binding information for the response sender that is specified for the server.

*HTTP Basic Authentication:*

Specifies the user ID and password to use for this port with HTTP transport-level basic authentication. You can enable transport-level authentication security independently of message-level security.

Click **Edit** to configure the basic authentication ID and password for transport-level authentication.

*HTTP SSL Configuration:*

Enables and configures transport-level Secure Socket Layer (SSL) security for this port. You can enable transport-level SSL security independently of message-level security.

Click **Edit** to specify the settings for transport-level HTTP SSL configuration for this port.

*Web services: Server security bindings collection:*

Use this page to view a list of server-side binding configurations for Web services security.

To view this administrative console page, complete the following steps:

1. Click **Enterprise Applications** > *application\_name*.
2. Under Related Items, click **Web Module** > *URI\_file\_name* > **Web Services: Server Security Bindings**.

*Port:*

Specifies the port in which messages are received from the request sender.

*Web Service:*

Specifies the name of the Web service.

*Request Receiver Binding:*

Specifies the binding configuration used to receive request messages from the request sender.

Click **Edit** to configure the signing information and encryption information and view a listing of trust anchors, intermediate certificates in the collection certificate store, key locators, trusted ID evaluators, and login mappings.

The binding information (for the request receiver) specified for the server must match the binding information (for the request sender) specified for the client.

*Response Sender Binding:*

Specifies the binding configuration used to send request messages to the response receiver.

Click **Edit** to configure the signing and encryption information, and to view a list of key locator objects for the response sender.

The binding information (for the response sender) specified for the server must match the binding information (for the response receiver) specified for the client.

## **Trust anchors**

A *trust anchor* specifies key stores that contain trusted root certificates that validate the signer certificate.

These key stores are used by the request receiver (as defined in the `ibm-webservices-bnd.xmi` file) and the response receiver (as defined in the `ibm-webservicesclient-bnd.xmi` file when Web services is acting as client) to validate the signer certificate of the digital signature. The key stores are critical to the integrity of the digital signature validation. If they are tampered with, the result of the digital signature verification is doubtful and comprised. Therefore, it is recommended that you secure these key stores. The binding configuration specified for the request receiver in the `ibm-webservices-bnd.xmi` file must match the binding configuration for the response receiver in the `ibm-webservicesclient-bnd.xmi` file.

The trust anchor is defined as `javax.security.cert.TrustAnchor` in the Java CertPath application programming interface (API). The Java CertPath API uses the trust anchor and the certificate store to validate the incoming X.509 certificate that is embedded in the SOAP message.

The Web services security implementation in WebSphere Application Server supports this trust anchor. In WebSphere Application Server, the trust anchor is represented as a Java key store object. The type, path, and password of the key store are passed to the implementation through the administrative console or by scripting.

## **Configuring trust anchors using the Assembly Toolkit**

This document describes how to configure trust anchors or trust stores at the application level. It does not describe how to configure trust anchors at the server or cell level. Trust anchors defined at the application level have a higher precedence over trust anchors defined at the server or cell level. You can configure an application-level trust anchor using the Assembly Toolkit or the administrative console. This document describes how to configure the application-level trust anchor using the Assembly Toolkit. For more information on creating and configuring trust anchors at the server or cell level, see either *Configuring the server security bindings using the Assembly Toolkit* or *Configuring the server security bindings using the administrative console*.

A trust anchor specifies key stores that contain trusted root certificates, which validate the signer certificate. These key stores are used by the request receiver (as defined in the `ibm-webservices-bnd.xml` file) and the response receiver (as defined in the `ibm-webservicesclient-bnd.xml` file when Web services is acting as client) to validate the signer certificate of the digital signature. The key stores are critical to the integrity of the digital signature validation. If they are tampered with, the result of the digital signature verification is doubtful and comprised. Therefore, it is recommended that you secure these key stores. The binding configuration specified for the request receiver in the `ibm-webservices-bnd.xml` file must match the binding configuration for the response receiver in the `ibm-webservicesclient-bnd.xml` file.

The steps in this document assume that you have already created a Web services-enabled Java 2 Platform, Enterprise Edition (J2EE) with Java Specification Requests (JSR) 109 enterprise application. If you have not created a Web services-enabled J2EE with JSR 109 enterprise application, see *Developing Web services*. Also, see either *Configuring the server security bindings using the Assembly Toolkit* or *Configuring the server security bindings using the administrative console* for an introduction on how to manage Web services security binding information on the server.

1. Configure the client-side response receiver, which is defined in the `ibm-webservicesclient-bnd.xml` bindings extensions file.
  - a. Launch the Assembly Toolkit and click **Windows > Open Perspective > J2EE**.
  - b. Select the Web services-enabled Enterprise JavaBeans (EJB) or Web module.
  - c. In the Package Explorer window, click the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
  - d. Right-click the `webservicesclient.xml` file, select **Open With > Web Services Client Editor**, and click the **Web Services Client Binding** tab. The Web Services Client Binding editor is displayed.
  - e. Locate the Port Qualified Name Binding section and either select an existing entry or click **Add**, to add a new port binding. The Web Services Client Port Binding editor displays for the selected port.
  - f. Locate the Trust Anchor section and click **Add**. The Trust Anchor dialog box is displayed.
    - 1) Enter a unique name within the port binding for the **Trust anchor name**.  
The name is used to reference the trust anchor that is defined.
    - 2) Enter the key store password, path, and key store type.  
The supported key store types are Java Cryptography Extension (JCE) and JCEKS.Click **Edit** to edit the selected trust anchor.  
Click **Remove** to remove the selected trust anchor.  
When you start the application, the configuration is validated in the run time while the binding information is loading.
  - g. Save the changes.
2. Configure the server-side request receiver, which is defined in the `ibm-webservices-bnd.xml` bindings extensions file.
  - a. Launch the Assembly Toolkit and click **Windows > Open Perspective > J2EE**.
  - b. Select the Web services enabled EJB or Web module.
  - c. In the Package Explorer window, click the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
  - d. Right-click the `webservices.xml` file, select **Open With > Web Services Editor**, and click the **Bindings** tab. The Web Services Bindings editor is displayed.
  - e. Locate the Web Service Description Bindings section and either select an existing entry or click **Add** to add a new Web services descriptor.
  - f. Click **Binding Configurations**. The Web Services Binding Configurations editor is displayed for the selected Web services descriptor.
  - g. Locate the Trust Anchor section and click **Add**. The Trust Anchor dialog box is displayed.
    - 1) Enter a unique name within the binding for the **Trust anchor name**.  
This unique name is used to reference the trust anchor defined.

- 2) Enter the key store password, path, and key store type. The supported key store types are JCE and JCEKS.

Click **Edit** to edit the selected trust anchor.

Click **Remove** to remove the selected trust anchor.

When you start the application, the configuration is validated in the run time while the binding information is loading.

- h. Save the changes.

This procedure defines trust anchors that can be used by the request receiver or the response receiver (if the Web services is acting as client) to verify the signer certificate.

The request receiver or the response receiver (if the Web service is acting as a client) uses the defined trust anchor to verify the signer certificate. The trust anchor is referenced using the trust anchor name.

To complete the signing information configuration process for request receiver, complete the following tasks:

1. Configure the server for request digital signature verification: Verifying the message parts
2. Configure the server for request digital signature verification: Choosing the verification method

To complete the process for the response receiver, if the Web services is acting as a client, complete the following tasks:

1. Configure the client for response digital signature verification: Verifying the message parts
2. Configure the client for response digital signature verification: Choosing the verification method

## Configuring trust anchors using the administrative console

This document describes how to configure trust anchors or trust stores at the application level. It does not describe how to configure trust anchors at the server or cell level. Trust anchors defined at the application level have a higher precedence over trust anchors defined at the server or cell level. For more information on creating and configuring trust anchors at the server or cell level, see either *Configuring the server security bindings using the Application Server Toolkit* or *Configuring the server security bindings using the administrative console*.

You can configure an application-level trust anchor using the Application Server Toolkit or the administrative console. This document describes how to configure the application-level trust anchor using the administrative console.

A trust anchor specifies key stores that contain trusted root certificates, which validate the signer certificate. These key stores are used by the request receiver (as defined in the `ibm-webservices-bnd.xmi` file) and the response receiver (as defined in the `ibm-webservicesclient-bnd.xmi` file when Web services is acting as client) to validate the signer certificate of the digital signature. The keystores are critical to the integrity of the digital signature validation. If they are tampered with, the result of the digital signature verification is doubtful and comprised. Therefore, it is recommended that you secure these keystores. The binding configuration specified for the request receiver in the `ibm-webservices-bnd.xmi` file must match the binding configuration for the response receiver in the `ibm-webservicesclient-bnd.xmi` file.

The steps in this document assume that you have already created a Web services-enabled Java 2 Platform, Enterprise Edition (J2EE) with Java Specification Requests (JSR) 109 enterprise application. If you have not created a Web services-enabled J2EE with JSR 109 enterprise application, see *Developing Web services*. Also, see either *Configuring the server security bindings using the Application Server Toolkit* or *Configuring the server security bindings using the administrative console* for an introduction on how to manage Web services security binding information for the server.

The following steps are for the client-side response receiver, which is defined in the `ibm-webservicesclient-bnd.xmi` file and the server-side request receiver, which is defined in the `ibm-webservices-bnd.xmi` file.

1. Click **Applications > Enterprise Applications > *enterprise\_application***.
2. In the Related Links section, click either **EJB Modules** or **Web Modules** and then click the Web services-enabled module in the **Uri** field.
3. Under Additional Properties, click **Web Services: Client Security Bindings** to edit the response receiver binding information, if Web services is acting as a client.
  - a. Under Response Receiver Binding, click **Edit**.
  - b. Under Additional Properties, click **Trust Anchors**.
  - c. Click **New** to create a new trust anchor.
  - d. Enter a unique name within the request receiver binding for the **Trust anchor name** field. The name is used to reference the trust anchor that is defined.
  - e. Enter the key store password, path, and key store type.
  - f. Click the trust anchor name link to edit the selected trust anchor.
  - g. Click **Remove** to remove the selected trust anchor or anchors.

When you start the application, the configuration is validated in the run time while the binding information is loading.
4. Return to the Web services-enabled module panel accessed in step 2.
5. Under Additional Properties, click **Web Services: Server Security Bindings** to edit the request receiver binding information.
  - a. Under Request Receiver Binding, click **Edit**.
  - b. Under Additional Properties, click **Trust Anchors**.
  - c. Click **New** to create a new trust anchor  
Enter a unique name within the request receiver binding for the **Trust anchor name** field. The name is used to reference the trust anchor that is defined.  
Enter the key store password, path, and key store type.  
Click the trust anchor name link to edit the selected trust anchor.  
Click **Remove** to remove the selected trust anchor or anchors.  
When you start the application, the configuration is validated in the run time while the binding information is loading.
6. Save the changes.

This procedure defines trust anchors that can be used by the request receiver or the response receiver (if the Web services is acting as client) to verify the signer certificate.

The request receiver or the response receiver (if the Web service is acting as a client) uses the defined trust anchor to verify the signer certificate. The trust anchor is referenced using the trust anchor name.

To complete the signing information configuration process for request receiver, complete the following tasks:

1. Configure the server for request digital signature verification: Verifying the message parts
2. Configure the server for request digital signature verification: Choosing the verification method

To complete the process for the response receiver, if the Web services is acting as client, complete the following tasks:

1. Configure the client for response digital signature verification: Verifying the message parts
2. Configure the client for response digital signature verification: Choosing the verification method

### ***Trust anchors collection:***

Use this page to view a list of keystore objects that contain trusted root certificates. These objects are used for certificate path validation of incoming X.509-formatted security tokens. Keystore objects within trust anchors contain trusted root certificates used by the CertPath API to validate the trust of a certificate chain.

To create the keystore file, use the key tool located in the `install_dir\java\jre\bin\keytool` directory.

To view this administrative console page, click **Servers > Application Servers > *server\_name***. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Trust Anchors**.

Click **New** to create a new trust anchor.

Click **Delete** to delete a trust anchor.

If you click **Update runtime**, the Web services security run time is updated with the default binding information, which is contained in the `ws-security.xml` file that was previously saved. If you make changes on this panel, you must complete the following steps:

1. Save your changes by clicking **Save** at the top of the administrative console. When you click **Save**, you are returned to the administrative console home panel.
2. Return to the Trust Anchors collection panel and click **Update runtime**. When you click **Update runtime**, the configuration changes made to the other Web services also are updated in the Web services security run time.

*Trust Anchor Name:*

Specifies the unique name used to identify the trust anchor.

*Key Store Path:*

Specifies the location of the keystore file that contains the trust anchors.

*Key Store Type:*

Specifies the type of keystore file.

The value for this field is either **JKS** or **JCEKS**.

#### ***Trust anchor configuration settings:***

Use this information to configure a trust anchor. Trust anchors point to key stores that contain trusted root or self-signed certificates. This information enables you to specify a name for the trust anchor and the information needed to access a key store. The application binding uses this name to reference a predefined trust anchor definition in the binding file (or the default).

To view this administrative console page, complete the following steps:

1. Click **Servers > Application Servers > *server\_name***.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Trust Anchors > New**.

*Trust Anchor Name:*

Specifies the unique name used by the application binding to reference a predefined trust anchor definition in the default binding.

#### *Key Store Password:*

Specifies the password needed to access the key store file.

#### *Key Store Path:*

Specifies the location of the keystore file.

Use `${USER_INSTALL_ROOT}` as this path expands to the WebSphere Application Server path on your machine.

#### *Key Store Type:*

Specifies the type of key store file.

The value in this field is either **JKS** or **JCEKS**.

**JKS** Specify this option if you are not using Java Cryptography Extensions (JCE).

#### **JCEKS**

Specify this option if you are using Java Cryptography Extensions. Although the JCEKS key store format is more secure, it decreases performance.

<b>Data type</b>	String
<b>Default</b>	JKS
<b>Range</b>	JKS, JCEKS

### **Collection certificate store**

A *collection certificate store* is a collection of nonroot, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs is used to check the signature of a digitally signed SOAP message.

The collection certificate stores are used when processing a received SOAP message. This collection is configured in the `securityRequestReceiverBindingConfig` section of the binding file for servers and in the `securityResponseReceiverBindingConfig` section of the binding file for clients.

A collection certificate store is one kind of certificate store. A certificate store is defined as `javax.security.cert.CertStore` in the Java CertPath application programming interface (API). The Java CertPath API defines the following types of certificate stores:

#### **Collection certificate store**

A collection certificate store accepts the certificates and CRLs as Java collection objects.

#### **Lightweight Directory Access Protocol certificate store**

The Lightweight Directory Access Protocol (LDAP) certificate store accepts certificates and CRLs as LDAP entries.

The CertPath API uses the certificate store and the trust anchor to validate the incoming X.509 certificate that is embedded in the SOAP message.

The Web services security implementation in the WebSphere Application Server supports the collection certificate store. Each certificate and CRL is passed as an encoded file. This configuration is done using either the administrative console or by scripting.

### **Configuring the client-side collection certificate store using the Assembly Toolkit**

A collection certificate store is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs are used to check the signature of a digitally signed SOAP message.

You can configure the collection certificate either by using the Assembly Toolkit or the WebSphere Application Server administrative console. Complete the following steps to configure the client-side collection certificate store using the Assembly Toolkit.

1. Launch the Assembly Toolkit and either click **Windows > Open Perspective > J2EE**.
2. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
3. In the Package Explorer window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
4. Right-click the **webservicesclient.xml** file and select **Open With > Web Services Client Editor**.
5. Click the **Port Binding** tab in the Web Services Client Editor within the Assembly Toolkit. The Web Services Client Port Binding window is displayed.
6. Select one of the Port Qualified Name Binding entries.
7. Expand the **Security Response Receiver Binding Configuration > Certificate Store List > Collection Certificate Store** section.
8. Click **Add** to create a new collection certificate store, click **Edit** to edit an existing certificate store, or click **Remove** to delete an existing certificate store.
9. Enter a name in the **Name** field. This name is referenced in the **Certificate store reference** field in the Signing info dialog box.
10. Leave the **Provider** field as IBM CertPath.
11. Click **Add** to enter the path to your certificate store. For example, the path might be: `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`. If you have additional certificate store paths, click **Add** to add the paths.
12. Click **OK** when you finish adding paths.

## Configuring the client-side collection certificate store using the administrative console

A collection certificate store is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs are used to check the signature of a digitally signed SOAP message.

You can configure the collection certificate either by using the WebSphere Application Server Toolkit or the WebSphere Application Server administrative console. Complete the following steps to configure the client-side collection certificate store using the administrative console.

1. Connect to the WebSphere Application Server administrative console. You can connect to the administrative console by typing `http://localhost:9090/admin` in your Web browser unless you have changed the port number.
2. Click **Applications > Enterprise Applications > *application\_name***.
3. Under Related Items, click either **Web Modules** or **EJB Modules** depending on the type of module you are securing.
4. Click the name of the module you are securing.
5. Under Additional Properties, click either **Web Services: Client Security Bindings** to add the collection certificate store to the client security bindings. If you do not see any entries, return to the WebSphere Application Server Toolkit and configure the security extensions for either the client or the server.

To configure the security extensions for the client, see the following topics:

- Configuring the client for response digital signature verification: Verifying the message parts
  - Configuring the client for response digital signature verification: Choosing the verification method
6. Under Response Receiver Binding, click **Edit** to edit the client security bindings.
  7. Click **Collection Certificate Store**.

8. Click a Certificate Store Name to edit an existing certificate store or click **New** to add a new certificate store name.
9. Enter a name in the **Certificate Store Name** field. The name entered in this field is a name that is referenced in the **Certificate Store** field on the Signing information configuration page.
10. Leave the **Certificate Store Provider** field value as IBM CertPath.
11. Click **Apply**.
12. Under Additional Properties, click **X.509 Certificates > New**.
13. Enter the path to your certificate store. For example, the path might be: `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`. If you have any additional certificate store paths to enter, click **New** and add the path names.
14. Click **OK**.

## Configuring the server-side collection certificate store using the Assembly Toolkit

A collection certificate store is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs are used to check the signature of a digitally signed SOAP message.

You can configure the collection certificate either by using the Assembly Toolkit or the WebSphere Application Server administrative console. Complete the following steps to configure the server-side collection certificate store using the Assembly Toolkit.

1. Launch the Assembly Toolkit and click **Windows > Open Perspective > J2EE**.
2. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
3. In the Package Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
4. Right-click the `webservices.xml` file, select **Open With > Web Services Editor**.
5. Click the **Binding Configurations** tab in the Web services editor within the Assembly Toolkit. The Web Service Binding Configuration window is displayed.
6. Select one of the Web service description binding entries under the Port Component Binding section.
7. Expand the **Request Receiver Binding Configuration Details > Certificate Store List > Collection Certificate Store** section.
8. Click **Add** to create a new collection certificate store, click **Edit** to edit an existing certificate store, or click **Remove** to delete an existing certification store.
9. Enter a name in the **Name** field. This name is referenced in the **Certificate store reference** field in the Signing info dialog.
10. Leave the **Provider** field as IBM CertPath.
11. Click **Add** to enter the path to your certificate store. For example, the path might be: `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`. If you have additional certificate store paths, click **Add** to add the paths.
12. Click **OK** when you finish adding paths.

### **Collection certificate store collection:**

Use this page to view a list of certificate stores containing untrusted, intermediary certificate files awaiting validation. Validation might consist of checking to see if the certificate is on a certificate revocation list (CRL), checking that the certificate has not expired, and checking that the certificate was issued by a trusted signer.

To view this administrative console page, complete the following steps:

1. Click **Servers > Application Servers > server\_name**.

2. Under Related Items, click **Web Services: Default bindings for Web Services Security > Collection Certificate Store**.
3. Click **New** to specify a store name and provider for a new collection certificate store.
4. Click **Delete** to delete a collection certificate store.

Using this panel, complete the following steps:

1. Specify a certificate store name and certificate store provider.
2. Save your changes by clicking **Save** at the top of the administrative console. When you click **Save**, you return to the administrative console home panel.
3. Return to the collection certificate store collection panel and click **Update runtime** to update the Web services security run time with the default binding information, which is found in the `ws_security.xml` file.

When you click **Update runtime**, the configuration changes made to the other Web services also are updated in the Web services security run time.

*Certificate Store Name:*

Specifies the name of the certificate store.

*Certificate Store Provider:*

Specifies the provider of the certificate store.

#### **Collection certificate store configuration settings:**

Use this page to specify the name and provider of a certificate store.

To view this administrative console page, complete the following steps:

1. Click **Servers > Application Servers > *server\_name***.
2. Under **Additional Properties**, click **Web Services: Default bindings for Web Services Security > Collection Certificate Store > New**.

*Certificate Store Name:*

Specifies the name for the certificate store. The application binding uses the certificate store name to reference a predefined binding.

*Certificate Store Provider:*

Specifies the provider for the certificate store implementation.

<b>Data type</b>	String
<b>Default</b>	IBM CertPath

#### **X.509 certificates collection:**

Use this page to view a list of X.509 certificates.

To view this administrative console page, complete the following steps:

1. Click **Servers > Application Servers > *server\_name***.
2. Under **Additional Properties**, click **Web Services: Default bindings for Web Services Security > Collection Certificate Store**.

3. On the Collection Certificate Store page under Additional Properties, click **X.509 Certificates**.
4. Click **New** to create a new path to an X.509 certificate or click **Delete** to delete a path to an X.509 certificate.

*X509 Certificate Path:*

Specifies the location of the X.509 certificate.

#### ***X.509 certificate configuration settings:***

Use this page to specify the location of your X.509 certificates.

To view this administrative console page, complete the following steps:

1. Click **Servers > Application Servers > *server\_name***.
2. Under **Additional Properties**, click **Web Services: Default bindings for Web Services Security > Collection Certificate Store**.
3. On the Collection Certificate Store page, under **Additional Properties**, click **X.509 Certificates > New**.

*X509 Certificate Path:*

Specifies the location of the X.509 certificate.

## **Configuring the server-side collection certificate store using the administrative console**

A *collection certificate store* is a collection of nonroot, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs is used to check the signature of a digitally signed SOAP message.

You can configure the collection certificate either by using the WebSphere Application Server Toolkit or the WebSphere Application Server administrative console. Complete the following steps to configure the server-side collection certificate store using the administrative console.

1. Connect to the WebSphere Application Server administrative console. You can connect to the administrative console by typing `http://localhost:9090/admin` in your Web browser unless you have changed the port number.
2. Click **Applications > Enterprise Applications > *application\_name***.
3. Under Related Items, click either **Web Modules** or **EJB Modules** depending on the type of module you are securing.
4. Click the name of the module you are securing.
5. Under Additional Properties, click **Web Services: Server Security Bindings** to add the collection certificate store to the server security bindings. If you do not see any entries, return to the WebSphere Application Server Toolkit and configure the security extensions for the server.

To configure the security extensions for the server, see the following topics:

- Configuring the server for request digital signature verification: verifying the message parts
  - Configuring the server for request digital signature verification: choosing the verification method
6. Click **Edit** under Request Receiver Binding to edit the server security bindings.
  7. Click **Collection Certificate Store**.
  8. Click a Certificate Store Name to edit an existing certificate store or click **New** to add a new certificate store name.
  9. Enter a name in the **Certificate Store Name** field. The name entered in this field is a name that is referenced in the **Certificate Store** field on the Signing information configuration page.

10. Leave the **Certificate Store Provider** field as IBM CertPath.
11. Click **Apply**.
12. Under Additional Properties, click **X.509 Certificates > New**.
13. Enter the path to your certificate store. For example, the path might be: `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`. If you have any additional certificate store paths to enter, click **New** and add the path names.
14. Click **OK**.

## Configuring default collection certificate stores at the server level in the WebSphere Application Server administrative console

A collection certificate store is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs are used to check the signature of a digitally signed SOAP message. A certificate store typically refers to a certificate store located in the file system. The location of the certificate store can vary from machine to machine, so you might configure a default collection certificate store for a specific machine and reference it from within the signing information. The signing information is found within the binding configurations of any application installed on the machine. This suggestion enables you to define a single collection certificate store for all of the applications that need to use the same certificates. You also can specify the default binding information at the cell level.

Complete the following steps to configure the default collection certificate store at the server level using the WebSphere Application Server administrative console:

1. Connect to the administrative console. You can access the administrative console by typing `http://localhost:9090/admin` in your Web browser unless you have changed the port number.
2. Click **Servers > Application Servers > server1**.
3. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Collection Certificate Store**.
4. Enter a name in the **Certificate Store Name** field. This name is referenced in the Certificate Store field on the Signing information configuration page.
5. Leave the **Certificate Store Provider** field value as IBM CertPath.
6. Click **Apply**.
7. Under Additional Properties, click **X.509 Certificates > New**.
8. Enter the path to your certificate store. For example, the path might be: `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`.  
If you have any additional certificate store paths to enter, click **New** and add the path names.
9. Click **OK**.

### Key locator

A *key locator* (`com.ibm.wsspi.wssecurity.config.KeyLocator`) is an abstraction of the mechanism that retrieves the key for digital signature and encryption.

You can use any of the following infrastructure from which to retrieve the keys depending upon the implementation:

- Java keystore file
- Database
- Lightweight Third Party Authentication (LDAP) server

Key locators search the key using some type of a clue. The following types of clues are supported:

- A string label of the key, which is explicitly passed through the application programming interface (API). The relationships between each key and its name (string label) is maintained inside the key locator.

- The execution context of the key locator; explicit information is not passed to the key locator. A key locator determines the appropriate key according to the execution context.

Current versions of key locators do not support the retrieval of verification keys because current Web services security implementations do not support the secret key-based signature. Because the key locators support the public key-based signature only, the key for verification is embedded in the X.509 certificate as a <BinarySecurityToken> element in the incoming message.

For example, key locators can obtain the identity of the caller from the context and can retrieve the public key of the caller for response encryption.

## Usage scenarios

This section describes the usage scenarios for key locators.

### Signing

The name of the signing key is specified in the Web services security configuration. This value is passed to the key locator and the actual key is returned. The corresponding X.509 certificate also can be returned.

### Verification

As described previously, key locators are not used in signature verification.

### Encryption

The name of the encryption key is specified in the Web services security configuration. This value is passed to the key locator and the actual key is returned.

### Decryption

The Web services security specification recommends using the key identifier instead of the key name. However, while the algorithm for computing the identifier for the public keys is defined in Internet Engineering Task Force (IETF) Request for Comment (RFC) 3280, there is no agreed upon algorithm for the secret keys. Therefore, the current implementation of Web services security uses the identifier only when public key-based encryption is performed. Otherwise, the ordinal key name is used.

When you use public key-based encryption, the value of the key identifier is embedded in the incoming encrypted message. Then, the Web services security implementation searches for all the keys managed by the key locator and decrypts the message using the key whose identifier value matches the one in the message.

When you use secret key-based encryption, the value of the key name is embedded in the incoming encrypted message. The Web services security implementation asks the key locator for the key with the name that matches the name in the message and decrypts the message using the key.

### ***Key locator collection:***

Use this page to view a list of available key locators. Key locators identify the keys needed for digital signature and encryption. A key locator must implement the `com.ibm.wsspi.wssecurity.config.KeyLocator` interface. The two default implementations are:

`com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator` and  
`com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator`.

To view this administrative console page, complete the following steps:

1. Click **Servers > Application Servers > *server\_name***.

2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Key Locators**.
3. Click **New** to create a key locator. Click **Delete** to delete a key locator.

Using this **Key Locator collection** panel, complete the following steps:

1. Specify a key locator name and key locator class name on the panel
2. Save your changes by clicking **Save** at the top of the administrative console. The administrative console home panel is displayed.
3. After saving your changes, return to the **Key Locator collection** panel to update the Web services security run time with the default binding information, which is found in the `ws_security.xml` file.
4. To update the Web services security run time, click **Update runtime**. When you click **Update runtime**, the configuration changes made to the other Web services also are updated in the Web services security run time.
5. After you define key locators, click the key locator name to specify additional properties and keys under **Additional Properties**.

*Key Locator Name:*

Specifies the unique name of the key locator.

*Key Locator Classname:*

Specifies the class name of the key locator in the key store file.

#### **Key locator configuration settings:**

Use this page to specify the settings for key locators.

To view this administrative console page, complete the following steps:

1. Click **Servers > Application Servers > server\_name**.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Key Locators > New**.

*Key Locator Name:*

Specifies the name of the key locator.

**Data type** String

*Key Locator Classname:*

Specifies the name for the key locator class implementation.

WebSphere Application Server has the following default key locator class implementations:

#### **com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator**

Maps an authenticated identity to a key. This class is used by the response sender. If encryption is used, this class is used to locate a key to encrypt the response message. The `com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator` class has the capability to map an authenticated identity from the invocation credential of the current thread to a key that is used to encrypt the message. If an authenticated identity is present on the current thread, the class maps the ID to the mapped name. For example, `user1` is mapped to `mappedName_1`. Otherwise, `name="default"`. When a matching key is not found, the authenticated identity is mapped to the default key specified in the binding file.

## **com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator**

Maps a name to an alias. This class is used by the response receiver, request sender, and request receiver. The encryption process uses this class to obtain a key to encrypt a message, and the digital signature process uses this class to obtain a key to sign a message. The `com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator` class maps a logical name to a key alias in the keystore file. For example, key #105115176771 is mapped to CN=Alice, O=IBM, c=US.

<b>Data type</b>	String
<b>Defaults</b>	<code>com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator</code>  <code>com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator</code>

### *Key Store Password:*

Specifies the password used to access the keystore file.

### *Key Store Path:*

Specifies the location of the keystore file.

Use `${USER_INSTALL_ROOT}` as this path expands to the WebSphere Application Server path on your machine.

### *Key Store Type:*

Specifies the type of keystore file.

The value for this field is either JKS or JCEKS:

**JKS** Use this option if you are not using Java Cryptography Extensions (JCE).

#### **JCEKS**

Use this option if you are using Java Cryptography Extensions.

<b>Default</b>	JKS
<b>Range</b>	JKS, JCEKS

## **Keys**

Keys are used for XML signature and encryption.

There are two predominant kinds of keys used in the current Web services security implementation:

- Public key - such as Rivest Shamir Adleman (RSA) encryption and Digital Signature Algorithm (DSA) encryption
- Secret key - such as Data Encryption Standard (DES) encryption

In public key-based signature, a message is signed using sender private key and is verified using the sender public key. In public key-based encryption, a message is encrypted using the receiver public key and is decrypted using the receiver private key. In secret key-based signature and encryption, the same key is used by both parties.

While the current implementation of Web services security can support both kinds of keys, there are a few items to note:

- Secret key-based signature is not supported.
- The format of the message differs slightly between public key-based encryption and secret key-based encryption.

### **Key collection:**

Use this page to view a list of logical names that are mapped to a key alias in the key store file.

To view this administrative console page, complete the following steps:

1. Click **Servers > Application Servers > *server\_name***.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Key Locators > *key\_locator\_name***.
3. Under Additional Properties, click **Keys**.
4. Click **New** to create a new key object in the key store file.
5. Click **Delete** to delete a mapping of a key object within the key store file.

*Key Name:*

Specifies the name of the key object found in the key store file.

*Key Alias:*

Specifies an alias for the key object.

The alias is used when the key locator searches for the key objects in the key store.

### **Key configuration settings:**

Use this page to define the mapping of a logical name to a key alias in a key store file.

To view this administrative console page, complete the following steps:

1. Click **Servers > Application Servers > *server\_name***.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Key Locators > *key\_locator\_name***.
3. Under Additional Properties, click **Keys > New**.

*Key Name:*

Specifies the name of the key object. This name is used by the key locator to find the key within the key store file.

*Key Alias:*

Specifies the alias for the key object contained in the key store file.

*Key Password:*

Specifies the password needed to access the key object within the key store file.

## **Web services security service provider programming interfaces**

Several Service Provider Interfaces (SPIs) are provided to extend the capability of the Web services security run time. The following list contains the SPIs that are available for WebSphere Application Server:

- `com.ibm.wsspi.wssecurity.config.KeyLocator` is an abstract for obtaining the keys for digital signature and encryption. The following list contains the default implementations:
  - `com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator`  
Implements the Java key store.
  - `com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator`

Provides a mapping of the authenticated identity to a key for encryption. Or, the implementation uses the default key that is specified. This implementation is typically used in the response sender configuration.

- `com.ibm.wsspi.wssecurity.config.CertInRequestKeyLocator`

Provides the capability of using the signer key for encryption in the response message. This implementation is typically used in the response sender configuration.

- `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` is an interface that is used to evaluate the trust for identity assertion. The default implementation is `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl`, which enables you to define a list of trusted identities.
- The Java Authentication and Authorization Service (JAAS) CallbackHandler application programming interfaces (APIs) are used for token generation by the request sender. This interface can be extended to generate a custom token that can be inserted in the Web services security header. The following list contains the default implementations that are provided by WebSphere Application Server:
  - `com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler`  
Presents a login prompt to gather the basic authentication data. Use this implementation in the client environment only.
  - `com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler`  
Collects the basic authentication data in the standard in (stdin) prompt. Use this implementation in the client environment only.
  - `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler`  
Reads the basic authentication data from the application binding file. This implementation might be used on the server side to generate a user name token.
  - `com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler`  
Generates a Lightweight Third Party Authentication (LTPA) token in the Web services security header as a binary security token. If basic authentication data is defined in the application binding file, it is used to perform a login, to extract the LTPA token from the WebSphere credentials, and to insert the token in the Web services security header. Otherwise, it will extract the LTPA security token from the invocation credentials (run as identity) and insert the token in the Web services security header.

The JAAS LoginModule API is used for token validation on the request receiver side of the message. You can implement a custom LoginModule API to perform validation of the custom token on the request receiver of the message. After the token is verified and validated, the token is set as the caller and then run as the identity in the WebSphere Application Server run time. The identity is used for authorization checks by the containers before a Java 2 Platform, Enterprise Edition (J2EE) resource is invoked. The following list presents the are the default AuthMethod configurations provided by WebSphere Application Server:

#### **BasicAuth**

Validates a user name token.

#### **Signature**

Maps the distinguished name (DN) of a verified certificate to a Java Authentication and Authorization Service (JAAS) subject.

#### **IDAssertion**

Maps a trusted identity to a JAAS subject.

**LTPA** Validates an LTPA token that is received in the message and creates a JAAS subject.

## **Configuring key locators using the Assembly Toolkit**

This task provides instructions on how to configure key locators using the Assembly Toolkit. You can configure key locators in various locations within the Assembly Toolkit. This task provides instructions on how to configure key locators at any of these locations because the concept is the same.

1. Launch the Assembly Toolkit and click **Windows > Open Perspective > J2EE**.
2. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
3. In the Package Explorer window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
4. Right-click the **webservicesclient.xml** file and click **Open With > Web Services Client Editor** or right-click the **webservices.xml** file and click **Open With > Web Services Editor**.
5. Click the **Port Binding** tab in the Web Services Client Editor within the Assembly Toolkit or the **Binding Configurations** tab in the Web Services Editor within the Assembly Toolkit.
6. Expand one of the **Binding Configuration** sections.
7. Expand the **Key Locators** section.
8. Click **Add** to create a new key locator, click **Edit** to edit an existing key locator, or click **Remove** to delete an existing key locator.
9. Enter a key locator name. The name entered for the **Key locator name** is used to refer to the key locator from the Encryption information and Signing Information sections.
10. Enter a key locator class. The key locator class is the implementation of the KeyLocator interface. When using default implementations, select a class from the menu.
11. Determine whether to click **Use key store**. Select this option when you use the default implementations as they use key stores. If you click **Use key store**, complete the following steps:
  - a. Enter a value in the **key store storepass** field. The key store storepass is the password used to access the key store.
  - b. Enter a path name in the **key store path** field. The key store path is the location on the file system where the key store resides. Make sure that the location can be found wherever you deploy the application.
  - c. Enter a type value in the **key store type** field. The valid types to enter are JKS and JCEKS. JKS is used when you are not using Java Cryptography Extensions (JCE). JCEKS is used when you are using JCE. Although the JCEKS type is more secure, it might decrease performance.
  - d. Click **Add** to create an entry for a key in the key store.
    - 1) Enter a value in the **Alias** field.  
The key alias is a reference to this particular key from the Signing Information section.
    - 2) Enter a value in the **Key pass** field.  
The key pass is the password associated with the certificate which is created using the Development Kit, Java Technology Edition keytool.exe file.
    - 3) Enter a value in the **Key name** field.  
The key name refers to the alias of the certificate as found in the key store.
12. Click **Add** to create a custom property. The property can be used by custom key locator implementations. For example, you can use properties with the WsIdKeyStoreMapKeyLocator default implementation. The key locator implementation has the following property names:
  - *id\_*, which maps to a credential user ID.
  - *mappedName\_*, which maps to the key alias to use for this user name.
  - *default*, which maps to a key alias to use when a credential does not have an associated *id\_* entry.

A typical set of properties for this key locator might be: `id_1=user1, mappedName_1=key1, id_2=user2, mappedName_2=key2, default=key3`. If user1 or user2 authenticates, then the associated key1 or key2 is used, respectively. However, if none of the user properties authenticate or the user is not user1 or user2, then key3 is used.

  - a. Enter a name in the **Name** field. The name entered is the property name.
  - b. Enter a value in the **Value** field. This value entered is the property value.

## Configuring key locators using the administrative console

This task provides instructions on how to configure key locators using the WebSphere Application Server administrative console. You can configure binding information in the administrative console. You must use the Assembly Toolkit to configure extensions. The following steps are used to configure a key locator in the administrative console for a specific application:

1. Connect to the administrative console by typing `http://:9090/admin` in your Web browser unless you have changed the port number.
2. Click **Applications > Enterprise Applications > *application\_name***.
3. Under Related Items, click either **Web Modules** or **EJB Modules**, depending on the type of module you are securing.
4. Click the name of the module you are securing.
5. Under Additional Properties, click either **Web Services: Client Security Bindings** or **Web Services: Server Security Bindings**, depending on whether you are adding the key locator to the client security bindings or to the server security bindings. If you do not see any entries, return to the Assembly Toolkit and configure the security extensions.
6. Edit the Request Sender Binding, Response Receiver Binding, Request Receiver Binding, or Response Sender Binding.
  - If you are editing your client security bindings, click **Edit** for either the Request Sender Binding or the Response Receiver Binding.
  - If you are editing your server security bindings, click **Edit** for either the Request Receiver Binding or the Response Sender Binding.
7. Click **Key Locators**.
8. Click **New** to configure a new key locator, select the box next to a key locator name and click **Delete** to delete a key locator, or click the name of a key locator to edit its configuration. If you are configuring a new key locator or editing an existing one, complete the following steps:
  - a. Specify a name for the key locator in the **Key Locator Name** field.
  - b. Specify a name for the key locator class implementation in the **Key Locator Classname** field. WebSphere Application Server has the following default key locator class implementations:

### **com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator**

This class is used by the response sender to map an authenticated identity to a key. If encryption is used, this class is used to locate a key to encrypt the response message. The `com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator` class has the capability to map an authenticated identity from the invocation credential of the current thread to a key that is used to encrypt the message. If an authenticated identity is present on the current thread, the class maps the ID to the mapped name. For example, `user1` is mapped to `mappedName_1`. Otherwise, `name="default"`. When a matching key is not found, the authenticated identity is mapped to the default key specified in the binding file.

### **com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator**

This class is used by the response receiver, the request sender, and the request receiver to map a name to an alias. Encryption uses this class to obtain a key to encrypt a message and digital signature uses this class to obtain a key to sign a message. The `com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator` class maps a logical name to a key alias in the key store file. For example, `key #105115176771` maps to `CN=Alice, O=IBM, C=US`.

- c. Specify the password used to access the key store password in the **Key Store Password** field. This field is optional because the key locator does not use a key store.
- d. Specify the path name used to access the key store in the **Key Store Path** field. This field is optional because the key locator does not use a key store. Use `${USER_INSTALL_ROOT}` because this path expands to the WebSphere Application Server path on your machine.

- e. Select a keystore type from the **Key Store Type** field. This field is optional because the key locator does not use a key store. Use the **JKS** option if you are not using Java Cryptography Extensions (JCE) and use **JCEKS** if you are using JCE.

### Trusted ID evaluator

Trusted ID evaluator (com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator) is an abstraction of the mechanism that evaluates whether the given ID name is trusted.

Depending upon the implementation, you can use various types of infrastructure to store a list of the trusted IDs, such as:

- Plain text file
- Database
- Lightweight Directory Access Protocol (LDAP) server

The trusted ID evaluator is typically used by the eventual receiver in a multi-hop environment. The Web services security implementation invokes the trusted ID evaluator and passes the identity name of the intermediary as a parameter. If the identity is evaluated and deemed trustworthy, the procedure continues. Otherwise, an exception is thrown and the procedure is stopped.

#### **Trusted ID evaluator collection:**

Use this page to view a list of trusted identity (ID) evaluators. The trusted ID evaluator determines whether to trust the identity-asserting authority. Once the ID is trusted, the WebSphere Application Server issues the proper credentials, which are used in a downstream call for invoking resources. The trusted ID evaluator implements the com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator interface.

To view this administrative console page, complete the following steps:

1. Click **Servers > Application Servers > server\_name**.
2. Under Additional Services, click **Web Services: Default bindings for Web Services Security > Trusted ID Evaluators**.
3. Click **New** to create a trusted ID evaluator or click **Delete** to delete a trusted ID evaluator.

Using this trusted ID evaluator collection panel, complete the following steps:

1. Specify a trusted ID evaluator name and trusted ID evaluator class name.
2. Save your changes by clicking **Save** at the top of the administrative console. When you click **Save**, you return to the administrative console home panel.
3. Return to the Trusted ID Evaluator collection panel to update the Web services security run time with the default binding information, which is found in the ws\_security.xml file.
4. Click **Update runtime**. The configuration changes made to the other Web services also are updated in the Web services security run time.

#### *Trusted ID Evaluator Name:*

Specifies the unique name of the trusted ID evaluator.

#### *Trusted ID Evaluator Classname:*

Specifies the class name of the trusted ID evaluator.

#### **Trusted ID evaluator configuration settings:**

Use this information to configure trust identity (ID) evaluators.

To view this administrative console page, complete the following steps:

1. Click **Servers > Application Servers > server\_name**.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Trust ID Evaluators > New**.

You must specify the name and value properties for the default trusted ID evaluator to create the trusted ID list for evaluation.

*Trusted ID Evaluator Name:*

Specifies the unique name used by the application binding to refer to a trusted identity (ID) evaluator defined in the default binding.

You must specify the trusted ID evaluator name in the form, `trustedId_n`, where `n` is an integer from 0 to `n`.

*Trusted ID Evaluator Class Name:*

Specifies the class name of the trusted ID evaluator.

**Default**

`com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl`

## Login mappings

Login mappings, found in the `ibm-webservices-bnd.xml` Extended Markup Language (XML) file, contains a mapping configuration. This mapping configuration defines how the Web services security handler maps the token `<ValueType>` element that is contained within the security token extracted from the message header, to the corresponding authentication method. The token `<ValueType>` element is contained within the security token extracted from a SOAP message header.

The sender-side Web services security handler generates and attaches security tokens based on the `<AuthMethods>` element that is specified in the deployment descriptor. For example, if the authentication method is `BasicAuth`, the sender-side security handler generates and attaches `UsernameToken` (with both user name and password) to the SOAP message header. The Web services security run time uses the Java Authentication and Authorization Service (JAAS) `javax.security.auth.callback.CallbackHandler` interface as a security provider to generate security tokens on the client side (or when Web services is acting as client).

The sender security handler invokes the `handle()` method of a `javax.security.auth.callback.CallbackHandler` interface implementation. This implementation creates the security token and passes the token back to the sender security handler. The sender's security handler constructs the security token based on the authentication information in the callback array. The security handler then inserts the security token into the Web Services Security message header.

The `CallbackHandler` interface implementation that you use to generate the required security token is defined in the `<loginBinding>` element in the `ibm-webservicesclient-bnd.xml` Web services security binding file. For example,

```
<loginBinding xmi:id="LoginBinding_1052760331526" authMethod="BasicAuth"
 callbackHandler="com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler"/>
```

The `<loginBinding>` element associates the `com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler` interface with the `BasicAuth` authentication method. WebSphere Application Server provides the following set of `CallbackHandler` interface implementations you can use to create various security token types:

### **com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler**

If there is no basic authentication data defined in the login binding information (this information is not the same as the HTTP basic authentication information), the previous token type prompts for

user name and password through a login panel. The implementation uses the basic authentication data defined in the login binding. Use this CallbackHandler with the BasicAuth authentication method. Do not use this CallbackHandler implementation on the server because it prompts you for login binding information.

**com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler**

If basic authentication data is not defined in the login binding (this information is not the same as the HTTP basic authentication information), the implementation prompts for the user name and password using standard in (stdin). The implementation uses the basic authentication data defined in the login binding. Use this CallbackHandler implementation with the BasicAuth authentication method. Do not use this CallbackHandler implementation on the server because it prompts you for login binding information.

**com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler**

This CallbackHandler implementation does not prompt. Rather, it uses the basic authentication data defined in the login binding (this information is not the same as the HTTP basic authentication information). This CallbackHandler implementation is meant for use with the BasicAuth authentication method. You must define the basic authentication data in the login binding information for this CallbackHandler implementation. You can use this implementation when Web services is running as a client and needs to send basic authentication (<wsse:UsernameToken>) to the downstream call.

**com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler**

The CallbackHandler generates Lightweight Third Party Authentication (LTPA) tokens from the run as JAAS Subject (invocation Subject) of the current WebSphere Application Server security context. However, if basic authentication data is defined in the login binding information (not the HTTP basic authentication information), the implementation uses the basic authentication data and LTPA token generated. The **Token Type URI** and **Token Type Local Name** values must be defined in the login binding information for this CallbackHandler implementation. The token value type is used to validate the token to the request sender and request receiver binding configuration. The Web services security run time inserts the LTPA token as a binary security token (<wsse:BinarySecurityToken>) into the message SOAP header. The value type is mandatory. (See LTPA for more information). Use this CallbackHandler implementation with the LTPA authentication method.

Figure 1 shows the sender security handler in the request sender message process.

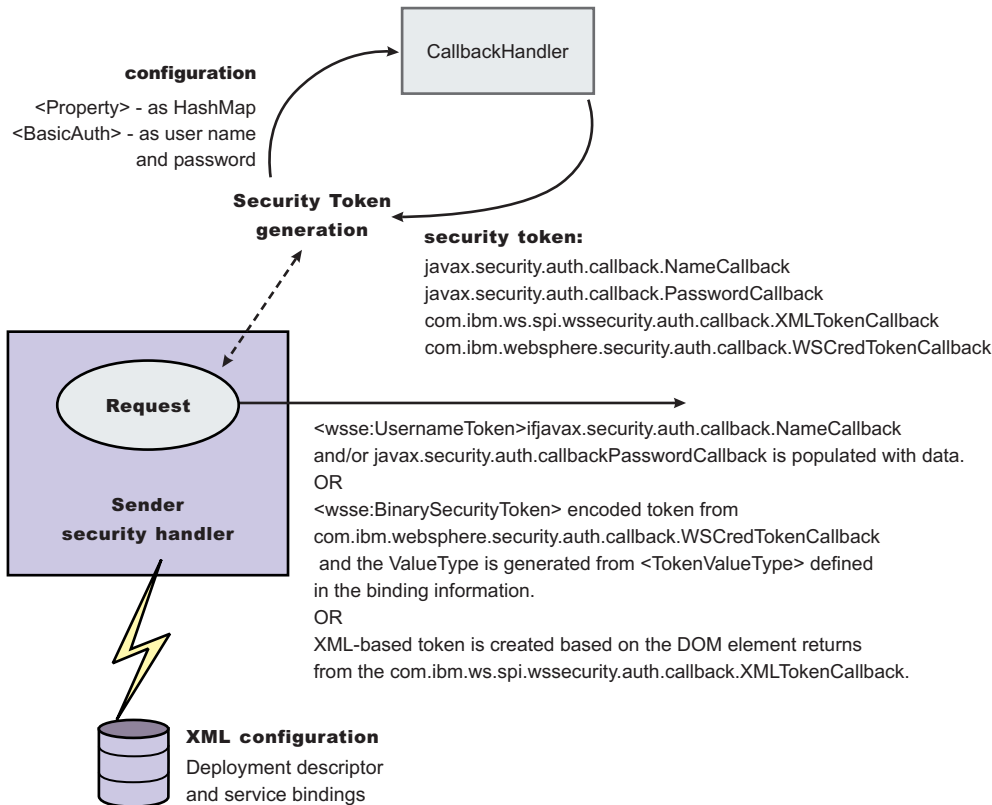

Figure 23. Request sender SOAP message process

You can configure the receiver-side security server to support multiple authentication methods and multiple types of security tokens. The following steps describe the request sender SOAP message process:

1. After receiving a message, the receiver Web services security handler compares the token type (in the message header) with the expected token types configured in the deployment descriptor.
2. The Web services security handler extracts the security token form the message header and maps the token <ValueType> element to the corresponding authentication method. The mapping configuration is defined in the <loginMappings> element in the `ibm-webservices-bnd.xml` XML file. For example:

```
<loginMappings xmi:id="LoginMapping_1051977980074" authMethod="LTPA"
 configName="WSLogin">
 <callbackHandlerFactory xmi:id="CallbackHandlerFactory_1051977980081"
 classname="com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl"/>
 <tokenValueType xmi:id="TokenValueType_1051977980081"
 uri="http://www.ibm.com/websphere/appserver/tokenype/5.0.2" localName="LTPA"/>
</loginMappings>
```

The `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory` interface is a factory for `javax.security.auth.callback.CallbackHandler`.

3. The Web services security run time initiates the factory implementation class and passes the authentication information from Web services security header to the factory class through the set methods.
4. The Web services security run time invokes the `newCallbackHandler()` method to obtain the `javax.security.auth.CallbackHandler` object, which generates the required security token.
5. When the security handler receives an LTPA `BinarySecurityToken`, it uses the `WSLogin` JAAS login configuration and the `newCallbackHandler()` method to validate the security token. If none of the expected token types are found in the SOAP message Web services security header, the request is rejected with an SOAP fault. Otherwise, the token type is used to map to a JAAS login configuration

for token validation. If authentication is successful, a JAAS Subject is created and associated with the running thread. Otherwise, the request is rejected with a SOAP fault.

The following table shows the authentication methods and the JAAS login configurations.

Authentication method	JAAS login configuration
BasicAuth	WSLogin
Signature	system.wssecurity.Signature
LTPA	WSLogin
IDAssertion	system.wssecurity.IDAssertion

Figure 2 shows the receiver security handler in the request receiver message process.

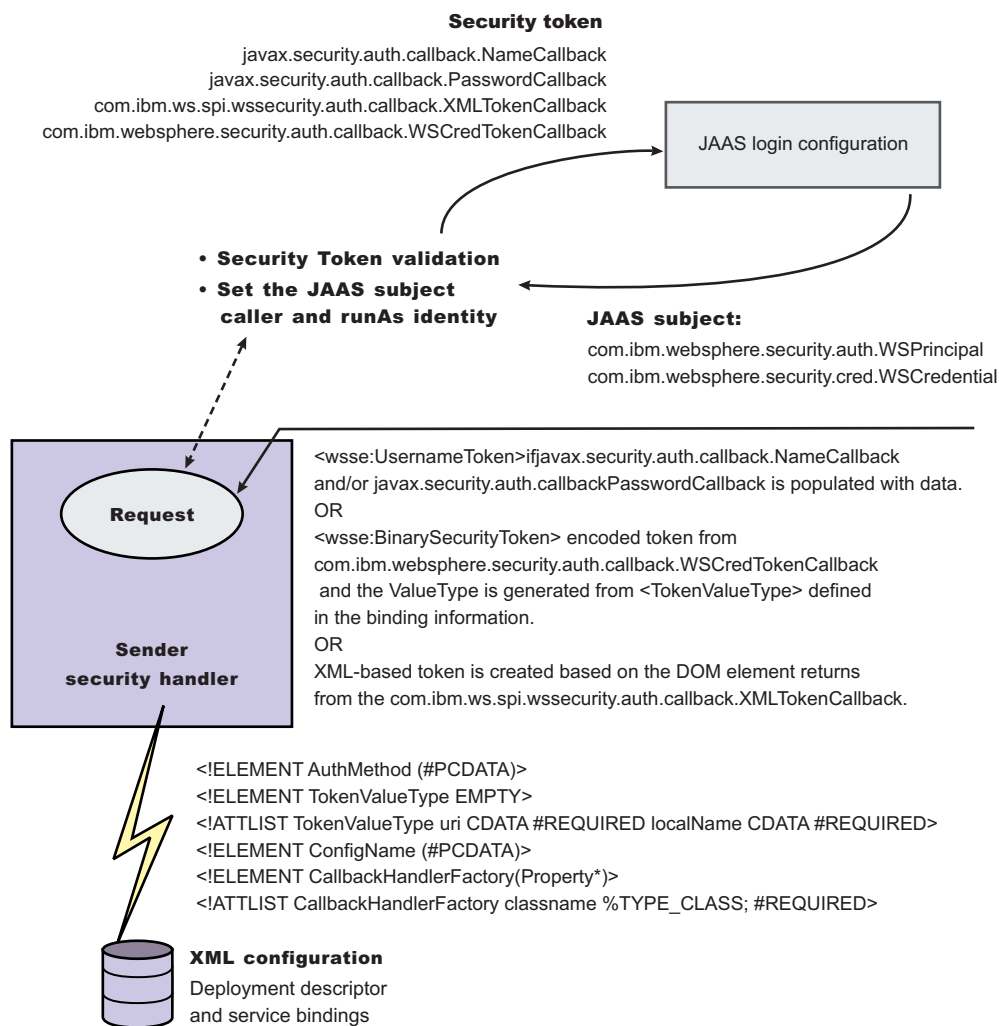

Figure 24. Request receiver SOAP message process

The default <LoginMapping> is defined in the server-level ws-security.xml files. If nothing is defined in the binding file information, the ws-security.xml default is used. However, an administrator can override the default by defining a new <LoginMapping> element in the binding file.

6. The client reads the default binding information in the `${install_dir}/properties/ws-security.xml` file.
7. The server run-time component loads the server-level `ws-security.xml` files, if they exist. The two files are merged in the run time to form one effective set of default binding information.

On a base application server, the server run time component only loads the server-level `ws-security.xml` file. The server-side `ws-security.xml` file and the application Web services security binding information are managed by the administrative console and by the WSADMIN. You can specify the binding information during application deployment either through the administrative console or through the WSADMIN file. The Web services security policy is defined in the deployment descriptor extension (`ibm-webservicesclient-ext.xmi`) and the bindings are stored in the IBM binding extension (`ibm-webservicesclient-bnd.xmi`). However, the `${install_dir}/properties/ws-security.xml` file defines the default binding value for the client. If the binding information is not specified in the binding file, the run time reads the binding information from the default `${install_dir}/properties/ws-security.xml` file.

### ***Login mappings collection:***

Use this page to view a list of configurations for validating security tokens within incoming messages. Login mappings map an authentication method to a Java Authentication and Authorization Service (JAAS) login configuration to validate the security token. Four authentication methods are predefined in the WebSphere Application Server: BasicAuth, Signature, IDAssertion, and Lightweight Third Party Authentication (LTPA).

To view this administrative console page, complete the following steps:

1. Click **Server > Application Servers > *server\_name***.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Login Mappings**.
3. Click **New** to create a login mapping or click **Delete** to delete a login mapping.

If you click **Update runtime**, the Web services security run time is updated with the default binding information, which is contained in the `ws-security.xml` file that was previously saved. After you specify the authentication method, the Java Authentication and Authorization Service (JAAS) configuration name, and the Callback Handler Factory class name on this panel, you must complete the following steps:

Click **Save** at the top of the administrative console. When you click **Save**, you return to the administrative console home panel.

Return to the Login Mappings collection panel and click **Update runtime**. When you click **Update runtime**, the configuration changes made to the other Web services also are updated in the Web services security run time.

#### *Authentication Method:*

Specifies the authentication method used for validating the security tokens.

The following authentication methods are available:

#### **BasicAuth**

The basic authentication method includes both a user name and a password in the security token. The information in the token is authenticated by the receiving server and used to create a credential.

#### **Signature**

The signature authentication method sends an X.509 certificate as a security token. For Lightweight Directory Access Protocol (LDAP) registries, the distinguished name (DN) is mapped

to a credential, which is based on the LDAP certificate filter settings. For local OS registries, the first attribute of the certificate, usually the common name (CN) is mapped directly to a user ID in the registry.

#### **IDAssertion**

The identity assertion method maps a trusted identity (ID) to a WebSphere Application Server credential. This authentication method only includes a user name in the security token. An additional token is included in the message for trust purposes. When the additional token is trusted, the IDAssertion token user name is mapped to a credential.

**LTPA** Lightweight Third Party Authentication (LTPA) validates an LTPA token.

*JAAS Configuration Name:*

Specifies the name of the Java Authentication and Authorization Service (JAAS) configuration.

*Callback Handler Factory Class Name:*

Specifies the name of the factory for the CallbackHandler class.

#### **Login mapping configuration settings:**

Use this page to specify the Java Authentication and Authorization Service (JAAS) login configuration settings used to validate security tokens within incoming messages.

To view this administrative console page, complete the following steps:

1. Click **Servers > Application Servers > server\_name**.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Login Mappings > New**.

*Authentication Method:*

Specifies the method of authentication.

You can use any string, but the string must match the element in the service-level configuration. The following words are reserved and have special meanings:

#### **BasicAuth**

Uses both a user name and a password.

#### **IDAssertion**

Uses only a user name, but requires that additional trust is established on the receiving server using a TrustedIDEvaluator mechanism.

#### **Signature**

Uses the distinguished name (DN) of the signer.

**LTPA** Validates a token.

*JAAS Configuration Name:*

Specifies the name of the Java Authentication and Authorization Service (JAAS) configuration.

Specify your JAAS configurations using the administrative console by clicking **Security > JAAS Configuration > Application**.

*Callback Handler Factory Class Name:*

Specifies the name of the factory for the CallbackHandler class.

You must implement the `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory` class in this field.

**Default:** `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory`

*Token Type URI:*

Specifies the namespace Uniform Resource Identifiers (URI), which denotes the type of security token accepted.

If binary security tokens are accepted, the value denotes the `ValueType` attribute in the element. The `ValueType` element identifies the type of security token and its namespace. If Extensible Markup Language (XML) tokens are accepted, the value denotes the top-level element name of the XML token.

If the reserved words are specified previously in the Authentication Method field, this field is ignored.

**Data type:** Unicode characters except for non-ASCII characters, but including the number sign (#), the percent sign (%), and the square brackets ([ ]).

*Token Type Local Name:*

Specifies the local name of the security token type, for example, X509v3.

If binary security tokens are accepted, the value denotes the `ValueType` attribute in the element. The `ValueType` attribute identifies the type of security token and its namespace. If Extensible Markup Language (XML) tokens are accepted, the value denotes the top-level element name of the XML token.

If the reserved words are specified previously in the Authentication Method field, this field is ignored.

*Nonce Maximum Age:*

Specifies the time, in seconds, before the nonce time stamp expires. Nonce is a randomly generated value.

You must specify a minimum of 300 seconds for the Nonce Maximum Age field. However, the maximum value cannot exceed the number of seconds specified in the Nonce Cache Timeout field for either the server level or the cell level. You can specify the **Nonce Maximum Age** value for the server level:

1. Click **Servers > Application Servers > *server\_name***.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security**.
3. Specify the **Nonce Maximum Age** value for the cell level by clicking **Security > Web Services > Properties**.

**Important:** The Nonce Maximum Age field on this panel is optional and only valid if the BasicAuth authentication method is specified. If you specify another authentication method and attempt to specify values for this field, the following error message displays and you must remove the specified value: Nonce is not supported for authentication methods other than BasicAuth.

If you specify BasicAuth, but do not specify values for the Nonce Maximum Age field, the Web services security run time searches for a Nonce Maximum Age value on the server level. If a value is not found on the server level, the run time searches the cell level. If a value is not found on either the server level or the cell level, the default is 300 seconds.

**Default** 300 seconds

**Range**

300 to Nonce Cache Timeout seconds

*Nonce Clock Skew:*

Specifies the clock skew value, in seconds, to consider when WebSphere Application Server checks the freshness of the message. Nonce is a randomly generated value.

You must specify a minimum of 0 seconds for the Nonce Clock Skew field. However, the maximum value cannot exceed the number of seconds specified in the Nonce Maximum Age on this Login Mappings panel.

**Important:** The Nonce Clock Skew field on this panel is optional and only valid if the BasicAuth authentication method is specified. If you specify another authentication method and attempt to specify values for this field, the following error message displays and you must remove the specified value: Nonce is not supported for authentication methods other than BasicAuth.

**Note:** If you specify BasicAuth, but do not specify values for the Nonce Clock Skew field, the Web services security run time searches for a Nonce Clock Skew value on the server level. If a value is not found on the server level, the run time searches the cell level. If a value is not found on either the server level or the cell level, the default is 0 seconds.

**Default**

0 seconds

**Range**

0 to Nonce Maximum Age seconds

## Configuring the client for request signing: Digitally signing message parts

Prior to completing these steps, read either of the following topics to become familiar with the Security Extensions tab and the Port Binding tab in the Web Services Client Editor within the Assembly Toolkit.

- Configuring the client security bindings using the WebSphere Application Server Toolkit
- Configuring the security bindings on a server acting as a client using the administrative console

These two tabs are used to configure the Web services security extensions and the Web services security bindings, respectively.

Complete the following steps to specify which message parts to digitally sign when configuring the client for request signing:

1. Launch the WebSphere Application Server Toolkit and click **Windows > Open Perspective > J2EE**.
2. Select the Web services-enabled Enterprise JavaBeans (EJB) or Web module.
3. In the Package Explorer window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
4. Right-click the **webservicesclient.xml** file and click **Open With > Web Services Client Editor**.
5. Click the **Security Extensions** tab, which is located at the bottom of the Web Services Client Editor within the Assembly Toolkit.
6. Expand **Request Sender Configuration > Integrity**. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification while the data is transmitted across the Internet. For more information on digitally signing SOAP messages, see XML digital signature.
7. Indicate which parts of the message to sign by clicking **Add** and selecting **body**, **timestamp**, or **SecurityToken**. The following list contains descriptions of the message parts

**Body** The body is the user data portion of the message.

## Timestamp

The time stamp determines if the message is valid based on the time that the message is sent and then received. If **timestamp** is selected, proceed to the next step and select **Add Created Time Stamp** to add a time stamp to a message.

## Securitytoken

The security token authenticates the client. If this option is selected, the message is signed.

You can choose to digitally sign the message using a time stamp if **Add Created Time Stamp** is selected and configured. You can digitally sign the message using a security token if a login configuration authentication method is selected.

- Optional: Expand the **Add Created Time Stamp** section and select this option if you want a time stamp added to the message. You can specify an expiration time for the time stamp, which helps defend against replay attacks. The lexical representation for duration is the [ISO 8601] extended format *PnYnMnDTnHnMnS*, where:

- *nY* represents the number of years
- *nM* represents the number of months
- *nD* represents the number of days
- *T* is the date and time separator
- *nH* represents the number of hours
- *nM* represents the number of minutes
- *nS* represents the number of seconds. The number of seconds can include decimal digits to arbitrary precision.

For example, to indicate a duration of 1 year, 2 months, 3 days, 10 hours, and 30 minutes, the format is: *P1Y2M3DT10H30M*. Typically, you configure a message time stamp for about 10 to 30 minutes, for example, 10 minutes is represented as: *P0Y0M0DT0H10M0S*. The *P* character precedes time and date values.

**Important:** If you configure the client and server signing information correctly, but receive a Soap body not signed error when executing the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the Web Services Client Editor within the Assembly Toolkit:

- Click **Security Extensions > Client Service Configuration Details** and indicate the actor information in the **Actor URI** field.
- Click **Security Extensions > Request Sender Configuration > Details** and indicate the actor information in the **Actor** field.

You must configure the same actor strings for the Web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the Web Services Editor within the WebSphere Application Server Toolkit:

- Click **Security Extensions > Server Service Configuration**.
- Click **Security Extensions > Response Sender Service Configuration Details > Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The **actor** fields might be different when you have Web services acting as a gateway to other Web services. However, in all other cases, make sure that the actor information matches on the client and server. When Web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, Web services do not process the message from a client. Instead, these Web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

After you specify which message parts to digitally sign when the client sends a message to a server.

Once you have specified which message parts to digitally sign, you must specify which method is used to digitally sign the message. See *Configuring the client for request signing: Choosing the digital signature method* for more information.

## Configuring the client for request signing: Choosing the digital signature method

Prior to completing these steps, read either of the following topics to become familiar with the Security Extensions tab and the Port Binding tab in the Web Services Client Editor within the Assembly Toolkit:

- *Configuring the client security bindings using the WebSphere Application Server Toolkit*
- *Configuring the security bindings on a server acting as a client using the administrative console*

These two tabs are used to configure the Web services security extensions and the Web services security bindings, respectively. You must specify which parts of the message sent by the client must be digitally signed. See *Configuring the client for request signing: Digitally signing message parts* for more information.

Complete the following steps to specify which message parts to digitally sign when configuring the client for request signing:

1. Launch the Assembly Toolkit and click **Windows > Open Perspective > J2EE**.
2. Select the Web services enabled EJB or Web module.
3. In the Package Explorer window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
4. Right-click the **webservicesclient.xml** file and click **Open With > Web Services Client Editor**.
5. Click the **Port Binding** tab.
6. Expand **Security Request Sender Binding Configuration > Signing Information**.
7. Select **Edit** to view the signing information and select a digital signature method from the **Signature method algorithm** field. The following table describes the purpose of this information. Some of these definitions are based on the XML-Signature specification, which is located at the following Web site <http://www.w3.org/TR/xmldsig-core>.

Name	Purpose
<b>Canonicalization method algorithm</b>	Canonicalizes the <SignedInfo> element before the information is digested as part of the signature operation.
<b>Digest method algorithm</b>	Applies to the data after transforms are applied, if specified, to yield the <DigestValue> element. Signing the <DigestValue> element binds the resource content to the signer key. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration.
<b>Signature method algorithm</b>	Converts the canonicalized <SignedInfo> element into the <SignatureValue> element. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration.
<b>Signing key name</b>	Represents the key entry associated with the signing key locator. The key entry refers to an alias of the key, which is found in the key store and is used to sign the request.
<b>Signing key locator</b>	Represents a reference to a key locator implementation class that locates the correct key store where the alias and the certificate exist.

**Important:** If you configure the client and server signing information correctly, but receive a Soap body not signed error when executing the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the Web Services Client Editor within the WebSphere Application Server Toolkit:

- Click **Security Extensions > Client Service Configuration Details** and indicate the actor information in the **Actor URI** field.
- Click **Security Extensions > Request Sender Configuration > Details** and indicate the actor information in the **Actor** field.

You must configure the same actor strings for the Web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the Web Services Editor within the WebSphere Application Server Toolkit:

- Click **Security Extensions > Server Service Configuration**.
- Click **Security Extensions > Response Sender Service Configuration Details > Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The **actor** fields might be different when you have Web services acting as a gateway to other Web services. However, in all other cases, make sure that the actor information matches on the client and server. When Web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, Web services do not process the message from a client. Instead, these Web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which method is used to digitally sign a message when the client sends a message to a server.

After you configure the client to digitally sign the message, you must configure the server to verify the digital signature. See [Configuring the server for request digital signature verification: Verifying the message parts](#) for more information.

## **Configuring the server for request digital signature verification: verifying the message parts**

Prior to completing these steps, read either of the following topics to become familiar with the Security Extensions tab and the Binding Configurations tab in the Web services editor within the WebSphere Application Server Toolkit:

- [Configuring the server security bindings using the WebSphere Application Server Toolkit](#)
- [Configuring the server security bindings using the administrative console](#)

You can use these two tabs to configure the Web services security extensions and the Web services security bindings, respectively. Also, you must specify which parts of the message sent by the client must be digitally signed. See [Configuring the client for request signing: Digitally signing message parts](#) to determine which message parts are digitally signed. The message parts specified for the client request sender must match the message parts specified for the server request receiver.

Complete the following steps to configure the server for request digital signature verification. The steps describe how to modify the extensions to indicate which parts of the request to verify.

1. Launch the WebSphere Application Server Toolkit and either click **Windows > Open Prospective > Java** or **Windows > Open Prospective > Resource**.
2. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.

3. In the Package Explorer window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
4. Right-click the `webservices.xml` file, and click **Open With > Web Services Editor**.
5. Click the **Security Extensions** tab in the Web services editor.
6. Expand the **Request Receiver Service Configuration Details > Required Integrity** section. Required integrity refers to the parts of the message that require digital signature verification. The purpose of digital signature verification is to make sure that the message parts have not been modified while transmitting across the Internet.
7. Indicate parts of the message to verify by clicking **Add**, and selecting one of the following three parts: body, timestamp, or SecurityToken. You can determine which parts of the message to verify by looking at the Web service request sender configuration in the client application. To view the Web service request sender configuration information in the Web services client editor, click the **Security Extensions** tab and expand **Request Sender Configuration > Integrity**. The following includes a list and description of the message parts:

**Body** This is the user data portion of the message.

**Timestamp**

The timestamp determines if the message is valid based on the time that the message is sent and then received. If timestamp option is selected, proceed to the next step to Add Created Time Stamp to the message.

**Securitytoken**

The security token authenticates the client. If the SecurityToken is selected, the message is signed.

8. Optional: Expand the **Add Received Time Stamp** section. The Add Received Time Stamp value indicates to validate the Add Created Time Stamp option configured by the client. You must select this option if you selected the Add Created Time Stamp on the client. The time stamp ensures message integrity by indicating the timeliness of the request. This option helps defend against replay attacks.

**Important:** If you configure the client and server signing information correctly, but receive a Soap body not signed error when executing the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the Web Services Client Editor within the WebSphere Application Server Toolkit:

- Click **Security Extensions > Client Service Configuration Details** and indicate the actor information in the **Actor URI** field.
- Click **Security Extensions > Request Sender Configuration > Details** and indicate the actor information in the **Actor** field.

You must configure the same actor strings for the Web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the Web Services Editor within the WebSphere Application Server Toolkit:

- Click **Security Extensions > Server Service Configuration**.
- Click **Security Extensions > Response Sender Service Configuration Details > Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The **actor** fields might be different when you have Web services acting as a gateway to other Web services. However, in all other cases, make sure that the actor information matches on the client and server. When Web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, Web services do not process the message from a client. Instead, these Web services send the request downstream. The downstream process that contains the correct

actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which message parts are digitally signed and must be verified by the server when the client sends a message to a server.

After you specify which message parts contain a digital signature that must be verified by the server, you must configure the server to recognize the digital signature method used to digitally sign the message. See *Configuring the server for request digital signature verification: Choosing the verification method* for more information.

## Configuring the server for request digital signature verification: choosing the verification method

Prior to completing these steps, read either of the following topics to become familiar with the Security Extensions tab and the Binding Configurations tab in the Web Services Editor within the WebSphere Application Server Toolkit:

- *Configuring the server security bindings using the WebSphere Application Server Toolkit*
- *Configuring the server security bindings using the administrative console*

You can use these two tabs to configure the Web services security extensions and Web services security bindings, respectively. You must specify which message parts contain digital signature information that must be verified by the server. See *Configuring the server for request digital signature verification: verifying the message parts*. The message parts specified for the client request sender must match the message parts specified for the server request receiver. Likewise, the digital signature method chosen for the client must match the digital signature method used by the server.

Complete the following steps to configure the server for request digital signature verification. The steps describe how to modify the extensions to indicate which digital signature method the server will use during verification.

1. Launch the WebSphere Application Server Toolkit and either click **Windows > Open Prospective > Java** or **Windows > Open Prospective > Resource**.
2. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
3. In the Package Explorer window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
4. Right-click the webservices.xml file, and click **Open With > Web Services Editor**.
5. Click the **Binding Configurations** tab.
6. Expand the **Security Request Receiver Binding Configuration Details > Signing Information** section.
7. Click **Edit** to edit the signing information. The signing information dialog is displayed, select or enter the following information:
  - Canonicalization method algorithm
  - Digest method algorithm
  - Signature method algorithm
  - Use certificate path reference
  - Trust anchor reference
  - Certificate store reference
  - Trust any certificate

For more conceptual information on digitally signing Simple Object Access Protocol (SOAP) messages, see *XML digital signature*. The following table describes the purpose for each of these selections. Some of the following definitions are based on the XML-Signature specification, which is located at the following Web address: <http://www.w3.org/TR/xmlsig-core>.

Name	Purpose
<b>Canonicalization method algorithm</b>	Canonicalizes the <SignedInfo> element before it is digested as part of the signature operation. The algorithm selected for the server request receiver configuration must match the algorithm selected in the client request sender configuration.
<b>Digest method algorithm</b>	Applies to the data after transforms are applied, if specified, to yield the <DigestValue> element. The signing of the <DigestValue> element binds resource content to the signer key. The algorithm selected for the server request receiver configuration must match the algorithm selected in the client request sender configuration.
<b>Signature method algorithm</b>	Converts the canonicalized <SignedInfo> element into the <SignatureValue> element. The algorithm selected for the server request receiver configuration must match the algorithm selected in the client request sender configuration.
<b>Use certificate path reference or Trust any certificate</b>	Validates a certificate or signature sent with a message. When a message is signed, the public key used to sign it is sent with the message. This public key or certificate might not be validated at the receiving end. By selecting <b>User certificate path reference</b> , you must configure a trust anchor reference and a certificate store reference to validate the certificate sent with the message. By selecting <b>Trust any certificate</b> , the signature is validated by the certificate sent with the message without the certificate itself being validated.
<b>Use certificate path reference: Trust anchor reference</b>	Refers to a key store that contains trusted, self-signed certificates and certificate authority (CA) certificates. These certificates are trusted certificates that you can use with any applications in your deployment.
<b>Use certificate path reference: Certificate store reference</b>	Contains a collection of X.509 certificates. These certificates are not trusted for all applications in your deployment, but might be used as an intermediary to validate certificates for an application. See

**Important:** If you configure the client and server signing information correctly, but receive a Soap body not signed error when executing the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the Web Services Client Editor within the WebSphere Application Server Toolkit:

- Click **Security Extensions > Client Service Configuration Details** and indicate the actor information in the **Actor URI** field.
- Click **Security Extensions > Request Sender Configuration > Details** and indicate the actor information in the **Actor** field.

You must configure the same actor strings for the Web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the Web Services Editor within the WebSphere Application Server Toolkit:

- Click **Security Extensions > Server Service Configuration**.
- Click **Security Extensions > Response Sender Service Configuration Details > Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead

of being forwarded downstream. The **actor** fields might be different when you have Web services acting as a gateway to other Web services. However, in all other cases, make sure that the actor information matches on the client and server. When Web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, Web services do not process the message from a client. Instead, these Web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified the method that the server uses to verify the digital signature in the message parts.

After you configure the client for request signing and the server for request digital signature verification, you must configure the server and the client to handle the response. Next, specify the response signing for the server. See *Configuring the server for response signing: Digitally signing message parts* for more information.

### Configuring the server for response signing: Digitally signing message parts

Prior to completing these steps, read either of the following topics to become familiar with the Security Extensions tab and the Binding Configurations tab in the Web Services Editor within the Assembly Toolkit:

- *Configuring the server security bindings using the WebSphere Application Server Toolkit*
- *Configuring the server security bindings using the administrative console*

These two tabs are used to configure the Web services security extensions and the Web services security bindings, respectively.

Complete the following steps to specify which message parts to digitally sign when configuring the server for response signing:

1. Launch the WebSphere Application Server Toolkit and click **Windows > Open Perspective > J2EE**.
2. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
3. In the Package Explorer window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
4. Right-click the **webservices.xml** file and click **Open With > Web Services Editor**.
5. Click the **Security Extensions** tab, which is located at the bottom of the Web Services Editor within the Assembly Toolkit.
6. Expand **Response Sender Service Configuration Details > Integrity**. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification while the data is transmitted across the Internet. For more information on digitally signing SOAP messages, see XML digital signature.
7. Indicate the parts of the message to sign by clicking **Add**, and selecting **Body**, **Timestamp**, or **Securitytoken**.

The following list contains descriptions of the message parts:

**Body** The body is the user data portion of the message.

#### Timestamp

The time stamp determines if the message is valid based on the time that the message is sent and then received. If **timestamp** is selected, proceed to the next step and click **Add Created Time Stamp**, which indicates that the time stamp is added to the message.

#### Securitytoken

The security token is used for authentication. If this option is selected, the authentication information is added to the message.

8. Optional: Expand the **Add Created Time Stamp** section. Select this option if you want a time stamp added to the message. You can specify an expiration time for the time stamp, which helps defend against replay attacks. The lexical representation for duration is the ISO 8601 extended format, *PnYnMnDTnHnMnS*, where:

- *nY* represents the number of years.
- *nM* represents the number of months.
- *nD* represents the number of days.
- *T* is the date and time separator.
- *nH* represents the number of hours.
- *nM* represents the number of minutes.
- *nS* represents the number of seconds. The number of seconds can include decimal digits to arbitrary precision.

For example, to indicate a duration of 1 year, 2 months, 3 days, 10 hours, and 30 minutes, the format is: P1Y2M3DT10H30M. Typically, you configure a message time stamp for about 10 to 30 minutes. 10 minutes is represented as: P0Y0M0DT0H10M0S. The *P* character precedes time and date values.

**Important:** If you configure the client and server signing information correctly, but receive a Soap body not signed error when executing the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the Web Services Client Editor within the Assembly Toolkit:

- Click **Security Extensions > Client Service Configuration Details** and indicate the actor information in the **Actor URI** field.
- Click **Security Extensions > Request Sender Configuration > Details** and indicate the actor information in the **Actor** field.

You must configure the same actor strings for the Web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the Web Services Editor within the WebSphere Application Server Toolkit:

- Click **Security Extensions > Server Service Configuration**.
- Click **Security Extensions > Response Sender Service Configuration Details > Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The **actor** fields might be different when you have Web services acting as a gateway to other Web services. However, in all other cases, make sure that the actor information matches on the client and server. When Web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, Web services do not process the message from a client. Instead, these Web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which message parts to digitally sign when the server sends a response to the client.

After you specifying which message parts to digitally sign, you must specify which method is used to digitally sign the message. See *Configuring the server for response signing: Choosing the digital signature method* for more information.

## Configuring the server for response signing: choosing the digital signature method

Prior to completing these steps, read either of the following topics to become familiar with the Security Extensions tab and the Binding Configurations tab in the Web Services Editor within the WebSphere Application Server Toolkit:

- Configuring the server security bindings using the WebSphere Application Server Toolkit
- Configuring the server security bindings using the administrative console

These two tabs are used to configure the Web services security extensions and the Web services security bindings, respectively.

Complete the following steps to specify which digital signature method to use when configuring the server for response signing:

1. Launch the Assembly Toolkit and click **Windows > Open Perspective > J2EE**.
2. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
3. In the Package Explorer window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
4. Right-click the **webservices.xml** file and click **Open With > Web Services Editor**.
5. Click the **Binding Configurations** tab.
6. Expand **Response Sender Binding Configuration Details > Signing Information**.
7. Click **Edit** to choose a signing method. The signing info dialog is displayed and either select or enter the following information:
  - **Canonicalization method algorithm**
  - **Digest method algorithm**
  - **Signature method algorithm**
  - **Signing key name**
  - **Signing key locator**

The following table describes the purpose of this information. Some of these definitions are based on the XML-Signature specification, which is located at the following address:  
<http://www.w3.org/TR/xmlsig-core>.

Name	Purpose
<b>Canonicalization method algorithm</b>	Canonicalizes the <SignedInfo> element before the information is digested as part of the signature operation. Use the same algorithm on the client response receiver. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration.
<b>Digest method algorithm</b>	Applies to the data after transforms are applied, if specified, to yield the <DigestValue> element. Signing the <DigestValue> binds resource content to the signer key. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration.
<b>Signature method algorithm</b>	Converts the canonicalized <SignedInfo> element into the <SignatureValue> element. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration.

Name	Purpose
<b>Signing key name</b>	Represents the key entry associated with the signing key locator. The key entry refers to an alias of the key, which is found in the key store and is used to sign the request.
<b>Signing key locator</b>	Represents a reference to a key locator implementation class that locates the correct key store where the alias and certificate exists. For more information on configuring key locators, see any of the following files: <ul style="list-style-type: none"> <li>• Configuring key locators using the WebSphere Application Server Toolkit</li> <li>• Configuring key locators using the administrative console</li> </ul>

You have specified which method is used to digitally sign a message when the server sends a message to a client.

After you configure the server to digitally sign the response message, you must configure the client to verify the digital signature contained in the response message. See *Configuring the client for response digital signature verification: Verifying the message parts* for more information.

### **Configuring the client for response digital signature verification: Verifying the message parts**

Prior to completing these steps, read either of the following topics to become familiar with the Security Extensions tab and the Port Binding tab in the Web Services Client Editor within the Assembly Toolkit:

- Configuring the client security bindings using the WebSphere Application Server Toolkit
- Configuring the security bindings on a server acting as a client using the administrative console

You can use these two tabs to configure the Web services security extensions and the Web services security bindings, respectively.

Complete the following steps to configure the client for response digital signature verification. The steps describe how to modify the extensions to indicate which parts of the response to verify.

1. Launch the Assembly Toolkit and click **Windows > Open Perspective > J2EE**.
2. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
3. In the Package Explorer window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
4. Right-click the **webservicesclient.xml** file and click **Open With > Web Services Client Editor**.
5. Click the **Security Extensions** tab.
6. Expand the **Response Receiver Configuration > Required Integrity** section. Required integrity refers to parts that require digital signature verification. Digital signature verification decreases the risk that the message parts have been modified while the message is transmitted across the Internet.
7. Indicate the parts of the message that must be verified. You can determine which parts of the message to verify by looking at the Web service response sender configuration. Click **Add** and select one of the following parts:

**Body** The body is the user data portion of the message.

#### **Timestamp**

The time stamp determines if the message is valid based on the time that the message is sent and then received. If the time stamp option is selected, proceed to the next step to add a received time stamp to the message.

## Securitytoken

The security token authenticates the client. If Securitytoken option is selected, the message is signed.

- Optional: Expand the **Add Received Time Stamp** section. Select **Add Received Time Stamp** to add the received time stamp to the message.

**Important:** If you configure the client and server signing information correctly, but receive a Soap body not signed error when executing the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the Web Services Client Editor within the WebSphere Application Server Toolkit:

- Click **Security Extensions > Client Service Configuration Details** and indicate the actor information in the **Actor URI** field.
- Click **Security Extensions > Request Sender Configuration > Details** and indicate the actor information in the **Actor** field.

You must configure the same actor strings for the Web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the Web Services Editor within the WebSphere Application Server Toolkit:

- Click **Security Extensions > Server Service Configuration**.
- Click **Security Extensions > Response Sender Service Configuration Details > Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The **actor** fields might be different when you have Web services acting as a gateway to other Web services. However, in all other cases, make sure that the actor information matches on the client and server. When Web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, Web services do not process the message from a client. Instead, these Web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which message parts are digitally signed and must be verified by the client when the server sends a response message to the client.

After you specify which message parts contain a digital signature that must be verified by the client, you must configure the client to recognize the digital signature method used to digitally sign the message. See [Configuring the client for response digital signature verification: Choosing the verification method](#) for more information.

## Configuring the client for response digital signature verification: choosing the verification method

Prior to completing these steps, read either of the following topics to become familiar with the **Security Extensions** tab and the **Port Binding** tab in the Web Services Editor within the Application Server Toolkit:

- Configuring the server security bindings using the WebSphere Application Server Toolkit
- Configuring the server security bindings using the administrative console

You can use these two tabs to configure the Web Services Security extensions and Web Services Security bindings, respectively. Also, you must specify which message parts contain digital signature information that must be verified by the client. See [Configuring the client for response digital signature verification: verifying the message parts to specify which message parts are digitally signed by the server and must be verified by the client](#). The message parts specified for the server response sender must match the

message parts specified for the client response receiver. Likewise, the digital signature method chosen for the server must match the digital signature method used by the client.

Complete the following steps to configure the client for response digital signature verification. The steps describe how to modify the extensions to indicate which digital signature method the client will use during verification.

1. Launch the WebSphere Application Server Toolkit and either click **Windows > Open Prospective > Java** or **Windows > Open Prospective > Resource**.
2. Select the Web services enabled EJB or Web module.
3. In the Package Explorer window, locate the **META-INF** directory for an EJB module or the **WEB-INF** directory for a Web module.
4. Right-click the `webservicesclient.xml` file, select **Open With > Web Services Client Editor**.
5. Click the **Port Binding** tab.
6. Expand the **Security Response Receiver Binding Configuration > Signing Information** section.
7. Click **Edit** to select a digital signature method. The signing info dialog displays and either select or enter the following information:
  - **Canonicalization method algorithm**
  - **Digest method algorithm**
  - **Signature method algorithm**
  - **Signing key name**
  - **Signing key locator**

For more conceptual information on digitally signing SOAP messages, see XML digital signature. The following table describes the purpose for each of these selections. Some of the following definitions are based on the XML-Signature specification, which can be found at: <http://www.w3.org/TR/xmlsig-core>.

Name	Purpose
<b>Canonicalization method algorithm</b>	The canonicalization method algorithm is used to canonicalize the <code>&lt;SignedInfo&gt;</code> element before it is digested as part of the signature operation.
<b>Digest method algorithm</b>	The digest method algorithm is the algorithm applied to the data after transforms are applied, if specified, to yield the <code>&lt;DigestValue&gt;</code> . The signing of the <code>&lt;DigestValue&gt;</code> binds resource content to the signer key. The algorithm selected for the client response receiver configuration must match the algorithm selected in the server response sender configuration.
<b>Signature method algorithm</b>	The signature method is the algorithm that is used to convert the canonicalized <code>&lt;SignedInfo&gt;</code> element into the <code>&lt;SignatureValue&gt;</code> element. The algorithm selected for the client response receiver configuration must match the algorithm selected in the server response sender configuration.
<b>Use certificate path reference or Trust any certificate</b>	When a message is signed, the public key used to sign it is transmitted with the message. To validate this public key at the receiving end, configure a certificate path reference. By selecting <b>User certificate path reference</b> , you must configure a trust anchor reference and certificate store reference to validate the certificate sent with the message. By selecting <b>trust any certificate</b> , the signature is validated by the certificate sent with the message without the certificate itself being validated.

Name	Purpose
<b>Use certificate path reference: Trust anchor reference</b>	A trust anchor is a configuration that refers to a keystore that contains trusted, self-signed certificates and certificate authority (CA) certificates. These certificates are trusted certificates that you can use with any applications in your deployment.
<b>Use certificate path reference: Certificate store reference</b>	A certificate store is a configuration that has a collection of X.509 certificates. These certificates are not trusted for all applications in your deployment, but might be used as an intermediary to validate certificates for an application.

**Important:** If you configure the client and server signing information correctly, but receive a Soap body not signed error when executing the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the Web Services Client Editor within the WebSphere Application Server Toolkit:

- Click **Security Extensions > Client Service Configuration Details** and indicate the actor information in the **Actor URI** field.
- Click **Security Extensions > Request Sender Configuration > Details** and indicate the actor information in the **Actor** field.

You must configure the same actor strings for the Web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the Web Services Editor within the WebSphere Application Server Toolkit:

- Click **Security Extensions > Server Service Configuration**.
- Click **Security Extensions > Response Sender Service Configuration Details > Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The **actor** fields might be different when you have Web services acting as a gateway to other Web services. However, in all other cases, make sure that the actor information matches on the client and server. When Web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, Web services do not process the message from a client. Instead, these Web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which method the client uses to verify the digital signature in the message parts.

After you configure the server for response signing and the client for request digital signature verification, verify that you have configured the client and the server to handle the message request.

## Configuring the client security bindings using the Assembly Toolkit

When configuring a client for Web services security, the bindings describe how to run the security specifications found in the extensions. Use the Web services client editor within the Assembly Toolkit to include the binding information in the client enterprise archive (EAR) file.

You can configure the client-side bindings from a pure client accessing a Web service or from a Web service accessing a downstream Web service. This document focuses on the pure client situation. However, the concepts, and in most cases the steps, also apply when a Web service is configured to communicate downstream to another Web service that has client bindings. Complete the following steps to edit the security bindings on a pure client (or server acting as a client) using the Assembly Toolkit:

1. Import the Web services client EAR file into the Assembly Toolkit. When you edit the client bindings on a server acting as a client, the same basic steps apply. Complete the following steps to import your client EAR file into the Assembly Toolkit. Refer to the Assembly Toolkit documentation for additional information.
  - a. Download and install the Assembly Toolkit. You can download the Assembly Toolkit from the following Web site: [http://www.ibm.com/support/docview.wss?rs=180&context=SSEQTP&q=ASTK&uid=swg24005125&loc=en\\_US&cs=utf-8&lang=en+en](http://www.ibm.com/support/docview.wss?rs=180&context=SSEQTP&q=ASTK&uid=swg24005125&loc=en_US&cs=utf-8&lang=en+en)
  - b. Start the Assembly Toolkit and open the Java perspective, by clicking **Window > Open Perspective > J2EE**.
  - c. Import the client EAR file by clicking **File > Import > EAR file**.
  - d. Click **Next**.
  - e. Enter the path name to the EAR file in the **EAR File** field or click **Browse** to locate the file.
  - f. Enter the project name in the **Project name** field.
  - g. Click **Finish**.
2. Open the Web services client editor within the Assembly Toolkit to begin editing the client bindings. To access the client bindings using the Assembly Toolkit, complete the following steps:
  - a. Open the Navigator by clicking **Window > Show View > Navigator**.
  - b. Expand your application Java archive (JAR) file from the Navigator.
  - c. Expand the J2EE client application (appClientModule, ejbModule, or WebContent), which are included in the client JAR package that you selected.
  - d. Expand the META-INF directory and locate the webservicessclient.xml file.
  - e. Right-click the webservicessclient.xml file and click **Open With > Web Services Client Editor**. In the Web services client editor (for webservicessclient.xml and outbound requests and inbound responses Web services configuration), there are several tabs at the bottom of the editor including References, Handlers, Security Extensions, Web Services Client Binding, and Port Binding. The security extensions are edited using the **Security Extensions** tab. The security bindings are edited using the Port Binding tab.
3. On the **Security Extensions** tab, select the port qualified name bindings that you want to configure. The Web services security extensions are configured for outbound requests and inbound responses. You need to configure the following information for Web services security extensions. These topics are discussed in more detail in other sections of the documentation.

#### **Request sender configuration details**

##### **Details**

Configuring the client for request signing: digitally signing message parts

##### **Integrity**

Configuring the client for request signing: digitally signing message parts

##### **Confidentiality**

Configuring the client for request encryption: encrypting the message parts

##### **Login Config**

###### **BasicAuth**

Configuring the client for basicauth authentication: specifying the method

###### **IDAssertion**

Configuring the client for identity assertion authentication: specifying the method

###### **Signature**

Configuring the client for signature authentication: specifying the method

###### **LTPA**

Configuring the client for LTPA token authentication: specifying LTPA token authentication

**ID Assertion**

Configuring the client for identity assertion authentication: specifying the method

**Add Created Time Stamp**

Configuring the client for request signing: digitally signing message parts

**Response receiver configuration details****Required Integrity**

Configuring the client for response digital signature verification: verifying the message parts

**Required Confidentiality**

Configuring the client for response decryption: decrypting message parts

**Add Received Time Stamp**

Configuring the client for response digital signature verification: verifying the message parts

4. From the **Port Binding** tab, select the port qualified name binding that you want to configure. The Web services security bindings are configured for outbound requests and inbound responses. You need to configure the following information for Web services security bindings. These topics are discussed in more details in other sections of the documentation.

**Security request sender binding configuration****Signing information**

Configuring the client for request signing: choosing the digital signature method

**Encryption information**

Configuring the client for request encryption: choosing the encryption method

**Key locators**

Configuring key locators using the Assembly Toolkit

**Login binding****Basic auth**

Configuring the client for basicauth authentication: collecting the authentication information

**ID assertion**

Configuring the client for identity assertion: Collecting the authentication method

**Signature**

Configuring the client for signature authentication: collecting the authentication information

**LTPA**

Configuring the client for LTPA token authentication: Collecting the authentication method information

**Security response receiver binding configuration****Signing information**

Configuring the client for response digital signature verification: choosing the verification method

**Encryption information**

Configuring the client for response decryption: choosing a decryption method

**Trust anchor**

Configuring trust anchors using the Assembly Toolkit

**Certificate store list**

Configuring the client-side collection certificate store using the Application Server Toolkit

**Key locators**

Configuring key locators using the Assembly Toolkit

**Important:** When configuring the security request sender binding configuration, you must synchronize the information used to perform the specified security with the security request receiver binding configuration, which is configured in the server EAR file. These two configurations must be synchronized in all respects because there is no negotiation during run time to determine the requirements of the server.

For example, when configuring the encryption information in the security request sender binding Configuration, you must use the public key from the server for encryption. Therefore, the key locator that you choose must contain the public key from the server configuration. The server must contain the private key to decrypt the message. This example illustrates the important relationship between the client and server configuration. Additionally, when configuring the security response receiver binding configuration, the server must send the response using security information known by this client security response receiver binding configuration.

The following table shows the related configurations between the client and the server. The client request sender and the server request receiver are relative configurations that must be synchronized with each other. The server response sender and the client response receiver are related configurations that must be synchronized with each other. Note that the related configurations are end points for any request or response. One end point must communicate its actions with the other end point because run time requirements are not negotiated.

Table 7. Related configurations

Client configuration	Server configuration
Request sender	Request receiver
Response receiver	Response sender

## Configuring the security bindings on a server acting as a client using the administrative console

When configuring a client for Web services security, the bindings describe how to run the security specifications found in the extensions. Use the Web Services Client Editor within the WebSphere Application Server Toolkit to include the binding information in the client enterprise archive (EAR) file.

You can configure the client-side bindings from a pure client accessing a Web service or from a Web service accessing a downstream Web service. Complete the following steps to find the location in which to edit the client bindings from a Web service that is running on the server. When a Web service communicates with another Web service, you must configure client bindings to access the downstream Web service.

1. Deploy the Web service using the WebSphere Application Server administrative console by clicking **Applications > Install New Application**. You can access the administrative console by typing `http://localhost:9090/admin` in your Web browser unless you have changed the port number. For more information on installing an application, see *Installing a new application*
2. Click **Applications > Enterprise Applications > *application\_name***.
3. Under Related Items, click either **Web Modules** or **EJB Modules**, depending upon which type of service is the client to the downstream service.
  - For Web modules, click the Web archive (WAR) file that you configured as the client.
  - For Enterprise JavaBeans (EJB) modules, click the Java archive (JAR) file that you configured as the client.
4. Click the name of the WAR or JAR file.
5. Under Additional Properties, click **Web Services: Client Security Bindings**. A table displays with the following columns:
  - Component Name

- Port
- Web Service
- Request Sender Binding
- Request Receiver Binding
- HTTP Basic Authentication
- HTTP SSL Configuration

For Web services security, you must edit the request sender binding and response receiver binding configurations. You can use the defaults for some of the information at the server level . Default bindings are convenient because you can configure commonly reused elements such as key locators once and then reference their aliases in the application bindings.

6. View the default bindings for the server using the administrative console by clicking **Servers > Application Server > server1**. Under Additional Properties, click **Web Services: Default bindings for Web Services Security**. You can configure the following sections. These topics are discussed in more detail in other sections of the documentation.

- Request sender binding
  - Signing information
  - Encryption information
  - Key locators
  - Login bindings
- Response receiver binding
  - Signing information
  - Encryption information
  - Trust anchors
  - Collection certificate store
  - Key locators

**Important:** When configuring the security request sender binding configuration, you must synchronize the information used to perform the specified security with the security request receiver binding configuration, which is configured in the server EAR file. These two configurations must be synchronized in all respects because there is no negotiation during run time to determine the requirements of the server. For example, when configuring the encryption information in the security request sender binding configuration, you must use the public key from the server for encryption. Therefore, the key locator that you choose must contain the public key from the server configuration. The server must contain the private key to decrypt the message. This example illustrates the important relationship between the client and server configuration. Additionally, when configuring the security response receiver binding configuration, the server must send the response using security information known by this client security response receiver binding configuration.

The following table shows the related configurations between the client and the server. The client request sender and the server request receiver are relative configurations that must be synchronized with each other. The server response sender and the client response receiver are related configurations that must be synchronized with each other. Note that related configurations are end points for any request or response. One end point must communicate its actions with the other end point because run time requirements are not required.

*Table 8. Related configurations*

Client configuration	Server configuration
Request sender	Request receiver
Response receiver	Response sender

## Configuring the server security bindings using the Assembly Toolkit

Create an Enterprise JavaBean (EJB) file Java archive (JAR) file or a Web archive (WAR) file containing the security binding file (`ibm-webservices-bnd.xmi`) and the security extension file (`ibm-webservices-ext.xmi`). If this archive is acting as a client to a downstream service, you also need the client-side binding file (`ibm-webservicesclient-bnd.xmi`) and the client-side extension file (`ibm-webservicesclient-ext.xmi`). These files are generated using the WSDL2Java command. You can edit these files using the Web Services Editor in the Assembly Toolkit.

When configuring server-side security for Web services security, the security extensions configuration specifies what security is performed, the security bindings configuration indicates how to perform what is specified in the security extensions configuration. You can use the defaults for some elements at the cell and server levels in the bindings configuration, including key locators, trust anchors, the collection certificate store, trusted ID evaluators, and login mappings and reference these elements from the WAR and JAR binding configurations.

Prior to importing the Web services enterprise archive (EAR) file into the Assembly Toolkit, make sure that you have already run the `wsdl2java` command on your Web service to enable your J2EE application. You must import the Web services enterprise archive (EAR) file into the Assembly Toolkit. Complete the following steps to import your EAR file into the Assembly Toolkit:

1. Download, install, and launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Import the application EAR file by clicking **File > Import > EAR file**.
4. Click **Next** and indicate both the EAR file name in the **EAR File** field and the project name in the **Project name** field.
5. Click **Finish**.

Refer to Assembly Toolkit documentation for more information.

Open the Web services editor in the Assembly Toolkit to begin editing the server security extensions and bindings. The following steps can locate the server security extensions and bindings. Other tasks specify how to configure each section of the extensions and bindings in more detail.

1. Expand your application module from the Navigator. If the Navigator is not shown, you can open it by clicking **Window > Show View > Navigator**.
2. If your application is a Web archive (WAR) file, perform the following steps:
  - a. Expand the **WebContent > WEB-INF** section.
  - b. Locate the **webservices.xml** file. The `webservices.xml` file represents the server-side (inbound) Web services configuration. The `webservicesclient.xml` file represents the client-side (outbound) Web services configuration.
    - 1) Configure the server for inbound requests and outbound responses security configuration by right-clicking the **webservices.xml** file and clicking **Open With > Web Services Editor**.
    - 2) Configure the client for outbound requests and inbound responses security configuration by right-clicking the **webservicesclient.xml** file and clicking **Open With > Web Services Client Editor**. For more information, see *Configuring the client security bindings using the Assembly Toolkit*.
3. If your application is an EJB Application (JAR) file, perform the following steps:
  - a. Expand the **ejbModule > META-INF** section.
  - b. Locate the **webservices.xml** file. The `webservices.xml` file represents the server-side (inbound) Web services configuration. The `webservicesclient.xml` file represents the client-side (outbound) Web services configuration.
    - 1) Configure the server for inbound requests and outbound responses security configuration by right-clicking the **webservices.xml** file and clicking **Open With > Web Services Editor**.

- 2) Configure the client for outbound requests and inbound responses security configuration by right-clicking the **webservicesclient.xml** file and clicking **Open With > Web Services Client Editor**. For more information, see *Configuring the client security bindings using the Assembly Toolkit*.
4. In the Web services editor (for the `webservices.xml` file and inbound requests and outbound responses Web services configuration), there are several tabs at the bottom of the editor including Web Services, Port Components, Handlers, Security Extensions, Bindings, and Binding Configurations. The security extensions are edited using the Security Extensions tab. The security bindings are edited using the Security Bindings tab.
  - a. Click the **Security Extensions** tab and select the port component binding to edit. The Web services security extensions are configured for inbound requests and outbound responses. You need to configure the following information for Web services security extensions. These topics are discussed in more detail in other topics in the documentation.

#### **Request receiver service configuration details**

##### **Required integrity**

## Configuring the server security bindings using the administrative console

Create an Enterprise JavaBean (EJB) file Java archive (JAR) file or Web archive (WAR) file containing the security binding file (`ibm-webservices-bnd.xmi`) and the security extension file (`ibm-webservices-ext.xmi`). If this archive is acting as a client to a downstream service, you also need the client-side binding file (`ibm-webservicesclient-bnd.xmi`) and the client-side extension file (`ibm-webservicesclient-ext.xmi`). These files are generated using the WSDL2Java command. You can edit these files using the Web Services Editor in the Assembly Toolkit.

When configuring server-side security for Web services security, the security extensions configuration specifies what security is to be performed while the security bindings configuration indicates how to perform what is specified in the security extensions configuration. You can use the defaults for some elements at the cell and server levels in the bindings configuration, including key locators, trust anchors, the collection certificate store, trusted ID evaluators, and login mappings and reference them from the WAR and JAR binding configurations.

The following steps describe how to edit bindings for a Web service after these bindings are deployed on a server. When one Web service communicates with another Web service, you also must configure the client bindings to access the downstream Web service.

1. Deploy the Web service using the WebSphere Application Server administrative console. The Administrative Console is accessible by typing `http://localhost:9090/admin` in a Web browser. After you log into the administration console, click **Applications > Install New Application** to deploy the Web service. For more information, see *Installing a new application*.
2. After you deploy the Web service, click **Applications > Enterprise Applications > *application\_name***.

3. Under Related Items, click either **Web Modules** or **EJB Modules** depending on which service you want to configure.
  - a. If you select **Web Modules**, click the WAR file that you want to edit.
  - b. If you select **EJB Modules**, click the JAR file that you want to edit.
4. After you select a WAR or JAR file, under **Additional Properties**, click **Web Services: Client Security Bindings** for outbound requests and inbound responses. Click **Web Services: Server Security Bindings** for inbound requests and outbound responses.
5. If you click **Web Services: Server Security Bindings**, the following sections can be configured. These topics are discussed in more detail in other sections of the documentation.
  - Request receiver binding
    - Signing Information
    - Encryption Information
    - Trust anchors
    - Collection certificate store
    - Key locators
    - Trusted ID evaluators
    - Login mappings
  - Response sender binding
    - Signing Information
    - Encryption Information
    - Key locators

## XML encryption

XML encryption is a specification developed by World Wide Web (WWW) Consortium (W3C) in 2002 that contains the steps to encrypt data, the steps to decrypt encrypted data the XML syntax to represent encrypted data, the information used to decrypt the data, and a list of encryption algorithms such as triple DES, AES, and RSA.

You can apply XML encryption to an XML element, XML element content, and arbitrary data, including an XML document. For example, suppose that you need to encrypt the CreditCard element shown in the example 1.

### Example 1: Sample XML document

```
<PaymentInfo xmlns='http://example.org/paymentv2'>
 <Name>John Smith</Name>
 <CreditCard Limit='5,000' Currency='USD'>
 <Number>4019 2445 0277 5567</Number>
 <Issuer>Example Bank</Issuer>
 <Expiration>04/02</Expiration>
 </CreditCard>
</PaymentInfo>
```

### Example 2: XML document with a common secret key

Example 2 shows the XML document after encryption. The EncryptedData element represents the encrypted CreditCard element. The EncryptionMethod element describes the applied encryption algorithm, which is triple DES in this example. The KeyInfo element contains the information to retrieve a decryption key, which is a KeyName element in this example. The CipherValue element contains the ciphertext obtained by serializing and encrypting the CreditCard element.

```
<PaymentInfo xmlns='http://example.org/paymentv2'>
 <Name>John Smith</Name>
 <EncryptedData Type='http://www.w3.org/2001/04/xmlenc#Element'
 xmlns='http://www.w3.org/2001/04/xmlenc#'>
```

```

 <EncryptionMethod
 Algorithm='http://www.w3.org/2001/04/xmlenc#tripledes-cbc' />
 <KeyInfo xmlns='http://www.w3.org/2000/09/xmldsig#'>
 <KeyName>John Smith</KeyName>
 </KeyInfo>
 <CipherData>
 <CipherValue>ydUNqHkMrD...</CipherValue>
 </CipherData>
 </EncryptedData>
</PaymentInfo>

```

### Example 3: XML document encrypted with the public key of the recipient

In example 2, it is assumed that both the sender and recipient have a common secret key. If the recipient has a public and private key pair, which is most likely the case, the CreditCard element can be encrypted as shown in example 3. The EncryptedData element is the same as the EncryptedData element found in Example 2. However, the KeyInfo element contains an EncryptedKey .

```

<PaymentInfo xmlns='http://example.org/paymentv2'>
 <Name>John Smith</Name>
 <EncryptedData Type='http://www.w3.org/2001/04/xmlenc#Element'
 xmlns='http://www.w3.org/2001/04/xmlenc#'>
 <EncryptionMethod
 Algorithm='http://www.w3.org/2001/04/xmlenc#tripledes-cbc' />
 <KeyInfo xmlns='http://www.w3.org/2000/09/xmldsig#'>
 <EncryptedKey xmlns='http://www.w3.org/2001/04/xmlenc#'>
 <EncryptionMethod
 Algorithm='http://www.w3.org/2001/04/xmlenc#rsa-1_5' />
 <KeyInfo xmlns='http://www.w3.org/2000/09/xmldsig#'>
 <KeyName>Sally Doe</KeyName>
 </KeyInfo>
 <CipherData>
 <CipherValue>yMTEy0TA1M...</CipherValue>
 </CipherData>
 </EncryptedKey>
 </KeyInfo>
 <CipherData>
 <CipherValue>ydUNqHkMrD...</CipherValue>
 </CipherData>
 </EncryptedData>
</PaymentInfo>

```

### XML Encryption in the WSS-Core

WSS-Core specification is under development by Organization for the Advancement of Structured Information Standards (OASIS). The specification describes enhancements to Simple Object Access Protocol (SOAP) messaging to provide quality of protection through message integrity, message confidentiality, and single message authentication. The message confidentiality is realized by encryption based on XML Encryption.

The WSS-Core specification supports encryption of any combination of body blocks, header blocks, their sub-structures, and attachments of a SOAP message. The specification also requires that when you encrypt parts of a SOAP message, you prepend a reference from the security header block to the encrypted parts of the message. The reference can be a clue for a recipient to identify which encrypted parts of the message to decrypt.

The XML syntax of the reference varies according to what information is encrypted and how it is encrypted. For example, suppose that the CreditCard element in example 4 is encrypted with either a common secret key or the public key of the recipient.

### Example 4: Sample SOAP message

```

<SOAP-ENV:Envelope
 SOAP-ENV:encodingStyle='http://schemas.xmlsoap.org/soap/encoding/'
 xmlns:SOAP-ENV='http://schemas.xmlsoap.org/soap/envelope/'>
 <SOAP-ENV:Body>
 <PaymentInfo xmlns='http://example.org/paymentv2'>
 <Name>John Smith</Name>
 <CreditCard Limit='5,000' Currency='USD'>
 <Number>4019 2445 0277 5567</Number>
 <Issuer>Example Bank</Issuer>
 <Expiration>04/02</Expiration>
 </CreditCard>
 </PaymentInfo>
 </SOAP-ENV:Body>
</SOAP-ENV:Envelope>

```

The resulting SOAP messages are shown in Examples 5 and 6. In these example, the ReferenceList and EncryptedKey elements are used as references, respectively.

### Example 5: SOAP message encrypted with a common secret key

```

<SOAP-ENV:Envelope
 SOAP-ENV:encodingStyle='http://schemas.xmlsoap.org/soap/encoding/'
 xmlns:SOAP-ENV='http://schemas.xmlsoap.org/soap/envelope/'>
 <SOAP-ENV:Header>
 <Security SOAP-ENV:mustUnderstand='1'
 xmlns='http://schemas.xmlsoap.org/ws/2003/06/secext'>
 <ReferenceList xmlns='http://www.w3.org/2001/04/xmlenc#'>
 <DataReference URI='#ed1' />
 </ReferenceList>
 </Security>
 </SOAP-ENV:Header>
 <SOAP-ENV:Body>
 <PaymentInfo xmlns='http://example.org/paymentv2'>
 <Name>John Smith</Name>
 <EncryptedData Id='ed1'
 Type='http://www.w3.org/2001/04/xmlenc#Element'
 xmlns='http://www.w3.org/2001/04/xmlenc#'>
 <EncryptionMethod
 Algorithm='http://www.w3.org/2001/04/xmlenc#tripleDES-cbc' />
 <KeyInfo xmlns='http://www.w3.org/2000/09/xmldsig#'>
 <KeyName>John Smith</KeyName>
 </KeyInfo>
 <CipherData>
 <CipherValue>ydUNqHkMrD...</CipherValue>
 </CipherData>
 </EncryptedData>
 </PaymentInfo>
 </SOAP-ENV:Body>
</SOAP-ENV:Envelope>

```

### Example 6: SOAP message encrypted with the public key of the recipient

```

<SOAP-ENV:Envelope
 SOAP-ENV:encodingStyle='http://schemas.xmlsoap.org/soap/encoding/'
 xmlns:SOAP-ENV='http://schemas.xmlsoap.org/soap/envelope/'>
 <SOAP-ENV:Header>
 <Security SOAP-ENV:mustUnderstand='1'
 xmlns='http://schemas.xmlsoap.org/ws/2003/06/secext'>
 <EncryptedKey xmlns='http://www.w3.org/2001/04/xmlenc#'>
 <EncryptionMethod
 Algorithm='http://www.w3.org/2001/04/xmlenc#rsa-1_5' />
 <KeyInfo xmlns='http://www.w3.org/2000/09/xmldsig#'>
 <KeyName>Sally Doe</KeyName>
 </KeyInfo>
 <CipherData>
 <CipherValue>yMTEy0TA1M...</CipherValue>
 </CipherData>
 </EncryptedKey>
 </Security>
 </SOAP-ENV:Header>
 <SOAP-ENV:Body>
 <PaymentInfo xmlns='http://example.org/paymentv2'>
 <Name>John Smith</Name>
 <EncryptedData Id='ed1'
 Type='http://www.w3.org/2001/04/xmlenc#Element'
 xmlns='http://www.w3.org/2001/04/xmlenc#'>
 <EncryptionMethod
 Algorithm='http://www.w3.org/2001/04/xmlenc#tripleDES-cbc' />
 <KeyInfo xmlns='http://www.w3.org/2000/09/xmldsig#'>
 <KeyName>John Smith</KeyName>
 </KeyInfo>
 <CipherData>
 <CipherValue>ydUNqHkMrD...</CipherValue>
 </CipherData>
 </EncryptedData>
 </PaymentInfo>
 </SOAP-ENV:Body>
</SOAP-ENV:Envelope>

```

```

 <ReferenceList>
 <DataReference URI='#ed1' />
 </ReferenceList>
 </EncryptedKey>
 </Security>
 </SOAP-ENV:Header>
 <SOAP-ENV:Body>
 <PaymentInfo xmlns='http://example.org/paymentv2'>
 <Name>John Smith</Name>
 <EncryptedData Id='ed1'
 Type='http://www.w3.org/2001/04/xmlenc#Element'
 xmlns='http://www.w3.org/2001/04/xmlenc#'>
 <EncryptionMethod
 Algorithm='http://www.w3.org/2001/04/xmlenc#tripleDES-cbc' />
 <CipherData>
 <CipherValue>ydUNqHkMrD...</CipherValue>
 </CipherData>
 </EncryptedData>
 </PaymentInfo>
 </SOAP-ENV:Body>
</SOAP-ENV:Envelope>

```

### Relationship to digital signature

The WSS-Core specification also provides message integrity, which is realized by a digital signature based on the XML-Signature specification.

A combination of encryption and digital signature over common data introduces cryptographic vulnerabilities.

## Securing Web services using XML encryption

WebSphere Application Server provides several different methods to secure your Web services. Extensible Markup Language (XML) encryption is one of these methods. You can secure your Web services using any of the following methods:

- XML digital signature
- XML encryption
- Basicauth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

XML encryption enables you to encrypt an XML element, the content of an XML element, or arbitrary data such as an XML document. Like XML digital signature, a message is sent by the client as the request sender to the server as the request receiver. The response is sent by the server as the response sender to the client as the request receiver. Unlike XML digital signature, which verifies the authenticity of the sender, XML encryption scrambles the message content using a key, which can be unscrambled by a receiver that possesses the same key. You can use XML encryption in conjunction with XML digital signature to scramble the content while verifying the authenticity of the message sender.

To use XML encryption to secure Web services, you must use the WebSphere Application Server Toolkit, which is available at the following Web

site:[http://www.ibm.com/support/docview.wss?rs=180&context=SSEQTP&q=ASTK&uid=swg24005125&loc=en\\_US&cs=utf-8&lang=en+en](http://www.ibm.com/support/docview.wss?rs=180&context=SSEQTP&q=ASTK&uid=swg24005125&loc=en_US&cs=utf-8&lang=en+en)

Complete the following steps.

1. Specify the encryption settings for the request sender. The message parts and the encryption method settings chosen for the request sender on the client must match the message parts and the method settings chosen for the request receiver on the server. To specify the encryption settings for the request sender:
  - a. Configure the client for request encryption: Encrypting the message parts.
  - b. Configure the client for request encryption: Choosing the encryption method.
2. Specify the encryption settings for the request receiver. The decryption settings chosen for the request receiver must match the encryption settings chosen for the request sender.  
To specify the decryption settings for the request receiver:
  - a. Configure the server for request decryption: Decrypting message parts.
  - b. Configure the server for request decryption: Choosing the decryption method.
3. Specify the encryption settings for the response sender. The message parts and the encryption method settings chosen for the response sender on the server must match the message parts and the method settings chosen for the response receiver on the client. To specify the encryption settings for the response sender:
  - a. Configure the server for response encryption: Encrypting message parts.
  - b. Configure the server for response encryption: Choosing the encryption method.
4. Specify the encryption settings for the response receiver.

**Remember:** The decryption settings chosen for the response receiver must match the encryption settings chosen for the response sender.

To specify the decryption settings for the response receiver, complete the following steps:

- a. Configure the client for response decryption: decrypting message parts.
- b. Configure the client for response decryption: choosing the decryption method.

After completing these steps, you have secured your Web services using XML encryption.

## Encryption information collection

Use this page to specify the configuration for the encrypting and decrypting parameters. This configuration is used to encrypt and decrypt parts of the message, including the body and user name token.

To view this administrative console page, complete the following steps:

1. Click **Enterprise Applications** > *application\_name*.
2. Under Related Items, click **Web Module**.
3. Under Additional Properties, click **Web Services: Server Security Bindings**.
4. Under Request Receiver Binding, click **Edit > Encryption Information**.
5. Click **New** to create an encryption method.
6. Click **Delete** to delete an encryption method.

### **Encryption Information:**

Specifies the name of the encryption information.

## Encryption information configuration settings

Use this page to configure the encryption and decryption parameters. You can use these parameters to encrypt and decrypt various parts of the message including the body and user name token.

To view this administrative console page:

1. Click **Applications > Enterprise Applications** > *application\_name*.
2. Under Related Items, click **Web Module** > *URI\_file\_name* > **Web Services: Server Security Bindings**.

3. Under Request Receiver Binding, click **Edit > Encryption Information > New**.

**Encryption Information Name:**

Specifies the name for the encryption information.

**Key Locator Reference:**

Specifies the name used to reference the key locator.

To specify key locator references, click **Servers > Application Servers > *server\_name***. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Key Locators**.

**Encryption Key Name:**

Specifies the name of the encryption key, which is resolved to the actual key by the specified key locator.

**Key Encryption Algorithm:**

Specifies the algorithm Uniform Resource Identifier (URI) of the key encryption method.

The following algorithms are supported:

- [http://www.w3.org/2001/04/xmlenc#rsa-1\\_5](http://www.w3.org/2001/04/xmlenc#rsa-1_5)
- <http://www.w3.org/2001/04/xmlenc#kw-tripledes>

**5.1 +** The following additional algorithms are supported:

- <http://www.w3.org/2001/04/xmlenc#kw-aes128>
- <http://www.w3.org/2001/04/xmlenc#kw-aes256>
- <http://www.w3.org/2001/04/xmlenc#kw-aes192>

**Data Encryption Algorithm:**

Specifies the algorithm URI of the data encryption method.

The following algorithm is supported:

- <http://www.w3.org/2001/04/xmlenc#tripledes-cbc>

**5.1 +** The following additional algorithms are supported:

- <http://www.w3.org/2001/04/xmlenc#aes128-cbc>
- <http://www.w3.org/2001/04/xmlenc#aes256-cbc>
- <http://www.w3.org/2001/04/xmlenc#aes192-cbc>

## Encryption information configuration settings

Use this page to configure the encryption and decryption parameters.

The specifications listed on this page for the signature method, digest method, and canonicalization method are located in the World Wide Web Consortium (W3C) document entitled, *XML Encryption Syntax and Processing: W3C Recommendation 10 Dec 2002*.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise Applications > *application\_name***.
2. Under Related Items, click **Web Module > *URI\_file\_name* > Web Services: Server Security Bindings**.

3. Under Response Sender Binding, click **Edit > Encryption Information**.
4. If the encryption information is not available, select **None**.
5. If the encryption information is available, select **Dedicated Encryption Information**.

Then, specify the configuration in the following fields:

***Encryption Information Name:***

Specifies the name for the encryption information.

***Key Locator Reference:***

Specifies the name used to reference the key locator.

To specify key locator references, click **Servers > Application Servers > *server\_name***. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Key Locators**.

***Encryption Key Name:***

Specifies the name of the encryption key, which is resolved to the actual key by the specified key locator.

***Key Encryption Algorithm:***

Specifies the algorithm URI of the key encryption method.

The following algorithms are supported:

- [http://www.w3.org/2001/04/xmlenc#rsa-1\\_5](http://www.w3.org/2001/04/xmlenc#rsa-1_5)
- <http://www.w3.org/2001/04/xmlenc#kw-tripledes>

**5.1+** The following additional algorithms are supported:

- <http://www.w3.org/2001/04/xmlenc#kw-aes128>
- <http://www.w3.org/2001/04/xmlenc#kw-aes256>
- <http://www.w3.org/2001/04/xmlenc#kw-aes192>

By default the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files. Before downloading these policy files, back up the existing policy files (`local_policy.jar` and `US_export_policy.jar` in the `jre/lib/security/` directory) prior to overwriting them in case you want to restore the original files later. To download the policy files, complete either of the following sets of steps:

- For WebSphere Application Server platforms using IBM Developer Kit, Java Technology Edition Version 1.4.1, including the AIX, Linux, and Windows platforms, you can obtain unlimited jurisdiction policy files by completing the following steps:

- Go to the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>
- Click **IBM SDK Policy files**.

The `unrestrict.zip` file is downloaded onto your machine.

- For WebSphere Application Server platforms using the Sun-based Java Development Kit (JDK) Version 1.4.1, including the Solaris environments and the HP-UX platform, you can obtain unlimited jurisdiction policy files by completing the following steps:

- Go to the following Web site: <http://java.sun.com/j2se/1.4.1/download.html>
- Locate the Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files 1.4.1 information and click **Download**. The `jce_policy-1_4_1.zip` file is downloaded onto your machine.

**Attention:**

After following either of these sets of steps, two Java Archive (JAR) files are placed in the JVM `jre/lib/security/` directory.

### **Data Encryption Algorithm:**

Specifies the algorithm Uniform Resource Identifiers (URI) of the data encryption method.

The following algorithm is supported:

- <http://www.w3.org/2001/04/xmlenc#tripleDES-cbc>

**5.1 +** The following additional algorithms are supported:

- <http://www.w3.org/2001/04/xmlenc#aes128-cbc>
- <http://www.w3.org/2001/04/xmlenc#aes256-cbc>
- <http://www.w3.org/2001/04/xmlenc#aes192-cbc>

By default the JCE is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit AES encryption algorithms, you must apply unlimited jurisdiction policy files.

### **Login bindings configuration settings**

Use this page to configure the encryption and decryption parameters.

The pluggable token uses the Java Authentication and Authorization Service (JAAS) `CallbackHandler` (`javax.security.auth.callback.CallbackHandler`) interface to generate the token that is inserted into the message. The following list describes the `Callback` support implementations:

#### **com.ibm.wsspi.wssecurity.auth.callback.BinaryTokenCallback**

This implementation is used for generating binary tokens inserted as `<wsse:BinarySecurityToken/@ValueType>` in the message.

#### **javax.security.auth.callback.NameCallback and javax.security.auth.callback.NameCallback**

This implementation is used for generating user name tokens inserted as `<wsse:UsernameToken>` in the message.

#### **com.ibm.wsspi.wssecurity.auth.callback.XMLTokenSenderCallback**

This implementation is used to generate Extensible Markup Language (XML) tokens and is inserted as the `<SAML: Assertion>` element in the message.

#### **com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback**

This implementation is used to obtain properties specified in the binding file.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise Applications > application\_name**.
2. Under Related Items, click **Web Module > URI\_file\_name > Web Services: Client Security Bindings**.
3. Under Request Sender Bindings, click **Edit > Login Binding**.

If the encryption information is not available, select **None**.

If the encryption information is available, select **Dedicated Login Binding** and specify the configuration in the following fields:

### **Authentication Method:**

Specifies the unique name for the authentication method.

### **Callback Handler:**

Specifies the name of the callback handler. The callback handler must implement the `javax.security.auth.callback.CallbackHandler` interface.

**Basic Auth User ID:**

Specifies the user name for basic authentication. The basic authentication method provides the capability to define a user ID and a password in the binding file.

**Basic Auth Password:**

Specifies the password for basic authentication.

**Token Type URI:**

Specifies the Uniform Resource Identifiers (URI) for the token type. This information is inserted as `<wsse:BinarySecurityToken>/ValueType` for the `<SAML: Assertion>` XML token.

**Token Type Local Name:**

Specifies the local name for the token type. This information is inserted as `<wsse:BinarySecurityToken>/ValueType` for the `<SAML: Assertion>` XML token.

## Request sender

The security handler on the request sender side of the SOAP message enforces the security constraints, located in the `ibm-webservicesclient-ext.xml` file, and bindings, located in the `ibm-webservicesclient-bnd.xml` file. These constraints and bindings apply both to J2EE application clients or when Web services is acting as a client. The security handler acts on the security constraints before sending the SOAP message. For example, the security handler might digitally sign the message, encrypt the message, create a time stamp, or insert a security token.

The security handler on the request sender side of the Simple Object Access Protocol (SOAP) message enforces the security constraints, located in the `ibm-webservicesclient-ext.xml` file, and the bindings, located in the `ibm-webservicesclient-bnd.xml` file. These constraints and bindings apply both to J2EE application clients or when Web services is acting as a client. The security handler acts on the security constraints before sending the SOAP message. Request sender security constraints must match the security constraint requirements defined in the request receiver. For example, the security handler might digitally sign the message, encrypt the message, create a time stamp, or insert a security token. You can specify the following security requirements for the request sender and apply them to the SOAP message:

### Integrity (digital signature)

You can select multiple parts of a message to sign digitally. The following list contains the integrity options:

- Body
- Time stamp
- Security token

### Confidentiality (encryption)

You can select multiple parts of a message to encrypt. The following list contains the confidentiality options:

- Body content
- Username token

### Security token

You can insert only one token into the message. The following list contains the security token options:

- Basic authentication, which requires both a user name and a password

- Identity assertion, which requires a user name only
- X.509 binary security token
- Lightweight Third Party Authentication (LTPA) binary security token
- Custom token , which is pluggable and supports custom-defined tokens in the SOAP message

### Timestamp

You can have a time stamp to indicate the timeliness of the message.

- Timestamp

### ***Request sender binding collection:***

Use this page to specify the binding configuration to send request messages for Web services security.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise Applications > application\_name**.
2. Under Related Items, click **Web Modules > URI\_file\_name > Web Services: Client Security Bindings**.
3. Under Request Sender Binding, click **Edit**.

### *Signing Information:*

Specifies the configuration for the signing parameters. Signing information is used to sign and validate parts of the message including the body and time stamp.

You can also use these parameters for X.509 validation when the Authentication Method is `IDAssertion` and the *ID Type* is `X509Certificate` in the server-level configuration. In such cases, you must fill in the Certificate Path fields only.

### *Encryption Information:*

Specifies the configuration for the encrypting and decrypting parameters. Encryption information is used for encrypting and decrypting various parts of a message including the body and user name token.

### *Key Locators:*

Specifies a list of key locator objects that retrieve the keys for digital signature and encryption from a key store file or a repository. The key locator maps a name or a logical name to an alias or maps an authenticated identity to a key. This logical name is used to locate a key in a key locator implementation.

### *Login Mappings:*

Specifies a list of configurations for validating tokens within incoming messages.

Login mappings map the authentication method to the Java Authentication and Authorization Service (JAAS) configuration.

To configure JAAS, use the administrative console and click **Security > JAAS Configuration**.

## **Configuring the client for request encryption: Encrypting the message parts**

Prior to completing these steps, read either of the following topics to familiarize yourself with the Security Extensions tab and the Port Binding tab in the Web services client editor within the Assembly Toolkit:

- Configuring the client security bindings using the Assembly Toolkit
- Configuring the security bindings on a server acting as a client using the administrative console

These two tabs are used to configure the Web services security extensions and Web services security bindings, respectively.

Complete the following steps to specify which message parts to encrypt when configuring the client for request encryption:

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services-enabled Enterprise JavaBeans (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the webservicessclient.xml file, and click **Open With > Web Services Client Editor**.
6. Click the **Security Extensions** tab, which is located at the bottom of the Web services client editor within the Assembly Toolkit.
7. Expand **Request Sender Configuration > Confidentiality**. Confidentiality refers to encryption while integrity refers to digital signing. Confidentiality reduces the risk of someone understanding the message flowing across the Internet. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the correct target. For more information on encrypting , see XML encryption.
8. Select the parts of the message that you want to encrypt by clicking **Add**. You can select one of the following parts:

**Bodycontent**

User data portion of the message

**UsernameToken**

Basic authentication information, if selected

After you specify which message parts to encrypt, you must specify which method to use to encrypt the request message. See Configuring the client for request encryption: Choosing the encryption method for more information.

## Configuring the client for request encryption: Choosing the encryption method

Prior to completing these steps, read either of the following topics to familiarize yourself with the **Security Extensions** tab and the **Port Binding** tab in the Web Services Client Editor within the Assembly Toolkit:

- Configuring the client security bindings using the Assembly Toolkit
- Configuring the security bindings on a server acting as a client using the administrative console

These two tabs are used to configure the Web Services Security extensions and Web Services Security bindings, respectively.

Complete the following steps to specify which encryption method to use when configuring the client for request encryption:

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the webservicessclient.xml file, and click **Open With > Web Services Client Editor**.
6. Click the **Port Binding** tab, which is located at the bottom of the Web services client editor within the Assembly Toolkit.
7. Expand **Security Request Sender Binding Configuration > Encryption Information**.

8. Select an encryption option and click **Edit** to view the encryption information or click **Add** to add another option. The following table describes the purpose of this information. Some of these definitions are based on the XML-Encryption specification, which is located at the following Web address: <http://www.w3.org/TR/xmlenc-core>

**Encryption name**

Refers to the name of the encryption information entry.

**Data encryption method algorithm**

Encrypts and decrypts data in fixed size, multiple octet blocks.

**Key encryption method algorithm**

Represents public key encryption algorithms that are specified for encrypting and decrypting keys.

**Encryption key name**

Represents a Subject (Owner field of the certificate) from a public key certificate found by the encryption key locator, which is used by the key encryption method algorithm to encrypt the private key. The private key is used to encrypt the data.

The key chosen must be a public key of the target. Encryption must be done using the public key and decryption must be done by the target using the private key (the personal certificate of the target).

**Encryption key locator**

Represents a reference to a key locator implementation class that locates the correct key store where the alias and the certificate exist. For more information on configuring key locators, see *Configuring key locators using the Assembly Toolkit* and *Configuring key locators using the administrative console*.

For more information, see *Configuring key locators using the Assembly Toolkit* and *Configuring key locators using the Administrative Console*.

You must specify which parts of the request message to encrypt. See *Configuring the client for request encryption: Encrypting the message parts if you have not previously specified this information*.

**Request receiver**

The security handler on the request receiver side of the Simple Object Access Protocol (SOAP) message enforces the security specifications defined in the IBM extension deployment descriptor (`ibm-webservices-ext.xmi`) and bindings (`ibm-webservices-bnd.xmi`). The request receiver defines the security requirement of the SOAP message. The security constraint for request sender must match the security requirement of the request receiver for the server to accept the request. If the incoming SOAP message does not meet all the security requirements defined, then the request is rejected with the appropriate fault code returned to the sender. For security tokens, the token is validated using Java Authentication and Authorization Service (JAAS) login configuration and authenticated identity is set as the identity for the downstream invocation.

For example, if there is a security requirement to have the SOAP body digitally signed by Joe Smith and if the SOAP body of the incoming SOAP message is not signed by Joe Smith, then the request is rejected.

You can define the following security requirements for the request receiver:

**Required integrity (digital signature)**

You can select multiple parts of a message to sign digitally. The following list contains the integrity options:

- Body
- Time stamp
- Security token

### **Required confidentiality (encryption)**

You can select multiple parts of a message to encrypt. The following list contains the confidentiality options:

- Body content
- Token

You can have multiple security tokens. The following list contains the security token options:

- Basic authentication, which requires both a user name and a password
- Identity assertion, which requires a user name only
- X.509 binary security token
- Lightweight Third Party Authentication (LTPA) binary security token
- Custom token, which is pluggable and supports custom-defined tokens validated by the JAAS login configuration

### **Received time stamp**

You can have a time stamp for checking the timeliness of the message.

- Time stamp

### ***Request receiver binding collection:***

Use this page to specify the binding configuration to receive request messages for Web services security.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise Applications > application\_name**.
2. Under Related Items, click **Web Modules > URI\_file\_name > Web Services: Server Security Bindings**.
3. Under Request Receiver Binding, click **Edit**.

### ***Signing Information:***

Specifies the configuration for the signing parameters. Signing information is used to sign and validate parts of a message including the body, the time stamp, and the user name token.

You also can use these parameters for X.509 certificate validation when the authentication method is IDAssertion and the ID Type is X509Certificate in the server-level configuration. In such cases, you must fill in the Certificate Path fields only.

### ***Encryption Information:***

Specifies the configuration for the encrypting and decrypting parameters. This configuration is used to encrypt and decrypt parts of the message that include the body and the user name token.

### ***Trust Anchors:***

Specifies a list of key store objects that contain the trusted root certificates that are issued by a certificate authority (CA).

The certificate authority authenticates a user and issues a certificate. The CertPath API uses the certificate to validate the certificate chain of incoming, X.509-formatted security tokens or trusted, self-signed certificates.

### ***Collection Certificate Store:***

Specifies a list of the untrusted, intermediate certificate files.

The collection certificate store contains a chain of untrusted, intermediate certificates. The CertPath API attempts to validate these certificates, which are based on the trust anchor.

#### *Key Locators:*

Specifies a list of key locator objects that retrieve the keys for digital signature and encryption from a key store file or a repository. The key locator maps a name or a logical name to an alias or maps an authenticated identity to a key. This logical name is used to locate a key in a key locator implementation.

#### *Trusted ID Evaluators:*

Specifies a list of trusted ID evaluators that determine whether to trust the identity-asserting authority or message sender.

The trusted ID evaluators are used to authenticate additional identities from one server to another server. For example, a client sends the identity of user A to server 1 for authentication. Server 1 calls downstream to server 2, asserts the identity of user A, and includes the user ID and password of server 1. Server 2 attempts to establish trust with server 1 by authenticating its user ID and password and checking the trust based on the TrustedIDEvaluator implementation. If the authentication process and the trust check are successful, server 2 trusts that server 1 authenticated user A and a credential is created for user A on server 2 to invoke the request.

#### *Login Mappings:*

Specifies a list of configurations for validating tokens within incoming messages.

Login mappings map the authentication method to the Java Authentication and Authorization Service (JAAS) configuration.

To configure JAAS, use the administrative console and click **Security > JAAS Configuration**.

## **Configuring the server for request decryption: Decrypting the message parts**

Complete this task to specify which parts of the request message must be decrypted by the server. You must know which parts of the request message the client encrypts because the server must decrypt the same message parts.

Prior to completing these steps, read either of the following topics to become familiar with the Security Extensions tab and the Binding Configurations tab:

- Configuring the server security bindings using the Assembly Toolkit
- Configuring the server security bindings using the administrative console

These two tabs are used to configure the Web services security extensions and Web services security bindings, respectively.

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the webservices.xml file, and click **Open With > Web Services Editor**.
6. Click the **Security Extensions** tab, which is located at the bottom of the Web services editor within the Assembly Toolkit.
7. Expand the **Request Receiver Service Configuration Details > Required Confidentiality** section.

8. Select the parts of the message to decrypt. The message parts selected for the request decryption on the server must match the message parts selected for the message encryption on the client. Click **Add** and select either of the following message parts:

**bodycontent**

The user data section of the message.

**usertoken**

This token is the basic authentication information.

After you specify which parts of the request message to decrypt, you must specify the method to use to decrypt the message. See *Configuring the server for request decryption: Choosing the decryption method* for more information.

## Configuring the server for request decryption: choosing the decryption method

Prior to completing these steps, read either of the following topics to become familiar with the **Security Extensions** tab and the **Binding Configurations** tab:

- *Configuring the server security bindings using the Assembly Toolkit*
- *Configuring the server security bindings using the administrative console*

These two tabs are used to configure the Web Services Security extensions and Web Services Security bindings, respectively.

Complete this task to specify which decryption method is used by the server to decrypt the request message. You must know which decryption method the client uses because the server must use the same method.

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the webservices.xml file, select **Open With > Web Services Editor**.
6. Click the **Binding Configurations** tab, which is located at the bottom of the Web services editor within the Assembly Toolkit.
7. Expand the **Request Receiver Binding Configuration Details > Encryption Information** section.
8. Click **Edit** to view the encryption information. The following table describes the purpose for each of these selections. Some definitions are taken from the XML-Encryption specification, which is located at the following Web address: <http://www.w3.org/TR/xmlenc-core>

**Encryption name**

Represents the name of this encryption information entry; an alias for the entry.

**Data encryption method algorithm**

Encrypts and decrypts data in fixed size, multiple octet blocks. This algorithm must be the same as the algorithm selected in the client request sender configuration.

**Key encryption method algorithm**

Represents algorithms specified for encrypting and decrypting keys. This algorithm must be the same as the algorithm selected in the client request sender configuration.

**Encryption key name**

Represents a Subject from a personal certificate, which is typically a distinguished name (DN) that is found by the encryption key locator. The subject is used by the key encryption method algorithm to decrypt the secret key, and the secret key is used to decrypt the data.

The key chosen must be a private key in the key store configured by the key locator. The key requires the same Subject used by the client to encrypt the data. Encryption must be done using the public key and decryption by using the private key (personal certificate). To ensure that the client encrypts the data with the correct public or private key, you must extract the public key from the server key store and add it to the key store specified in the encryption configuration information for the client request sender.

For example, the personal certificate of a server is CN=Bob, O=IBM, C=US. Therefore the server contains the public and private key pair. The client sending the request should encrypt the data using the public key for CN=Bob, O=IBM, C=US. The server decrypts the data using the private key for CN=Bob, O=IBM, C=US.

### **Encryption key locator**

Represents a reference to a key locator implementation class that finds the correct keystore where the alias and the certificate exist. For more information on configuring key locators, go to the following sections: [Configuring key locators using the Assembly Toolkit](#) and [Configuring key locators using the Administrative Console](#).

It is important to note that for decryption, the encryption key name chosen must refer to a personal certificate that can be located by the key locator of the server referenced in the encryption information. Enter the Subject of the personal certificate here, which is typically a Distinguished Name (DN). The Subject uses the default key locator to find the key. If a custom key locator is written, the encryption key name can be anything used by the key locator to find the correct encryption key. The encryption key locator references the implementation class that finds the correct key store where this alias and certificate exist. Refer to [Configuring key locators using the Assembly Toolkit](#) and [Configuring key locators using the Administrative Console](#) for more information.

You must specify which parts of the request message to decrypt. See [Configuring the server for request decryption: Decrypting the message parts](#) if you have not previously specified this information.

### **Response sender**

The response sender defines the security requirements of the Simple Object Access Protocol (SOAP) response message. The security handler acts on the security constraints defined for the response in the IBM extension deployment descriptors, located in the `ibm-webservices-ext.xmi` file and the bindings, located in the `ibm-webservices-bnd.xmi` file. The security handler signs, encrypts, or generates the time stamp for the SOAP response message before the response is send to the caller.

#### **Integrity constraints (digital signature)**

You can select which parts of the message are digitally signed.

- Body
- Time stamp

#### **Confidentiality (encryption)**

You can encrypt the body content of the message.

#### **Time stamp**

You can have a time stamp for checking the timeliness of the message.

The security constraints that apply to the SOAP response message must match the security requirements defined in the response receiver. Otherwise, the response is rejected by the response receiver (caller).

#### ***Response sender binding collection:***

Use this page to specify the binding configuration for sender response messages for Web services security.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise Applications > *application\_name***.

2. Under Related Items, click **Web Modules** > *URI\_file\_name* > **Web Services: Server Security Bindings**.
3. Under Response Sender Binding, click **Edit**.

#### *Signing Information:*

Specifies the configuration for the signing parameters.

You also can use these parameters for X.509 certificate validation when the authentication method is IDAssertion and the ID Type is X509Certificate in the server-level configuration. In such cases, you must fill-in the **Certificate Path** fields only.

#### *Encryption Information:*

Specifies the configuration for the encryption and decryption parameters.

#### *Key Locators:*

Specifies a list of key locator objects that retrieve the keys for a digital signature and encryption from a key store file or a repository. The key locator maps a name or logical name to an alias or maps an authenticated identity to a key. This logical name is used to locate a key in a key locator implementation.

## **Configuring the server for response encryption: encrypting the message parts**

Prior to completing these steps, read either of the following topics to become familiar with the Security Extensions tab and the Binding Configurations tab in the Web services editor within the Assembly Toolkit:

- Configuring the server security bindings using the Assembly Toolkit
- Configuring the server security bindings using the administrative console

These two tabs are used to configure the Web services security extensions and the Web services security bindings, respectively.

Complete the following steps to specify which parts of the response message to encrypt when configuring the server for response encryption:

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window** > **Open Perspective** > **Other** > **J2EE**.
3. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the `webservices.xml` file, select **Open With** > **Web Services Editor**.
6. Click the **Security Extensions** tab, which is located at the bottom of the Web Services Editor within the Assembly Toolkit.
7. Expand **Response Sender Service Configuration Details** > **Confidentiality**. Confidentiality refers to encryption while integrity refers to digital signing. Confidentiality reduces the risk of someone understanding the message flowing across the Internet. With confidentiality specifications, the response is encrypted before it is sent and decrypted when it is received at the correct target. For more information on encrypting, see XML encryption.
8. Select the parts of the response that you want to encrypt by clicking **Add** and selecting **Bodytoken** or **UsernameToken**. The following information describes the message parts:

#### **Bodycontent**

User data portion of the message.

#### **UsernameToken**

Basic authentication information, if selected.

A user name token does not appear in the response so you do not need to select this option for the response. If you select this option, make sure that you also select it for the client response receiver. If you do not select this option, make sure that you do not select it for the client response receiver.

After you specify which message parts to encrypt, you must specify which method to use message encryption. See *Configuring the server for response encryption: Choosing the encryption method* for more information.

## Configuring the server for response encryption: Choosing the encryption method

Prior to completing these steps, read either of the following topics to become familiar with the Security Extensions tab and the Binding Configurations tab in the Web services editor within the Assembly Toolkit:

- *Configuring the server security bindings using the Assembly Toolkit*
- *Configuring the server security bindings using the administrative console*

These two tabs are used to configure the Web services security extensions and Web services security bindings, respectively.

Complete the following steps to specify which method the server uses to encrypt the response message:

1. Launch the Assembly Toolkit.
2. Click **Windows > Open Perspective > J2EE** to access the Assembly Toolkit perspective.
3. Select the Web services enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the `webservices.xml` file, and click **Open With > Web Services Editor**.
6. Click the **Binding Configurations** tab, which is located at the bottom of the Web Services Editor within the Assembly Toolkit.
7. Expand **Response Sender Binding Configuration Details > Encryption Information**.
8. Click **Edit** to view the encryption information. The following table describes the purpose of this information. Some of these definitions are based on the XML-Encryption specification, which is located at the following Web address: <http://www.w3.org/TR/xmlenc-core>

### Encryption name

Refers to the name of the encryption information entry.

### Data encryption method algorithm

Encrypts and decrypts data in fixed size, multiple octet blocks. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration.

### Key encryption method algorithm

Represents public key encryption algorithms that are specified for encrypting and decrypting keys. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration.

### Encryption key name

Represents a Subject from a public key certificate typically distinguished name (DN) that is found by the encryption key locator and used by the key encryption method algorithm to encrypt the private key. The private key is used to encrypt the data.

The key name chosen in the server response sender encryption information must be the public key of the key configured in the client response receiver encryption information. Encryption by the response sender must be done using the public key and decryption must be done by the response receiver using the associated private key (the personal certificate of the response receiver).

## Encryption key locator

The encryption key locator represents a reference to a key locator implementation class that finds the correct key store where the alias and the certificate exist. For more information on configuring key locators, see *Configuring key locators using the Assembly Toolkit* and *Configuring key locators using the administrative console*.

The encryption key name chosen must refer to a public key of the response receiver. For the encryption key name, use the Subject of the public key certificate, typically a Distinguished Name (DN). The name chosen is used by the default key locator to find the key. If you write a custom key locator, the encryption key name might be anything used by the key locator to find the correct encryption key (a public key). The encryption key locator references the implementation class that finds the correct key store where the alias and certificate exist. For more information, see *Configuring key locators using the Assembly Toolkit* and *Configuring key locators using the Administrative Console*.

You must specify which parts of the response message to encrypt. See *Configuring the server for response encryption: Encrypting the message parts* if you have not previously specified this information.

## Response receiver

The response receiver defines the security requirements of the response received from a request to a Web service. The security constraints for response sender must match the security requirements of the response receiver. If the constraints do not match, the response is not accepted by the caller or the sender. The security handler enforces the security constraints based on the security requirements defined in the IBM extension deployment descriptor, located in the `ibm-webservicesclient-ext.xml` file and in the bindings, located in the `ibm-webservicesclient-bnd.xml` file.

For example, the security requirement might have the response Simple Object Access Protocol (SOAP) body encrypted. If the SOAP body of the SOAP message is not encrypted, the response is rejected and the appropriate fault code is communicated back to the caller of the Web services.

You can specify the following security requirements for a response receiver:

### Required integrity (digital signature)

You can select which parts of a message are digitally signed. The following list contains the integrity options:

- Body
- Time stamp

### Required confidentiality (encryption)

You can encrypt the body content of the message.

### Received time stamp

You can have a time stamp for checking the timeliness of the message.

### ***Response receiver binding collection:***

Use this page to specify the binding configuration for receiver response messages for Web services security.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise Applications > application\_name**.
2. Under Related Items, click **Web Modules > URI\_file\_name > Web Services: Server Security Bindings**.
3. Under Response Sender Binding, click **Edit**.

*Signing Information:*

Specifies the configuration for the signing parameters. Signing information is used to sign and to validate parts of the message including the body and the time stamp.

You can also use these parameters for X.509 validation when the authentication method is `IDAssertion` and the *ID type* is `X509Certificate` in the server-level configuration. In such cases, you must fill in the certificate path fields only.

#### *Encryption Information:*

Specifies the configuration for the encryption and decryption parameters. Encryption information is used for encrypting and decrypting various parts of a message, including the body and the user name token.

#### *Trust Anchors:*

Specifies a list of key store objects that contain the trusted root certificates that are self-signed or issued by a certificate authority.

The certificate authority authenticates a user and issues a certificate. After the certificate is issued, the key store objects, which contain these certificates, use the certificate for certificate path or certificate chain validation of incoming X.509-formatted security tokens.

#### *Collection Certificate Store:*

Specifies a list of the untrusted, intermediate certificate files.

The collection certificate store contains a chain of untrusted, intermediate certificates. The CertPath API attempts to validate these certificates, which are based on the trust anchor.

#### *Key Locators:*

Specifies a list of key locator objects that retrieve the keys for a digital signature and encryption from a key store file or a repository. The key locator maps a name or logical name to an alias or maps an authenticated identity to a key. This logical name is used to locate a key in a key locator implementation.

## **Configuring the client for response decryption: Decrypting the message parts**

Prior to completing these steps, read either of the following topics to become familiar with the Security Extensions tab and the Port Binding tab in the Web Services Client Editor within the Assembly Toolkit:

- Configuring the client security bindings using the Assembly Toolkit
- Configuring the security bindings on a server acting as a client using the administrative console

These two tabs are used to configure the Web services security extensions and the Web services security bindings, respectively.

Complete the following steps to specify which response message parts to decrypt when configuring the client for response decryption. The server response encryption and client response decryption configurations must match.

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services enabled EJB or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the `webservicesclient.xml` file, click here **Open With > Web Services Client Editor**.
6. Click the **Security Extensions** tab, which is located at the bottom of the Web services client editor within the Assembly Toolkit.

7. Expand the **Response Receiver Configuration > Required Confidentiality** section.
8. Select the parts of the message that you must decrypt by clicking **Add** and selecting either **Bodycontent** or **Usenametoken**. The following information describes these message parts:

**Bodycontent**

The user data portion of the message.

**Usenametoken**

The basic authentication information, if selected.

The information selected in this step is encrypted by the server in the response sender.

**Important:** A username token is typically not sent in the response. Thus, you usually do not need to select username token.

After you specify which message parts to decrypt, you must specify which method to use when decrypting the response message. See *Configuring the client for response decryption: Choosing a decryption method* for more information.

## Configuring the client for response decryption: Choosing a decryption method

Prior to completing these steps, read either of the following topics to become familiar with the **Security Extensions** tab and the **Port Binding** tab in the Web Services Client Editor within the Assembly Toolkit:

- *Configuring the client security bindings using the Assembly Toolkit*
- *Configuring the security bindings on a server acting as a client using the administrative console*

These two tabs are used to configure the Web services security extensions and Web services security bindings, respectively.

Complete the following steps to specify which decryption method to use when the client decrypts the response message. The server response encryption and client response decryption configurations must match.

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the `webservicesclient.xml` file, and click **Open With > Web Services Client Editor**.
6. Click the **Port Binding** tab, which is located at the bottom of the Web services client editor within the Assembly Toolkit.
7. Expand the **Security Response Receiver Binding Configuration > Encryption Information** section. For more information on encrypting and decrypting Simple Object Access Protocol (SOAP) messages, see XML encryption.
8. Click **Edit** to view the encryption information. The following table describes the purpose for this information. Some of these definitions are based on the XML-Encryption specification, which is located at the following Web address: <http://www.w3.org/TR/xmlenc-core>

**Encryption name**

Refers to the alias used for the encryption information entry.

**Data encryption method algorithm**

Encrypts and decrypts data in fixed size, multiple octet blocks.

**Key encryption method algorithm**

Represents public key encryption algorithms specified for encrypting and decrypting keys.

### Encryption key name

Represents a Subject from a personal certificate, which is typically a distinguished name (DN) that is found by the encryption key locator. The Subject is used by the key encryption method algorithm to decrypt the secret key. The secret key is used to decrypt the data.

**Important:** The key chosen must be a private key of the client. Encryption must be done using the public key and decryption must be done by the private key (personal certificate). For example, the personal certificate of the client is: CN=Alice, O=IBM, C=US. Therefore, the client contains the public and private key pair. The target server that sends the response encrypts the secret key using the public key for CN=Alice, O=IBM, C=US. The client decrypts the secret key using the private key for CN=Alice, O=IBM, C=US

### Encryption key locator

The encryption key locator represents a reference to a key locator implementation class that finds the correct key store where the alias and the certificate exist. For more information on configuring key locators, see [Configuring key locators using the Assembly Toolkit](#) and [Configuring key locators using the administrative console](#).

For decryption, the encryption key name chosen must refer to a personal certificate that can be located by the client key locator. The Subject (owner field of the certificate) of the personal certificate should be entered in the Encryption key name, this is typically a Distinguished Name (DN). The default key locator uses the Encryption key name to find the key within the keystore. If you write a custom key locator, the encryption key name can be anything used by the key locator to find the correct encryption key. The encryption key locator references the implementation class that locates the correct key store where this alias and certificate exists. For more information, see [Configuring key locators using the Assembly Toolkit](#) and [Configuring key locators using the administrative console](#).

You must specify which parts of the request message to decrypt. See the topic [Configuring the client for response decryption: Decrypting the message parts if you have not previously specified this information](#).

## Securing Web services using basicauth authentication

WebSphere Application Server provides several different methods to secure your Web services. Extensible Markup Language (XML) digital signature is one of these methods. You might also secure your Web services using any of the following methods:

- XML digital signature
- XML encryption
- Basicauth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

With the basicauth authentication method, the request sender generates a basicauth security token using a callback handler. The request receiver retrieves the basicauth security token from the SOAP message and validates it using a Java Authentication and Authorization Service (JAAS) login module. Trust is established using user name and password validation. To use basicauth authentication to secure Web services, complete the following tasks:

1. Secure the client for basicauth authentication.
  - a. Configure the client for basicauth authentication: Specifying the method
  - b. Configure the client for basicauth authentication: Collecting the authentication information
2. Secure the server for basicauth authentication.

- a. Configure the server to handle basicauth authentication
- b. Configure the server to validate basicauth authentication information

After completing these steps, you have secured your Web services using basicauth authentication.

## Configuring the client for basic authentication: Specifying the method

BasicAuth refers to the user ID and password of a valid user in the registry of the target server. Collection of BasicAuth information can occur in many ways including through a GUI prompt, a standard in (Stdin) prompt, or specified in the bindings, which prevents user interaction. For more information on BasicAuth authentication, see: BasicAuth authentication method.

**Attention:** **5.1+** WebSphere Application Server supports nonce (randomly generated token) with BasicAuth authentication. For more information, see Nonce.

Complete the following steps to specify BasicAuth as the authentication method:

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services enabled Enterprise JavaBean (EJB) module or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the webservicescClient.xml file, and click **Open With > Web Services Client Editor**.
6. Click the **Security Extensions** tab, which is located at the bottom of the Web services client editor within the Assembly Toolkit.
7. Expand the **Request Sender Configuration > Login Configuration** section. The only valid login configuration choices for a pure client are BasicAuth and Signature.
8. Select **BasicAuth** to authenticate the client using a user ID and a password. This user ID and password must be specified in the target user registry. The other choice, Signature, attempts to authenticate the client using the certificate used to digitally sign the message.

For more information on getting started with the Web services client editor within the Assembly Toolkit, see either of the following topics:

- Configuring the client security bindings using the Assembly Toolkit
- Configuring the security bindings on a server acting as a client using the administrative console

After you specify the BasicAuth authentication method, you must specify how to collect the authentication information. See Configuring the client for basic authentication: Collecting the authentication information.

### **BasicAuth authentication method:**

When you use the BasicAuth authentication method, the security token that is generated is a <wsse:UsernameToken> element with <wsse:Username> and <wsse>Password> elements.

WebSphere Application Server supports text passwords but not password digest because passwords are not stored and cannot be retrieved from the server. On the request sender side, a callback handler is invoked to generate the security token. On the request receiver side, a Java Authentication and Authorization Service (JAAS) login module is used to validate the security token. These two operations, token generation and token validation, are described in the following sections.

### **BasicAuth token generation**

The request sender generates a BasicAuth security token using a callback handler. The security token returned by the callback handler is inserted in the Simple Object Access Protocol (SOAP) message. The callback handler that is used is specified in the <LoginBinding> element of the

bindings file, `ibm-webservicesclient-bnd.xml`. The following callback handler implementations are provided with WebSphere Application Server and can be used with the BasicAuth authentication method:

- `com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler`
- `com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler`
- `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler`

You can add your own callback handlers that implement the `javax.security.auth.callback.CallbackHandler` method.

### BasicAuth token validation

The request receiver retrieves the BasicAuth security token from the SOAP message and validates it using a JAAS login module. The `<wsse:Username>` and `<wsse:Password>` elements in the security token are used to perform the validation. If the validation is successful, the login module returns a JAAS Subject. This Subject is set as the identity of the running thread. If the validation fails, the request is rejected with a SOAP fault exception.

The JAAS login configuration is specified in the `<LoginMapping>` element of the bindings file. Default bindings are specified in the `ws-security.xml` file. However, you can override these bindings using the application-specific `ibm-webservices-bnd.xml` file. The configuration information consists of a `CallbackHandlerFactory` and a `ConfigName` value. The `CallbackHandlerFactory` option specifies the name of a class that is used for creating the JAAS `CallbackHandler` object. WebSphere Application Server provides the `com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl` `CallbackHandlerFactory` implementation. The `ConfigName` value specifies a JAAS configuration name entry. WebSphere Application Server searches the `security.xml` file for a matching configuration name entry. If a match is not found, it searches the `wsjaas.conf` file for a match. WebSphere Application Server provides the `WSLogin` default configuration entry, which is suitable for the BasicAuth authentication method.

### Configuring the client for basic authentication: collecting the authentication information

BasicAuth refers to the user ID and the password of a valid user in the registry of the target server. Collection of BasicAuth information can occur in many ways including through a user interface prompt, a standard in (Stdin) prompt, or specified in the bindings, which prevents user interaction. For more information on BasicAuth authentication, see BasicAuth authentication method.

Complete this task to specify the authentication information needed for BasicAuth authentication:

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the `webservicesclient.xml` file, and click **Open With > Web Services Client Editor**.
6. Click the **Port Binding** tab, which is located at the bottom of the Web services client editor within the Assembly Toolkit.
7. Expand the **Security Request Sender Binding Configuration > Login Binding** section.
8. Click **Edit** or **Enable** to view the login binding information. The login binding information displays and enter the following information:

#### Authentication method

Specifies the type of authentication. Select **BasicAuth** to use basic authentication.

### **Token value type URI and Token value type local name**

When you select BasicAuth, you cannot edit the token value type URI and the local name values. Specifies values for custom authentication types. For BasicAuth authentication, leave these values blank.

### **Callback handler**

Specifies the Java Authentication and Authorization Server (JAAS) callback handler implementation for collecting the BasicAuth information. You can use the following default implementations for the callback handler:

#### **com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler**

This implementation is used for non-user interface console prompts.

#### **com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler**

This implementation is used for user interface panel prompts.

#### **com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler**

This implementation is used when you plan to always enter the user ID and password in the BasicAuth user ID and password section that follows.

### **Basic Authentication user ID and Basic Authentication password**

Specifies values for the BasicAuth user ID and password, regardless of the default callback handler indicated previously, these user ID and password values are used to authenticate to the server for the Web services security authentication. If you leave these values blank, use either the GUIPromptCallbackHandler or the StdinPromptCallbackHandler implementation, but only on a pure client. Always fill-in these values for any Web service that acts as a client to another Web service that you want to specify for BasicAuth for authentication downstream. If you want the client identity of the originator to flow downstream, configure the Web service client to use either ID assertion or Lightweight Third Party Authentication (LTPA).

### **Property**

Specifies properties with name and value pairs for custom callback handlers to use. For BasicAuth authentication, you do not need to enter any information. To enter a new property, click **Add** and enter the new property and value.

**Other basic authentication entries:** There is a basic authentication entry in the Port Qualified Name Binding Details section. This entry is used for HTTP transport authentication, which might be required if the router servlet is protected.

Information specified in the Web services security basic authentication section overrides the basic authentication information specified in the Port Qualified Name Binding Details section for authorizing the Web service.

For a server that acts as a client, do not specify a user interface or non-user interface prompt callback handler. To configure BasicAuth authentication from one Web service to a downstream Web service, select the `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler` implementation and explicitly specify the BasicAuth user ID and password. If you want the client identity of the originator to flow downstream, configure the Web service client to use ID assertion.

To use the BasicAuth authentication method, you must specify the method in the **Login Configuration** section of the Assembly Toolkit. See *Configuring the client for basicauth authentication: Specifying the method* if you have not previously specified this information.

### ***Identity assertion authentication method:***

When using the identity assertion (IDAssertion) authentication method, the security token generated is a `<wsse:UsernameToken>` element that contains a `<wsse:Username>` element.

On the request sender side, a callback handler is invoked to generate the security token. On the request receiver side, the security token is validated. These two operations, token generation and token validation operations, are described in the following sections.

#### **Identity assertion token validation:**

The request receiver retrieves the IDAssertion security token from the SOAP message and validates it using a Java Authentication and Authorization Service (JAAS) login module. With identity assertion, special processing is required to establish trust before asserting the identity as the established identity of the running thread. This special processing is defined by the <IDAssertion> element in the deployment descriptor file, `ibm-webservices-ext.xmi`. If all the validation checks are successful, the asserted identity is set as the identity of the running thread of. If the validation fails, the request is rejected with a SOAP fault exception.

The JAAS login configuration is specified in the <LoginMapping> element of the bindings file. Default bindings are specified in the `ws-security.xml` file. However, you can override these bindings using the application specific `ibm-webservices-bnd.xmi` file. The configuration information consists of `CallbackHandlerFactory` and a `ConfigName`. `CallbackHandlerFactory` specifies the name of a class that is used for creating the JAAS `CallbackHandler` object. WebSphere Application Server provides the `com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl` `CallbackHandlerFactory` implementation. `ConfigName` specifies a JAAS configuration name entry.

WebSphere Application Server searches the `security.xml` file for a matching configuration name entry. If a match is not found it searches the `wsjaas.conf` file. WebSphere Application Server provides the `system.wssecurity.IDAssertion` default configuration entry, which is suitable for the identity assertion authentication method.

The <IDAssertion> element in the `ibm-webservices-ext.xmi` deployment descriptor file specifies the special processing required when using the identity assertion authentication method. The <IDAssertion> element is composed of two sub-elements: <IDType> and <TrustMode>.

The <IDType> element specifies the method for asserting the identity. The supported values for asserting the identity are:

- Username
- Distinguished name (DN)
- X.509 certificate

When <IDType> is *username*, a username token (for example, Bob) is provided. This user name is mapped to a user in the user registry and is the asserted identity after successful trust validation. When the <IDType> value is *DN*, a user name token containing a distinguished name is provided (for example, `cn=Bob Smith, o=ibm, c=us`). This DN is mapped to a user in the user registry and this user is the asserted identity after successful trust validation. When the <IDType> is *X509Certificate*, a binary security token containing an X509 certificate is provided and the SubjectDN value from the certificate (for example, `cn=Bob Smith, o=ibm, c=us`) is extracted. This SubjectDN value is mapped to a user in the user registry and this user is the asserted identity after successful trust validation.

The <TrustMode> element specifies how the trust authority, or asserting authority, provides trust information. The supported values are:

- Signature
- BasicAuth
- No value specified

When the <TrustMode> value is *Signature* the signature is validated. Then, the signer (for example, `cn=IBM Authority, o=ibm, c=us`) is mapped to an identity in the user registry (for example, `IBMAuthority`).

To ensure that the asserting authority is trusted, the mapped identity (for example, `IBMAuthority`) is validated against a list of trusted identities. When the `<TrustMode>` element is `BasicAuth`, there is a user name token with a user name and password, which is the user name and password of the asserting authority.

The user name and password are validated. If they are successfully validated, that user name (for example, `IBMAuthority`) is validated against a list of trusted identities. If a value is not specified for `<TrustMode>`, trust is presumed and additional trust validation is not performed. This type of identity assertion is called *presumed trust mode*. Use the presumed trust mode only in an environment where the trust is established using some other mechanism.

If all the validations described previously succeed, the asserted identity (for example, `Bob`) is set as the identity of the running thread. If any of the validations fail, the request is rejected with a SOAP fault exception.

## Configuring the server to handle `BasicAuth` authentication information

`BasicAuth` refers to the user ID and the password of a valid user in the registry of the target server. After a request is received that contains basic authentication information, the server needs to log in to form a credential. The credential is used for authorization. If the user ID and the password supplied are not valid, an exception is thrown and the request ends without invoking the resource. For more information on `BasicAuth` authentication, see `BasicAuth`.

Complete the following steps to configure the server to handle `BasicAuth` authentication information:

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the `META-INF` directory for an EJB module or the `WEB-INF` directory for a Web module.
5. Right-click the `webservices.xml` file, and click **Open With > Web Services Editor**.
6. Click the **Security Extensions** tab, which is located at the bottom of the Web services editor within the Assembly Toolkit.
7. Expand the **Request Receiver Service Configuration Details > Login Configuration** section. You can select the following options:
  - `BasicAuth`
  - Signature
  - ID assertion
  - Lightweight Third Party Authentication (LTPA)
8. Select **BasicAuth** to authenticate the client with a user ID and a password. The client must specify a valid user ID and password in the server user registry.

You can select multiple login configurations, which means that different types of security information might be received at the server. The order in which the login configurations are added decides the order in which they are processed when a request is received. Problems can occur if you have multiple login configurations added that have security tokens in common. For example, ID assertion contains a `BasicAuth` token. For ID assertion to work properly, list ID assertion ahead of `BasicAuth` in the processing list or the `BasicAuth` processing overrides the `IDAssertion` processing.

After you specify how the server handles `BasicAuth` authentication information, you must specify how the server validates the authentication information. See `Configuring the server to validate basicauth` authentication information for more information.

## Configuring the server to validate BasicAuth authentication information

BasicAuth refers to the user ID and the password of a valid user in the registry of the target server. Once a request is received that contains basic authentication information, the server needs to log in to form a credential. The credential is used for authorization. If the user ID and the password supplied is invalid, an exception is thrown and the request ends without invoking the resource. For more information on BasicAuth authentication, see BasicAuth.

Complete the following steps to specify how the server validates the BasicAuth authentication information:

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the `webservices.xml` file, select **Open With > Web Services Editor**.
6. Click the **Binding Configurations** tab, which is located at the bottom of the Web services editor within the Assembly Toolkit.
7. Expand the **Request Receiver Binding Configuration Details > Login Mapping** section.
8. Click **Edit** to view the login mapping information or click **Add** to add new login mapping information. The login mapping dialog is displayed. Select or enter the following information:

### Authentication method

Specifies the type of authentication that occurs. Select **BasicAuth** to use basic authentication.

### Configuration name

Specifies the Java Authentication and Authorization Service (JAAS) login configuration name. For the BasicAuth authentication method, enter `WSLogin` for the JAAS login Configuration name.

### Use token valid type

Determines if you want to specify a custom token type. For the default authentication method selections, you do not need to specify this option.

### Token value type URI and Token value type URI local name

When you select BasicAuth, you cannot edit the token value type URI and local name values. Specifies custom authentication types. For BasicAuth authentication leave these fields blank.

### Callback handler factory class name

Creates a JAAS CallbackHandler implementation that understands the following callbacks:

- `javax.security.auth.callback.NameCallback`
- `javax.security.auth.callback.PasswordCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.BinaryTokenCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.XMLTokenReceiverCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback`

### Callback handler factory property name and Callback handler factory property value

Specifies callback handler properties for custom callback handler factory implementations. You do not need to specify any properties for the default callback handler factory implementation. For BasicAuth, you do not need to enter any property values.

### Login mapping property name and Login mapping property value

Specifies properties for a custom login mapping. For the default implementations including BasicAuth, leave these fields blank.

You must specify how the server handles the BasicAuth authentication method. See Configuring the server to handle BasicAuth authentication information if you have not previously specified this information.

## Identity assertion

Identity assertion is a method for expressing the identity of the sender (for example, user name) in a SOAP message. When identity assertion is used as an authentication method, the authentication decision is performed based only on the name of the identity, and on other information such as passwords and certificates.

### ID type

The Web Services Security implementation in WebSphere Application Server can handle these identity types:

#### User name

Denotes the user name, such as the one in the local operating system (for example, "alice"). This name is embedded in the <Username> element within the <UsernameToken> element.

**DN** Denotes the distinguished name (DN) for the user, such as "CN=alice, O=IBM, C=US". This name is embedded in the <Username> element within the <UsernameToken> element.

#### X.509 certificate

Represents the identity of the user as an X.509 certificate instead of a string name. This certificate is embedded in the <BinarySecurityToken> element.

### Managing trust

The intermediary host in the SOAP message itinerary can assert claimed identity of the initial sender. Two methods (called *trust mode*) are supported for this assertion:

#### Basic authentication

The intermediary adds its user name and password pair to the message.

#### Signature

The intermediary digitally signs the <UsernameToken> element of the initial sender.

**Note:** This trust mode does not support the X.509 certificate ID type.

### Typical scenario

ID assertion is typically used in the multihop environment where the SOAP message passes through one or more intermediary hosts. The intermediary host authenticates the initial sender. The following scenario describes the process:

1. The initial sender sends a SOAP message to the intermediary host with some embedded authentication information. This authentication information might be a user name and a password pair with an Lightweight Third Party Authentication (LTPA) token.
2. The intermediary host authenticates the initial sender according to the embedded authentication information.
3. The intermediary host removes the authentication information from the SOAP message and replaces it with the <UsernameToken> element, which contains a user name.
4. The intermediary host asserts the trust according to the trust mode.
5. The intermediary host sends the updated SOAP message to the ultimate receiver.
6. The ultimate receiver checks the trust against the intermediary host information according to the configured trust mode. Also, the trusted ID evaluator is invoked.
7. If trust is established by the final receiver, the receiver invokes the Web service under the authorization of the user name (that is, the initial sender) in the SOAP message.

## Securing Web services using identity assertion authentication

WebSphere Application Server provides several different methods to secure your Web services. Extensible Markup Language (XML) digital signature is one of these methods. You might also secure your Web services using any of the following methods:

- XML digital signature
- XML encryption
- Basicauth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

With the identity assertion authentication method, the security token generates a `<wsee:Username Token>` element that contains a `<wsse:Username>` element. On the request sender side, a callback handler is invoked to generate the security token. On the request receiver side, the security token is validated. Unlike basicauth authentication, trust is established through the use of a security token rather than through user name and password validation. To use identity assertion authentication to secure Web services, complete the following tasks:

1. Secure the client for identity assertion authentication.
  - a. Configure the client for identity assertion authentication: Specifying the method.
  - b. Configure the client for identity assertion authentication: Collecting the authentication information.
2. Secure the server for identity assertion authentication.
  - a. Configure the server to handle identity assertion authentication.
  - b. Configure the server to validate identity assertion authentication information.

After completing these steps, you have secured your Web services using identity assertion authentication.

### Configuring the client for identity assertion: specifying the method

This task is used to configure identity assertion authentication. The purpose of identity assertion is to assert the authenticated identity of the originating client from a Web service to a downstream Web service. Do not attempt to configure identity assertion from a pure client. Identity assertion works only when you configure on the client-side of a Web service acting as a client to a downstream Web service.

In order for the downstream Web service to accept the identity of the originating client (just the user name), you must supply a special trusted BasicAuth credential that the downstream Web service trusts and can authenticate successfully. You must specify the user ID of the special BasicAuth credential in a trusted ID evaluator on the downstream Web service configuration. For more information on trusted ID evaluators, see Trusted ID evaluators.

Complete the following steps to specify identity assertion as the authentication method:

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the `webservicesclient.xml` file, and click **Open With > Web Services Client Editor**.
6. Click the **Security Extensions** tab, which is located at the bottom of the Web services client editor within the Assembly Toolkit.
7. Expand the **Request Sender Configuration > Login Configuration** section.

8. Select **IDAssertion** as the authentication method. For more conceptual information on identity assertion authentication, see ID assertion.
9. Expand the **IDAssertion** section.
10. For the ID Type, select **Username**. This value works with all registry types and originating authentication methods.
11. For the Trust Mode, select either **BasicAuth** or **Signature**.
  - By selecting **BasicAuth**, you must include basic authentication information (user ID and password), which the downstream Web service has specified in the trusted ID evaluator as a trusted user ID. See Configuring the client for signature authentication: Collecting the authentication information to specify the user ID and password information.
  - By selecting **Signature** the certificate configured in the signature information section used to sign the data also is that is used as the trusted subject. The Signature is used to create a credential and user ID, which the certificate mapped to the downstream registry, is used in the trusted ID evaluator as a trusted user ID.

See Configuring the client security bindings using the Assembly Toolkit for more information on the Web services client editor within the Assembly Toolkit.

After you specify identity assertion as the authentication method used by the client, you must specify how to collect the authentication information. See Configuring the client for identity assertion authentication: Collecting the authentication information for more information.

## Configuring the client for identity assertion: Collecting the authentication method

This task is used to configure identity assertion authentication. The purpose of identity assertion is to assert the authenticated identity of the originating client from a Web service to a downstream Web service. Do not attempt to configure identity assertion from a pure client. Identity assertion works only when you configure on the client-side of a Web service acting as a client to a downstream Web service.

In order for the downstream Web service to accept the identity of the originating client (just the user name), you must supply a special trusted BasicAuth credential that the downstream Web service trusts and can authenticate successfully. You must specify the user ID of the special BasicAuth credential in a trusted ID evaluator on the downstream Web service configuration. For more information on trusted ID evaluators, see Trusted ID evaluators.

Complete the following steps to specify how the client collects the authentication information:

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the webservicessclient.xml file, and click **Open With > Web Services Client Editor**.
6. Click the **Port Binding** tab, which is located at the bottom of the Web Services Client Editor within the Assembly Toolkit.
7. Expand the **Security Request Sender Binding Configuration > Login Binding** section.
8. Click **Edit** to view the login binding information and select **IDAssertion**. The login binding dialog is displayed. Select or enter the following information:

### Authentication method

The authentication method specifies the type of authentication that occurs. Select **IDAssertion** to use identity assertion.

**Token value type URI and Token value type Local name**

When you select IDAssertion, you cannot edit the token value type Universal Resource Identifier (URI) and the local name. Specifies custom authentication types. For IDAssertion authentication, leave these values blank.

**Callback handler**

Specifies the Java Authentication and Authorization Service (JAAS) callback handler implementation for collecting the BasicAuth information. Specify the `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler` implementation for IDAssertion.

**Basic authentication User ID and Basic authentication Password**

In this field the trust mode entered in the extensions is BasicAuth. Specifies the trusted user ID and password in these fields. The user ID specified must be an ID that is trusted by the downstream Web service. The Web service trusts the user ID if it is entered as a trusted ID in a trusted ID evaluator in the downstream Web service bindings. If the trust mode entered in the extensions is Signature, you do not need to specify any information in this field.

**Property Name and Property Value**

Specifies properties with name and value pairs, for use by custom callback handlers. For IDAssertion, you do not need to specify any information in this field.

To use the identity assertion authentication method, you must specify the method in the **Security Extensions** section of the Assembly Toolkit. See *Configuring the client for identity assertion authentication*: specifying the method if you have not previously specified this information.

**Configuring the server to handle identity assertion authentication**

Use this task to configure identity assertion authentication. The purpose of identity assertion is to assert the authenticated identity of the originating client from a Web service to a downstream Web service. Do not attempt to configure identity assertion from a pure client.

For the downstream Web service to accept the identity of the originating client (user name only), you must supply a special trusted BasicAuth credential that the downstream Web service trusts and can authenticate successfully. You must specify the user ID of the special BasicAuth credential in a trusted ID evaluator on the downstream Web service configuration. For more information on trusted ID evaluators, see *Trusted ID evaluators*. The server side passes the special BasicAuth credential into the trusted ID evaluator, which returns `true` or `false` that this ID is trusted. Once it is trusted, the user name of the client is mapped to the credential, which is used for authorization.

Complete the following steps to configure the server to handle identity assertion authentication information:

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the `webservices.xml` file, and click **Open With > Web Services Editor**.
6. Click the **Security Extensions** tab, which is located at the bottom of the Web services editor within the Assembly Toolkit.
7. Expand the **Request Receiver Service Configuration Details > Login Configuration** section. The options you can select are:
  - **BasicAuth**
  - **Signature**
  - **ID assertion**
  - **Lightweight Third Party Authentication (LTPA)**

8. Select **IDAssertion** to authenticate the client using the identity assertion data provided. The user ID of the client must be in the target user registry configured in WebSphere Application Server global security. You can select global security in the administrative console by clicking **Security > Global security**.

You can select multiple login configurations, which means that different types of security information can be received at the server. The order in which the login configurations are added determines the processing order when a request is received. Problems can occur if you have multiple login configurations added that have common security tokens. For example, ID assertion contains a BasicAuth token, which is the trusted token. For ID assertion to work properly, you must list ID assertion ahead of BasicAuth in the list or BasicAuth processing overrides ID assertion processing.

9. Expand the **IDAssertion** section and select both the **ID Type** and the **Trust Mode**.

- a. For ID Type, the options are:

- Username
- Distinguished name (DN)
- X509certificate

These choices are just preferences and are not guaranteed. Most of the time the Username option is used. You must choose the same ID Type as the client.

- b. For Trust Mode, the options are:

- BasicAuth
- Signature

The Trust Mode refers to the information sent by the client as the trusted ID.

- 1) If you select **BasicAuth**, the client sends basic authentication data (user ID and password). This basicauth data is authenticated to the configured user registry. When the authentication occurs successfully, the user ID must be part of the trusted ID evaluator trust list.
- 2) If you select **Signature**, the client signing certificate is sent. This certificate must be mappable to the configured user registry. For **Local OS**, the common name (CN) of the distinguished name (DN) is mapped to a user ID in the registry. For **Lightweight Directory Access Protocol (LDAP)**, the DN is mapped to the registry for the ExactDN mode. If it is in the CertificateFilter mode, attributes are mapped accordingly. In addition, the user name from the credential generated must be in the Trusted ID Evaluator trust list.

For more information on getting started with the Web Services Editor within the Assembly Toolkit , see [Configuring the server security bindings using the Assembly Toolkit](#).

After you specify how the server handles identity assertion authentication information, you must specify how the server validates the authentication information. See [Configuring the server to validate identity assertion authentication information](#) for more information.

## Configuring the server to validate identity assertion authentication information

Use this task to configure identity assertion authentication. The purpose of identity assertion is to assert the authenticated identity of the originating client from a Web service to a downstream Web service. Do not attempt to configure identity assertion from a pure client.

For the downstream Web service to accept the identity of the originating client (user name only), you must supply a special trusted BasicAuth credential that the downstream Web service trusts and can authenticate successfully. You must specify the user ID of the special BasicAuth credential in a trusted ID evaluator on the downstream Web service configuration. For more information on trusted ID evaluators, see [Trusted ID evaluators](#). The server side passes the special BasicAuth credential into the trusted ID evaluator, which returns a true or false response that this ID is trusted. Once it is trusted, the user name of the client is mapped to the credential, which is used for authorization.

Complete the following steps to validate the identity assertion authentication information:

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the webservices.xml file, and click **Open With > Web Services Editor**.
6. Click the **Binding Configurations** tab, which is located at the bottom of the Web services editor within the Assembly Toolkit.
7. Expand the **Request Receiver Binding Configuration Details > Login Mapping** section.
8. Click **Edit** to view the login mapping information. Click **Add** to add new login mapping information. The login mapping dialog is displayed. Select or enter the following information:

**Authentication method**

Specifies the type of authentication that occurs. Select **IDAssertion** to use basic authentication.

**Configuration name**

Specifies the Java Authentication and Authorization Service (JAAS) login configuration name. For the IDAssertion authentication method, enter `system.wssecurity.IDAssertion` for the Java Authentication and Authorization Service (JAAS) login configuration name.

**Use token value type**

Determines if you want to specify a custom token type. For the default authentication method selections, you do not need to specify this option.

**Token value type URI and Token value type local name**

When you select ID assertion, you cannot edit the token value type URI and local name values. Specifies custom authentication types. For the ID assertion authentication method, leave these values blank.

**Callback Handler Factory Class name**

Creates a JAAS CallbackHandler implementation that understands the following callbacks:

- `javax.security.auth.callback.NameCallback`
- `javax.security.auth.callback.PasswordCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.BinaryTokenCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.XMLTokenReceiverCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback`

For any of the default authentication methods (BasicAuth, IDAssertion, and Signature), use the callback handler factory default implementation. Enter the following class name for any of the default Authentication methods including IDAssertion:

```
com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl
```

This implementation creates the correct callback handler for the default implementations.

**Callback handler factory property name and Callback handler factory property value**

Specifies callback handler properties for custom callback handler factory implementations. The default callback handler factory implementation does not need any specified properties. For ID assertion, leave these values blank.

**Login mapping property name and Login mapping property value**

Specifies properties for a custom login mapping. For the default implementations including IDAssertion, leave these values blank.

9. Expand the **Trusted ID Evaluator** section.

10. Click **Edit** to see a dialog that displays all the trusted ID evaluator information. The following table describes the purpose of this information.

**Class name**

Refers to the implementation of the trusted ID evaluator that you want to use. Enter the default implementation as `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl`. If you want to implement your own trusted ID evaluator, you must implement the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` interface.

**Property name**

Represents the name of this configuration. Enter `BasicIDEvaluator`.

**Property value**

Defines the name and value pairs that can be used by the trusted ID evaluator implementation. For the default implementation, the trusted list is defined here. When a request comes in and the trusted ID is verified, the user ID, as it appears in the user registry, must be listed in this property. Specify the property as a name and value pair where the name is `trustedId_n`. *n* is an integer starting from 0 and the value is the user ID associated with that name. An example list with the trusted names include two properties.

For example: `trustedId_0 = user1, trustedId_1 = user2`. The previous example means that both `user1` and `user2` are trusted. `user1` and `user2` must be listed in the configured user registry.

11. Expand the **Trusted ID Evaluator Reference** section.
12. Click **Enable** to add a new entry. The text you enter for the **Trusted ID Evaluator Reference** must be the same as the name entered previously in the **Trusted ID Evaluator**. Make sure that the name matches exactly because the information is case sensitive. If an entry is already specified, you can change it by clicking **Edit**.

You must specify how the server handles the identity assertion authentication method. See [Configuring the server to handle identity assertion authentication](#) if you have not previously specified this information.

## Securing Web services using signature authentication

WebSphere Application Server provides several different methods to secure your Web services. Extensible Markup Language (XML) digital signature is one of these methods. You might secure your Web services using any of the following methods:

- XML digital signature
- XML encryption
- Basicauth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

With the signature authentication method, the request sender generates a signature security token using a callback handler. The security token returned by the callback handler is inserted in the Simple Object Access Protocol (SOAP) message. The request receiver retrieves the Signature security token from the SOAP message and validates it using a Java Authentication and Authorization Service (JAAS) login module. To use signature authentication to secure Web services, complete the following tasks:

1. Secure the client for signature authentication.
  - a. Configure the client for signature authentication: specifying the method.
  - b. Configure the client for signature authentication: collecting the authentication information.
2. Secure the server for signature authentication.
  - a. Configure the server to handle signature authentication.

- b. Configure the server to validate signature authentication information.

After completing these steps, you have secured your Web services using signature authentication.

## Configuring the client for signature authentication: specifying the method

This task is used to configure signature authentication. A signature refers to the use of an X.509 certificate to login on the target server. For more information on signature authentication, see Signature authentication method.

Complete the following steps to specify signature as the authentication method:

1. Launch the Assembly Toolkit.
2. Click **Windows > Open Perspective > J2EE** to access the Assembly Toolkit perspective.
3. Select the Web services-enabled Enterprise JavaBean(EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the webservicessclient.xml file, and click **Open With > Web Services Client Editor**.
6. Click the **Security Extensions** tab, which is located at the bottom of the Web Services Client Editor within the Assembly Toolkit.
7. Expand the **Request Sender Configuration > Login Configuration** section. The following login configuration options are valid for a managed client and Web services acting as a client are:

### **BasicAuth**

Use this option for a managed client.

### **Signature**

Use this option for a managed client.

### **IDAssertion**

Use this option for Web services acting as a client.

8. Select **Signature** to authenticate the client using the certificate used to digitally sign the request.

For more information on getting started with the Web services client editor within the Assembly Toolkit , see Configuring the client security bindings using the Assembly Toolkit.

After you specify signature as the authentication method, you must specify how to collect the authentication information. See Configuring the client for signature authentication: Collecting the authentication information for more information.

### **Signature authentication method:**

When using the signature authentication method, the security token is generated with a <ds:Signature> and a <wsse:BinarySecurityToken> element.

On the request sender side, a callback handler is invoked to generate the security token. On the request receiver side, a Java Authentication and Authorization Service (JAAS) login module is used to validate the security token. These two operations, token generation and token validation, are described in the following sections.

### **Signature token generation**

The request sender generates a Signature security token using a callback handler. The security token returned by the callback handler is inserted in the SOAP message. The callback handler is specified in the <LoginBinding> element of the bindings file, `ibm-webservicessclient-bnd.xml`. WebSphere Application Server provides the following callback handler implementation that can be used with the Signature authentication method:

```
com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler
```

You can add your own callback handlers that implement the `javax.security.auth.callback.CallbackHandler` implementation.

### Security token validation

The request receiver retrieves the Signature security token from the Simple Object Access Protocol (SOAP) message and validates it using a JAAS login module. The `<ds:Signature>` and `<wsse:BinarySecurityToken>` elements in the security token are used to perform the validation. If the validation is successful, the login module returns a Java Authentication and Authorization Service (JAAS) Subject. This Subject then is set as the identity of the running thread. If the validation fails, the request is rejected with a SOAP fault exception.

The JAAS login configuration is specified in the `<LoginMapping>` element of the bindings file. Default bindings are specified in the `ws-security.xml` file. However, you can override these bindings using the application-specific `ibm-webservices-bnd.xmi` file. The configuration information consists of a `CallbackHandlerFactory` and a `ConfigName`. The `CallbackHandlerFactory` specifies the name of a class that is used for creating the JAAS `CallbackHandler` object. WebSphere Application Server provides the `com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImp` `CallbackHandlerFactory` implementation. The `ConfigName` specifies a JAAS configuration name entry. WebSphere Application Server searches in the `security.xml` file for a matching configuration name entry. If a match is not found, it searches the `wsjaas.conf` file. WebSphere Application Server provides the `system.wssecurity.Signature` default configuration entry, which is suitable for the signature authentication method.

### Configuring the client for signature authentication: collecting the authentication information

This task is used to configure signature authentication. A signature refers to the use of an X.509 certificate to login on the target server. For more information on signature authentication, see `Signature authentication method`.

Complete the following steps to specify how the client collects the authentication information for signature authentication:

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the `webservicesclient.xml` file, and click **Open With > Web Services Client Editor**.
6. Click the **Port Binding** tab, which is located at the bottom of the Web services client editor within the Assembly Toolkit.
7. Expand the **Security Request Sender Binding Configuration > Signing Information** and click **Edit** to modify the signing key name and signing key locator. To create new signing information, click **Enable**. The certificate that is sent to log in at the server is the one configured in the Signing Information section. Review the section on Key locators to understand how the signing key name maps to a key within the key locator entry.

The following list describes the purpose of this information. Some of these definitions are based on the XML-Signature specification, which is located at the following Web address:  
<http://www.w3.org/TR/xmlsig-core>

#### Canonicalization method algorithm

Canonicalizes the `SignedInfo` element before it is digested as part of the signature operation.

#### Digest method algorithm

Represents the algorithm that is applied to the data after transforms are applied, if specified, to yield the `<DigestValue>` element. The signing of the `DigestValue` element binds the resource

content to the signer key. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration.

#### **Signature method algorithm**

Represents the algorithm that is used to convert the canonicalized <SignedInfo> value into the <SignatureValue> value. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration.

#### **Signing key name**

Represents the key entry associated with the signing key locator. The key entry refers to an alias of the key, which is used to sign the request.

#### **Signing key locator**

Represents a reference to a key locator implementation. For more information on configuring key locators, see Key locators.

8. Expand the **Security Request Sender Binding Configuration > Login Binding** section.
9. Click **Edit** to view the login binding information. Then, select or enter the following information:

#### **Authentication method**

Specifies the type of authentication that occurs. Select **Signature** to use signature authentication.

#### **Token value type URI and Token value type URI local name**

When you select **Signature**, you cannot edit the Token value type URI and Local name values. Specifies custom authentication types. For signature authentication, leave these fields blank.

#### **Callback handler**

Specifies the Java Authentication and Authorization Server (JAAS) callback handler implementation for collecting signature information. Enter the following callback handler for signature authentication:

```
com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler
```

This callback handler is used because the signature method does not require user interaction.

#### **Basic authentication User ID and Basic authentication Password**

Leave the BasicAuth fields blank when Signature authentication is used.

#### **Property name and property value**

This field enables you to enter properties and name and value pairs for use by custom callback handlers. For signature authentication, you do not need to enter any information.

**Other customization entries:** There is a basic authentication entry in the Port Qualified Name Binding Details section. This entry is used for HTTP transport authentication, which might be required if the router servlet is protected.

Information specified in the Web services security signature authentication section overrides the basic authentication information specified in the Port Qualified Name Binding Details section for authorizing the Web service.

To use the signature authentication method, you must specify the authentication method in the **Login Config** section of the Assembly Toolkit. See Configuring the client for signature authentication: specifying the method if you have not previously specified this information.

## **Configuring the server to support signature authentication**

Use this task to configure signature authentication at the server. Signature authentication refers to an X.509 certificate sent by the client to the server. The certificate is used to authenticate to the user registry configured at the server. After a request is received by the server that contains the certificate, the server needs to log in to form a credential. The credential is used for authorization. If the certificate supplied

cannot be mapped to an entry in the user registry, an exception is thrown and the request ends without invoking the resource. For more information on signature authentication, see [Signature authentication method](#).

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the webservices.xml file, and click **Open With > Web Services Editor**.
6. Click the **Security Extensions** tab, which is located at the bottom of the Web Services Editor within the Assembly Toolkit.
7. Expand the **Request Receiver Service Configuration Details > Login Configuration** section. You can select from the following options:
  - BasicAuth
  - Signature
  - ID assertion
  - Lightweight Third Party Authentication (LTPA)
8. Select **Signature** to authenticate the client using an X509 certificate. The certificate that is sent from the client is the certificate that issued for signing the message. You must be able to map this certificate to the configured user registry. For Local operating system (OS) registries, the common name (cn) of the distinguished name (DN) is mapped to a user ID in the registry. For Lightweight Directory Access Protocol (LDAP), you can configure multiple mapping modes:
  - EXACT\_DN is the default mode that directly maps the DN of the certificate to an entry in the LDAP server.
  - CERTIFICATE\_FILTER is the mode that provides the LDAP advanced configuration with a place to specify a filter that maps specific attributes of the certificate to specific attributes of the LDAP server.

For more information on getting started with the Web services editor within the Assembly Toolkit, see [Configuring the server security bindings using the Assembly Toolkit](#).

After you specify how the server handles signature authentication information, you must specify how the server validates the authentication information. See [Configuring the server to validate signature authentication information](#) for more information.

## Configuring the server to validate signature authentication information

Use this task to configure signature authentication at the server. Signature authentication refers to an X.509 certificate sent by the client to the server. The certificate is used to authenticate to the user registry configured at the server. Once a request is received by the server that contains the certificate, the server needs to log in to form a credential. The credential is used for authorization. If the certificate supplied cannot be mapped to an entry in the user registry, an exception is thrown and the request ends without invoking the resource. For more information on signature authentication, see [Signature authentication method](#).

Complete the following steps to configure the server to validate signature authentication:

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the webservices.xml file, and click **Open With > Web Services Editor**.

6. Click the **Binding Configurations** tab, which is located at the bottom of the Web services editor within the Assembly Toolkit.
7. Expand the **Request Receiver Binding Configuration Details > Login Mapping** section.
8. Click **Edit** to view the login mapping information or click **Add** to add new login mapping information. The login mapping dialog is displayed and you select (or enter) the following information:

**Authentication method**

Specifies the type of authentication. Select **Signature** to use signature authentication.

**Configuration name**

Specifies the Java Authentication and Authorization Service (JAAS) login configuration name. For the signature authentication method, enter `system.wssecurity.Signature` for the JAAS login configuration name. This specification logs in with the `com.ibm.wsspi.wssecurity.auth.module.SignatureLoginModule` JAAS login module.

**Use token value type**

Determines if you want to specify a custom token type. For the default authentication method selections, you can leave this field blank.

**URI and local name**

When you select Signature method, you cannot edit the token value type URI and local name values. Specifies custom authentication types. For signature authentication, you can leave this field blank.

**Callback handler factory class name**

Creates a JAAS CallbackHandler implementation that understands the following callback handlers:

- `javax.security.auth.callback.NameCallback`
- `javax.security.auth.callback.PasswordCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.BinaryTokenCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.XMLTokenReceiverCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback`

For any of the default authentication methods (BasicAuth, IDAssertion, and Signature), use the callback handler factory default implementation. Enter the following class name for any of the default authentication methods including signature:

```
com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl
```

This implementation creates the correct callback handler for the default implementations.

**Callback handler factory property name and callback handler factory property value**

Specifies callback handler properties for custom callback handler factory implementations. You do not need to specify any properties for the default callback handler factory implementation. For signature, you can leave this field blank.

**Login mapping property name and login mapping property value**

Specifies properties for a custom login mapping to use. For the default implementations including signature, you can leave this field blank.

Specify how the server handles the signature authentication method. See *Configuring the server to handle signature authentication* if you have not previously specified this information.

## Token type overview

The proposed Web services security draft defined two types of security tokens:

- Username token
- Binary security token

A user name token consists of a user name and, optionally, password information. You can include a user name token directly in the <Security> header within the message. Binary tokens, such as X.509 certificates, Kerberos tickets, Lightweight Third Party Authentication (LTPA) tokens, or other non-XML formats, require a special encoding for inclusion. The Web services security specification describes how to encode binary security tokens such as X.509 certificates and Kerberos tickets, and it also describes how to include opaque encrypted keys. The specification also includes extensibility mechanisms that you can use to further describe the characteristics of the credentials that are included with a message.

WebSphere Application Server, Version 5.0.2 supports user name tokens, which include both user name and password for basic authentication and user name, which is used for identity assertion. The WebSphere Application Server, Version 5.0.2 binary security token implementation supports both X.509 certificates and LTPA binary security. You extend the implementation to generate other types of tokens. However, Kerberos tickets are not supported in WebSphere Application Server, Version 5.0.2. Each type of token is processed by a corresponding token generation and validation module. The binary token generation and validation modules are pluggable that is based on the Java Authentication and Authorization Service (JAAS) framework. For example, an arbitrary XML-based token format is supported using the JAAS pluggable framework. WebSphere Application Server, Version 5.0.2 does not support an XML-based token that is used in the SecurityTokenReference.

You can define the types of tokens that the message can accept in the deployment descriptor extension file, `ibm.webservices-ext.xmi`. A message receiver might support one or more types of security tokens. The following example shows that the receiver supports four types of security tokens:

**Important:** In the following code sample, several lines were split into multiple lines due to the width of the printed page. See the close bracket for an indication of where each line of code ends.

```
?xml version="1.0" encoding="UTF-8"?>
<com.ibm.etools.webservice.wsext:WsExtension xmi:version="2.0"
xmlns:xmi="http://www.omg.org/XMI"
xmlns:com.ibm.etools.webservice.wsext=
"http://www.ibm.com/websphere/appserver/schemas/5.0.2/wsext.xmi"
xmi:id="WsExtension_1052760331306" routerModuleName="StockQuote.war">
 <wsDescExt xmi:id="WsDescExt_1052760331306" wsDescNameLink="StockQuoteFetcher">
 <pcBinding xmi:id="PcBinding_1052760331326" pcNameLink="urn:xmltoday-delayed-quotes"
scope="Session">
 <serverServiceConfig
xmi:id="ServerServiceConfig_1052760331326" actorURI="myActorURI">
 <securityRequestReceiverServiceConfig
xmi:id="SecurityRequestReceiverServiceConfig_1052760331326">
 <loginConfig xmi:id="LoginConfig_1052760331326">
 <authMethods xmi:id="AuthMethod_1052760331326" text="BasicAuth"/>
 <authMethods xmi:id="AuthMethod_1052760331327" text="IDAssertion"/>
 <authMethods xmi:id="AuthMethod_1052760331336" text="Signature"/>
 <authMethods xmi:id="AuthMethod_1052760331337" text="LTPA"/>
 </loginConfig>
 </idAssertion xmi:id="IDAssertion_1052760331336" idType="Username" trustMode="Signature"/>
 </serverServiceConfig>
 </pcBinding>
 </wsDescExt>
</com.ibm.etools.webservice.wsext:WsExtension>
```

The message sender might choose one of the token types that are supported by the receiver when sending a message. You can define the type of token to be used by the sending side in the client descriptor extension file, `ibm-webservicesclient-ext.xmi`. The following example shows that the sender chooses to send a UsernameToken to the receiver:

**Important:** In the following code sample, several lines were split into multiple lines due to the width of the printed page. See the close bracket for an indication of where each line of code ends.

```
<?xml version="1.0" encoding="UTF-8"?>
<com.ibm.etools.webservice.wsext:WsClientExtension xmi:version="2.0"
xmlns:xmi="http://www.omg.org/XMI"
xmlns:com.ibm.etools.webservice.wsext=
"http://www.ibm.com/websphere/appserver/schemas/5.0.2/wsext.xmi"
xmi:id="WsClientExtension_1052760331496">
 <ServiceRefs xmi:id="ServiceRef_1052760331506" serviceRefLink="service/StockQuoteService">
 </ServiceRefs>
</com.ibm.etools.webservice.wsext:WsClientExtension>
```

```

 <portQnameBindings xmi:id="PortQnameBinding_1052760331506"
portQnameLocalNameLink="StockQuote">
 <clientServiceConfig xmi:id="ClientServiceConfig_1052760331506"
actorURI="myActorURI">
 <securityRequestSenderServiceConfig
xmi:id="SecurityRequestSenderServiceConfig_1052760331506" actor="myActorURI">
 <loginConfig xmi:id="LoginConfig_1052760331506" authMethod="BasicAuth"/>

```

## Username token element

You can use the UsernameToken element to propagate a user name and, optionally, password information. Also, you can use this token type to carry basic authentication information. Both a user name and a password are used to authenticate the message. A UsernameToken containing the user name is used in identity assertion, which establishes the identity of the user based on the trust relationship.

The following example shows the syntax of the UsernameToken element:

```

<UsernameToken Id="...">
 <Username>...</Username>
 <Password Type="...">...</Password>
</UsernameToken>

```

The Web services security specification defines the following password types:

### **wsse:PasswordText (default)**

This type is the actual password for the user name.

### **wsse:PasswordDigest**

The type is the digest of the password for the user name. The value is a base64-encoded SHA1 hash value of the UTF8-encoded password.

WebSphere Application Server supports the default PasswordText type. However, it does not support password digest because most user registry security policies do not expose the password to the application software.

The following example illustrates the use of the <UsernameToken> element:

```

<S:Envelope xmlns:S="http://www.w3.org/2001/12/soap-envelope"
 xmlns:wsse="http://schemas.xmlsoap.org/ws/2002/04/secext">
 <S:Header>
 ...
 <wsse:Security>
 <wsse:UsernameToken>
 <wsse:Username>Joe</wsse:Username>
 <wsse:Password>ILoveJava</wsse:Password>
 </wsse:UsernameToken>
 </wsse:Security>
 </S:Header>
</S:Envelope>

```

### **Nonce, a randomly generated token:**

*Nonce* is a randomly generated, cryptographic token used to prevent the theft of user name tokens used with SOAP messages. Nonce is used with the basicauth authentication method.

Without nonce, when a user name token is passed from one machine to another machine using a non-secure transport, such as HTTP, the token might be intercepted and used in a replay attack. The same key might be reused when the username token is transmitted between the client and the server, which leaves it vulnerable to attack. The user name token can be stolen even if you use XML digital signature and XML encryption.

To help eliminate these replay attacks, the <wsse:Nonce> and <wsu:Created> elements are generated within the <wsse:usernameToken> element and used to validate the message. The request receiver or response

receiver checks the freshness of the message to verify the difference between when the message is created and the current time falls within a specified time period. Also, WebSphere Application Server verifies that the receiver has not processed the token within the specified time period. These two features are used to lessen the chance that a user name token is used for a replay attack.

### **Configuring nonce for the application level:**

*Nonce* is a randomly generated, cryptographic token used to thwart the highjacking of username tokens used with SOAP messages. Nonce is used in conjunction with the BasicAuth authentication method.

This task provides instructions on how to configure nonce for the application level using the WebSphere Application Server administrative console. You can configure nonce at the application level and cell level. However, you must consider the order of precedence:

1. Application level
2. Server level

If you configure nonce on the application level and the server level, the values specified for the application level take precedence over the values specified for the server level.

1. Connect to the administrative console by typing `http://localhost:9090/admin` in your Web browser unless you have changed the port number.
2. Click **Servers > Application Servers > server1**.
3. Under Additional Properties, click **Web Services: Default Bindings for Web Services Security > Login Mappings > New**.
4. Specify (optional) a value, in seconds, for the **Nonce Maximum Age** field. This panel is optional and only valid if the BasicAuth authentication method is specified. If you specify another authentication method and attempt to specify values for this field, the following error message displays and you must remove the specified value:

Nonce is not supported for authentication methods other than BasicAuth.

If you specify BasicAuth, but do not specify values for the Nonce Maximum Age field, the Web services security run time searches for a Nonce Maximum Age value on the server level. If a value is not found on the server level, the run time searches the cell level. If a value is not found on either the server level or the cell level, the default is 300 seconds.

The value specified for the Nonce Maximum Age field indicates how long the nonce is valid. You must specify a minimum of 300 seconds, but the value cannot exceed the number of seconds specified for the Nonce Cache Timeout field for either the server level

You can specify the Nonce Cache Timeout value for the server level by completing the following steps:

- a. Click **Servers > Application Servers > server\_name**.
- b. Under Additional Properties, click **Web Services: Default bindings for Web Services Security**.

You can specify the Nonce Cache Timeout value for the cell level by clicking **Security > Web Services > Properties**.

5. Specify (optional) a value, in seconds, for the **Nonce Clock Skew** field. The value specified for the Nonce Clock Skew field specifies the amount of time, in seconds, to consider when the message receiver checks the timeliness of the value. This panel is optional and only valid if the BasicAuth authentication method is specified. If you specify another authentication method and attempt to specify values for this field, the following error message displays and you must remove the specified value:

Nonce is not supported for authentication methods other than BasicAuth.

If you specify BasicAuth, but do not specify values for the **Nonce Clock Skew** field, the Web services security run time searches for a Nonce Clock Skew value on the server level. If a value is not found on the server level, the run time searches the cell level. If a value is not found on either the server level or the cell level, the default is 0 seconds.

Consider the following information when you set this value:

- Difference in time between the message sender and the message receiver if the clocks are not synchronized.
- Time needed to encrypt and transmit the message.
- Time needed to get through network congestion.

6. Restart the server.

### **Configuring nonce for the server level:**

*Nonce* is a randomly generated, cryptographic token used to prevent the theft of username tokens used with SOAP messages. Nonce is used in conjunction with the BasicAuth authentication method.

This task provides instructions on how to configure nonce for the server level using the WebSphere Application Server administrative console. You can configure nonce at the application level and the cell level. However, you must consider the order of precedence:

1. Application level
2. Server level

If you configure nonce on the application level and the server level, the values specified for the application level take precedence over the values specified for the server level. In a WebSphere Application Server environment, you must specify values for the Nonce Cache Timeout, Nonce Maximum Age, and Nonce Clock Skew fields on the server level to use nonce effectively. Complete the following steps to configure nonce on the server level:

1. Connect to the administrative console by typing `http://localhost:9090/admin` in your Web browser unless you have changed the port number.
2. Click **Servers > Application Servers > server1**.
3. Under Additional Properties, click **Web Services: Default Bindings for Web Services Security**.
4. Specify a value, in seconds, for the **Nonce Cache Timeout** field. The value specified for the Nonce Cache Timeout field indicates how long the nonce remains cached before it is expunged. You must specify a minimum of 300 seconds. However, if you do not specify a value, the default is 600 seconds. This field is required for the server level.
5. Specify (optional) a value, in seconds, for the **Nonce Maximum Age** field. The value specified for the Nonce Maximum Age field indicates how long the nonce is valid. You must specify a minimum of 300 seconds, but the value cannot exceed the number of seconds specified for the Nonce Cache Timeout field on the server level.

You can specify the Nonce Cache Timeout value for the cell level by clicking **Security > Web Services > Properties**.

This field is required for the server level.

6. Specify a value, in seconds, for the **Nonce Clock Skew** field. The value specified for the Nonce Clock Skew field specifies the amount of time, in seconds, to consider when the message receiver checks the timeliness of the value. Consider the following information when you set this value:
  - Difference in time between the message sender and the message receiver if the clocks are not synchronized.
  - Time needed to encrypt and transmit the message.
  - Time needed to get through network congestion.

You must specify at least 0 seconds for the Nonce Clock Skew field. However, the maximum value cannot exceed the number of seconds specified in the Nonce Maximum Age field on the server level. If you do not specify a value, the default is 0 seconds.

7. Restart the server. If you change the Nonce Cache Timeout value and do not restart the server, the change is not recognized by the server.

## Binary security token

The ValueType attribute identifies the type of the security token, for example, an LTPA token. The EncodingType indicates how the security token is encoded, for example, Base64Binary. The BinarySecurityToken element defines a security token that is binary encoded. The encoding is specified using the EncodingType attribute. The value type and space are specified using the ValueType attribute. The Web services security implementation for WebSphere Application Server, Version 5.0.2 supports both LTPA and X.509 certificate binary security tokens.

A binary security token has the following attributes that are used for interpretation:

- Value type
- Encoding type

The following example depicts an LTPA binary security token in a Web services security message header:

```
<wsse:BinarySecurityToken xmlns:ns7902342339871340177=
 "http://www.ibm.com/websphere/appserver/tokentype/5.0.2"
 EncodingType="wsse:Base64Binary"
 ValueType="ns7902342339871340177:LTPA">
 MIZ6LGPt2CzXBQfio9wZTo1VotWov0NW3Za6IU5K7Li78DSnIK6iHj3hxXgrUn6p4wZI
 8Xg26havepvmSJ8XxiACMihTJuh1t3ufsrjbFQJOqh5VcRvI+AKEaNmNtEgEV65jUYAC9
 C/iwBBWk5U/6DIk7LfXcTT0ZPAd+3D3nCS0f+6tnqMou8EG9mtMeTKccz/pJVTZjaRSo
 msu0sewsOKfl/WPsjW0bR/2g3NaVvBy18VITFBpUbGFVGgzHRjBKAGo+ctkl80nIVLlk
 TUjt/XdYvEpOr6QoddGi4okjDGPyoDxcvKZnReXww5UsoqlpfXwN4KG9as=
</wsse:BinarySecurityToken></wsse:Security></soapenv:Header>
```

As shown in the example, the token is Base64Binary encoded.

## XML token

XML tokens are offered in two formats, Security Assertion Markup Language (SAML) and Extensible rights Markup Language (XrML).

XML-based security tokens are growing in popularity. Two well-known formats are:

- Security Assertion Markup Language (SAML)
- Extensible rights Markup Language (XrML)

Using textensibility of the <wsse:Security> header in XML-based security tokens, you can directly insert these security tokens into the header.

SAML assertions are attached to Web services security messages using Web Services by placing assertion elements inside the <wsse:Security> header. The following example illustrates a Web services security message with a SAML assertion token.

```
<S:Envelope xmlns:S="...">&
 <wsse:Security xmlns:wsse="...">
 <saml:Assertion
 MajorVersion="1"
 MinorVersion="0"
 AssertionID="SecurityToken-ef375268"
 Issuer="elliottw1"
 IssueInstant="2002-07-23T11:32:05.6228146-07:00"
 xmlns:saml="urn:oasis:names:tc:SAML:1.0:assertion">
```

```

 ...
 </saml:Assertion>
 </wsse:Security>
</S:Header>
<S:Body>
 ...
</S:Body>
</S:Envelope>

```

For more information on SAML and XrML, see Resources for learning.

## Security token

A security token represents a set of claims made by a client that might include a name, password, identity, key, certificate, group, privilege, and so on.

Web services security provides a general-purpose mechanism to associate security tokens with messages for single message authentication. A specific type of security token is not required by Web services security. Web services security is designed to be extensible and support multiple security token formats to accommodate a variety of authentication mechanisms. For example, a client might provide proof of identity and proof of a particular business certification.

A security token is embedded in the SOAP message within the SOAP header. The security token within the SOAP header is propagated from the message sender to the intended message receiver. On the receiving side, the WebSphere Application Server security handler authenticates the security token and sets up the caller identity on the running thread.

## Securing Web services using a pluggable token

WebSphere Application Server provides several different methods to secure your Web services; a pluggable token is one of these methods. You might secure your Web services using any of the following methods:

- XML digital signature
- XML encryption
- Basicauth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

Complete the following steps to secure your Web services using a pluggable token:

1. Generate a security token using the Java Authentication and Authorization Service (JAAS) CallbackHandler interface. The Web services security run time uses the JAAS CallbackHandler interface as a plug-in to generate security tokens on the client side or when Web services is acting as a client.
2. Configure your pluggable token. To use pluggable tokens to secure your Web services, you must configure both the client request sender and the server request receiver. You can configure your pluggable tokens using either the WebSphere Application Server administrative console or the WebSphere Application Server Toolkit. For more information, see the following topics:
  - Configuring pluggable tokens using the WebSphere Application Server Toolkit
  - Configuring pluggable tokens using the administrative console

## Configuring pluggable tokens using the Assembly Toolkit

This document describes how to configure a pluggable token in the request sender (`ibm-webservicesclient-ext.xmi` and `ibm-webservicesclient-bnd.xmi` file) and request receiver (`ibm-webservices-ext.xmi` and `ibm-webservices-bnd.xmi` file).

The pluggable token is required for the request sender and request receiver because they are a pair. The request sender and the request receiver must match for the receiver to accept a request.

Prior to completing these steps, it is assumed that you have already created a Web services-enabled Java 2 Platform, Enterprise Edition (J2EE) with a Web Services for J2EE (JSR 109) enterprise application. If not, see *Developing Web services to create Web services-enabled J2EE with a JSR 109 enterprise application*. See either of the following topics for an introduction of how to manage Web services security binding information for the server:

- Configuring the server security bindings using the Assembly Toolkit
- Configuring the server security bindings using the administrative console

You must specify the security constraints in the `ibm-webservicesclient-ext.xmi` and the `ibm-webservices-ext.xmi` files for the required tokens using the Assembly Toolkit.

Complete the following steps to configure the request sender using the `ibm-webservicesclient-ext.xmi` and `ibm-webservicesclient-bnd.xmi` files:

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
4. In the Package Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the `webservicesclient.xml` file, and click **Open With > Web Services Client Editor**.
6. Click the **Security Extensions** tab. The Web service client security extensions editor is displayed.
  - a. Under Service References, select an existing service reference or click **Add** to create a new reference.
  - b. Under Port QName Bindings, select an existing port qualified name for the selected service reference or click **Add** to create a new port name binding.
  - c. Under Request Sender Configuration: Login Configuration, select an exiting authentication method or type in a new one in the editable list box (Lightweight Third Party Authorization (LTPA) is a supported token generation when Web services is acting as client).
  - d. Click **File > Save** to save the changes.
7. Click the **Web Services Client Binding** tab. The Web services client binding editor is displayed.
  - a. Under Port Qualified Name Binding, select an existing entry or click **Add** to add a new port name binding. The Web Services Client Binding editor displays for the selected port.
  - b. Under Login Binding, click **Edit** or **Enable**. The Login Binding dialog box is displayed.
    - 1) In the Authentication Method field, enter the authentication method. The authentication method that you enter in this field must match the authentication method defined on the Security Extension tab for the same Web service port. This field is mandatory.
    - 2) (Optional) Enter the token value type information in the **URI** and **Local name** fields. These fields are ignored for the BasicAuth, Signature, and IDAssertion authentication methods, but required for other authentication methods. The token value type information is inserted into the `<wsse:BinarySecurityToken>@ValueType` element for binary security token and is used as the namespace for the XML-based token.
    - 3) Enter an implementation of the Java Authentication and Authorization Service (JAAS) `javax.security.auth.callback.CallbackHandler` interface. This field is mandatory.

- 4) Enter the basic authentication information in the **User ID** and **Password** fields. The basic authentication information is passed to the construct of the CallbackHandler implementation. The use of the basic authentication information depends on the implementation of CallbackHandler.
  - 5) In the **Property** field, add name and value pairs. These pairs are passed to the construct of the CallbackHandler implementation as java.util.Map values.
  - 6) Click **OK**.  
Click **Disable** under Login Binding on the Web Services Client Port Binding tab to remove the authentication method login binding.
  - c. Click **File > Save** to save the changes.
8. In the Package Explorer window, right-click the webservices.xml file and click **Open With > Web Services Editor**. The Web Services window displays.
    - a. Click the **Security Extensions** tab. The Web Service Security Extensions editor is displayed.
      - 1) Under Web Service Description Extension, select an existing service reference or click **Add** to create a new extension.
      - 2) Under Port Component Binding, select an existing port qualified name for the selected service reference or click **Add** to create a new one.
      - 3) Under Request Receiver Service Configuration Details: Login Configuration, select an existing authentication method or click **Add** and enter a new method in the Add AuthMethod field that displays. You can select multiple authentication methods for the request receiver. The security token of the incoming message is authenticated against the authentication methods in the order that they are specified in the list. Click **Remove** to remove the selected authentication method or methods.
    - b. Click **File > Save** to save the changes.
    - c. Click the **Bindings** tab. The Web services bindings editor is displayed.
      - 1) Under Web Service Description Bindings, select an existing entry or click **Add** to add a new Web services descriptor.
      - 2) Click the **Binding Configurations** tab. The Web services binding configurations editor is displayed for the selected Web services descriptor.
      - 3) Under Request Receiver Binding Configuration Details: Login Mapping, click **Add** to create a new login mapping or click **Edit** to edit the selected login mapping. The Login mapping dialog is displayed.
        - a) In the Authentication method field, enter the authentication method. The information entered in this field must match the authentication method defined on the Security Extensions tab for the same Web service port. This field is mandatory.
        - b) In the Configuration name field, enter a JAAS login configuration name. You must define the JAAS login configuration name in the WebSphere Application Server administrative console under **Security > JAAS Configuration > Application Logins**. This is a mandatory field. For more information, see "Configuring Java Authentication and Authorization Service login" in the Information Center.
        - c) (Optional) Select **Use Token value type** and enter the token value type information in the URI and Local name fields. This information is optional for BasicAuth, Signature and IDAssertion authentication methods, but required for any other authentication method. The token value type is used to validate the <wsse:BinarySecurityToken>@ValueType element for binary security tokens and to validate the namespace of the XML-based token.
        - d) Under Callback Handler Factory, enter an implementation of the com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory interface in the **Class name** field. This field is mandatory.
        - e) Under Callback Handler Factory property, click **Add** and enter the name and value pairs for the Callback Handler Factory Property. These name and value pairs are passed as

java.util.Map to the com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory.init() method. The use of these name and value pairs is determined by the CallbackHandlerFactory implementation.

- f) Under Login Mapping Property, click **Add** and enter the name and value pairs for the Login mapping property. These name and value pairs are available to the JAAS Login Modules through the com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback JAAS Callback interface. Click **Remove** to delete the selected login mapping.
  - g) Click **OK**.
- d. Click **File > Save** to save the changes.

The previous steps define how to configure the request sender to create security tokens in the Simple Object Access Protocol (SOAP) message and to configure the request receiver to validate the security tokens found in the incoming SOAP message. WebSphere Application Server supports pluggable security tokens.

You can use the authentication method defined in the login bindings and login mappings to generate security tokens in the request sender and validate security tokens in the request receiver.

After you configure pluggable tokens, you must configure both the client and the server to support pluggable tokens. See the following topics to configure the client and the server:

- Configuring the client for LTPA token authentication: Specifying LTPA token authentication
- Configuring the client for LTPA token authentication: Collecting the authentication information
- Configuring the server to handle LTPA token authentication
- Configuring the server to validate LTPA token authentication information

## Configuring pluggable tokens using the Administrative Console

Prior to completing these steps, it is assumed that you have already created a Web services-enabled Java 2 Platform, Enterprise Edition (J2EE) with a Web Services for J2EE (JSR 109) enterprise application. If not, see Developing Web services to create Web services-enabled J2EE with a JSR 109 enterprise application. See either of the following topics for an introduction of how to manage Web services security binding information for the server:

- Configuring the server security bindings using the Assembly Toolkit
- Configuring the server security bindings using the administrative console

This document describes how to configure a pluggable token in the request sender (ibm-webservicesclient-ext.xmi and ibm-webservicesclient-bnd.xmi file) and request receiver (ibm-webservices-ext.xmi and ibm-webservices-bnd.xmi file).

**Important:** The pluggable token is required for the request sender and request receiver as they are a pair. The request sender and the request receiver must match for a request to be accepted by the receiver.

Prior to completing these steps, it is assumed that you deployed a Web services-enabled enterprise application to the WebSphere Application Server.

Use the following steps to configure the client-side request sender (ibm-webservicesclient-bnd.xmi file) or server-side request receiver (ibm-webservices-bnd.xmi file) using the WebSphere Application Server Administrative Console.

1. Click **Applications > Enterprise Applications > enterprise\_application**.
2. Under Related Items, click either **EJB Modules > Uri** or **Web Modules > Uri**. The *Uri* is the Web services-enabled module

- a. Under Additional Properties, click **Web Services: Client Security Bindings** to edit the response sender binding information, if Web services is acting as client.
  - 1) Under Response Sender Binding, click **Edit**.
  - 2) Under Additional Properties, click **Login Binding**.
  - 3) Select **Dedicated Login Binding** to define a new login binding.
    - a) Enter the authentication method, this must match the authentication method defined in IBM extension deployment descriptor. The authentication method must be unique in the binding file.
    - b) Enter an implementation of the JAAS `javax.security.auth.callback.CallbackHandler` interface.
    - c) Enter the basic authentication information (User ID and Password) and the basic authentication information is passed to the construct of the `CallbackHandler` implementation. The usage of the basic authentication information is up to the implementation of the `CallbackHandler`.
    - d) Enter the token value type, it is optional for `BasicAuth`, `Signature` and `IDAssertion` authentication methods but required for any other authentication method. The token value type is inserted into the `<wsse:BinarySecurityToken>@ValueType` for binary security token and used as the namespace of the XML based token.
    - e) Click **Properties**. Define the property with name and value pairs. These pairs are passed to the construct of the `CallbackHandler` implementation as `java.util.Map`.  
Select **None** to deselect the login binding.
- b. Under Additional Properties, click **Web Services: Server Security Bindings** to edit the request receiver binding information.
  - 1) Under Request Receiver Binding, click **Edit**.
  - 2) Under Additional Properties, click **Login Mappings**.
  - 3) Click **New** to create new login mapping.
    - a) Enter the authentication method, this must match the authentication method defined in the IBM extension deployment descriptor. The authentication method must be unique in the login mapping collection of the binding file.
    - b) Enter a JAAS Login Configuration name. The JAAS Login Configuration must be defined in **Security > JAAS Configuration > Application Logins**. For more information, see "Configuring Java Authentication and Authorization Service login" in the Information Center.
    - c) Enter an implementation of the `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory` interface. This is a mandatory field.
    - d) Enter the token value type, it is optional for `BasicAuth`, `Signature` and `IDAssertion` authentication methods but required for any other authentication method. The token value type is used to validate against the `<wsse:BinarySecurityToken>@ValueType` for binary security token and against the namespace of the XML based token.
    - e) Enter the name and value pairs for the "Login Mapping Property" by clicking **Properties**. These name and value pairs are available to the JAAS Login Module or Modules by `com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback` JAAS Callback. **Note:** This is true when editing existing login mappings but not when creating new login mappings.
    - f) Enter the name and value pairs for the "Callback Handler Factory Property", these name and value pairs is passed as `java.util.Map` to the `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory.init()` method. The usage of these name and value pairs is up to the `CallbackHandlerFactory` implementation.
  - c. Click authentication method link to edit the selected login mapping.
  - d. Click **Remove** to remove the selected login mapping or mappings.
3. Click **Save** in the upper-left section of the Administrative Console.

The previous steps define how to configure the request sender to create security tokens in the Simple Object Access Protocol (SOAP) message and the request receiver to validate the security tokens found in the incoming SOAP message. WebSphere Application Server supports pluggable security tokens.

You can use the authentication method defined in the login bindings and login mappings to generate security tokens in the request sender and validate security tokens in the request receiver.

Once you have configured pluggable tokens, you must configure both the client and the server to support pluggable tokens. See the following topics to configure the client and the server:

- Configuring the client for LTPA token authentication: specifying LTPA token authentication
- Configuring the client for LTPA token authentication: collecting the authentication information
- Configuring the server to handle LTPA token authentication
- Configuring the server to validate LTPA token authentication information

## Pluggable token support

You can extend the WebSphere Application Server login mapping mechanism to handle new types of authentication tokens. WebSphere Application Server provides a pluggable framework to generate security tokens on the sender-side of the message and to validate the security token on the receiver-side of the message. The framework is based on the Java Authentication and Authorization Service (JAAS) Application Programming Interfaces (APIs). Pluggable security token support provides plug-in points to support customer security token types including token generation, token validation, and client identity mapping to a WebSphere Application Server identity that is used by the Java 2 platform, Enterprise Edition (J2EE) authorization engine. Moreover, the pluggable token generation and validation framework supports XML-based tokens to be inserted into the Web service message header and validated on the receiver-side validation.

Use the `javax.security.auth.callback.CallbackHandler` implementation to create a new type of security token following these guidelines:

- Use a constructor that takes a user name (a string or null, if not defined), a password (a `char[]` or null, if not defined) and `java.util.Map` (empty, if properties are not defined).
- Use `handle()` methods that can process the following implementations:
  - `javax.security.auth.callback.NameCallback`
  - `javax.security.auth.callback.PasswordCallback`
  - `com.ibm.wsspi.wssecurity.auth.callback.XMLTokenCallback`
  - `com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl`

If:

1. Either the `javax.security.auth.callback.NameCallback` or the `javax.security.auth.callback.PasswordCallback` implementation is populated with data, then a `<wsse:UsernameToken>` element is created.
2. `com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl` is populated, the `<wsse:BinarySecurityToken>` element is created from the `com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl` implementation.
3. `com.ibm.wsspi.wssecurity.auth.callback.XMLTokenCallback` is populated, a XML-based token is created based on the Document Object Model (DOM) element that is returned from the `XMLTokenCallback`.

Encode the token byte by using the security handler and not by using the `javax.security.auth.callback.CallbackHandler` implementation.

You can implement the `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory` interface, which is a factory for instantiating the `javax.security.auth.callback.CallbackHandler` implementation. For your own implementation, you must provide the `javax.security.auth.callback.CallbackHandler` interface. The Web service security run time instantiates the factory implementation class and passes the authentication

information from the Web services message header to the factory class through the setter methods. The Web services security run time then invokes the `newCallbackHandler()` method of the factory implementation class to obtain an instance of the `javax.security.auth.CallbackHandler` object. The object is passed to the JAAS login configuration.

The following is an example the definition of the `CallbackHandlerFactory` interface:

```
public interface com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory {
 public void setUsername(String username);
 public void setRealm(String realm);
 public void setPassword(String password);
 public void setHashMap(Map properties);
 public void setTokenByte(byte[] token);
 public void setXMLToken(Element xmlToken);
 public CallbackHandler newCallbackHandler();
}
```

## Configuring the client for LTPA token authentication: specifying LTPA token authentication

Use this task to configure Lightweight Third-Party Authentication (LTPA) token authentication. Only configure the client for LTPA token authentication if the authentication mechanism configured in WebSphere Application Server is LTPA. When a client authenticates to a WebSphere Application Server, the credential created contains an LTPA token. When a Web service calls a downstream Web service, you can configure the first Web service to send the LTPA token from the originating client. Do not attempt to configure LTPA from a pure client. LTPA works only when you configure the client-side of a Web service acting as a client to a downstream Web service. For the downstream Web service to validate the LTPA token, the LTPA keys on both servers must be the same.

Complete the following steps to specify LTPA token as the authentication method:

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the `webservicesclient.xml` file, and click **Open With > Web Services Client Editor**.
6. Click the **Security Extensions** tab, which is located at the bottom of the Web services client editor within the Assembly Toolkit.
7. Expand the **Request Sender Configuration > Login Configuration** section.
8. Select **LTPA** as the authentication method. For more conceptual information on LTPA authentication, see LTPA.

After you specify LTPA token as the authentication method, you must specify how to collect the LTPA token information. See [Configuring the client for LTPA token authentication: Collecting the authentication information](#) for more information.

## Configuring the client for LTPA token authentication: Collecting the authentication method information

Use this task to configure Lightweight Third-Party Authentication (LTPA) token authentication. Do not configure the client for LTPA token authentication unless the authentication mechanism configured in WebSphere Application Server is LTPA. When a client authenticates to a WebSphere Application Server, the credential created contains an LTPA token. When a Web service calls a downstream Web service, you can configure the first Web service to send the LTPA token from the originating client. Do not attempt to configure LTPA from a pure client. LTPA works only when you configure the client-side of a Web service acting as a client to a downstream Web service. In order for the downstream Web service to validate the LTPA token, the LTPA keys on both servers must be the same.

Complete the following steps to specify how to collect the LTPA token authentication information:

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the webservicessclient.xml file, and click **Open With > Web Services Client Editor**.
6. Click the **Port Binding** tab, which is located at the bottom of the Web services client editor within the Assembly Toolkit.
7. Expand the **Security Request Sender Binding Configuration > Login Binding** section.
8. Click **Edit** to view the login binding information and select **LTPA**. If LTPA is not already there, enter it as an option. The login binding dialog is displayed. Select or enter the following information:

#### **Authentication method**

Specifies the type of authentication that occurs. Select **LTPA** to use identity assertion.

#### **Token value type URI and token value type local name**

When you select **LTPA**, you must edit the **token value type URI** and the **local name** fields. Specifies values for custom authentication types, which are authentication methods not mentioned in the specification. For the token value type URI field, enter the following string: `http://www.ibm.com/websphere/appserver/tokentype/5.0.2`. For the local name field, enter the following string: `LTPA`.

#### **Callback handler**

Specifies the Java Authentication and Authorization Service (JAAS) callback handler implementation for collecting the LTPA information. Specify the `com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler` implementation for LTPA.

#### **Basic authentication user ID and basic authentication password**

For LTPA, you can leave these fields empty.

#### **Property name and property value**

For LTPA, you can leave these fields empty.

See Configuring the client for LTPA token authentication: Specifying LTPA token authentication if you have not previously specified this information.

## **Configuring the server to handle LTPA token authentication information**

This task is used to configure Lightweight Third-Party Authentication (LTPA). LTPA is a type of authentication mechanism in WebSphere Application Server security that defines a particular token format. The purpose of the LTPA token authentication is to flow the LTPA token from the first Web service, which authenticated the originating client, to the downstream Web service. Do not attempt to configure LTPA from a pure client. Once the downstream Web service receives the LTPA token, it validates the token to verify that the token has not been modified and has not expired. For validation to be successful, the LTPA keys used by both the sending and receiving servers must be the same.

Complete the following steps to specify that LTPA is authentication method. The authentication method indicated in these steps must match the authentication method specified for the client.

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the webservicess.xml file, select **Open With > Web Services Editor**.

6. Click the **Security Extensions** tab, which is located at the bottom of the Web services client editor within the Assembly Toolkit.
7. Expand the **Request Receiver Service Configuration Details > Login Configuration** section. You can select from the following options:
  - BasicAuth
  - Signature
  - ID assertion
  - LTPA
8. Select **LTPA** to authenticate the client using the LTPA token received from the request.

After you specify the authentication method, you must specify the information that the server must validate. See *Configuring the server to validate LTPA token authentication information* for more information.

## Configuring the server to validate LTPA token authentication information

This task is used to configure Lightweight Third-Party Authentication (LTPA). LTPA is a type of authentication mechanism in WebSphere Application Server security that defines a particular token format. The purpose of the LTPA token authentication is to flow the LTPA token from the first Web service, which authenticated the originating client, to the downstream Web service. Do not attempt to configure LTPA from a pure client. Once the downstream Web service receives the LTPA token, it validates the token to verify that the token has not been modified and has not expired. For validation to be successful, the LTPA keys used by both the sending and receiving servers must be the same.

Complete the following steps to specify how the server must validate the LTPA token authentication information:

1. Launch the Assembly Toolkit.
2. Open the J2EE perspective by clicking **Window > Open Perspective > Other > J2EE**.
3. Select the Web services-enabled Enterprise JavaBean (EJB) or Web module.
4. In the Project Navigator window, locate the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
5. Right-click the webservices.xml file, and click **Open With > Web Services Editor**.
6. Click the **Binding Configurations** tab, which is located at the bottom of the Web services client editor within the Assembly Toolkit.
7. Expand the **Request Receiver Binding Configuration Details > Login Mapping** section.
8. Click **Edit** to view the login mapping information. The login mapping information is displayed. Select or enter the following information:

### Authentication method

Specifies the type of authentication that occurs. Select **LTPA** to use LTPA token authentication.

### Configuration name

Specifies the Java Authentication and Authorization Service (JAAS) login configuration name. For the LTPA authentication method, enter `WSLogin` for the JAAS login configuration name. This configuration understands how to validate an LTPA token.

### Use token value type

Determines if you want to specify a custom token type. For LTPA authentication, you must select this option because LTPA is considered a custom type. LTPA is not in the Web Services Security Specification.

### Token value type URI and local name

Specifies custom authentication types. If you select **Use Token value type** you must enter data into the Token value Type URI and local name fields. For the token value type URI field, enter the following string: `http://www.ibm.com/websphere/appserver/tokentype/5.0.2`. For the local name, enter the following string: `LTPA`

**Callback handler factory class name**

Creates a JAAS CallbackHandler implementation that understands the following callback handlers:

- `javax.security.auth.callback.NameCallback`
- `javax.security.auth.callback.PasswordCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.BinaryTokenCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.XMLTokenReceiverCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback`

For any of the default authentication methods (BasicAuth, IDAssertion, Signature, and LTPA), use the callback handler factory default implementation. Enter the following class name for any of the default authentication methods including LTPA:

```
com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl
```

This implementation creates the correct callback handler for the default implementations.

**Callback handler factory property**

Specifies callback handler properties for custom callback handler factory implementations. Default callback handler factory implementation does not any property specifications. For LTPA, you can leave this field blank.

**Login mapping property**

Specifies properties for a custom login mapping. For default implementations including LTPA, you can leave this field blank.

See *Configuring the server to handle LTPA token authentication* if you have not previously specified this information.

***Lightweight Third Party Authentication:***

When you use the lightweight third party authentication (LTPA) method, the `<wsse:BinarySecurityToken>` security token generated is. On the request sender side, the security token is generated by invoking a callback handler. On the request receiver side, the security token is validated by a Java Authentication and Authorization Service (JAAS) login module.

The following information describes token generation and token validation operations.

**LTPA token generation**

The request sender uses a callback handler to generate an LTPA security token. The callback handler returns a security token that is inserted in the Simple Object Access Protocol (SOAP) message. Specify the appropriate callback handler in the `<LoginBinding>` element of the bindings file (`ibm-webservicesclient-bnd.xmi`). The following callback handler implementation can be used with the LTPA authentication method:

- `com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler`

You can add your own callback handlers that implement the `javax.security.auth.callback.CallbackHandler` property.

When using the LTPA authentication method (or any authentication method other than BasicAuth, Signature or IDAssertion), the `TokenType` attribute of the `<LoginBinding>` element in the bindings file (`ibm-webservicesclient-bnd.xmi`) must be specified. The values to use for the LTPA `TokenType` attribute are:

- `uri="http://www.ibm.com/websphere/appserver/tokentype/5.0.2"`
- `localName="LTPA"`

**LTPA token validation**

The request receiver retrieves the LTPA security token from the SOAP message and validates the message using a JAAS login module. The `<wsse:BinarySecurityToken>` security token is used to

perform the validation. If the validation is successful, the login module returns a JAAS Subject. Subsequently, this Subject is set as the identity of the running thread. If the validation fails, the request is rejected with a SOAP fault.

The appropriate JAAS login configuration to use is specified in the bindings file <LoginMapping> element. Default bindings specified in the `ws-security.xml` file, but these can be overridden using the application-specific `ibm-webservices-bnd.xml` file. The configuration information consists of a `CallbackHandlerFactory`, a `ConfigName` and a `TokenValueType` attribute. The `CallbackHandlerFactory` specifies the name of a class to use to create the JAAS `CallbackHandler` object. A `CallbackHandlerFactory` implementation is provided (`com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl`). The `ConfigName` attribute specifies a JAAS configuration name entry. The Web services security run time first searches the `security.xml` file for a matching entry and if a matching entry is not found, the run time searches the `wsjaas.conf` file. A default configuration entry suitable for the LTPA authentication method is provided (`WSLogin`). An appropriate `TokenValueType` element is located in the LTPA `LoginMapping` section of the default `ws-security.xml` file.

---

## Tuning Web services based on Web Services for J2EE

Performance considerations are the same for Web services applications that are developed and implemented based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) and regular J2EE applications. See "Tuning performance" in the Information Center for more information about analyzing and tuning J2EE applications.

You can use the Performance Monitoring Infrastructure (PMI) to measure the time required to process Web services requests. To monitor Web services application performance:

1. Enable PMI services in application server through the administrative console. See "Enabling performance monitoring services in the application server through the administrative console" in the Information Center. Select the Web Service module, named `webServicesModule`, in step 7.
2. Monitor performance with Tivoli Performance Viewer. See "Monitoring performance with Tivoli Performance Viewer (formerly Resource Analyzer)" in the Information Center. In the left-hand pane of the performance view, expand the host and server and select **Web Services**. Run the Web services client application.

Measurements are available for the following items:

- Number of Web services loaded by the application server
- Number of requests received
- Number of requests dispatched to an implementation bean
- Number of requests dispatched with successful replies
- Average time in milliseconds between receiving the request and returning the reply
- Average time in milliseconds between receiving the request and dispatching it to the bean
- Average time in milliseconds between dispatch and receipt of reply from the bean
- Average time in milliseconds between receipt of reply from bean to return of result to client
- Average size of request and reply
- Average size of request
- Average size of reply

---

## Troubleshooting Web services based on Web Services for J2EE

Select the Web services topic area you want to troubleshoot:

- Command-line tools
- Java compiler errors
- Runtime errors and exceptions
- Client runtime errors and exceptions

- Serialization or deserialization errors

## Troubleshooting command-line tools for Web services based on Web Services for J2EE

This topic discusses troubleshooting command-line tools for Web services that are developed and implemented based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) specification.

### WSDL2Java command-line tool

#### Using a proxy server to access the Internet while executing the WSDL2Java command causes your connection to time out

If you are using an environment that requires a proxy server to access the Internet during the execution of the **WSDL2Java** command, the **WSDL2Java** command might not find the Internet information because the proxy server has the potential to time out. For example, if the input `wsdl` file is located on the Internet instead of a local drive, and you need to retrieve it from the Internet, the **WSDL2Java** command fails to find it because the proxy server timed out.

You can work around this problem by editing the `WSDL2Java.bat` file when using a Windows operating system or the `WSDL2Java.sh` file if you are using a UNIX operating system. These files are located in the `<install_root>/WebSphere/AppServer/bin` directory.

If you are using a Windows operating system, set your proxy host and port values in the `WSDL2Java.bat` file:

```
PROXY_INFO="-Dproxy.httpHost=yourProxyHost -Dproxy.httpPort=yourProxyPort
```

If you are using a UNIX operating system, set your proxy host and port values in the `WSDL2Java.sh` file:

```
PROXY_INFO="-Dproxy.httpHost=yourProxyHost -Dproxy.httpPort=yourProxyPort
```

#### Emitter failure error occurs when running the WSDL2Java command on a WSDL document containing a JMS-style endpoint URL

If you run the **WSDL2Java** command-line tool on a WSDL document that contains a JMS-style endpoint URL, for example `jms:/...`, the `urlprotocols.jar` file that contains the custom protocol handler for the JMS protocol must be in the CLASSPATH. The error **WSWS3099E: Error: Emitter failure. Invalid endpoint address in port <x> in service <y>: <jms-url-string>** can be avoided by making sure the `urlprotocols.jar` file is in the CLASSPATH.

To add the `urlprotocols.jar` file to the CLASSPATH:

On Windows platforms, edit the `install_root\bin\setupCmdLine.bat` and locate the line which sets the `WAS_CLASSPATH` environment variable. Add `%install_root%\lib\urlprotocols.jar` to the end of the line that sets the `WAS_CLASSPATH` environment variable.

On UNIX platforms, edit the `install_root/bin/setupCmdLine.sh` file and add `$install_root/lib/urlprotocols.jar` to the end of the line that sets the `WAS_CLASSPATH` environment variable.

Make sure to use the proper delimiter character for your platform, for example, use a semi-colon (;) for Windows platforms and a colon (:) for UNIX platforms.

## Troubleshooting compiled bindings for Web services based on Web Services for J2EE

This topic discusses troubleshooting compiled bindings of Web services that are developed and implemented based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) specification.

### Context root not recognized when mapping the default XML namespace to a Java package

When you map the default XML namespace to a Java package the context root is not recognized. If two namespaces are the same up to the first slash, they are mapped to the same Java package. For example, the XML namespaces `http://www.ibm.com/foo` and `http://www.ibm.com/bar` both map to the Java package `www.ibm.com`. Use the `-NStoPkg` option of the **Java2WSDL** command to specify the package for the fully qualified namespace.

### Java code to WSDL mapping cannot be reversed back to the original Java code

If you find that a WSDL file you created with the **Java2WSDL** command-line tool cannot be compiled when regenerated into Java code using the **WSDL2Java** command-line tool it is because the Java API for XML-based remote procedure call (JAX-RPC) mapping from Java code to WSDL is not reversible back to the original Java code.

To troubleshoot this problem review the WSDL file that was generated by the **Java2WSDL** tool using the information in Mapping between Java, WSDL and XML and the JAX-RPC specification available through Web services: Resources for learning. Use this information to determine which elements in the WSDL file are causing the problem. You can modify the WSDL file, or the original Java interface used to generate the WSDL file, and run the **Java2WSDL** command again.

## Troubleshooting the run time of Web services based on Web Services for J2EE

This topic discusses troubleshooting the run time of Web services that are developed and implemented based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) specification.

You can troubleshoot run time errors and exceptions as follows:

- Trace SOAP messages
- Trace the components of Web services based Web Services for J2EE

### Tracing SOAP messages

This topic discusses tracing SOAP messages that request Web services that are developed and implemented based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) specification.

You can trace the SOAP messages exchanged between a client and the server using the **TCPMon** command tool. The **TCPMon** command redirects messages from one port to another and records them. The WebSphere Application Server listens on port 9080. To trace messages sent to the application server, the **TCPMon** command is configured to listen on port 9088 and redirect them to 9080. The client is redirected to use port 9088 to access the Web service.

Redirecting an application client to a different port is most easily done by changing the SOAP address in the client's Web Services Description Language (WSDL) file to use port 9088 and then running the **wsdeploy** command-line tool on the client enterprise archive (EAR) file to regenerate the service implementation.

You should confirm that the server providing the Web service is running. The following task is performed on the machine providing the Web service.

To trace SOAP messages in Web services:

1. Set up a development and unmanaged client execution environment for Web services based on Web Services for J2EE
2. Run the **java -Djava.ext.dirs=%WAS\_EXT\_DIRS%** command. A window labeled TCPMonitor displays.
3. Configure the TCPMonitor to listen on port 9088 and forward messages to port 9080.
  - a. In the **Listen Port #** field, enter 9088.
  - b. Click **Listener**
  - c. In the **TargetHostname** field, enter localhost.
  - d. In the **Target Port #** field, enter 9080.
  - e. Click **Add**.
  - f. Click on the **Port 9088** tab that displays on the top of the page.

The messages exchanged between the client and server appear in the TCPMonitor Request and Response pane.

Save the message data and analyze it.

## Tracing Web services components based on Web Services for J2EE

The following are tasks in which you can enable trace for Web services that are developed and implemented based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) specification.

1. Enable trace for a Web services unmanaged client.
  - a. Create a trace properties file by copying `%install_root%\WebSphere\AppServer\properties\TraceSettings.properties` file to the same directory as your client application Java archive (JAR) file.
  - b. Edit the properties file and change the value of `traceFileName` to output the trace data. For example, `traceFileName=c:\\temp\\myAppClient.trc`.
  - c. Edit the properties file to remove `com.ibm.ejs.ras.*=all=enabled` and add `com.ibm.ws.webservices.*=all=enabled`.
  - d. Add the option `-DtraceSettingsFile=<trace_properties_file>` to the Java command-line used to run the client, where `trace_properties_file` represents the name of the properties file created in steps 1-2. For example, **java -DtraceSettingsFile=TraceSettings.properties myApp.myAppMainClass**.
2. Enable trace for a Web services managed client.
  - a. Invoke the **launchClient** command-line tool with the following options:  
`-CCtrace=com.ibm.ws.webservices.*=all=enabled-CCtracefile=traceFileName` For example:  
**`%install_root%\bin\launchClient MyAppClient.ear-  
CCtrace=com.ibm.ws.webservices.*=all=enabled -CCtracefile=myAppClient.trc`**

See `launchClient` tool for more information.
3. Enable trace for a Web Services for J2EE server application.
  - a. Start WebSphere Application Server.
  - b. Open the administrative console.
    - a. Click **Servers >Application Servers > server**.
    - a. Click **Diagnostic Trace Service**.
    - a. In the **Trace Specification** field, delete the text `*=all=enabled` and add `com.ibm.ws.webservices.*=all=enabled`.
    - b. Click **Save** and **Apply**.

For more information see "Enabling trace" in the Information Center.

## Troubleshooting the run time for a Web services client based on Web Services for J2EE

This topic discusses troubleshooting Web services clients that are developed and implemented based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) specification.

### Malformed URL exception displays when running a client that uses a JMS-style endpoint URL

If you are using the `launchClient` command to run a managed or unmanaged client that uses a JMS-style endpoint URL, the `urlprotocols.jar` file that contains the custom protocol handler for the JMS protocol must be in the CLASSPATH. The malformed URL exception can be avoided by making sure the `urlprotocols.jar` file is in the CLASSPATH.

To add the `urlprotocols.jar` file to the CLASSPATH:

On Windows platforms, edit the `install_root\bin\setupCmdLine.bat` and locate the line which sets the `WAS_CLASSPATH` environment variable. Add `%install_root%\lib\urlprotocols.jar` to the end of the line that sets the `WAS_CLASSPATH` environment variable.

On UNIX platforms, edit the `install_root/bin/setupCmdLine.sh` file and add `$install_root/lib/urlprotocols.jar` to the end of the line that sets the `WAS_CLASSPATH` environment variable.

## Troubleshooting serialization and deserialization in Web services based on Web Services for J2EE

The following are problems you might encounter performing serialization and deserialization in Web services that are developed and implemented based on the Web Services for Java 2 platform Enterprise Edition (J2EE) specification.

### Time zone information in deserialized `java.util.Calendar` is not as expected

When the client and server are based on Java code and a `java.util.Calendar` is received, the time zone in the received `java.util.Calendar` instance might be different from that of the `java.util.Calendar` instance that was sent.

This occurs because `java.util.Calendar` is encoded as an `xsd:dateTime` for transmission. An `xsd:dateTime` is required to encode the correct time (base time plus or minus a time zone offset), but is not required to preserve locale information, including the original time zone.

The fact that the time zone for the current locale is not preserved needs to be accounted for when comparing `Calendar` instances. The `java.util.Calendar` class `equals` method checks that the time zones are the same when determining equality. Since the time zone in a deserialized `Calendar` instance might not match the current locale, the `before` and `after` comparison methods should be used to test that two `Calendars` refer to the same date and time as shown below:

```
java.util.Calendar c1 = ...// Date and time in time zone 1
java.util.Calendar c2 = ...// Same date and equivalent time, but in time zone 2

// c1 and c2 are not equal because their time zones are different
if (c1.equals (c2)) System.out.println("c1 and c2 are equal");

// but c1 and c2 do compare as "not before and not after" since they represent
the same date and time
if (!c1.after(c2) & !c1.before(c2) {
 System.out.println("c1 and c2 are equivalent");
}
```

## Mixing Web services client and server bindings causes exceptions

Web Services for J2EE and Java API for XML-based remote procedure call (JAX-RPC) do not support "round-trip" mapping between Java code and a Web Services Description Language (WSDL) document for all Java types. For example, you cannot turn (serialize) a Java Date into XML code and then turn it back (deserialize) into a Java Date. It deserializes as Java Calendar.

If you have a Java implementation that you create a WSDL document from, and you generate client bindings from the WSDL document, the client classes can be different from the server classes even though the client classes have the same package and class names. The Web service client classes must be kept separate from the Web service server classes. For example, do not place the Web service server bindings classes in a utility Java archive (JAR) file and then include a Web service client JAR file that references the same utility JAR file.

If you do not keep the Web service client and server classes separate, a variety of exceptions can occur, depending on the Java classes used. The following is a sample stack trace error that can occur:

```
com.ibm.ws.webservices.engine.PivotHandlerWrapper TRAS0014I: The following exception was logged
 java.lang.NoSuchMethodError: com.ibm.wssvt.acme.websvcs.ExtWSPolicyData:
 method getStartDate()Ljava/util/Date; not found
at com.ibm.wssvt.acme.websvcs.ExtWSPolicyData_Ser.addElement(ExtWSPolicyData_Ser.java: 210)
at com.ibm.wssvt.acme.websvcs.ExtWSPolicyData_Ser.serialize (ExtWSPolicyData_Ser.java:29)
at com.ibm.ws.webservices.engine.encoding.SerializationContextImpl.serializeActual
 (SerializationContextImpl.java 719)
at com.ibm.ws.webservices.engine.encoding.SerializationContextImpl.serialize
 (SerializationContextImpl.java: 463)
```

The problem is caused by using an interface like the following for the Service Endpoint Interface in the service implementation:

```
package server;
public interface Test_SEI extends java.rmi.Remote {
 public java.util.Calendar getCalendar () throws java.rmi.RemoteException;
 public java.util.Date getDate() throws java.rmi.RemoteException;
}
```

When this interface is compiled and run through the **Java2WSDL** command-line tool, the WSDL document maps the methods as follows:

```
<wsdl:message name="getDateResponse">
 <wsdl:part name="getDateReturn" type="xsd:dateTime"/>
</wsdl:message>

<wsdl:message name="getCalendarResponse">
 <wsdl:part name="getCalendarReturn" type="xsd:dateTime"/>
</wsdl:message>
```

The JAX-RPC mapping implemented by the **Java2WSDL** tool has mapped both `java.util.Date` and `java.util.Calendar` to the XML type `xsd:dateTime`. The next step is to use the generated WSDL file to create a client for the Web service. When you run the **WSDL2Java** command-line tool on the generated WSDL, the generated classes include a different version of `server.Test_SEI`, for example:

```
package server;
public interface Test_SEI extends java.rmi.Remote {
 public java.util.Calendar getCalendar() throws java.rmi.RemoteException;
 public java.util.Date getDate() throws java.rmi.RemoteException;
}
```

**Note:** The client version of the `server.Test_SEI` interface is different from the server version in that both `getCalendar` and `getDate` methods return `java.util.Calendar`. The serialization and deserialization code that the client expects is the client version of the SEI. If the server version inadvertently appears in the client's CLASSPATH, at either compilation or execution time, an exception occurs.

In addition to the `NoSuchMethod` error, the `IncompatibleClassChangeError` and `ClassCastException` can occur, however, almost any run-time exception can occur. The best practice is to be diligent about separating client Web services bindings classes from server Web services bindings classes. The client bindings classes and server bindings classes should never be placed in the same module and, if they are in the same application, should not have bindings classes in utility JAR files that are shared between modules.

## Frequently asked questions about Web services based on Web Services for J2EE

This topic presents frequently asked questions about Web services that are developed and implemented based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) specification.

- What IBM development tools work with Web Services for J2EE?
- Is Web Services for J2EE part of the J2EE specification?
- What is the relationship between Web Services for J2EE and the Web Service Invocation Framework (WSIF)?
- What is the relationship between Apache SOAP 2.3 and Web Services for J2EE?
- What is the relationship between the Apache Axis component of the Web services technology preview available with WebSphere Application Server 5.0 and Web Services for J2EE?
- What standards does the Web Services for J2EE component of WebSphere Application Server 5.0 support?
- Does Web Services for J2EE interoperate with other SOAP implementations, like .NET?
- Why can I not use a JavaBean to implement a SOAP Java Messaging Service (JMS) service?
- Does the SOAP JMS support interoperate with other vendors?
- How does two-way messaging with SOAP JMS work? Can it support multiple clients making simultaneous requests?

### What IBM development tools work with Web Services for J2EE?

WebSphere Studio Application Developer Version 5.1 and the Assembly Toolkit Version 5.1 both support the use of Web Services for J2EE. The Application Assembly Tool, included with WebSphere Application Server, and WebSphere Studio Application Developer versions earlier than Version 5.01, do not support Web Services for J2EE.

### Is Web Services for J2EE part of the J2EE specification?

For WebSphere Application Server 5.0.2, the Web Services for J2EE Version 1.0 specification is an addition to J2EE 1.3. J2EE 1.4 requires support for Web Services for J2EE Version 1.1. There are minor differences between the J2EE 1.3 Version (JSR-109 Version 1.0) and the J2EE 1.4 Version (JSR-109 Version 1.1).

### What is the relationship between Web Services for J2EE and the Web Service Invocation Framework (WSIF)?

Web Services for J2EE and WSIF represent two different programming models for accessing Web services. Web Services for J2EE is standard, Java-centric, and more statically bound to Web Services Description Language (WSDL) documents due to the use of generated stubs. WSIF directly models WSDL. WSIF is more suitable when dynamically interpreting WSDL. WebSphere Application Server Version 6.0 leverages both technologies to achieve dynamic, high performing standards-based Web services implementations.

### What is the relationship between Apache SOAP 2.3 and Web Services for J2EE?

Apache SOAP shipped with WebSphere Application Server Versions 4.0 and 5.0. It continues to co-exist with Web Services for J2EE. Apache SOAP is a proprietary API and applications written for it are not

portable to other SOAP implementations. Applications written for Web Services for J2EE should be portable to any vendor's implementation that supports Web Services for J2EE.

### **What is the relationship between the Apache Axis component of the Web services technology preview available with WebSphere Application Server 5.0 and Web Services for J2EE?**

The Web services technology preview leveraged the work that IBM contributed to the Apache Axis code base. The Web Services for J2EE support included with WebSphere Application Server 5.0.2 and Version 5.1 is derived from Apache Axis, but has diverged and contains many IBM-specific features to enhance performance, scalability, reliability, interoperability, and integration with the WebSphere Application Server.

### **What standards does the Web Services for J2EE component of WebSphere Application Server 5.0 support?**

The following standards are supported by the Web Services for J2EE component of WebSphere Application Server 5.0:

- SOAP Version 1.1
- Web Services Description Language (WSDL) Version 1.1
- Web Services for J2EE (JSR-109) Version 1.0
- Java API for XML-Based RPC (JAX-RPC) Version 1.0
- SOAP with attachments API for Java (SAAJ) Version 1.1

### **Does Web Services for J2EE interoperate with other SOAP implementations, like .NET?**

WebSphere Application Server Version 5.0.2 and Version 5.1 support Web services that are consistent with the the WS-I Basic Profile 1.0, and should interoperate with any other vendor conforming to this specification.

### **Why can I not use a Java bean to implement a SOAP Java Messaging Service (JMS) service?**

The SOAP JMS support uses Message Driven Beans (MDB) to implement the JMS endpoint. MDBs can only be used in the EJB container and delegate to an enterprise bean. If you want to use a Java bean instead of an enterprise bean to implement the service endpoint, you must create a "facade" enterprise bean that delegates to the Java bean.

### **Does the SOAP JMS support interoperate with other vendors?**

No. There is currently no specification for SOAP JMS, therefore each vendor chooses its own implementation technique.

### **How does two-way messaging with SOAP JMS work? Can it support multiple clients making simultaneous requests?**

Before a client issues a two-way request, it creates a temporary JMS queue to receive the response. This temporary queue is specified as the **replyTo** destination in the outgoing JMS request message. After the server processes the request, it directs the response to the **replyTo** destination specified in the request message. The client deletes the temporary queue after the response has been received. The server is able to handle simultaneous requests from multiple clients since each incoming request message contains the destination to which the reply should be sent.

---

## **Web services: Resources for learning**

This topic provides relevant supplemental information about the following Web services-related topics:

- Web services overview
  - Including the WebSphere Version 5 Web Services Handbook
- Developing Web services:

Including developing Web services based on the Java 2 platform, Enterprise Edition (J2EE) and Java API for XML-based remote procedure call (JAX-RPC) specifications.

- Web services gateway

Including an overview of the gateway and information about the WebSphere Application Server Edge components that are used for distributed gateway deployment.

- Universal Description Discovery and Integration (UDDI)

Including an overview about UDDI and information about the UDDI Java API.

- Web Services Invocation Framework (WSIF)

A look into the Apache Software Foundation and its maintenance of WSIF.

- SOAP

Including an overview about SOAP and information about the SOAP syntax and processing rules.

- Security

Including a roadmap to security, the WS-Security specification, best practices, a profile of the OASIS Security Assertion Markup Language (SAML) and more.

- Samples

Includes WebSphere Application Server Samples Gallery and Samples Central for Web services gateway, UDDI and WSIF.

- Other references

The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

### **Web services overview**

- WebSphere Version 5 Web Services Handbook

This IBM Redbook describes the new concept of Web services from various perspectives. It presents the major building blocks Web services rely on. Well-defined standards and new concepts are presented and discussed.

- IBM Web Services architecture debuts

Introducing IBM Web services, a distributed software architecture of service components. This brief overview and in-depth interview on IBM DeveloperWorks cover the fundamental concepts of Web services architecture and what they mean for developers. The interview with IBM professional Rod Smith explores which types of developers Web services targets, how Web services reduces development time, what developers could be doing with Web services now, and takes a glance at the economics of dynamically discoverable services.

- Web services (r)evolution, Part 1

This article focuses on the benefits and challenges of building Web services applications. Web services might be an evolutionary step in designing distributed applications, however, they are not without their problems. Outlined are the difficulties developers face in creating a truly workable distributed system of Web services. This article also outlines author Graham Glass' plan for building peer-to-peer Web applications.

### **Developing Web services**

- JSR 109: Implementing Enterprise Web services

This document describes the Java 2 platform, Enterprise Edition (J2EE) specification.

- Java API for XML-based RPC (JAX-RPC): Core Web services API in the Java platform

This document reviews the JAX-RPC specification which enables Java technology developers to develop SOAP-based interoperable and portable Web services.

- **5.1+** A developer introduction to JAX-RPC, Part 1: Learn the ins and outs of the JAX-RPC type-mapping system. The Java API for XML-based Remote Procedure Calls (JAX-RPC) is an important step forward in the quest for Web services interoperability. This IBM developerWorks article explains the mapping between WSDL/XML types and Java types. It explains how the JAX-RPC standard defines this feature and some of the important points on designing an interoperable type system.
- **5.1+** A developer introduction to JAX-RPC, Part 2: Mine the JAX-RPC specification to improve Web service interoperability. This IBM developerWorks article explains how you can achieve the next level of Web service interoperability using the JAX-RPC standard client and server side interface definitions and message processing model. It includes information on developing JAX-RPC handlers and handler chains.
- **5.1+** Getting Started with JAX-RPC. This article explains some of the basic JAX-RPC programming concepts. It describes the JAX-RPC client and server programming models and provides some simple examples to illustrate their use. The article is intended to give developers a good grasp of how to use JAX-RPC to develop or use Web services.
- Web Services Description Language  
This article is a detailed overview of Web Services Description Language (WSDL), which includes programming specifications.

### Web services gateway

- The IBM Web services gateway: Technical Overview. A different version of the gateway is available as a component of a product called IBM WebSphere Business Connection. This brief technical summary from WebSphere Business Connection applies equally well to the version of the gateway in WebSphere Application Server.
- Information Center for WebSphere Application Server Edge components. This Information Center contains a library of PDF online books covering all aspects of the WebSphere Application Server Edge components. Scaling the Web services gateway builds upon the load-balancing capabilities of these components.

### UDDI

- Universal Description, Discovery and Integration  
This article is a detailed overview of Universal Description, Discovery and Integration (UDDI).
- UDDI4J: Matchmaking for Web services  
Reviewed in this article are the basics of UDDI, the Java API to UDDI, and how you can use this technology to start building, testing, and deploying your own Web services.

### WSIF

- The Apache Software Foundation. The Apache Software Foundation provides support for the Apache community of open-source software projects. Of particular interest is the Apache Web services project. The WSIF source code has been donated by IBM to the Apache Software Foundation, and is maintained here as an Apache project.

### SOAP

- SOAP  
This article is a detailed overview of SOAP, which includes programming specifications.
- SOAP Security Extensions: Digital Signature  
This document specifies the syntax and processing rules of a SOAP header entry to carry digital signature information within a SOAP 1.1 Envelope

### Security

- Security in a Web Services World: A Proposed Architecture and Roadmap

This document describes a proposed model for addressing security within a Web service environment. It defines a comprehensive Web Services Security model that supports, integrates, and unifies several popular security models, mechanisms, and technologies, including both symmetric and public key technologies, in a way that enables a variety of systems to securely interoperate in a platform and language-neutral manner. It also describes a set of specifications and scenarios that show how these specifications can be used together.

- Web Services Security (WS-Security)

The Web Services Security specifications describe enhancements to SOAP messaging to provide quality of protection through message integrity, message confidentiality, and single message authentication. These mechanisms can be used to accommodate a wide variety of security models and encryption technologies. Web Services Security also provides a general-purpose mechanism for associating security tokens with messages. Additionally, Web Services Security describes how to encode binary security tokens. Specifically, the specification describes how to encode X.509 certificates and Kerberos tickets, as well as how to include opaque encrypted keys. It also includes extensibility mechanisms that can be used to further describe the characteristics of the credentials that are included with a message.

- SOAP Security Extensions: Digital Signature

This document specifies the syntax and processing rules of a SOAP header entry to carry digital signature information within a SOAP 1.1 Envelope

- Web Services Security Addendum

This document describes clarifications, enhancements, best practices, and errata of the Web Services Security specification.

- WS-Security Profile of the OASIS Security Assertion Markup Language (SAML) Working Draft 04, 10 September 2002

This document proposes a set of standards for SOAP extensions used to increase message confidentiality.

- Web Services Security: SOAP Message Security Working Draft 12, Monday 21 April 2003

This document describes the support for multiple token formats, trust domains, signature formats, and encryption technologies.

- JSR 55:Certification Path API

This document provides a short description of the certification path API.

- XML-Signature Syntax and Processing

This document specifies XML digital signature processing rules and syntax. XML signatures provide integrity, message authentication, or signer authentication services for data of any type, whether located within the XML that includes the signature or elsewhere.

- Canonical XML Version 1.0

This specification describes a method for generating a physical representation, the canonical form, of an XML document that accounts for the permissible changes.

- Exclusive XML Canonicalization Version 1.0

Canonical XML [XML-C14N] specifies a standard serialization of XML that, when applied to a subdocument, includes the subdocument's ancestor context including all of the namespace declarations and attributes in the "xml:" namespace.

- XML Encryption Syntax and Processing

This document specifies a process for encrypting data and representing the result in XML.

- Decryption Transform for XML Signature

This document specifies an XML Signature "decryption transform" that enables XML Signature applications to distinguish between those XML Encryption structures that were encrypted before signing, and must not be decrypted, and those that were encrypted after signing, and must be decrypted, for the signature to validate.

- WS-Security

This document specifies resources for the April 2002 Web Services Security Specification. The following addenda and drafts are available:

– <http://schemas.xmlsoap.org/ws/2002/07/secext/>

- <http://schemas.xmlsoap.org/ws/2002/07/utility/>
- OASIS draft 12 for secext
- OASIS draft 12 for utility
- Specification: Web Services Security (WS-Security) Version 1.0 05 April 2002  
A major area of gateway security is based upon this emerging standard.
- XML Encryption Syntax and Processing W3C Recommendation 10 December 2002
- XML-Signature Syntax and Processing W3C Recommendation 12 February 2002
- Web Services Security Addendum
- Web Services Security Core Specification Working Draft 01, 20 September 2002
- Web Services Security: SOAP Message Security Working Draft 13, Thursday, 01 May 2003
- Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile, RFC3280, April 2002
- OASIS Web Services Security Technical Committee

### Samples

- Samples Gallery
- Samples Central. Samples and associated documentation for the following Web services components are available through the Samples Central page of the IBM WebSphere Developer Domain Web site:
  - The Web services gateway.
  - The IBM private UDDI registry.
  - The Web Services Invocation Framework (WSIF).

### Other references

## Chapter 9. Overview: Online garden retailer Web services scenarios

This set of scenarios is inspired by an online retailer called Plants by WebSphere. Plants by WebSphere uses Web services support in WebSphere Application Server to improve communications with its suppliers. The more advanced scenarios describe Web services support available only in particular editions of WebSphere Application Server. Consult your product documentation to confirm what is supported by your edition.

You might recognize Plants by WebSphere as a sample application available in the WebSphere Samples Gallery. These scenarios are loosely related. They describe how the fictional online retailer could use a variety of Web services technologies, some of which are beyond those currently demonstrated by the sample.

Web services are middleware. Using Web services you can connect applications together, no matter how each application is implemented or where it is located. For example, Web services can connect retailers to wholesale suppliers. Middleware is not new. What is new in Web services is that this connectivity is based upon open standards and Web technologies. Web services operate at a level of abstraction that is similar to the Internet, and they can work with any operating system, hardware platform or programming language that can be Web-enabled.

The Plants by WebSphere storefront sells plants and gardening supplies. As customers order merchandise, the site checks the merchandise availability in its inventory database. The scenarios show how the inventory system can grow in stages, using various Web services technologies to improve its capabilities.

- Before Web services

As featured in the Samples Gallery, the Plants by WebSphere application already has Web services capabilities. See below for a description of how the online garden retailer might have operated *prior* to adopting Web services technology. Key Web services components are introduced. To determine which components are available with the particular editions of WebSphere Application Server that you have purchased, consult the documentation for each edition.

- Static inquiry on supplier

In this scenario, the garden retailer turns the existing Web application into a Web service for checking the inventory of its main wholesale garden supplier.

- Dynamic inquiry on supplier

In this scenario, the garden retailer uses Web services to perform an inventory search of several wholesale suppliers.

- Cross supplier inquiry

In this scenario, the garden retailer makes its Web service available for use by others who need the service.

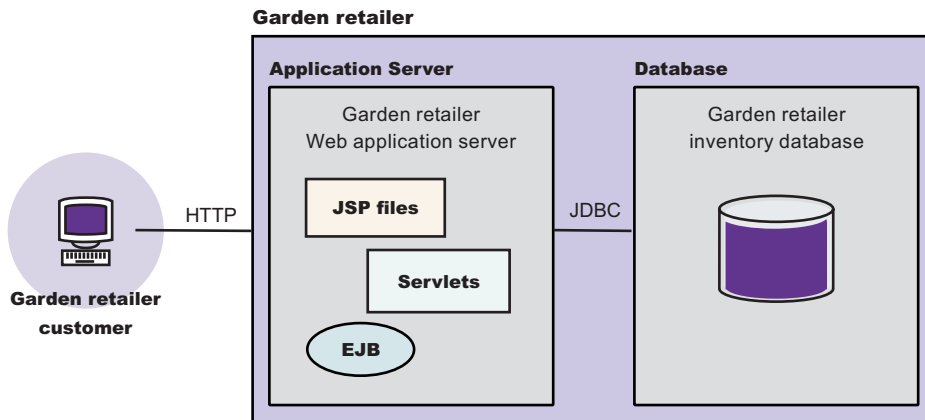

At present, these scenarios provide descriptions rather than step by step instructions. To gain experience with Web services coding, see the WebSphere Samples Gallery. It provides detailed instructions for building, configuring, and running the Plants by WebSphere sample application and others.

### Before Web services

Suppose that the Plants by WebSphere storefront does not use Web services. The garden retailer has established an impressive Internet storefront enabling customers to shop and order merchandise. To determine whether a customer order can be filled, Web applications rely on enterprise beans to query the Plants by WebSphere inventory database. If the item is in stock, the site confirms the order to the customer.

If a customer orders an item that is out of stock, the site notifies the customer that the item is out of stock, and encourages the customer to place the item on backorder. Later, long after the customer has left the Plants by WebSphere site, the site administrator or inventory manager might call or fax the supplier to obtain more inventory.

## Introducing Web services

Web services could give Plants by WebSphere an automated way to have out of stock items shipped to its warehouse or directly to customers. If suppliers can be contacted quickly enough, Plants by WebSphere does not have to inform its customers that the item was out of stock. Plants by WebSphere could begin to reduce its own inventory if doing so is a desirable business move.

Web services is built on the following core technologies:

- **XML (Extensible Markup Language)**

XML solves the problem of data independence. You use it to describe data, and also to map that data into and out of any application or programming language.

To have their applications exchange information such as merchandise price and availability, Plants by WebSphere and its supplier will put the data in a set of XML tags to which both parties agree.

For more information, see the XML specification on [www.w3.org](http://www.w3.org).

- **WSDL (Web Services Description Language)**

You use this XML-based language to create a description of an underlying application. It is this description that turns an application into a Web service, by acting as the interface between the underlying application and other Web-enabled applications.

Plants by WebSphere has an application capable of querying the supplier inventory. To enable communication with the supplier over the Internet, the company turns the application into a Web service.

For more information, see the WSDL specification on [www.w3.org](http://www.w3.org)

- **SOAP (Simple Object Access Protocol)**

SOAP is the core communications protocol for the Web, and most Web services use this protocol to talk to each other.

SOAP is an XML format for Web services requests. According to the SOAP specification, SOAP is "a lightweight protocol for exchange of information in a decentralized, distributed environment. It is an XML based protocol that consists of three parts: an envelope that defines a framework for describing what is in a message and how to process it, a set of encoding rules for expressing instances of application-defined datatypes, and a convention for representing remote procedure calls and responses. SOAP can potentially be used in combination with a variety of other protocols; however, the only bindings defined in this document describe how to use SOAP in combination with HTTP and HTTP Extension Framework.

Because they are external to the Plants by WebSphere intranet, communications with its suppliers will utilize SOAP over HTTP. Web services operating within the company intranet can use other transports, such as local Java bindings. The Web Services Invocation Framework (WSIF) component described below can help Plants by WebSphere applications dynamically choose the optimal transport mechanism for a given situation.

For more information, see the SOAP specification on [www.w3.org](http://www.w3.org).

- **Web Services for J2EE**

Web Services for J2EE, also known as JSR-109, defines how J2EE applications create and access Web services.

Chapter 8, “Using Web services based on Web Services for J2EE,” on page 395 describes how to implement a Web service interface to an existing application, then deploy your Web service within the application server.

- **Java API for Remote Procedure Calls**

JAX-RPC, also known as JSR-101, defines how Java applications access Web services.

The WebSphere product line provides these additional components to help you get the most out of your Web services. The scenarios describe in greater detail how Plants by WebSphere uses each one.

### **A private Universal Description, Discovery and Integration (UDDI) registry**

A private UDDI registry provides a way to publish and discover information about the Web services that are available within your organization. It does the same job for Web services that a business telephone directory does for business addresses and telephone numbers.

If you publish your Web service to UDDI, you make it available for other people to discover and reuse. Reuse of the service saves cost and effort, and publication minimizes the risk of duplicate services being developed.

You publish your Web service to UDDI after you have deployed it to the application server - unless you are also using the Web services gateway, in which case you use the gateway to publish the service to UDDI.

For more information, see Chapter 11, “Enabling the IBM WebSphere UDDI Registry,” on page 693.

### **A Web Services Invocation Framework (WSIF)**

SOAP bindings for Web services are part of the WSDL specification. So when you think of using a Web service, you probably think of assembling a SOAP message and sending it across the network to the service endpoint, using some SOAP client API. But if you invoke a Web service using WSIF, then a client application can dynamically choose the optimal transport mechanism to use to invoke Web service operations.

For example, a Web service provider might offer a SOAP binding for the service and a local Java binding that allows you to treat the local service implementation (a Java class) as a Web service. If the client is deployed in the same environment as the service, then the local Java binding for the service can be used. This provides more efficient communication with the service by making direct Java calls rather than using the SOAP binding.

To deploy a Web service as a WSIF-enabled service, you first develop and deploy the Web service, then you develop the WSIF client based on the WSDL document for that Web service - unless you are also using the Web services gateway, in which case the gateway automatically redeploys your Web service as a WSIF-enabled service.

For more information, see Chapter 10, “Web Services Invocation Framework (WSIF): Enabling Web services,” on page 651.

### **A Web services gateway**

You use the gateway to handle Web service invocations between Internet and Intranet environments. You use it to make your internal Web services available externally, and to make external Web services available to your internal systems. You also use it to specify:

- The transport mechanisms (or channels) on which messages can be carried to and from the service.
- The filters (if any) that act upon these incoming and outgoing messages.
- The UDDI registries (if any) to which you want the service to be published
- The levels of security that you want to apply to the service.

When you deploy a Web service to the gateway, the gateway creates a copy of the WSDL file for that service and stores it at a new Web address. Users of the service through the gateway then use the gateway copy of the WSDL file. So (if possible) you should decide whether or not you want to use the gateway before you make the Web addresses of your deployed services available to others.

For more information, see Chapter 12, “Web services gateway: Enabling Web services,” on page 823.

### **WS-Security (Web services security)**

Web services security for WebSphere Application Server is based on standards included in the Web services security (WS-Security) specification that address how to provide protection for messages exchanged in a Web service environment. It defines the core facilities for protecting the integrity and confidentiality of a message and provides mechanisms for associating security-related claims with the message. Web services security is a message-level standard based on securing SOAP messages through XML digital signature, confidentiality through XML encryption, and credential propagation through security tokens.

For more information, see “Securing Web services based on WS-Security” on page 483.

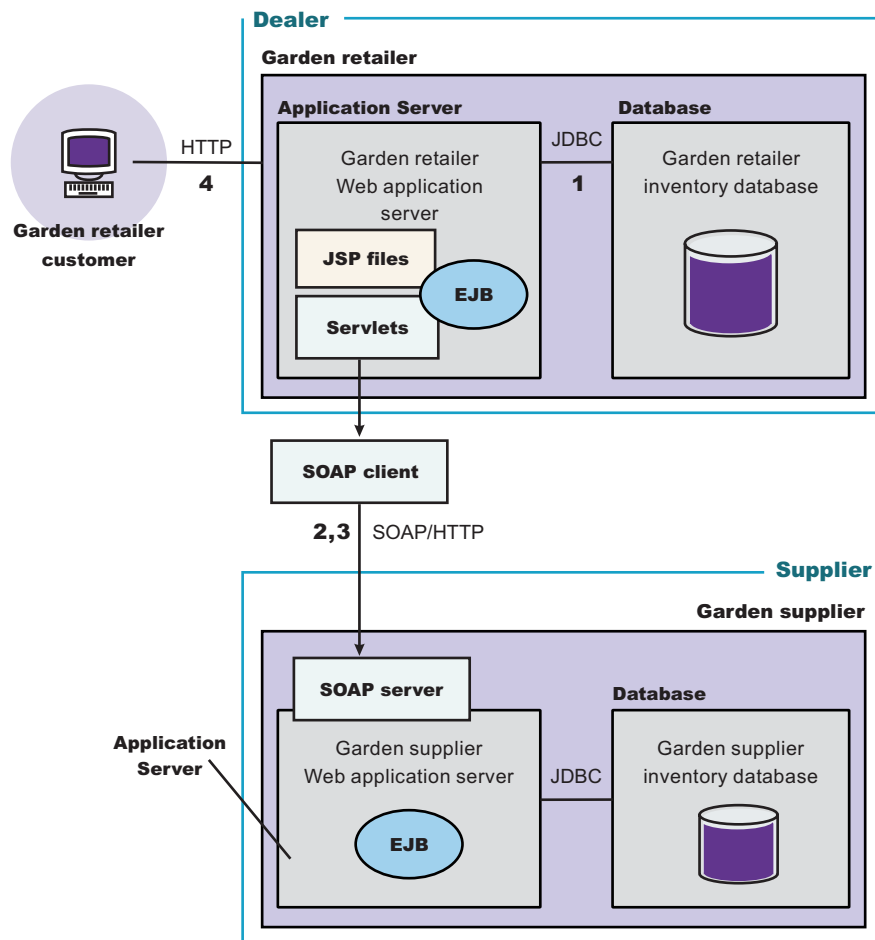

---

## **Web services scenario: Static inquiry on supplier**

In this scenario, an online supply retailer turns an application into a Web service for checking the inventory of its main supplier.

Plants by WebSphere is an Internet storefront that sells plants and gardening supplies. The company realizes that its existing Web application can be “wrapped” with Web services programming interfaces. For example, the BackOrderStock session bean can be turned into a SOAP Web services client that interacts with a Supplier Web services application located at the supplier. Specifically, the BackOrderStock session bean functionality is turned into a Web services for J2EE client and a JAX-RPC client. These two client

are J2EE and Java standards for Web services clients.

### How out of stock items are handled

The following events happen when a customer on the Plants by WebSphere site orders an item that is not available according to the Plants by WebSphere inventory:

1. Plants by WebSphere checks its own inventory.  
The application powering the Web site checks the Plants by WebSphere inventory database. It discovers that the item is not in stock.
2. Plants by WebSphere uses a Web service to check the supplier inventory.  
The application invokes a SOAP client that communicates with a SOAP server at the supplier site to ascertain whether the supplier has the item in stock. The supplier data is sent to Plants by WebSphere.
3. Plants by WebSphere either obtains the out of stock item, or does not.  
If the supplier indicates that the item is in stock, the application powering Plants by WebSphere determines whether to order the item on behalf of the customer. The exchange of data can include checking a price threshold above which Plants by WebSphere will not order the wholesale item. It could also include decision-making information such as how long the supplier will require to deliver the item, or a date on which the manufacturer plans to discontinue the item.
4. Plants by WebSphere notifies its customer of the outcome, as soon as possible.  
If the supplier can be consulted quickly enough, Plants by WebSphere does not have to bother its customer with concerns about availability. It simply confirms that the item is available, as though the

item is in stock at Plants by WebSphere. If the supplier inventory temporarily lacks the item, or Plants by WebSphere opted not to order the item from the supplier, Plants by WebSphere will issue an appropriate response to the customer.

See the Samples Gallery for details of the Supplier application, a business to business (B2B) application that uses a message-driven bean (MDB), a stateless session bean, and Java message service.

### **Web services technologies used in this scenario**

This scenario uses the following Web services technologies.

#### **XML (Extensible Markup Language)**

XML is used to standardize the exchange of data between Plants by WebSphere and its supplier.

#### **Web Services for J2EE**

Web Services for J2EE, also known as JSR-109, defines how J2EE applications create and access Web services.

#### **Java API for Remote Procedure Calls**

JAX-RPC, also known as JSR-101, defines how Java applications access Web services.

#### **WSDL (Web Services Description Language)**

WSDL is used to turn the existing application into a Web service, by acting as the interface between the underlying application and other Web-enabled applications.

#### **SOAP (Simple Object Access Protocol)**

SOAP is the protocol by which the Web service communicates with the supplier over the Internet.

---

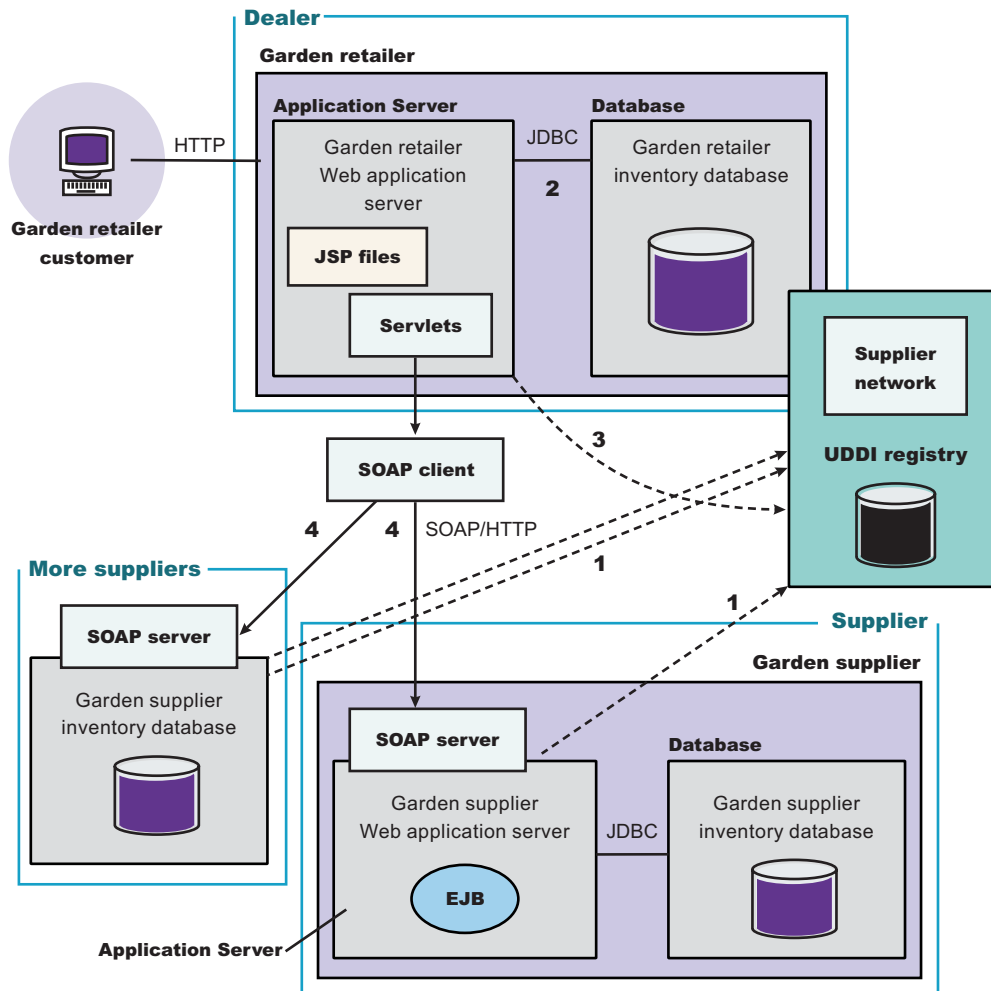

## **Web services scenario: Dynamic inquiry on supplier**

This document describes a scenario in which an online garden supply retailer uses Web services to perform an inventory search of several wholesale suppliers.

In the "static inquiry on suppliers" scenario, the Plants by WebSphere IT staff establishes connections with each supplier separately, and makes changes as suppliers come and go. It would be convenient to query multiple suppliers at the same time, without necessarily even providing a list of particular suppliers to query. Furthermore, Plants by WebSphere managers would like to be able to shop around quickly according to criteria such as the lowest wholesale price or fastest availability.

In a "dynamic inquiry on suppliers" scenario, several plant and garden suppliers have published Web services to a Universal Description, Discovery, and Integration. (UDDI) registry. Suppliers create inventory Web services that use a standard interface. They publish their Web services to the centralized registry. Perhaps the registry has been established by the Plant Wholesalers Association. Or maybe a small Internet company established the buyer-seller site after finding that suppliers and retailers each would pay

a small monthly rate for the convenience of the service.

### How out of stock items are handled

The following events happen when a customer on the Plants by WebSphere site orders an item that is not available according to the Plants by WebSphere inventory.

1. In advance, the suppliers publish their Web services to a UDDI registry for just such an occasion. In this way, they notify inquiring retailers, such as Plants by WebSphere, that their inventories are available to check.

2. Plants by WebSphere checks its own inventory.

The application powering the Web site checks the Plants by WebSphere inventory database. It discovers that the item is not in stock.

3. Plants by WebSphere uses a UDDI4J client to consult the UDDI registry for suppliers whose inventories it can check.

Plants by WebSphere can invoke a Web service that queries the UDDI registry for suppliers. Then in turn, the Web service at the site of each supplier is invoked. The administrator is presented with a list of suppliers from which the requested item is available, perhaps including price and availability data.

4. Plants by WebSphere uses the Web services to check the supplier inventories.

The application invokes a Web services for J2EE client or JAX-RPC client that communicates with a SOAP server at the supplier site to ascertain whether the supplier has the item in stock. The supplier data is sent to Plants by WebSphere.

5. Plants by WebSphere either obtains the out of stock item, or does not.  
If the supplier indicates that the item is in stock, the application powering Plants by WebSphere determines whether to order the item on behalf of the customer. The exchange of data can include checking a price threshold above which Plants by WebSphere will not order the wholesale item. It could also include decision-making information such as how long the supplier will require to deliver the item, or a date on which the manufacturer plans to discontinue the item.
6. Plants by WebSphere notifies its customer of the outcome, as soon as possible.  
If the supplier can be consulted quickly enough, Plants by WebSphere does not have to bother its customer with concerns about availability. It simply confirms that the item is available, as though the item is in stock at Plants by WebSphere. If the supplier inventory temporarily lacks the item, or Plants by WebSphere opted not to order the item from the supplier, Plants by WebSphere will issue an appropriate response to the customer.

### **Web services technologies used in this scenario**

This scenario uses the following Web services technologies.

#### **XML (Extensible Markup Language)**

XML is used to standardize the exchange of data between Plants by WebSphere and its supplier.

#### **Web Services for J2EE**

Web Services for J2EE, also known as JSR-109, defines how J2EE applications create and access Web services.

#### **Java API for Remote Procedure Calls**

JAX-RPC, also known as JSR-101, defines how Java applications access Web services.

#### **WSDL (Web Services Description Language)**

WSDL is used to turn the existing application into a Web service, by acting as the interface between the underlying application and other Web-enabled applications.

#### **SOAP (Simple Object Access Protocol)**

SOAP is the protocol by which the Web service communicates with the supplier over the Internet.

#### **A Universal Description, Discovery and Integration (UDDI) registry**

By publishing their Web services to UDDI, suppliers make them available for Plants by WebSphere and other retailers to discover and reuse. This saves development time, effort and cost, and helps minimize the need to maintain several different implementations of the same application at Plants by WebSphere and various other retailers who need to contact the suppliers for inventory data.

Particular editions of WebSphere Application Server provide a private UDDI registry that can be used in an intranet environment.

---

## **Web services scenario: Cross supplier inquiry**

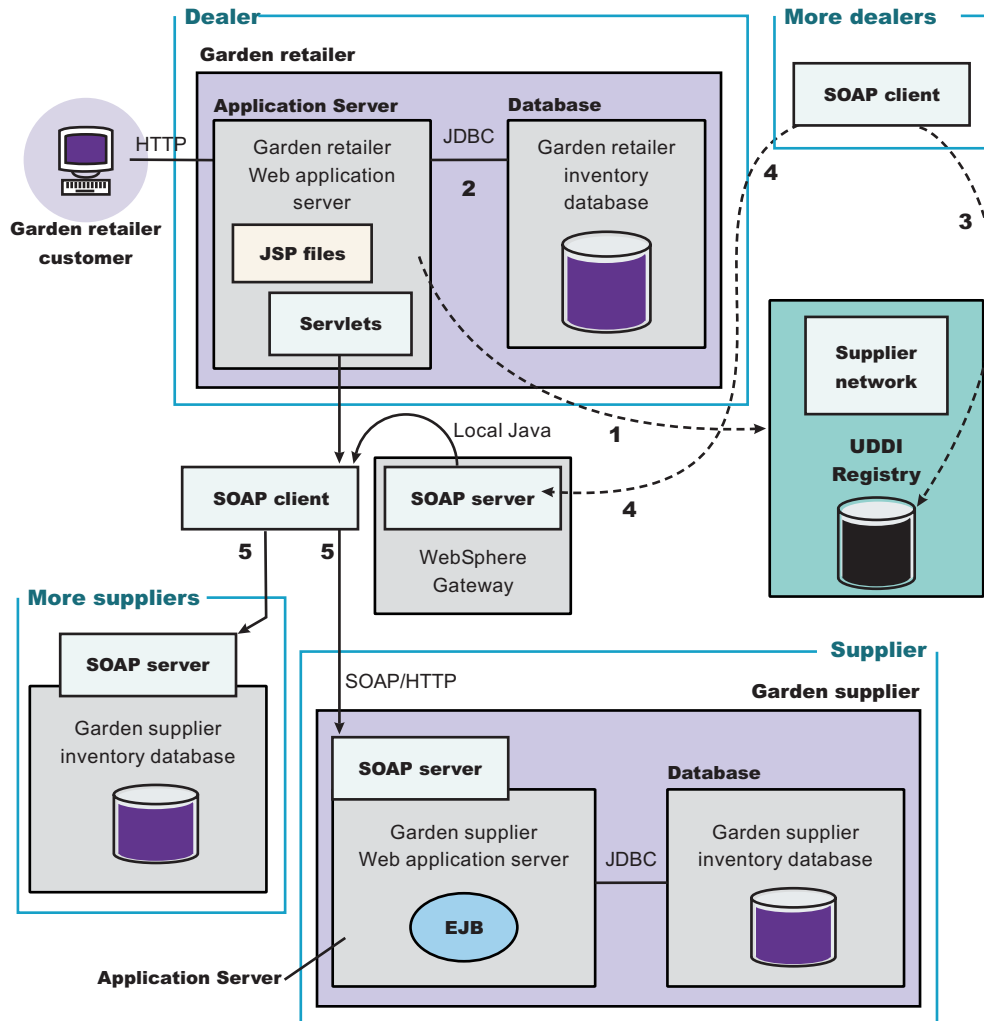

This document describes a scenario in which an online garden supply retailer uses Web services to integrate its inventory system with the inventory systems of other retailers. Also using Web services, the main Internet storefront can check supplier inventories on behalf of itself or other retailers.

The marketers at Plants by WebSphere confirm with market data that people are likely to purchase plants and gardening supplies in tandem with purchases of other goods, such as gardening books. To increase the visibility of Plants by WebSphere, the company arranges with various other merchant sites to include Plants by WebSphere inventory as part of their own.

At one site, Web services and other technologies are used to insert data about Plants by WebSphere items into Web pages that match the look and feel of the rest of the site. When a customer orders a

Plants by WebSphere item at a site other than Plants by WebSphere, the second site relies on the Plants by WebSphere inventory Web service to make sure that the item is in stock, and to query suppliers as needed.

The second site does not have to implement its own Web services to perform the same function as those developed by Plants by WebSphere. The second site might want to implement sophisticated function by creating its own Web service.

### How out of stock items are handled

The following events happen when a customer orders an item from one of the sites that re-sells items from Plants by WebSphere.

1. In advance, Plants by WebSphere publishes its Web service to a public UDDI registry.  
In this way, other retailers are made aware of the inventory Web service available from Plants by WebSphere. In this scenario, Plants by WebSphere probably will enable the Web service to check its own inventory as well as that of suppliers.
2. The re-seller checks the Plants by WebSphere inventory.  
The application powering the Web site checks the Plants by WebSphere inventory database. It discovers that the item is not in stock.
3. The re-seller consults the UDDI registry for suppliers whose inventories it can check.
4. The re-seller uses the Web services to check the supplier inventories.

The application invokes a Web services for J2EE or JAX-RPC SOAP client that communicates with a SOAP server at the supplier site to ascertain whether the supplier has the item in stock. The supplier data is sent to the reseller.

5. The re-seller either obtains the out of stock item, or does not.
6. The re-seller notifies its customer of the outcome, as soon as possible.

### **Web services technologies used in this scenario**

This scenario uses the following Web services technologies.

#### **XML (Extensible Markup Language)**

XML is used to standardize the exchange of data between Plants by WebSphere and its supplier.

#### **WSDL (Web Services Description Language)**

WSDL is used to turn the existing application into a Web service, by acting as the interface between the underlying application and other Web-enabled applications.

#### **SOAP (Simple Object Access Protocol)**

SOAP is the protocol by which the Web service communicates with the supplier over the Internet.

#### **A Universal Description, Discovery and Integration (UDDI) registry**

By publishing their Web services to UDDI, suppliers make them available for Plants by WebSphere and other retailers to discover and reuse. This saves development time, effort and cost, and helps minimize the need to maintain several different implementations of the same application at Plants by WebSphere and various other retailers who need to contact the suppliers for inventory data.

Public UDDI registries are run by a consortium named UDDI Operators Council, which includes IBM, NTT, SAP, and Microsoft.

Particular editions of WebSphere Application Server provide a private UDDI registry that can be used in an intranet environment.

#### **Web Services Invocation Framework (WSIF)**

In addition to publishing SOAP/HTTP bindings to the public UDDI registry for use by other vendors, Plants by WebSphere might also have published to an internal private UDDI registry with additional optimized bindings. A Web service provider such as Plants by WebSphere might offer a SOAP binding for the service and a local Java binding that allows you to treat the local service implementation (a Java class) as a Web service. If the client is deployed in the same environment as the service, then the local Java binding for the service can be used. This provides more efficient communication with the service by making direct Java calls rather than using the SOAP binding.

#### **Web services gateway**

Plants by WebSphere could use a gateway to handle Web service invocations between Internet and Intranet environments. A Web services gateway makes the internal Web service available externally. It takes care of these considerations:

- The transport mechanisms (or channels) on which messages can be carried to and from the service
- The filters (if any) that act upon these incoming and outgoing messages
- The UDDI registries (if any) to which to publish the service
- The levels of security that you want to apply to the service

---

## Chapter 10. Web Services Invocation Framework (WSIF): Enabling Web services

The Web Services Invocation Framework (WSIF) is a WSDL-oriented Java API. You use this API to invoke Web services dynamically, regardless of the service implementation format (for example enterprise bean (EJB)) or the service access mechanism (for example Java Messaging Service (JMS)).

Using WSIF, you can move away from the usual Web services programming model of working directly with the SOAP APIs, towards a model where you interact with representations of the services. You can therefore work with the same programming model regardless of how the service is implemented and accessed.

If you want to know more about the issues that WSIF addresses, see [Goals of WSIF](#).

If you want to know how WSIF addresses these issues, see [An overview of WSIF](#).

To use WSIF, see the following topics:

- Using WSIF to invoke Web services.
- WSIF system management and administration.
- WSIF API.

For more information about working with WSIF, visit the Web sites listed in [Web services: Resources for Learning](#).

---

### Goals of WSIF

SOAP bindings for Web services are part of the WSDL specification, therefore when most developers think of using a Web service, they immediately think of assembling a SOAP message and sending it across the network to the service endpoint, using a SOAP client API. For example: using Apache SOAP the client creates and populates a Call object that encapsulates the service endpoint, the identification of the SOAP operation to invoke, the parameters to send, and so on.

While this process works for SOAP, it is limited in its use as a general model for invoking Web services for the following reasons:

- Web services are more than just SOAP services.
- Tying client code to a particular protocol implementation is restricting.
- Incorporating new bindings into client code is hard.
- Multiple bindings can be used in flexible ways.
- A freer Web services environment enables intermediaries.

The goals of the Web Services Invocation Framework (WSIF) are therefore:

- To give a binding-independent mechanism for Web service invocation.
- To free client code from the complexities of any particular protocol used to access a Web service.
- To enable dynamic selection between multiple bindings to a Web service.
- To help the development of Web service intermediaries.

### WSIF - Web services are more than just SOAP services

You can deploy as a Web service any application that has a WSDL-based description of its functional aspects and access protocols. If you are using the Java 2 platform, Enterprise Edition (J2EE) environment, then the application is available over multiple transports and protocols.

For example, you can take a database-stored procedure, expose it as a stateless session bean, then deploy it into a SOAP router as a SOAP service. At each stage, the fundamental service is the same. All

that changes is the access mechanism: from Java Database Connectivity (JDBC) to Remote Method Invocation over Internet Inter-Orb Protocol (RMI-IIOP) and then to SOAP.

The WSDL specification defines a SOAP binding for Web services, but you can add binding extensions to the WSDL so that, for example, you can offer an enterprise bean as a Web service using RMI-IIOP as the access protocol. You can even treat a single Java class as a Web service, with in-thread Java method invocations as the access protocol. With this broader definition of a Web service, you need a binding-independent mechanism for service invocation.

## **WSIF - Tying client code to a particular protocol implementation is restricting**

If your client code is tightly bound to a client library for a particular protocol implementation, it can become hard to maintain.

For example, if you move from Apache SOAP to Java Messaging Service (JMS) or enterprise bean, the process can take a lot of time and effort. To avoid these problems, you need a protocol implementation-independent mechanism for service invocation.

## **WSIF - Incorporating new bindings into client code is hard**

As is explained in Web services are not just SOAP services, if you want to make an application that uses a custom protocol work as a Web service, you can add extensibility elements to WSDL to define the new bindings. But in practice, achieving this capability is hard. For example you have to design the client APIs to use this protocol. If your application uses just the abstract interface of the Web service, you have to write tools to generate the stubs that enable an abstraction layer. These tasks can take a lot of time and effort. What you need is a service invocation mechanism that allows you to update existing bindings, and to add new bindings.

## **WSIF - Multiple bindings can be used in flexible ways**

Imagine that you have successfully deployed an application that uses a Web service which offers multiple bindings. For example, imagine that you have a SOAP binding for the service and a local Java binding that lets you treat the local service implementation (a Java class) as a Web service.

The local Java binding for the service can only be used if the client is deployed in the same environment as the service. In this case, it is more efficient to communicate with the service by making direct Java calls than by using the SOAP binding.

If your clients could switch the actual binding used based on run-time information, they could choose the most efficient available binding for each situation. To take advantage of Web services that offer multiple bindings, you need a service invocation mechanism that can switch between the available service bindings at run-time, without having to generate or recompile a stub.

## **WSIF - Enabling a freer Web services environment promotes intermediaries**

Web services offer application integrators a loosely-coupled paradigm. In such environments, intermediaries can be very powerful.

Intermediaries are applications that intercept the messages that flow between a service requester and a target Web service, and perform some mediating task (for example logging, high-availability or transformation) before passing on the message. They can be as small as a simple Web service, or as large as the Web services gateway. The Web Services Invocation Framework (WSIF) is designed to make building intermediaries both possible and simple. Using WSIF, intermediaries can add value to the service invocation without needing transport-specific programming.

---

## An overview of WSIF

The Web Services Invocation Framework (WSIF) provides a Java API for invoking Web services, independent of the format of the service or the transport protocol through which it is invoked. This framework addresses all of the issues identified in the goals of WSIF.

WSIF provides the following features:

- An API that provides binding-independent access to any Web service.
- A close relationship with WSDL, so it can invoke any service that you can describe in WSDL.
- A stubless and completely dynamic invocation of a Web service.
- The capability to plug a new or updated implementation of a binding into WSIF at run-time.
- The option to defer the choice of a binding until run-time.

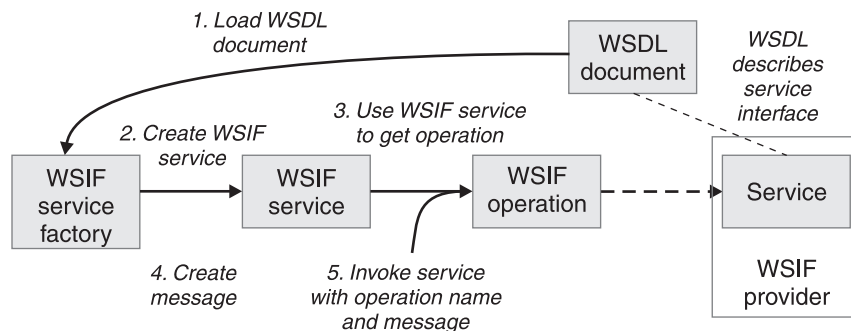

WSIF is designed to work both in an unmanaged environment (stand-alone) and inside a managed container. You can use the Java Naming and Directory Interface (JNDI) to find the WSIF service, or you can use the location described in the WSDL.

For more conceptual information about WSIF and WSDL, see the following topics:

- WSIF and WSDL
- WSIF architecture
- Using WSIF with Web services that offer multiple bindings
- WSIF usage scenarios
- Dynamic invocation

## WSIF architecture

The Web Services Invocation Framework (WSIF) architecture is shown in the figure.

The components of this architecture include:

### WSDL document

The Web service WSDL document contains the location of the Web service. The binding document defines the protocol and format for operations and messages defined by a particular portType.

### WSIF service

The WSIFService interface is responsible for generating an instance of the WSIFOperation interface to use for a particular invocation of a service operation. For more information, see Finding a port factory or service

### WSIF operation

The run-time representation of an operation, called WSIFOperation is responsible for invoking a service based on a particular binding. For more information, see WSIF API reference: Using ports.

### WSIF provider

A WSIF provider is an implementation of a WSDL binding that can run a WSDL operation through a binding-specific protocol. WSIF includes SOAP providers, JMS providers, Java providers and EJB providers. For more information, see Using the WSIF providers.

## Using WSIF with Web services that offer multiple bindings

Using WSIF, a client application can choose dynamically the optimal binding to use for invoking Web service operations.

For example, a Web service might offer a SOAP binding, and also a local Java binding so that you can treat the local service implementation (a Java class) as a Web service. If a client application is deployed in the same environment as the service, then this client can use the local Java binding for the service. This provides more efficient communication between the client and the service by making direct Java calls rather than indirect calls using the SOAP binding.

For more information on how to configure a client to dynamically select between multiple bindings, see [Developing a WSIF service](#).

## WSIF and WSDL

WSDL is the acronym for Web Services Description Language.

In WSDL a service is defined in three distinct sections:

- The **portType**. This section defines the abstract interface offered by the service. A portType defines a set of *operations*. Each operation can be In-Out (request-response), In-Only, Out-Only and Out-In (Solicit-Response). Each operation defines the input and/or output *messages*. A message is defined as a set of *parts*, and each part has a schema-defined type.
- The **binding**. This section defines how to map between the abstract portType and a real service format and protocol. For example the SOAP binding defines the encoding style, the SOAPAction header, the namespace of the body (the targetURI), and so on.
- The **port**. This section defines the actual location (endpoint) of the available service. For example, the HTTP Web address at which a SOAP service is available.

Currently in WSDL, each port has one and only one binding, and each binding has a single portType. But (more importantly) each service (portType) can have multiple ports, each of which represents an alternative location and binding for accessing that service.

The Web Services Invocation Framework (WSIF) follows the semantics of WSDL as much as possible:

- The WSIF dynamic invocation API directly exposes run-time equivalents of the model from WSDL. For example, invocation of an operation involves executing an operation with an input message.
- WSDL has extension points that support the addition of new ports and bindings. This enables WSDL to describe new systems. The equivalent concept in WSIF is a provider, that enables WSIF to understand a class of extensions and thereby to support a new service implementation type.

As a metadata-based invocation framework, WSIF follows the design of the metadata. As WSDL is extended, WSIF is updated to follow.

The implicit and primary type system of WSIF is XML schema. WSIF supports invocation using dynamic proxies, which in turn support Java type systems, but when you use the `WSIFMessage` interface it is your responsibility to populate `WSIFMessage` objects with data based on the XML schema types as defined in the WSDL document. You should define your object types by a canonical and fixed mapping from schema types into the run-time.

For more information on WSDL, see [Web services: Resources for learning](#).

## WSIF usage scenarios

This topic describes two brief scenarios that illustrate the role WSIF plays in the emerging Web services environment.

## Scenario: Redevelopment and redeployment

When you first implement a Web service, you create a simple prototype. When you want to move a prototype Web service into production, you often need to redevelop and redeploy it.

The Web Services Invocation Framework (WSIF) uses the same API calls irrespective of the underlying technologies, therefore if you use WSIF:

- You can reimplement and redeploy your services without changing the client code.
- You can use existing reliable and high-performance infrastructures like Remote Method Invocation over Internet Inter-Orb Protocol (RMI-IIOP) and Java Messaging Service (JMS) without sacrificing the location-independence that the Web service model offers.

## Scenario: Service Flow composition

A service flow typically invokes a Web service, then passes the response from one Web service to the next Web service, perhaps performing some transformation in the middle.

There are two key aspects to this flow that WSIF provides:

- A representation of the service invocation based on the metadata in WSDL.
- The ability to build invocations based solely on the portType, which can therefore be used in any implementation.

For example, imagine that you build a meta-service that uses a number of services to build a process. Initially, several of those services are simple Java bean prototypes that are written and exposed through SOAP, but you plan to reimplement some of them as EJB components, and to out-source others.

If you use SOAP, it ties up multiple threads for every onward invocation, because they pass through the Web server and servlet engine and on to the SOAP router. If you use WSIF to call the beans directly, you get much better performance compared to SOAP and you do not lose access or location transparency. Using WSIF, you can replace the Java bean implementations with EJB implementations without changing the client code. To move some of the Web services from local implementations to external SOAP services, you just update the WSDL.

## Dynamic invocation

For the Web Services Invocation Framework (WSIF), dynamic invocation means providing the following levels of support when invoking Web services:

1. Support for WSDL extensions and bindings that were not known at build time.
2. Support for Web services that were not known at build time.

WSIF supports (1) through the use of providers.

The providers support (2) by using the WSDL description to access the target service.

---

## Using WSIF to invoke Web services

You invoke a Web service dynamically by using the WSIF API directly.

You only specify the location of the WSDL file for the service, the name of the operation to invoke, and any operation arguments. All the information needed to access the Web service (the abstract interface, the binding, and the service endpoint) is available through the WSDL.

This kind of invocation does not require stub classes and does not need a separate compilation cycle.

More information on using the Web Services Invocation Framework (WSIF) to invoke Web services is provided in the following topics:

- Using the WSIF providers.
- Developing a WSIF service.
- Using complex types.
- Using the Java Naming and Directory Interface (JNDI).
- Passing SOAP messages with attachments using WSIF.
- Interacting with the J2EE container in WebSphere Application Server.
- Running WSIF as a client.

## Using the WSIF providers

A Web Services Invocation Framework (WSIF) provider is an implementation of a WSDL binding that can run a WSDL operation through a binding-specific protocol.

Providers implement the interface between the WSIF API and the actual implementation of a service. Providers are pluggable within the WSIF framework, and are registered according to the namespace of the WSDL extension that they implement. Some providers use the Java 2 platform, Enterprise Edition (J2EE) programming model to utilize J2EE services. If a provider is available, but its required class libraries are not, then the provider is disabled.

WebSphere Application Server includes the following WSIF providers:

- SOAP (over HTTP) provider.
- JMS providers (SOAP over JMS, and native JMS).
- Java provider.
- EJB provider.

## Using the SOAP provider

The SOAP provider allows WSIF stubs and dynamic clients to invoke SOAP services.

The Web Services Invocation Framework (WSIF) SOAP provider supports SOAP 1.1 over HTTP. The SOAP provider uses Apache SOAP 2.3 for parsing and creating SOAP messages, but it is not limited to invoking services from Apache SOAP.

The WSIF SOAP provider supports:

- SOAP-ENC encoding.
- RPC style and Document style SOAP messages.
- SOAP messages with attachments.

The SOAP provider is not transactional.

If you have a Web service that you expect multiple clients to use connecting over SOAP, then before you deploy the service you must set up your application deployment descriptor file `dds.xml` to handle multiple connections correctly. For more information, see WSIF troubleshooting tips.

For an example of the sort of code changes that need to be made in the WSDL file for a SOAP provider, see the following topics:

- The SOAP over JMS provider - writing the WSDL extension.
- SOAP messages with attachments - Writing the WSDL extensions.

## Using the JMS providers

The JMS providers enable a WSIF service to be invoked through JMS.

The Java Messaging Service (JMS) is an API for transport technology. The mapping to a JMS destination is defined during deployment and maintained by the container.

The JMS destination endpoint for a Web service can be realized in any of the following ways:

- The JMS destination for the queue can be the Web service implementation.

- The JMS destination can be (but is not required to be) associated with a message-driven bean by the EJB container, thereby allowing the message-driven bean to be the Web service implementation.
- (For SOAP over JMS) The JMS destination can unwrap the JMS message and route the SOAP message to a Web service that is implemented as a stateless session bean.

The JMS destination endpoint must respect the interaction model expected by the client and defined by the WSDL. It must return a response if one is required.

When the JMS destination endpoint creates the JMS response message the following rules must be followed:

- The response message must be sent to `JMSReplyTo` from the incoming request.
- The `JMSCorrelationID` value of the response message must be set to the `JMSMessageID` value from the request message.
- The response must be sent with a `deliveryMode` value equal to the `JMSDeliveryMode` value of the request message.
- The response must be sent with a `priority` value equal to the `JMSPriority` value of the request message.
- The `timeToLive/JMSExpiration` value must be set to a value that equals the `JMSExpiration` value of the request message.

The client does not see any of these headers. The container receives the JMS message and (for SOAP over JMS) removes the SOAP message to send to the client.

See also the following topics:

- Using the SOAP over JMS provider
- Using the native JMS provider
- The JMS providers - Configuring the client and server

#### ***Using the SOAP over JMS provider:***

For information on working with the Java Messaging Service (JMS) API, see [Using the JMS providers](#).

The SOAP message, including the SOAP envelope, is wrapped with a JMS message and put on the appropriate queue. The container receives the JMS message and removes the SOAP message to send to the client.

For detailed implementation information, see the following topics:

- The SOAP over JMS provider - writing the WSDL extension
- The JMS providers - Configuring the client and server

#### *The SOAP over JMS provider - Writing the WSDL extension:*

If a SOAP message contains only XML, then it can be carried on the Java Messaging Service (JMS) transport with the JMS message body type **TextMessage**.

The WSDL binding extension for SOAP over JMS varies only slightly from the SOAP over HTTP binding.

#### **Selecting the SOAP over JMS binding**

You set the `transport` attribute of the `<soap:binding>` tag to indicate that JMS is used. If you also set the `style` attribute to `rpc` (Remote Procedure Call), then the Web Services Invocation Framework (WSIF) assumes that an operation is invoked on the Web service endpoint:

```
<soap:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/jms"/>
```

#### **Setting the JMS address**

For SOAP over JMS, the `<wsdl:port>` tag must contain a `<jms:address>` element. This element provides the information required for a client to connect correctly to the Web service using the

JMS programming model. Typically, it is the stubs generated to support the SOAP over JMS binding that act as the JMS client. Alternatively, the Web service client can use the JMS programming model directly.

The `<jms:address>` element takes this form:

```
<jms:address
 destinationStyle="queue"
 jmsVendorURI="http://ibm.com/ns/mqseries"?
 initialContextFactory="com.ibm.NamingFactory"?
 jndiProviderURL="iiop://something:900/wherever"?
 jndiConnectionFactoryName="orange"
 jndiDestinationName="fred"
/>
```

where attributes marked with a question mark (?) are optional.

The optional `jmsVendorURI` attribute is a string that uniquely identifies the JMS implementation. WSIF ignores this URI, which is used by the client developer and perhaps the client implementation to determine if it has access to the correct JMS provider in the client run-time.

The optional attributes `initialContextFactory` and `jndiProviderURL` can only be omitted if the run-time has a default Java Naming and Directory Interface (JNDI) provider configured.

The `jndiConnectionFactoryName` attribute gives the name of a JMS `ConnectionFactory` object, which can be looked up within the JNDI context given by the `jndiContext` attribute. This `ConnectionFactory` object is used to create a JMS connection to the JMS provider instance that owns the queue. In a simple configuration, the same `ConnectionFactory` object is used by the server message listener and by the clients. However the server and the clients can use different `ConnectionFactory` objects, provided that they all create connections to the same JMS provider instance.

### Setting the JMS headers and properties

You use the `<jms:property>` tag to set the JMS headers and properties. This tag maps either a message part, or a literal value, into a JMS property:

```
<jms:property name="Priority" {part="requestPriority" | value="fixedValue"}/>
```

If the `<jms:property>` has a literal value, then it can also be nested within the `<jms:address>` tag:

```
<jms:property name="Priority" value="fixedValue" />
```

This form of the `<jms:property>` tag is also used in the native JMS binding.

Here is an example of a WSDL that defines a SOAP over JMS binding:

```
<!-- Example: SOAP over JMS Text Message -->
<?xml version="1.0" encoding="UTF-8"?>
<wsdl:definitions
 name="StockQuoteInterfaceDefinitions"
 targetNamespace="urn:StockQuoteInterface"
 xmlns:tns="urn:StockQuoteInterface"
 xmlns:xsd="http://www.w3.org/2000/10/XMLSchema"
 xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
 xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/">
 <wsdl:message name="GetQuoteInput">
 <part name="symbol" type="xsd:string"/>
 </wsdl:message>
 <wsdl:message name="GetQuoteOutput">
 <part name="value" type="xsd:float"/>
 </wsdl:message>
```

```

<wsdl:portType name="StockQuoteInterface">
 <wsdl:operation name="GetQuote">
 <wsdl:input message="tns:GetQuoteInput"/>
 <wsdl:output message="tns:GetQuoteOutput"/>
 </wsdl:operation>
</wsdl:portType>

<wsdl:binding name="StockQuoteSoapJMSBinding" type="tns:StockQuoteInterface">
 <soap:binding style="rpc"
 transport="http://schemas.xmlsoap.org/soap/jms"/>
 <wsdl:operation name="GetQuote">
 <soap:operation soapAction="urn:StockQuoteInterface#GetQuote"/>
 <wsdl:input>
 <soap:body use="encoded" namespace="urn:StockQuoteService"
 encodingStyle="http://schemas.xmlsoap.org/soap/encoding"/>
 </wsdl:input>
 <wsdl:output>
 <soap:body use="encoded" namespace="urn:StockQuoteService"
 encodingStyle="http://schemas.xmlsoap.org/soap/encoding"/>
 </wsdl:output>
 </wsdl:operation>
</wsdl:binding>
<wsdl:service name="StockQuoteService">
 <wsdl:port name="StockQuoteServicePort"
 binding="sqi:StockQuoteSoapJMSBinding">
 <jms:address destinationStyle="queue"
 jndiConnectionFactoryName="myQCF"
 jndiDestinationName="myQ"
 initialContextFactory="com.ibm.NamingFactory"
 jndiProviderURL="iiop://something:900/" />
 </wsdl:port>
</wsdl:service>
</wsdl:definitions>

```

### **Using the native JMS provider:**

Using the native JMS provider, WSIF clients can treat a JMS destination as a Web service.

For information on working with the Java Messaging Service (JMS) API, see [Using the JMS providers](#).

For detailed implementation information, see the following topics:

- [The native JMS provider - Writing the WSDL extension](#)
- [The JMS providers - Configuring the client and server](#)

#### *The native JMS provider - Writing the WSDL extension:*

The WSDL extensions for the Java Messaging Service (JMS) are identified with the namespace prefix `jms`. For example, `<jms:binding>`.

### **Operations**

The supported operations are either one-way operations (send for JMS point-to-point messaging, or publish for JMS publish and subscribe messaging) or request-response operations (send and receive for JMS point-to-point messaging). The WSDL operations therefore specify either an input message only, or an input and an output message.

### **Fault messages**

Operations that describe message interfaces with a native JMS binding do not have fault messages. No assumptions are made about the message schema or the semantics of message properties, therefore no distinction can be made between output and fault messages.

### **Setting the JMS message body type**

You use the `<jms:binding>` extension to specify the JMS message body type:

```
<wsdl:binding ... >
 <jms:binding type="messageBodyType" />
 ...
</wsdl:binding>
```

where *messageBodyType* is either `ObjectMessage` or `TextMessage`.

### Specifying the parts to use for the input and output messages

For JMS text messages and JMS object messages created from one or more WSDL message parts, you use the `<jms:input>` and `<jms:output>` extensions to specify the message parts to use for the JMS messages:

```
<wsdl:input ... >
 <jms:input parts="part1 part2 ..." />
</wsdl:input>

<wsdl:output ... >
 <jms:output parts="part1 part2 ..." />
</wsdl:output>
```

In the next example, the WSDL message has just one part that contains the complete message body. This message body might result from a mapping of some other representation (see **Mapping data types**).

```
<wsdl:input ... >
 <jms:input parts="part1" />
</wsdl:input>
```

If no parts are defined, then all the message parts are used.

### Mapping data types

You use the `<format>` extensions to map data types:

```
<wsdl:binding ... >
 <jms:binding type="..." />

 <format:typeMapping encoding="Java" style="Java">
 <format:typeMap typeName="..." formatType="targetType"/>
 </format:typemapping>
 ...
</wsdl:binding>
```

The value of *targetType* is dependent on the JMS message body type (see **Setting the JMS message body type**). For JMS object messages, the target data type implements the `java.io.Serializable` class. For JMS text messages, the target data type is always `java.lang.String`.

The `<format>` extensions are also used in other bindings that deal with Java interfaces.

### Setting the JMS headers and properties

JMS does not make assumptions about message headers. For example, if the JMS provider is `MQSeries` then each JMS message carries an `RFH2` header. However you can access data in this message header indirectly, by getting and setting JMS message properties.

When you want your application to pass a property into the Web Services Invocation Framework (WSIF) as a part on the WSIF message, you use a `<jms:property>` tag. When you want to hard code an actual property value into the WSDL, you use a `<jms:propertyValue>` tag. The `<jms:propertyValue>` tag contains a specification of a literal value and its associated XML schema type.

You can specify `<jms:property>` and `<jms:propertyValue>` extensions within the `<wsdl:input>` tag in the binding operation, and also within the `<jms:address>` tag. For the `<wsdl:output>` tag in the

binding operation, you can only specify the `<jms:property>` extension. Property values that are set in the `<jms:property>` tag take precedence over values set in the `<<jms:propertyValue>` tag, and property values that are set in the binding operation (in the `<input>` and `<output>` tags) take precedence over values set in the `<jms:address>` tag.

Here is an example of the `<jms:property>` and `<jms:propertyValue>` tags nested within the `<input>` and `<output>` tags:

```
<wsdl:input ... >
 <jms:property name="propertyName" part="partName" />
 <jms:propertyValue name="propertyName"
 type="xsdType" value="actualValue" />
</wsdl:input>
<wsdl:output ... >
 <jms:property name="propertyName" part="partName" />
</wsdl:output>
```

where *propertyName* identifies the JMS property that is associated with the header field, and *partName* identifies the message part that is associated with the property.

The JMS property identified by *propertyName* can be user-defined, or it can be one of the following predefined JMS message header fields:

Value	Java type
JMSMessageId	java.lang.String
JMSTimeStamp	long
JMSCorrelationId	byte [ ] or java.lang.String
JMSReplyTo	javax.jms.Destination
JMSDestination	javax.jms.Destination
JMSDeliveryMode	int
JMSRedelivered	boolean
JMSType	java.lang.String
JMSExpiration	long

See the JMS specification for restrictions that apply when setting JMS header field values. Attempts to set restricted values are ignored.

For application-defined JMS message properties, the Java types used in the native JMS binding implementation (used for calls to the corresponding JMS methods) are derived from the XML schema type in the abstract interface (`<wsdl:part>` tag), and from the type mapping information in the format binding (`<format:typemap>` tag).

## Handling transactions

Independent of other JMS properties, the asynchronous processing of request-response operations has implications for callers running in a transaction scope. The send request part and the receive response part are separated into two transactions, because the send needs to be committed in order for the request message to become visible. Implementations that process WSDL for asynchronous request-response operations (such as WSIF) must therefore take the following additional actions:

- They must ensure that the send request transaction returns a correlation ID to the user, and provides a **callback** with which users can pass in the response message to process the receive response transaction.
- They might implement their own response message “listener” in order to recognize the arrival of response messages, and to manage the correlation to the request message.

The JMS text message contains a **java.lang.String**. In this example, the WSDL message contains only one part that represents the whole message body:

```

<!-- Example 1: JMS Text Message -->

<wsdl:definitions ... >

 <!-- simple or complex types for input and output message -->
 <wsdl:types> ... </wsdl:types>

 <wsdl:message name="JmsOperationRequest"> ... </wsdl:message>
 <wsdl:message name="JmsOperationResponse"> ... </wsdl:message>

 <wsdl:portType name="JmsPortType">
 <wsdl:operation name="JmsOperation">
 <wsdl:input name="Request"
 message="tns:JmsOperationRequest"/>
 <wsdl:output name="Response"
 message="tns:JmsOperationResponse"/>
 </wsdl:operation>
 </wsdl:portType>

 <wsdl:binding name="JmsBinding" type="JmsPortType">
 <jms:binding type="TextMessage" />

 <format:typemapping style="Java" encoding="Java">
 <format:typemap name="xsd:String" formatType="String" />
 </format:typemapping>

 <wsdl:operation name="JmsOperation">
 <wsdl:input message="JmsOperationRequest">
 <jms:input parts="requestMessageBody" />
 </wsdl:input>
 <wsdl:output message="JmsOperationResponse">
 <jms:output parts="responseMessageBody" />
 </wsdl:output>
 </wsdl:operation>
 </wsdl:binding>

 <wsdl:service name="JmsService">
 <wsdl:port name="JmsPort" binding="JmsBinding">
 <jms:address destinationStyle="queue"
 jndiConnectionFactoryName="myQCF"
 jndiDestinationName="myDestination"/>
 </wsdl:port>
 </wsdl:service>

</wsdl:definitions>

```

As an extension to the previous JMS message example, the following example WSDL describes a request-response operation in which specific JMS property values of the request and response message are set for the request message and retrieved from the response message.

The JMS properties in the request message are set according to the values in the input message. Likewise, selected JMS properties of the response message are copied to the corresponding values of the output message. The direction of the mapping is determined by the appearance of the `<jms:property>` tag in the input or output section, respectively.

```

<!-- Example 2: JMS Message with JMS Properties -->
<wsdl:definitions ... >

 <!-- simple or complex types for input and output message -->
 <wsdl:types> ... </wsdl:types>

 <wsdl:message name="JmsOperationRequest">
 <wsdl:part name="myInt" type="xsd:int"/>
 ...
 </wsdl:message>

 <wsdl:message name="JmsOperationResponse">
 <wsdl:part name="myString" type="xsd:String"/>
 ...
 </wsdl:message>

 <wsdl:portType name="JmsPortType">
 <wsdl:operation name="JmsOperation">
 <wsdl:input name="Request"
 message="tns:JmsOperationRequest"/>
 <wsdl:output name="Response"
 message="tns:JmsOperationResponse"/>
 </wsdl:operation>
 </wsdl:portType>

 <wsdl:binding name="JmsBinding" type="JmsPortType">
 <!-- the JMS message type may be any of the above -->
 <jms:binding type="..." />

 <format:typemapping style="Java" encoding="Java">
 <format:typemap name="xsd:int" formatType="int" />
 ...
 </format:typemapping>

 <wsdl:operation name="JmsOperation">
 <wsdl:input message="JmsOperationRequest">
 <jms:property message="tns:JmsOperationRequest" parts="myInt" />
 <jms:propertyValue name="myLiteralString"
 type="xsd:string" value="Hello World" />
 ...
 </wsdl:input>
 <wsdl:output message="JmsOperationResponse">
 <jms:property message="tns:JmsOperationResponse" parts="myString" />
 ...
 </wsdl:output>
 </wsdl:operation>
 </wsdl:binding>

 <wsdl:service name="JmsService">
 <wsdl:port name="JmsPort" binding="JmsBinding">
 <jms:address destinationStyle="queue"
 jndiConnectionFactoryName="myQCF"
 jndiDestinationName="myDestination"/>
 </wsdl:port>
 </wsdl:service>
</wsdl:definitions>

```

### ***The JMS providers - Configuring the client and server:***

This topic assumes that you installed a Java Messaging Service (JMS) provider when you installed WebSphere Application Server (either the JMS provider that is embedded in WebSphere Application Server, or another provider such as WebSphere MQ). If not, install one now as described in Installing and configuring a JMS provider.

To enable a service to be invoked through JMS by a Web Services Invocation Framework (WSIF) client application, complete the following steps:

1. Use the administrative console to create and configure a queue connection factory and a queue destination as described in *Configuring JMS provider resources*.
2. Use the administrative console to add the new queue destination to the list of JMS Server destination names for your application server as described in *Managing JMS servers on Application Server* (not part of a deployment manager cell) or *Managing JMS servers in a deployment manager cell*. Ensure that the Initial State is started.
3. Put the JNDI names of the queue destination and queue connection factory, as well as your JNDI configuration, in the WSDL file.

You should also understand the specific ways in which WSIF interacts with JMS:

- Only input JMS properties are supported.
- WSIF needs two queues when invoking an operation: one for the request message and one for the reply. The replyTo queue is by default a temporary queue, which WSIF creates on behalf of the application. You can specify a permanent queue by setting the JMSReplyTo property to the JNDI name of a queue.
- WSIF uses the default values for properties set by the JMS implementation. However in MQSeries and in some other JMS implementations, messages are persistent by default, and the default temporary queue is of type temporary dynamic and cannot have persistent messages written to it. Therefore your JMS listener can fail to write a persistent response message to the temporary replyTo queue.

**Note:** If you are using MQSeries, you need to create a temporary model queue that is of type permanent dynamic, then pass this model as the tempmodel of your queue connection factory. This will ensure that persistent messages are written to a temporary replyTo queue that is of type permanent dynamic.

## Using the Java provider

Using the WSIF Java provider, WSIF can invoke Java code.

This means that, in a thin-client environment such as a Java Virtual Machine (JVM) or Tomcat test run-time, you can define shortcuts to local Java programs.

The Web Services Invocation Framework (WSIF) Java provider is not intended for use in a Java 2 platform, Enterprise Edition (J2EE) environment. There is a difference between a client using the WSIF Java provider to invoke a Java component, and implementing a Web service as a Java component on the server side.

The Java binding exploits the format binding for type mapping. Using the format binding, your WSDL can define the mapping between XML schema types and Java types.

The Java provider requires that the targeted Java classes reside in the class path of the client. The Java method is invoked synchronously, in-process, in-thread, with the current thread and Object Request Broker (ORB) contexts.

The Java provider is not transactional.

For examples of the code changes that need to be made in the WSDL file, see *The Java provider - Writing the WSDL extension*.

### ***The Java provider - Writing the WSDL extension:***

The Java provider supports the invocation of a method on a local Java object.

To use the Java provider, you need the following binding specified in the WSDL:

```

<!-- Java binding -->
<binding >
 <java:binding />
 <format:typeMapping style="Java" encoding="Java"/>?
 <format:typeMap name="qname" formatType="nmtoken"/>*
 </format:typeMapping>
 <operation>*
 <java:operation
 methodName="nmtoken"
 parameterOrder="nmtoken"
 returnPart="nmtoken"?
 methodType="instance|constructor" />
 <input name="nmtoken"? />?
 <output name="nmtoken"? />?
 <fault name="nmtoken"? />?
 </operation>
</binding>

```

In this example:

- A question mark (?) means optional, and an asterisk (\*) means 0 or more.
- The name attribute of the <format:typeMap> element is a qualified name of a simple or complex type used by one of the Java operations.
- The formatType attribute of the <format:typeMap> element is the fully qualified class name for the Java class to which the element specified by name maps.
- The methodName attribute of the <java:operation> element is the name of the method on the Java object that is called by the operation.
- The parameterOrder attribute of the <java:operation> element contains a white space-separated list of part names that define the order in which they are passed to the Java object method.
- The methodType attribute of the <java:operation> element must be set to either instance or constructor. The value specifies whether the method that is invoked on the object is an instance method or a constructor for the object.

In the next example, the className attribute of the <java:address> element specifies the fully qualified class name of the object containing the method to invoke:

```

<service ... >
 <port>*
 <java:address
 className="nmtoken"/>
 </port>
</service>

```

## Using the EJB provider

Using the EJB provider, WSIF clients can invoke enterprise beans.

The EJB client JAR file must be available in the client run-time with the current provider. The enterprise bean is invoked using normal EJB invocation methods, using Remote Method Invocation over Internet Inter-Orb Protocol (RMI-IIOP), with the current security and transaction contexts. If the EJB provider is invoked within a transaction, the transaction is passed to the onward service and the standard EJB transaction attribute applies.

If there are multiple implementations of the service, it is up to the service providers to make sure that every implementation offers the same semantics. For example, in the case of transactions, the bean deployer must specify TX\_REQUIRES\_NEW to force a new transaction.

For examples of the code changes that need to be made in the WSDL file, see The EJB provider - Writing the WSDL.

### *The EJB provider - Writing the WSDL extension:*

The EJB provider supports the invocation of an enterprise bean through Remote Method Invocation over Internet Inter-Orb Protocol (RMI-IIOP).

To use the EJB provider, you need the following binding specified in the WSDL:

```
<!-- EJB binding -->
<binding >
 <ejb:binding />
 <format:typeMapping style="Java" encoding="Java"/>?
 <format:typeMap name="qname" formatType="nmtoken"/>*
 </format:typeMapping>
 <operation>*
 <ejb:operation
 methodName="nmtoken"
 parameterOrder="nmtoken"
 returnPart="nmtoken"?
 interface="remote|home" />
 <input name="nmtoken"? />?
 <output name="nmtoken"? />?
 <fault name="nmtoken"? />?
 </operation>
</binding>
```

In this example:

- A question mark (?) means optional, and an asterisk (\*) means 0 or more.
- The name attribute of the <format:typeMap> element is a qualified name of a simple or complex type used by one of the EJB operations.
- The formatType attribute of the <format:typeMap> element is the fully qualified class name for the Java class to which the element specified by name maps.
- The methodName attribute of the <ejb:operation> element is the name of the method on the enterprise bean that is called by the operation.
- The parameterOrder attribute of the <ejb:operation> element contains a white space-separated list of part names that define the order in which they are passed to the EJB method.
- The interface attribute of the <ejb:operation> element must be set to either remote or home. The value specifies the interface of the enterprise bean on which the method named by the methodName attribute is accessible.

In the next example:

- The className attribute of the <ejb:address> element specifies the fully qualified class name of the home interface class of the enterprise bean.
- The jndiName attribute of the <ejb:address> element specifies the full Java Naming and Directory Interface (JNDI) name that is used to look up the enterprise bean.
- The initialContextFactory attribute of the <ejb:address> element is optional and specifies the initial context factory class.
- The jndiProviderURL attribute of the <ejb:address> element is optional and specifies the JNDI provider Web address.

```
<service ... >
 <port>*
 <ejb:address
 className="nmtoken"
 jndiName="nmtoken"
 initialContextFactory="nmtoken" ?
 jndiProviderURL="nmtoken" ? />
 </port>
</service>
```

## Developing a WSIF service

A Web Services Invocation Framework (WSIF) service is a Web service that uses WSIF.

To develop a WSIF service, develop the Web service (or use an existing Web service), then develop the WSIF client based on the WSDL document for that Web service.

There are also two pre-built WSIF Samples available for download from the Samples Central page of the DeveloperWorks WebSphere Web site:

- The Address Book Sample.
- The Stock Quote Sample.

For more information on using the pre-built Samples, see the documentation that is included in the download package.

To develop a WSIF service, complete the following steps:

1. Develop the Web service.

Use Web services tools to discover, create, and publish the Web service. You can develop Java bean, enterprise bean, and URL Web services. You can use Web service tools to create skeleton Java code and a sample application from a WSDL document. For example, an enterprise bean can be offered as a Web service, using Remote Method Invocation over Internet Inter-Orb Protocol (RMI-IIOP) as the access protocol. Or you can use a Java class as a Web service, with native Java invocations as the access protocol.

You can use the WebSphere Studio Application Developer to create a Web service from a Java application, as described in its StockQuote service tutorial. The Java application that you use in this scenario returns the last trading price from the Internet Web site [www.xmltoday.com](http://www.xmltoday.com), given a stock symbol. Using the Web service wizard, you generate a binding WSDL document named `StockQuoteService-binding.wsdl` and a service WSDL document named `StockQuoteService-service.wsdl` from the `StockQuoteService.java` bean. You then deploy the Web service to a Web server, generate a client proxy to the Web service, and generate a sample application that accesses the `StockQuoteService` through the client proxy. You test the `StockQuote` Web service, publish it using the IBM UDDI Explorer, and then discover the `StockQuote` Web service in the IBM UDDI Test Registry.

2. Develop the WSIF client. The information you need to develop a WSIF client is provided in the following topics:

- [Developing the WSIF client - the Address Book Sample](#) gives example code to show how you define a Web service in WSDL.
- [Using the WSIF providers](#) describes the available providers, and gives example code of how their WSDL extensions are coded.
- [WSIF API](#) defines the main interfaces that your client uses to support the invocation of Web services defined in WSDL.

The Address Book Sample is written for synchronous interaction. If you are using a JMS provider, your WSIF client might need to act asynchronously. WSIF provides two main features that meet this requirement:

- A **correlation service** that assigns identifiers to messages so that the request can match up with the (eventual) response.
- A **response handler** that picks up the response from the Web service at a later time.

For more information, see the WSIF API topic [WSIFOperation - Asynchronous interactions](#) reference.

## Developing the WSIF client - the Address Book Sample

The code fragments in this topic show you how to use the Web Services Invocation Framework (WSIF) API to invoke the AddressBook Sample Web service dynamically.

This is example code for dynamic invocation of the AddressBook sample Web service using WSIF:

```
try {
 String wsdlLocation="clients/addressbook/AddressBookSample.wsdl";

 // The starting point for any dynamic invocation using wsif is a
 // WSIFServiceFactory. We create ourselves one via the newInstance
 // method.
```

```

WSIFServiceFactory factory = WSIFServiceFactory.newInstance();

// Once we have a factory, we can use it to create a WSIFService object
// corresponding to the AddressBookService service in the wsdl file.
// Note: since we only have one service defined in the wsdl file, we
// do not need to use the namespace and name of the service and can pass
// null instead. This also applies to the port type, although values have
// been used below for illustrative purposes.
WSIFService service = factory.getService(
 wsdlLocation, // location of the wsdl file
 null, // service namespace
 null, // service name
 "http://www.ibm.com/namespace/wsif/samples/ab", // port type namespace
 "AddressBookPT" // port type name
);

// The AddressBook.wsdl file contains the definitions for two complexType
// elements within the schema element. We will now map these complexTypes
// to Java classes. These mappings are used by the Apache SOAP provider
service.mapType(
 new javax.xml.namespace.QName(
 "http://www.ibm.com/namespace/wsif/samples/ab/types",
 "address"),
 Class.forName("com.ibm.www.namespace.wsif.samples.ab.types.WSIFAddress"));
service.mapType(
 new javax.xml.namespace.QName(
 "http://www.ibm.com/namespace/wsif/samples/ab/types",
 "phone"),
 Class.forName("com.ibm.www.namespace.wsif.samples.ab.types.WSIFPhone"));
// We now have a WSIFService object. The next step is to create a WSIFPort
// object for the port we wish to use. The getPort(String portName) method
// allows us to generate a WSIFPort from the port name.
WSIFPort port = null;

if (portName != null) {
 port = service.getPort(portName);
}
if (port == null) {
 // If no port name was specified, attempt to create a WSIFPort from
 // the available ports for the port type specified on the service
 port = getPortFromAvailablePortNames(service);
}

// Once we have a WSIFPort, we can create an operation. We are going to execute
// the addEntry operation and therefore we attempt to create a WSIFOperation
// corresponding to it. The addEntry operation is overloaded in the wsdl ie.
// there are two versions of it, each taking different parameters (parts).
// This overloading requires that we specify the input and output message
// names for the operation in the createOperation method so that the correct
// operation can be resolved.
// Since the addEntry operation has no output message, we use null for its name.
WSIFOperation operation =
 port.createOperation("addEntry", "AddEntryWholeNameRequest", null);

// Create messages to use in the execution of the operation. This should
// be done by invoking the createXXXXXMessage methods on the WSIFOperation.
WSIFMessage inputMessage = operation.createInputMessage();
WSIFMessage outputMessage = operation.createOutputMessage();
WSIFMessage faultMessage = operation.createFaultMessage();

// Create a name and address to add to the addressbook
String nameToAdd="Chris P. Bacon";
WSIFAddress addressToAdd =
 new WSIFAddress (1,
 "The Waterfront",
 "Some City",
 "NY",

```

```

 47907,
 new WSIFPhone (765, "494", "4900"));

// Add the name and address to the input message
inputMessage.setObjectPart("name", nameToAdd);
inputMessage.setObjectPart("address", addressToAdd);

// Execute the operation, obtaining a flag to indicate its success
boolean operationSucceeded =
 operation.executeRequestResponseOperation(
 inputMessage,
 outputMessage,
 faultMessage);

if (operationSucceeded) {
 System.out.println("Successfully added name and address to addressbook\n");
} else {
 System.out.println("Failed to add name and address to addressbook");
}

// Start from fresh
operation = null;
inputMessage = null;
outputMessage = null;
faultMessage = null;

// This time we will lookup an address from the addressbook.
// The getAddressFromName operation is not overloaded in the
// wsdl and therefore we can simply specify the operation name
// without any input or output message names.
operation = port.createOperation("getAddressFromName");

// Create the messages
inputMessage = operation.createInputMessage();
outputMessage = operation.createOutputMessage();
faultMessage = operation.createFaultMessage();

// Set the name to find in the addressbook
String nameToLookup="Chris P. Bacon";
inputMessage.setObjectPart("name", nameToLookup);

// Execute the operation
operationSucceeded =
 operation.executeRequestResponseOperation(
 inputMessage,
 outputMessage,
 faultMessage);

if (operationSucceeded) {
 System.out.println("Successful lookup of name '"+nameToLookup+"' in addressbook");

 // We can obtain the address that was found by querying the output message
 WSIFAddress addressFound = (WSIFAddress) outputMessage.getObjectPart("address");
 System.out.println("The address found was:");
 System.out.println(addressFound);
} else {
 System.out.println("Failed to lookup name in addressbook");
}

} catch (Exception e) {
 System.out.println("An exception occurred when running the sample.");
 e.printStackTrace();
}
}

```

The preceding code refers to the following Sample method:

```

WSIFPort getPortFromAvailablePortNames(WSIFService service)
 throws WSIFException {
 String portChosen = null;

 // Obtain a list of the available port names for the service
 Iterator it = service.getAvailablePortNames();
 {
 System.out.println("Available ports for the service are: ");
 while (it.hasNext()) {
 String nextPort = (String) it.next();
 if (portChosen == null)
 portChosen = nextPort;
 System.out.println(" - " + nextPort);
 }
 }
 if (portChosen == null) {
 throw new WSIFException("No ports found for the service!");
 }
 System.out.println("Using port " + portChosen + "\n");

 // An alternative way of specifying the port to use on the service
 // is to use the setPreferredPort method. Once a preferred port has
 // been set on the service, a WSIFPort can be obtained via getPort
 // (no arguments). If a preferred port has not been set and more than
 // one port is available for the port type specified in the WSIFService,
 // an exception is thrown.
 service.setPreferredPort(portChosen);
 WSIFPort port = service.getPort();
 return port;
}

```

The Web service uses the following classes:

#### **WSIFAddress:**

```

public class WSIFAddress implements Serializable {

 //instance variables
 private int streetNum;
 private java.lang.String streetName;
 private java.lang.String city;
 private java.lang.String state;
 private int zip;
 private WSIFPhone phoneNumber;

 //constructors
 public WSIFAddress () { }

 public WSIFAddress (int streetNum,
 java.lang.String streetName,
 java.lang.String city,
 java.lang.String state,
 int zip,
 WSIFPhone phoneNumber) {
 this.streetNum = streetNum;
 this.streetName = streetName;
 this.city = city;
 this.state = state;
 this.zip = zip;
 this.phoneNumber = phoneNumber;
 }

 public int getStreetNum() {
 return streetNum;
 }

 public void setStreetNum(int streetNum) {

```

```

 this.streetNum = streetNum;
 }

 public java.lang.String getStreetName() {
 return streetName;
 }

 public void setStreetName(java.lang.String streetName) {
 this.streetName = streetName;
 }

 public java.lang.String getCity() {
 return city;
 }

 public void setCity(java.lang.String city) {
 this.city = city;
 }

 public java.lang.String getState() {
 return state;
 }

 public void setState(java.lang.String state) {
 this.state = state;
 }

 public int getZip() {
 return zip;
 }

 public void setZip(int zip) {
 this.zip = zip;
 }

 public WSIFPhone getPhoneNumber() {
 return phoneNumber;
 }

 public void setPhoneNumber(WSIFPhone phoneNumber) {
 this.phoneNumber = phoneNumber;
 }
}

```

### **WSIFPhone:**

```

public class WSIFPhone implements Serializable {

 //instance variables
 private int areaCode;
 private java.lang.String exchange;
 private java.lang.String number;

 //constructors
 public WSIFPhone () { }

 public WSIFPhone (int areaCode,
 java.lang.String exchange,
 java.lang.String number) {
 this.areaCode = areaCode;
 this.exchange = exchange;
 this.number = number;
 }

 public int getAreaCode() {
 return areaCode;
 }
}

```

```

 public void setAreaCode(int areaCode) {
 this.areaCode = areaCode;
 }

 public java.lang.String getExchange() {
 return exchange;
 }

 public void setExchange(java.lang.String exchange) {
 this.exchange = exchange;
 }

 public java.lang.String getNumber() {
 return number;
 }

 public void setNumber(java.lang.String number) {
 this.number = number;
 }
}

```

### **WSIFAddressBook:**

```

public class WSIFAddressBook {
 private Hashtable name2AddressTable = new Hashtable();

 public WSIFAddressBook() {
 }

 public void addEntry(String name, WSIFAddress address)
 {
 name2AddressTable.put(name, address);
 }

 public void addEntry(String firstName, String lastName, WSIFAddress address)
 {
 name2AddressTable.put(firstName+" "+lastName, address);
 }

 public WSIFAddress getAddressFromName(String name)
 throws IllegalArgumentException
 {
 if (name == null)
 {
 throw new IllegalArgumentException("The name argument must not be " +
 "null.");
 }
 return (WSIFAddress)name2AddressTable.get(name);
 }
}

```

The following code is the corresponding WSDL file for the Web service:

```

<?xml version="1.0" ?>

<definitions targetNamespace="http://www.ibm.com/namespace/wsif/samples/ab"
 xmlns:tns="http://www.ibm.com/namespace/wsif/samples/ab"

 <ejb:address className="services.addressbook.ejb.AddressBookHome"
 jndiName="ejb/samples/wsif/AddressBook"
 classLoader="services.addressbook.ejb.AddressBook.ClassLoader"/>
 </port>
</service>
</definitions>

```

## Using complex types

WSIF supports user-defined complex types through the mapping of complex types to Java classes.

You specify this mapping manually or automatically as described in the following sections:

- Manual mapping of complex types.
- Automatic mapping of complex types.

Any calls to the WSIFService mapType and mapPackage methods used for manual mapping override any equivalent mapping information that is produced automatically. This override helps to maintain backwards compatibility, and also accommodates less standard mappings.

### Manual mapping of complex types

The method to use when you create these mappings manually depends on the provider that is used. For the Java and EJB providers, the mappings are specified in the WSDL file in the binding element. The following example provides the syntax for specifying the mapping:

```

<binding >
 <ejb:binding|java:binding/>
 <format:typeMapping style="Java" encoding="Java"/>?
 <format:typeMap name="qname" formatType="nmtoken"/>*
 </format:typeMapping>
 ...
</binding>

```

In this example:

- A question mark (“?”) means “optional” and an asterisk (“\*”) means “0 or more”.
- The `format:typeMap` **name** attribute is a qualified name of a complex type or simple type used by one of the operations.
- The `format:typeMap` **formatType** attribute is the fully qualified class name for the Java class to which the element specified by **name** maps.

If you use the Apache SOAP provider then you specify the mapping of a complex type to a Java class in the client code through two methods on the `org.apache.wsif.WSIFService` interface:

```
public void mapType(QName elementType, Class javaType)
```

and

```
public void mapPackage(String namespaceURI, String packageName)
```

Use the **mapType** method to specify a mapping between an XML schema element and a Java class. The method takes a `QName` representing the complex type or simple type, and the corresponding Java class to which it maps.

Use the **mapPackage** method to specify a more general mapping between a namespace and a Java package. Any custom, complex or simple type whose namespace matches that of the mapping is mapped to a Java class in the corresponding package. The name of the actual class is derived from the name of the complex type using standard XML to Java naming conventions.

### Automatic mapping of complex types

For complex types defined in the WSDL, where a generated bean is used to represent this type in Java, the Web Services Invocation Framework (WSIF) programming model requires that a call is made to the `WSIFService.mapType()` method. This call tells WSIF the package and class name of the bean representing the XML schema type that is identified with a `QName`. To make things easier, the `WSIFService.mapPackage()` method provides a mechanism to specify a wildcard version of this, where any class within a specified package is mapped to the namespace of a `QName`. This is a mechanism for manually mapping an XML schema type to a Java class and back again (one mapping entry provides a bidirectional mapping).

There are many ways to convert a `QName` representing an XML schema type name to a Java package name and class. To enable automatic type mapping, set the `WSIF_FEATURE_AUTO_MAP_TYPES` feature on the `WSIFServiceFactory` instance:

```
WSIFServiceFactory factory = WSIFServiceFactory.newInstance();
factory.setFeature(WSIFConstants.WSIF_FEATURE_AUTO_MAP_TYPES, new Boolean(true));
```

WSIF maps types by converting the URI part of the XML schema type `<tt>QName</tt>` to a package name, and converting the local part to a class name. WSIF does this mapping using the `WSIFUtils` methods `<tt>getPackageNameFromNamespaceURI</tt>` and `<tt>getJavaClassNameFromXMLName</tt>`.

## Using the Java Naming and Directory Interface (JNDI)

This example task shows you how to use WSIF to bind a reference to a Web service, then look up the reference using JNDI.

You access a Web service through information provided in the WSDL document for the service. If you do not know where to find the WSDL document for the service, but you know that it has been registered in a UDDI registry, then you look it up in the registry. Java programs access Java objects and resources in a similar manner, but using a JNDI interface.

The following example shows how, using the Web Services Invocation Framework (WSIF), you can bind a reference to a Web service then look up the reference using JNDI.

### Specifying the argument values for the Web service

The Web service is represented in WSIF by an instance of the `org.apache.wsif.naming.WSIFServiceRef` class. This simple Referenceable object has the following constructor:

```
public WSIFServiceRef(
 String WSDL,
 String sNS,
 String sName,
 String ptNS,
 String ptName)
{
 [...]
}
```

In this example

- *WSDL* is the location of the WSDL file containing the definition of the service.
- *sNS* is the full namespace for the service definition (you can specify `null` if only one service is defined in the WSDL file).
- *sName* is the local name for the service definition (you can specify `null` if only one service is defined in the WSDL file).
- *ptNS* is the full namespace for the port type within the service that you want to use (you can specify `null` if only one port type is available for the service).
- *ptName* is the local name for the port type (you can specify `null` if only one port type is available for the service).

For example, if the WSDL file for the Web service is available from the Web address `http://localhost/WSDL/Example.WSDL` and contains the following service and port type definitions:

```
<definitions targetNamespace="http://hostname/namespace/example"
 xmlns:abc="http://hostname/namespace/abc"
[...]
 <portType name="ExamplePT">
 <operation name="exampleOp">
 <input name="exampleInput" message="tns:ExampleInputMsg"/>
 </operation>
 </portType>
[...]
 <service name="abc:ExampleService">
[...]
 </service>
[...]
</definitions>
```

You can specify the following argument values for the `WSIFServiceRef` class:

- *WSDL* is `http://localhost/WSDL/Example.WSDL`
- *sNS* is `http://hostname/namespace/abc`
- *sName* is `ExampleService`
- *ptNS* is `http://hostname/namespace/example`
- *ptName* is `ExamplePT`

### Binding the service using JNDI

To bind the service reference in the naming directory using JNDI, you can use the `com.ibm.websphere.naming.JndiHelper` class in WebSphere Application Server:

```
[...]
import com.ibm.websphere.naming.JndiHelper;
import org.apache.wsif.naming.*;
```

```
[...]
try {
 Context startingContext = new InitialContext();
 WSIFServiceRef ref = new WSIFServiceRef("http://localhost/WSDL/Example.WSDL",
 "http://hostname/namespace/abc"
 "ExampleService",
 "http://hostname/namespace/example",
 "ExamplePT");

 JndiHelper.recursiveRebind(startingContext,
 "myContext/mySubContext/myServiceRef", ref);

}
catch (NamingException e) {
 // Handle error.
}
[...]
```

## Looking up the service using JNDI

The following code fragment shows the lookup of a service using JNDI:

```
[...]
try {
[...]
```

```
 InitialContext ic = new InitialContext();
 WSIFService myService =
 (WSIFService) ic.lookup("myContext/mySubContext/myServiceRef");
[...]
```

```
}
catch (NamingException e) {
 // Handle error.
}
[...]
```

## Passing SOAP messages with attachments using WSIF

The W3C SOAP Messages with Attachments document describes a standard way to associate a SOAP message with one or more attachments in their native format (for example GIF or JPEG) by using a multipart MIME structure for transport. It defines specific use of the "Multipart/Related" MIME media type, and rules for the use of URI references to entities bundled within the MIME package. It thereby outlines a technique for carrying a SOAP 1.1 message within a MIME multipart/related message in such a way that the SOAP processing rules for a standard SOAP message are not changed.

The Web Services Invocation Framework (WSIF) supports passing attachments in a MIME message using the SOAP provider. The attachment is a `javax.activation.DataHandler` object. The `mime:multipartRelated`, `mime:part` and `mime:content` tags are used to describe the attachment in the WSDL.

For more information, see the following topics:

- SOAP messages with attachments - Writing the WSDL extensions.
- SOAP messages with attachments - Passing attachments to WSI.
- SOAP messages with attachments - Working with types and type mappings.

The following scenarios are not supported:

- Using DIME.
- Passing in `javax.xml.transform.Source` and `javax.mail.internet.MimeMultipart`.
- Using the `mime:mimeXml` WSDL tag.
- Nesting a `mime:multipartRelated` tag inside a `mime:part` tag.
- Using types that extend `DataHandler`, `Image`, and so on.
- Using types that contain `DataHandler`, `Image`, and soon.
- Using Arrays or Vectors of `DataHandlers`, `Images`, and so on.
- Using multiple in/out or output attachments.

The MIME headers from the incoming message are not preserved for referenced attachments. The outgoing message contains new MIME headers for Content-Type, Content-Id and Content-Transfer-Encoding that are created by WSIF.

## SOAP messages with attachments - Writing the WSDL extensions

The following example WSDL illustrates a simple operation that has one attachment called attch:

```
<binding name="MyBinding" type="tns:abc" >
 <soap:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/http"/>
 <operation name="MyOperation">
 <soap:operation soapAction=""/>
 <input>
 <mime:multipartRelated>
 <mime:part>
 <soap:body use="encoded" namespace="http://mynamespace"
 encodingStyle="http://schemas.xmlsoap.org/soap/encoding"/>
 </mime:part>
 <mime:part>
 <mime:content part="attch" type="text/html"/>
 </mime:part>
 </mime:multipartRelated>
 </input>
 </operation>
</binding>
```

In this type of WSDL extension:

- There must be a part attribute (in this example attch) on the input message for the operation (in this example MyOperation). There can be other input parts to MyOperation that are not attachments.
- In the binding input there must either be a <soap:body> tag or a <mime:multipartRelated> tag, but not both.
- For MIME messages, the <soap:body> tag is inside a <mime:part> tag. There must only be one <mime:part> tag that contains a <soap:body> tag in the binding input and that must not contain a <mime:content> tag as well, because a content type of text/xml is assumed for the <soap:body> tag.
- There can be multiple attachments in a MIME message, each described by a <mime:part> tag.
- Each <mime:part> tag that does not contain a <soap:body> tag contains a <mime:content> tag that describes the attachment itself. The type attribute inside the <mime:content> tag is not checked or used by the Web Services Invocation Framework (WSIF). It is there to suggest to the application using WSIF what the attachment contains. Multiple <mime:content> tags inside a single <mime:part> tag means that the backend service expects a single attachment with a type specified by one of the <mime:content> tags inside that <mime:part> tag.
- The parts="..." attribute (optional) inside the <soap:body> tag is assumed to contain the names of all the MIME parts as well as the names of all the SOAP parts in the message.

## SOAP messages with attachments - Passing attachments to WSIF

The following code fragment can invoke the service described by the example WSDL in the topic writing the WSDL extensions:

```
import javax.activation.DataHandler;
. . .
DataHandler dh = new DataHandler(new FileDataSource("myimage.jpg"));
WSIFServiceFactory factory = WSIFServiceFactory.newInstance();
WSIFService service = factory.getService("my.wsdl",null,null,"http://mynamespace","abc");
WSIFOperation op = service.getPort().createOperation("MyOperation");
WSIFMessage in = op.createInputMessage();
in.setObjectPart("attch",dh);
op.executeInputOnlyOperation(in);
```

The associated type mapping in the DeploymentDescriptor.xml file depends upon your SOAP server. For example if you use Tomcat with SOAP 2.3, then the DeploymentDescriptor.xml file contains the following type mapping:

```

<isd:mappings>
<isd:map encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"
 xmlns:x="http://mynamespace"
 qname="x:datahandler"
 javaType="javax.activation.DataHandler"
 java2XMLClassName="org.apache.soap.encoding.soapenc.MimePartSerializer"
 xml2JavaClassName="org.apache.soap.encoding.soapenc.MimePartSerializer" />
</isd:mappings>

```

In this case, the backend service is invoked with the following signature:

```
public void MyOperation(DataHandler dh);
```

You can also use stubs to pass attachments into the Web Services Invocation Framework (WSIF):

```

DataHandler dh = new DataHandler(new FileDataSource("myimage.jpg"));
WSIFServiceFactory factory = WSIFServiceFactory.newInstance();
WSIFService service = factory.getService("my.wsdl", null, null, "http://mynamespace", "abc");
MyInterface stub = (MyInterface)service.getStub(MyInterface.class);
stub.MyOperation(dh);

```

Attachments can also be returned from an operation, but at present only one attachment can be returned as the return parameter.

## SOAP messages with attachments - Working with types and type mappings

By default, attachments are passed into the Web Services Invocation Framework (WSIF) as `DataHandler` objects. If the part on the message that is the `DataHandler` object maps to a `<mime:part>` tag in the WSDL, then WSIF automatically maps the fully qualified name of the WSDL type to the `DataHandler` class and sets up that type mapping with the SOAP provider.

In your WSDL, you might have defined a schema for the attachment (for instance as a `binary[]` type). WSIF silently ignores this mapping and treats the attachment as a `DataHandler` object, unless you explicitly issue a `mapType()` method. WSIF lets the SOAP provider set the MIME content type based on the type of the `DataHandler` object, instead of the `type` attribute specified for the `<mime:content>` tag in the WSDL.

## Interacting with the J2EE container in WebSphere Application Server

Interaction with a container is limited to the following aspects:

- Using the application server administrative console to define Web services to WebSphere Application Server. This task is described in *Using the Java Naming and Directory Interface (JNDI) and WSIF system management and administration*. As part of the definition of a service, the administrator might define a “preferred port”.
- Using the Web Services Invocation Framework (WSIF) to make log and trace calls to the J2EE services in WebSphere Application Server, as described in *Trace and logging for WSIF*.
- Using WSIF providers to access Java 2 platform, Enterprise Edition (J2EE) services. For example using the EJB provider to access the Java Naming and Directory Interface (JNDI) and make calls to remote enterprise beans.
- Using WSIF to wrap the use of container services so that, when WSIF is run in an unmanaged (thin) environment, the operation can succeed.

## Running WSIF as a client

The Web Services Invocation Framework (WSIF) runs in the WebSphere Application Server application client container, and in similar clients from other suppliers.

To simplify the process of launching client applications in the WebSphere Application Server application client, use the `launchClient` tool as described in *Running application clients*.

---

## WSIF system management and administration

The Web Services Invocation Framework (WSIF) is provided as a stand-alone JAR file named `wsif.jar`. The JAR file contains the core WSIF classes, and the Java, EJB, SOAP over HTTP and SOAP over JMS providers. Additional providers are packaged as separate JAR files.

When you install WebSphere Application Server, the `wsif.jar` file is put on the WebSphere or Java Virtual Machine (JVM) class path.

WSIF requires no further configuration. WSIF is a thin abstraction layer between application code and the relevant invocation infrastructure.

For specific information on other aspects of managing your WSIF system, see the following topics:

- Maintaining the WSIF properties file
- Enabling security for WSIF
- Trace and logging for WSIF
- Troubleshooting the Web Services Invocation Framework
- WSIF (Web Services Invocation Framework) messages

### Maintaining the WSIF properties file

The Web Services Invocation Framework (WSIF) properties are stored in the `wsif.jar` file, in a properties file named `wsif.properties`. This properties file is kept on the class path, so that WSIF can find it and the client administrator can use it to configure WSIF.

Here is a copy of the initial contents of the `wsif.properties` file. All the possible properties are listed and described.

```
Two properties are used to override which WSIFProvider is selected when there
exists multiple providers supporting the same namespace URI. These properties are:
#
wsif.provider.default.CLASSNAME=N
wsif.provider.uri.M.CLASSNAME=URI
#
CLASSNAME is the WSIFProvider class name
N is the number of following default wsif.provider.uri.M.CLASSNAME properties
M is a number from 1 to N to uniquely identify each wsif.provider.uri.M.CLASSNAME
property key.
For example the following two properties would override the default SOAP provider
to be the Apache SOAP provider:
#
wsif.provider.default.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=1
wsif.provider.uri.1.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=\
http://schemas.xmlsoap.org/wsdl/soap/
#

maximum number of milliseconds to wait for a response to a synchronous request.
Default value if not defined is to wait forever.
wsif.syncrequest.timeout=10000

maximum number of seconds to wait for a response to an async request.
if not defined on invalid defaults to no timeout
wsif.asyncrequest.timeout=60
```

### Enabling security for WSIF

The Web Services Invocation Framework (WSIF) interacts with a security manager in the following ways:

- WSIF runs in the Java 2 platform, Enterprise Edition (J2EE) security context without modification.
- When WSIF is run under a J2EE container, port implementations can use the security context to pass on security tokens or credentials as necessary.

- WSIF implementations can automatically convert J2EE security context into appropriate context for onward services.

For WSIF to interact effectively with the WebSphere Application Server security manager, enable the following permission in the `was.policy` file: **FilePermission** to load the WSDL. This permission is required when a WSDL file is referred to using the `file://` protocol.

## Troubleshooting the Web Services Invocation Framework

For information on resolving WebSphere-level problems, see "Diagnosing and fixing problems" in the Information Center.

To identify and resolve Web Services Invocation Framework (WSIF)-related problems, you can use the standard WebSphere Application Server trace and logging facilities. If you encounter a problem that you think might be related to WSIF, you can check for error messages in the WebSphere Application Server administrative console, and in the application server `stdout.log` file. You can also enable the application server debug trace to provide a detailed exception dump.

A list of the WSIF run-time system messages, with details of what each message means, is provided in Message reference for WSIF.

Here is a checklist of major WSIF activities, with advice on common problems associated with each activity:

### Create service

Handcrafted WSDL can cause numerous problems. To help ensure that your WSDL is valid, use a tool such as WebSphere Studio to create your service.

### Define transport mechanism

For the Java Messaging Service (JMS), check that you have set up the Java Naming and Directory Interface (JNDI) correctly, and created the necessary connection factories and queues.

For SOAP, make sure that the deployment descriptor file `dds.xml` is correct - preferably by creating it using WebSphere Studio or similar tooling.

### Create client - Java code

Follow the correct format for creating a WSIF service, port, operation and message. For examples of correct code, see the Address Book Sample.

### Compile code (client and service)

Check that the build path against code is correct, and that it contains the correct levels of JAR files.

Create a valid EAR file for your service in preparation for deployment to a Web server.

### Deploy service

When you install and deploy the service EAR file, check carefully any messages given when the service is deployed.

### Server setup and start

Make sure that the WebSphere Application Server `server.policy` file (in the `/properties` directory) has the correct security settings. For more information, see Enabling security for WSIF.

### WSIF setup

Check that the `wsif.properties` file is correctly set up. For more information, see Maintaining the WSIF properties file.

### Run client

Either check that you have defined the class path correctly to include references to your client classes, WSIF JAR files and any other necessary JAR files, or (preferably) run your client using the WebSphere Application Server `launchClient` tool.

Here is a list of common errors, and information on their probable causes:

- **"No class definition" errors received when running client code.**

This problem usually indicates an error in the class path setup. Check that the relevant JAR files are included.

- **“Cannot find WSDL” error.**

Some likely causes are:

- The application server is not running.
- The server location and port number in the WSDL are not correct.
- The WSDL is badly formed (check the error messages in the application server `stdout.log` file).
- The application server has not been restarted since the service was installed.

You might also try the following checks:

- Can you load the WSDL into your Web browser from the location specified in the error message?
- Can you load the corresponding WSDL binding files into your Web browser?

- **Your Web service EAR file does not install correctly onto the application server.**

It is likely that the EAR file is badly formed. Verify the installation by completing the following steps:

- For an EJB binding, run the WebSphere Application Server tool `\bin\dumpnamespace`. This tool lists the current contents of the JNDI directory.
- For a SOAP over HTTP binding, open the `http://pathToServer/WebServiceName/admin/list.jsp` page (if you have the SOAP administration pages installed). This page lists all currently installed Web services.
- For a SOAP over JMS binding, complete the following checks:
  - Check that the queue manager is running.
  - Check that the necessary queues are defined.
  - Check the JNDI setup.
  - Use the “display context” option in the `jmsadmin` tool to list the current JNDI definitions.
  - Check that the Remote Procedure Call (RPC) router is running.

- **There is a permissions problem or security error.**

Check that the WebSphere Application Server `server.policy` file (in the `/properties` directory) has the correct security settings. For more information, see *Enabling security for WSIF*.

- **Using WSIF with multiple clients causes a SOAP parsing error.**

Before you deploy a Web service to WebSphere Application Server, you must decide on the scope of the Web service. The deployment descriptor file `dds.xml` for the Web service includes the following line:

```
<isd:provider type="java" scope="Application"
```

You can set the `Scope` attribute to `Application` or `Session`. The default setting is `Application`, and this value is correct if each request to the Web service does not require objects to be maintained for longer than a single instance. If `Scope` is set to `Application` the objects are not available to another request during the execution of the single instance, and they are released on completion. If your Web service needs objects to be maintained for multiple requests, and to be unique within each request, you must set the scope to `Session`. If `Scope` is set to `Session`, the objects are not available to another request during the life of the session, and they are released on completion of the session. If scope is set to `Application` instead of `Session`, you might get the following SOAP error:

```
SOAPException: SOAP-ENV:ClientParsing error, response was:
FWK005 parse may not be called while parsing.;
nested exception is:
```

```
[SOAPException: faultCode=SOAP-ENV:Client; msg=Parsing error, response was:
```

```
FWK005 parse may not be called while parsing.;
targetException=org.xml.sax.SAXException:
FWK005 parse may not be called while parsing.]
```

- **5.1+ Using the same names for JMS messaging queues and queue connection factories that run on application servers on different machines can cause JNDI lookup errors.** You should not use the same names for messaging queues and queue connection factories that run on application servers on different machines, because WSIF always looks first for JMS destinations locally, and only uses the full JNDI reference if it cannot find the destination locally. For example, if you run a Web service on a remote machine, and have an application server running locally that uses the same names

for the messaging queues and queue connection factories, then WSIF will find and use the local queues even if the remote JNDI destination is provided in full in the WSDL service definition.

## Trace and logging for WSIF

If you want to enable trace for the Web Services Invocation Framework (WSIF) API within WebSphere Application Server, and have trace, stdout and stderr for the application server written to a well-known location, see "Enabling trace" in the Information Center.

WSIF offers trace points at the opening and closing of ports, the invocation of services, and the responses from services.

To trace the WSIF API, you need to specify the following trace string:

```
wsif=all=enabled
```

WSIF also includes a SimpleLog utility through which you can run trace when using WSIF outside of WebSphere Application Server. To enable this utility, complete the following steps:

1. Create a file named `commons-logging.properties` with the following contents:

```
org.apache.commons.logging.LogFactory=org.apache.commons.logging.impl.LogFactoryImpl
org.apache.commons.logging.Log=org.apache.commons.logging.impl.SimpleLog
```

2. Create a file named `simplelog.properties` with the following contents:

```
org.apache.commons.logging.simplelog.defaultlog=trace
org.apache.commons.logging.simplelog.showShortLogname=true
org.apache.commons.logging.simplelog.showdatetime=true
```

3. Put both these files, and the `commons-logging.jar` file, on the class path.

The SimpleLog utility writes trace to the `System.err` file.

## WSIF (Web Services Invocation Framework) messages

This topic contains a list of the WSIF run-time system messages, with details of what each message means.

WebSphere system messages are logged from a variety of sources, including application server components and applications. Messages logged by application server components and associated IBM products start with a unique message identifier that indicates the component or application that issued the message.

For more information about the message identifier format, see the topic "Message reference" in the Information Center.

### **WSIF0001E: An extension registry was not found for the element type "{0}"**

**Explanation:** Parameters: {0} element type. No extension registry was found for the element type specified.

**User Response:** Add the appropriate extension registry to the port factory in your code.

### **WSIF0002E: A failure occurred in loading WSDL from "{0}"**

**Explanation:** Parameters: {0} location of the WSDL file. The WSDL file could not be found at the location specified or did not parse correctly

**User Response:** Check that the location of the WSDL file is correct. Check that any network connections required are available. Check that the WSDL file contains valid WSDL.

### **WSIF0003W: An error occurred finding pluggable providers: {0}**

**Explanation:** Parameters: {0} specific details about the error. There was a problem locating a WSIF pluggable provider using the J2SE 1.3 JAR file extensions to support service providers architecture. The WSIF trace file will contain the full exception details.

**User Response:** Verify that a META-INF/services/org.apache.wsif.spi.WSIFProvider file exists in a provider jar, that each class referenced in the META-INF file exists in the class path, and that each class implements org.apache.wsif.spi.WSIFProvider. The class in error will be ignored and WSIF will continue locating other pluggable providers.

**WSIF0004E: WSDL contains an operation type “{0}” which is not supported for “{1}”**

**Explanation:** Parameters: {0} name of the operation type specified. {1} name of the portType for the operation. An operation type which is not supported has been specified in the WSDL.

**User Response:** Remove any operations of the unsupported type from the WSDL. If the operation is required then make sure all messages have been correctly specified for the operation.

**WSIF0005E: An error occurred when invoking the method “{1}” . (“{0}” )**

**Explanation:** Parameters: {0} name of communication type. For example EJB or Apache SOAP. {1} name of the method that failed. An error was encountered when invoking a method on the Web service using the communication shown in brackets.

**User Response:** Check that the method exists on the Web service and that the correct parts have been added to the operation as described in the WSDL. Network problems might be a cause if the method is remote and so check any required connections.

**WSIF0006W: Multiple WSIFProvider found supporting the same namespace URI “{0}” . Found (“{1}” )**

**Explanation:** Parameters: {0} the namespace URI. {1} a list of the WSIFProvider found.. There are multiple org.apache.wsif.spi.WSIFProvider classes in the service provider path that support the same namespace URI.

**User Response:** A following WSIF0007I message will be issued notifying which WSIFProvider will be used. Which WSIFProvider is chosen is based on settings in the wsif.properties file, or if not defined in the properties, the last WSIFProvider found will be used. See the wsif.properties file for more details on how to define which provider should be used to support a namespace URI.

**WSIF0007I: Using WSIFProvider “{0}” for namespaceURI “{1}”**

**Explanation:** Parameters: {0} the classname of the WSIFProvider being used. {1} the namespaceURI the provider will be used to support.. Either a previous WSIF0006W message has been issued or the SetDynamicWSIFProvider method has been used to override the provider used to support a namespaceURI.

**User Response:** None. See also WSIF0006W.

**WSIF0008W: WSIFDefaultCorrelationService removing correlator due to timeout. ID:“{0}”**

**Explanation:** Parameters: {0} the ID of the correlator being removed from the correlation service. A stored correlator is being removed from the correlation service due to its timeout expiring.

**User Response:** Determine why no response has been received for the asynchronous request within the timeout period. The wsif.asyncrequest.timeout property of the wsif.properties file defines the length of the timeout period.

**WSIF0009I: Using correlation service - “{0}”**

**Explanation:** Parameters: {0} the name of the correlation service being used. This identifies the name of the correlation service that will be used to process asynchronous requests.

**User Response:** None. If a correlation service other than the default WSIF supplied one is required, ensure that it is correctly registered in the JNDI java:comp/wsif/WSIFCorrelationService namespace.

**WSIF0010E: Exception thrown while processing asynchronous response - “{0}”**

**Explanation:** Parameters: {0} the error message string of the exception. While processing the response from an executeRequestResponseAsync call an exception was thrown.

**User Response:** Use the exception error message string to determine the cause of the error. The WSIF trace will have more details on the error including the exception stack trace.

**WSIF0011I: Preferred port “{0}” was not available**

**Explanation:** Parameters: {0} the user’s preferred port. The preferred port set by the user on org.apache.wsif.WSIFService is not available

**User Response:** None unless this message appears for long periods of time in which case the user might want to pick a different port as their preferred port.

---

## WSIF API

The WSIF API supports the invocation of services defined in WSDL. WSIF is intended for use in both WSIF clients and Web service intermediaries.

The WSIF API is driven by the abstract service description in WSDL; it is completely independent of the actual binding used. This independence makes the API more natural to work with because it uses WSDL terms to refer to message parts, operations, and so on.

The WSIF API was designed for the WSDL usage model: Pick a port that supports the port type needed, then invoke the operation by providing the necessary abstract input message consisting of the required parts, without worrying about how the message is mapped to a specific binding protocol.

Other Web service APIs, for example SOAP APIs, are not designed on WSDL, but for a specific binding protocol with its associated syntax; for example, target URIs and encoding styles.

The WSIF API main interfaces are described in the following topics:

- Creating a message for sending to a port (the `WSIFMessage` interface).
- WSIF API reference: Finding a port factory or service (the `WSIFService` interface and the `WSIFServiceFactory` class).
- WSIF API reference: Using ports (the `WSIFPort` interface and the `WSIFOperation` interface).

**Note:** You must ensure that your application uses only one thread to call WSIF.

For additional technical details of the WSIF API, see the WSIF Javadoc.

### WSIF API reference: Creating a message for sending to a port

For message management (that is, message construction and parsing) the underlying API is modeled on WSDL semantics. There is a simple and direct mapping from the WSDL model to the Web Services Invocation Framework (WSIF) classes.

In WSDL, a message describes the abstract type of the input or output to an operation. The corresponding WSIF class is `WSIFMessage`, which represents in memory the actual input or output of an operation. A `WSIFMessage` class is a container for a set of named parts. The `WSIFMessage` interface separates the actual representation of the data from the abstract type defined by WSDL. WSDL defines messages as XML schema types. There are two natural ways to represent a WSDL message in a run-time environment:

- The generated Java class, based on a WSDL to Java mapping such as that provided by a Java API for XML-based remote procedure call (JAX-RPC).
- The XML representation of the data, for example using SOAP Encoding.

Each option offers benefits in different scenarios. The Java class is the natural approach when WSIF is used in a standard Java client. However, in other scenarios where WSIF is used in an intermediary, it might be more efficient to keep a WSDL message in the SOAP encoded format.

The style used to define messages must be consistent within the message, so all the parts in one message must be consistent. A string - `getRepresentationStyle()` - always returns `null`. This indicates that parts on this `WSIFMessage` class are represented as Java objects.

You add parts to a `WSIFMessage` class with the `setObjectPart` or `setTypePart` methods. Each part is named. Part names within a message are unique. If you set a part more than once, the last setting is the one that is used.

You retrieve parts by name from a `WSIFMessage` class with the `getObjectPart` or `getTypePart` methods. If the named part does not exist, the method returns a `WSIFException` exception.

You can use Iterators to retrieve parts from the message through the `getParts()` and `getPartNames()` methods.

The order in which you set the parts is not important, but the message implementation might be more efficient if the parts are set in the parameter order specified by WSDL.

WSIFMessage classes are cloneable and serializable. If the parts set are not cloneable, the implementation can try to clone them using serialization. If the parts are not serializable either, then a `CloneNotSupportedException` exception is thrown if cloning is attempted.

WSIFMessage classes can be sent between Java Virtual Machines (JVMs).

In addition to the containing parts, a WSIFMessage class also has a message name. This is required for operation overloading, which is supported by WSDL and WSIF.

Here is the Javadoc for the WSIFMessage interface.

## WSIF API reference: Finding a port factory or service

To find a port you use the WSIFService interface, which is a factory for ports.

The port factory models and supports the WSDL approach in which a service is available on one or more ports. The factory hides the implementation of the port from the user. The Web Services Invocation Framework (WSIF) supports dynamic ports that are based on a particular protocol and transport, and configured using the WSDL at run-time. For example, the dynamic SOAP port can invoke any SOAP service based on the WSDL description of that service. Using this service you can hide and modify the set of available ports at run-time.

Here is the WSIFService interface.

To find a service from a WSDL document at a Web address, or from a code-generated code base, you can use the WSIFServiceFactory class.

### WSIFService interface

The WSIFService interface is responsible for generating an instance of the WSIFOperation interface to use for a particular invocation of a service operation.

The Web Services Invocation Framework (WSIF) service stores a list of providers that can each generate a WSIF operation for a particular WSDL binding. This service looks up providers by the provider type. For example the service knows about one provider that handles SOAP ports and other providers that handle Java ports that you define. In a managed environment, the container can configure the WSIFService interface.

Here is the Javadoc for the WSIFService interface.

A WSIFService implementation can choose a preferred port based on a number of criteria. The WSIFService implementation can set the preferred port, or it can be set by calling the `setPreferredPort` method.

The `getPort` method returns an instance of the WSIFPort class that is used to invoke a service on the port. Variants of the `getPort` method are used to define the characteristics of the port to be created:

- the `getPort` method with no arguments returns the preferred port.
- the `getPort` method with a string argument returns the port named by the string containing the WSDL identifier for the selected port.

The return value is `null` if the port name is not valid.

If a port is chosen (either by the `WSIFService` implementation, or by the `setPreferredPort` method), then the `WSIFService` implementation validates that the relevant provider exists and is configured. If the provider fails this validation check, the `WSIFService` interface chooses any other port for which a provider is defined. For example, if the preferred port is SOAP over JMS but the JMS libraries are not available, then WSIF chooses another port. If no preferred port is set, or the preferred port is not available, the `WSIF` implementation chooses the first available port listed in the WSDL.

The `getAvailablePortNames()` method returns, as an iteration of strings, the list of WSDL port names filtered by the set of available providers.

The `getDefinition()` method returns the WSDL definition for the service. If the WSDL definition is not available, this method returns `null`.

### **WSIFServiceFactory class**

To find a service from a WSDL document at a Web address, or from a code-generated code base, you can use the `WSIFServiceFactory` class.

**Note:** When you create a `WSIFService` interface from a `WSIFServiceFactory` class, you can specify a `ClassLoader` object to use in locating the WSDL file. You need to specify this object when the WSDL file is in a JAR file. In such a case, specify the location of the WSDL file relative to the root of the JAR file, using forward slashes (/) with the preceding slash removed.

For example:

```
com/myCompany/wsd1/MyWSDLFile.wsdl
```

rather than

```
/com/myCompany/wsd1/MyWSDLFile.wsdl
```

Here is the Javadoc for the `WSIFServiceFactory` class.

The `WSIFServiceFactory` class returns `null` if no service is found with that identifier.

### **WSIF API reference: Using ports**

A `WSIFPort` interface handles the details of invoking an operation. The port provides access to the actual implementation of the service.

A WSDL document can provide many different WSDL bindings, and these bindings can drive multiple ports. The client can choose a port, the service stub can choose a port, or the Web Services Invocation Framework (WSIF) can choose a default port.

The port offers an interface to retrieve an `Operation` object. A `WSIFOperation` interface offers the ability to execute the given operation.

If the port is serialized and deserialized at a later time, then WSIF ensures that the client provides the correct information to the server to identify the instance. If the server instance is no longer available, then it is up to the server to decide whether to throw a fault or provide a new instance. That behavior can depend on the type of service.

For example, for an enterprise bean the `WSIFPort` interface stores the EJB Home, and uses it to select the bean before each invocation. It is the responsibility of the client to serialize or maintain the port instance if it wants instance support. The client must create a new operation and messages for each invocation.

Here is the `WSIFPort` interface.

Here is the WSIFOperation interface.

### **WSIFPort interface**

The port implements a factory method for the WSIFOperation interface.

Here is the Javadoc for the WSIFPort interface.

The createOperation(String) method returns a new instance of a WSIFOperation object. If the operationName value is not valid or the operation is overloaded, then the method throws an exception.

The createOperation(String, String, String) method supports overloaded WSDL operations. You can overload based on the input parameters, but not on the output parameters.

It is the duty of the client to call the close method when a port is no longer in use. In many cases, where the transport is sessionless, like HTTP, this has no effect. However, if the port is using a session-based protocol such as MQSeries, Java Messaging Service (JMS), or External Call Interface (ECI), this supports the port in caching an open connection to the server and then closing it as required. Responsibly-written applications will call the close method if appropriate.

### **WSIFOperation interface**

You use the WSIFOperation interface to invoke a service based on a particular binding.

The WSIFOperation interface is the run-time representation of an operation. This interface provides methods to create input, output, and fault messages, and to invoke the operation.

Here is the Javadoc for the WSIFOperation interface.

#### **createInputMessage, createOutputMessage and createFaultMessage**

These are factory methods to create the messages required by the invocation methods. All invocation methods require an input message.

#### **executeRequestResponseOperation**

This method invokes “In Out” operations.
