#### **executeInputOnlyOperation**

This method invokes “In only” operations.

#### **executeRequestResponseOperation**

If this method is used for invocation, then an output and a fault message are instantiated and passed on the call to the method. If the method returns true, then the output message contains the response message. If the message returns false, then a fault occurred and is returned in the fault message.

#### **executeRequestResponseAsync**

This method allows “In Out” operations to be invoked with the reply handled using an alternate thread. Use of this method is discussed further in WSIFOperation - Asynchronous interactions.

#### **setContext and getContext**

Use of these methods is discussed in WSIFOperation - Context.

All of the **executeNnnn** methods fail with an exception if there is an error in processing the request in the WSIF provider.

Setting the timeouts for synchronous and asynchronous operations is discussed in WSIFOperation - Synchronous and asynchronous timeouts.

**WSIFOperation - Context:** Although WSDL does not define context, a number of uses of the Web Services Invocation Framework (WSIF) require the ability to pass context to the port that is invoking the service. For example, a SOAP over HTTP port might require an HTTP user name and password. This

information is specific to the invocation, but is not a parameter of the service. In general, context is defined as a set of name-value pairs. However, because Web services tend to define the types of data using XML schema types, WSIF represents the name-value pairs of the context using the same representation that WSIFMessage classes use; that is a set of named parts, each of which equates to an instance of an XML schema type.

You use the WSIFOperation interface setContext and getContext methods to pass context information to the binding. The port implementation can use this context, for example to update a SOAP header. There is no definition of how a port can utilize the context.

The parameter of the setContext and getContext methods is a WSIFMessage interface, and this interface has named parts defining the context information. The WSIFConstants class defines constants for the part names that can be set in a context WSIFMessage interface.

The following code fragment shows how to set the user name and password for HTTP basic authentication:

```
// set a basic authentication header
WSIFMessage headers = new WSIFDefaultMessage();
headers.setObjectPart(WSIFConstants.CONTEXT_HTTP_USER, "user name");
headers.setObjectPart(WSIFConstants.CONTEXT_HTTP_PSWD, "password");
operation.setContext(headers);
```

The WSIFOperation interface ignores context parts that it does not support. For example, the previous code is ignored by the WSIF Java provider.

The WSIFConstants class includes the following constants that can be used for context part names:

- CONTEXT\_HTTP\_USER
- CONTEXT\_HTTP\_PSWD
- CONTEXT\_SOAP\_HEADERS

The HTTP header values are expected to be of type String, and the SOAP header value is expected to be of type java.util.List, which should contain entries of type org.w3c.dom.Element.

***WSIFOperation - Asynchronous interactions reference:*** The Web Services Invocation Framework (WSIF) supports asynchronous operation. In this mode of operation, the client puts the request message as part of one transaction, and carries on with the thread of execution. The response message is then handled by a different thread, with a separate transaction. The SOAP over JMS and native JMS providers are the only WSIF providers that currently support asynchronous operation.

The WSIFPort class uses the supportsAsync method to test if asynchronous operation is supported.

An asynchronous operation is initiated with the WSIFOperation interface executeRequestResponseAsync method. This method lets a Remote Procedure Call (RPC) method be invoked asynchronously. The method returns before the operation is completed, and the thread of execution continues.

The response to the asynchronous request is processed by the WSIFOperation interface fireAsyncResponse or processAsyncResponse methods.

To initiate the request, there are two forms of the executeRequestResponseAsync method:

```
public WSIFCorrelationId executeRequestResponseAsync
 (WSIFMessage input, WSIFResponseHandler handler)
```

and

```
public WSIFCorrelationId executeRequestResponseAsync (WSIFMessage input)
```

**executeRequestResponseAsync(WSIFMessage input, WSIFResponseHandler handler)**

This method takes an input message and a WSIFResponseHandler handler. The handler is

invoked on another thread when the operation completes. When using this method the client listener calls the `fireAsyncResponse` method, which then calls the `WSIFResponseHandler` interface `executeAsyncResponse` method. Here is the Javadoc for the `WSIFResponseHandler` interface.

#### **executeRequestResponseAsync(WSIFMessage input)**

This method only takes an input message, and does not use a response handler. The client listener processes the response by calling the `WSIFOperation` interface `processAsyncResponse` method. This process updates the `WSIFMessage` output and fault messages with the result of the request.

WSIF supports correlation between the asynchronous request and response. When the request is sent, the `WSIFOperation` object is serialized into the `WSIFCorrelationService` object. The `executeRequestResponseAsync` methods return a `WSIFCorrelationId` object which identifies the serialized `WSIFOperation` object. The client listener can use this to match a response to a particular request.

The correlation service is located with the `WSIFCorrelationServiceLocator` class `getCorrelationService()` method in the `org.apache.wsif.utils` package.

In a managed container a default correlation service is defined in the default Java Naming and Directory Interface (JNDI) namespace using the name: `java:comp/wsif/WSIFCorrelationService`. If this correlation service is not available, then WSIF uses the `WSIFDefaultCorrelationService`.

Here is the Javadoc for the `WSIFCorrelationService` interface.

and this is the correlator ID:

```
public interface WSIFCorrelator extends Serializable {
 public String getCorrelationId();
}
```

The client must implement its own response message listener or message data base so that it can recognize the arrival of response messages. This client implementation manages the correlation of the response message to the request and call of one of the asynchronous response processing methods. As an example of the requirement for a client listener, the following code fragment shows what can be in the `onMessage` method of a Java Messaging Service (JMS) listener:

```
public void onMessage(Message msg) {
 WSIFCorrelationService cs = WSIFCorrelationServiceLocator.getCorrelationService();
 WSIFCorrelationId cid = new JmsCorrelationId(msg.getJMSCorrelationID());
 WSIFOperation op = cs.get(cid);
 op.fireAsyncResponse(msg);
}
```

#### ***WSIFOperation - Synchronous and asynchronous timeouts reference:***

When you use the Web Services Invocation Framework (WSIF) with the Java Messaging Service (JMS) you can set timeouts for synchronous and asynchronous operations.

Default values for these timeouts are defined in the WSIF properties file:

```
maximum number of milliseconds to wait for a response to a synchronous request.
Default value if not defined is to wait forever.
wsif.syncrequest.timeout=10000

maximum number of seconds to wait for a response to an async request.
if not defined on invalid defaults to no timeout
wsif.asyncrequest.timeout=60
```

If you use these default values, a synchronous request (such as a WSIFOperation interface executeRequestResponseOperation method call) times out after ten seconds, and an asynchronous request (such as a WSIFOperation interface executeRequestResponseAsync method call) times out after sixty seconds.

**Note:**

The code that processes both of these timeout values uses milliseconds as its unit of time. The WSIFProperties class getAsyncTimeout method multiplies the wsif.asyncrequest.timeout value by 1000, to convert the value from seconds to milliseconds.

You can override these default values for a given request by setting a JMS property on the operation request with the <jms:property> and <jms:propertyValue> WSDL elements. Set the name of the property to be the name of the timeout from the WSIF properties file.

The following example sets synchronous requests to time out after two minutes (120 seconds):

```
<jms:propertyValue name="wsif.syncrequest.timeout" type="xsd:string" value="120000"/>
```

and the following example disables asynchronous timeouts (a value of zero means wait forever):

```
<jms:propertyValue name="wsif.asyncrequest.timeout" type="xsd:string" value="0"/>
```

When an asynchronous timeout expires, no listener or message data base waiting for the response is notified. The asynchronous timeout is only used to tell the correlation service that the stored WSIFOperation can be deleted.

---

## Chapter 11. Enabling the IBM WebSphere UDDI Registry

Welcome to the IBM WebSphere UDDI Registry.

Use the table of contents (on the left and below) to view the various topics for a specific product or technology. Select the topic you are interested in to either open documentation locally or find information about how to locate documentation.

### UDDI Registry terminology

The directory location of the WebSphere Application Server is referred to as **<AppServer-install-dir>** and the directory location of the WebSphere Deployment manager as **<DeploymentManager-install-dir>**. The default locations are:

#### Windows

**<AppServer-install-dir>**

C:\Progra~1\WebSphere\AppServer\

**<DeploymentManager-install-dir>**

C:\Progra~1\WebSphere\DeploymentManager\

#### Linux/Solaris/HP Platforms

**<AppServer-install-dir>**

/opt/WebSphere/AppServer/

**<DeploymentManager-install-dir>**

/opt/WebSphere/DeploymentManager/

#### AIX Platform

**<AppServer-install-dir>**

/usr/WebSphere/AppServer/

<DeploymentManager-install-dir>  
/usr/WebSphere/DeploymentManager/

#### z/OS Platform

<AppServer-install-dir>  
/WebSphere390/V5R0M0/AppServer/  
<DeploymentManager-install-dir>  
/WebSphere390/V5R0M0/DeploymentManager/

## UDDI Registry definitions

### bindingTemplate

Technical information about a service entry point and construction specifications.

### businessEntity

Information about the party who publishes information about a family of services.

### businessService

Descriptive information about a particular service.

### publisherAssertion

Information about a relationship between two parties, asserted by one or both.

### tModel

Short for technical model.

A tModel is a data structure representing a reusable concept, such as a Web service type, a protocol used by Web services, or a category system.

tModel keys within a service description are a technical "fingerprint" that you can use to trace the compatibility origins of a given service. They provide a common point of reference that allows you to identify compatible services.

tModels are used to establish the existence of a variety of concepts and to point to their technical definitions. tModels that represent value sets such as category, identifier, and relationship systems are used to provide additional data to the UDDI core entities to facilitate discovery along a number of dimensions. This additional data is captured in keyedReferences that reside in category Bags, identifierBags, or publisherAssertions. The tModelKey attributes in these keyedReferences refer to the value set that relates to the concept or namespace being represented. The keyValues contain the actual values from that value set. In some cases keyNames are significant, such as for describing relationships and when using the general keywords value set. In all other cases, however, keyNames are used to provide a human readable version of what is in the keyValue.

---

## An overview of IBM UDDI Registries

The Universal Description, Discovery and Integration (UDDI) specification defines a way to publish and discover information about Web services. The term 'Web service' describes specific business functionality exposed by a company, usually through an Internet connection, to allow another company, or its subsidiaries, or software program to use the service.

### Universal Business Registries (IBM UBR)

The IBM Universal Business Registry is one of a group of Web-based registries that expose information about a business or other entity and its technical interfaces (or APIs). These registries are run by multiple Operator Sites, and can be used by anyone who wants to make information available about one or more businesses or entities, as well as anyone who wants to find that information. Although there are Universal Business Registries (sometimes referred to as 'public UDDI registries') hosted worldwide, including one hosted by IBM, enterprises may wish to host their own internal registries behind their firewall to better manage their internal implementation of Web services.

For more detailed information about UDDI in general visit <http://www.uddi.org>

## IBM WebSphere UDDI Registry

The IBM WebSphere UDDI Registry is a directory for Web services that is implemented using the UDDI specifications. In contrast with the IBM UBR, this component of WebSphere Network Deployment is a product offering for companies or industries to implement.

A critical component of IBM's dynamic e-business infrastructure, IBM WebSphere UDDI Registry solves the problem of discovery of technical components for an enterprise and its partners by:

- Providing control, flexibility and confidentiality so that an enterprise can protect its e-business investments
- Increasing efficiency by making it easier to identify technical assets
- Leveraging existing infrastructures

For example, the IBM WebSphere UDDI Registry could be used in the following way within a large enterprise:

A company has a legacy application that provides telephone numbers and Human Resources (HR) information of employees. This is turned into a Web service and published to the registry. A developer in the same company needs to write an application for a procurement function that also needs to provide HR information to the supplier. The application should allow the supplier to have access to the employee account codes once the employee provides his name or serial number. Before Web Services, the developer had three choices:

1. Would not have known about the similar application
2. Knew about it but could not reuse due to technical barriers
3. Knew about it and reused only after significant time and negotiation

With UDDI, the developer can search for the "web service" and reuse the existing technical component in their new application for the supplier in a matter of minutes. The developer saves time and gets the application up and running sooner than they would have otherwise -- increasing efficiency and saving the company time and money. The IBM WebSphere UDDI Registry is the first version 2 standard-compliant UDDI registry for private enterprise work. The IBM WebSphere UDDI Registry:

- Supports the public UDDI V2.0 standard
- Leverages the proven, reliable WebSphere Application Server technology
- Uses a relational database, such as DB2, for its persistent store.

---

## Migrating from a previous version of IBM WebSphere UDDI Registry

### Migrating from the IBM WebSphere UDDI Registry on WebSphere Application Server 4.0

If you have previously installed the IBM WebSphere UDDI Registry V1.1 (or later refreshes) on WebSphere Application Server V4.0, take the following steps in order to migrate to the UDDI Registry that is available as part of WebSphere Application Server for Network Deployment.

1. If you have made any changes to the configuration properties in the file `uddi.properties`, which is located in the `properties` subdirectory of your WebSphere Application Server install tree, make a copy of this file (or make a note of all the changes), so that you can reapply the changes to the file after you have installed WebSphere Application Server V5.0.
2. If you have made any other configuration changes, for example to the UDDI user console style sheets or to the SOAP interface properties, make a note of them, and reapply them after upgrading to the new UDDI version.
3. Uninstall the IBM WebSphere UDDI Registry using Add/Remove Programs on Windows platforms, or `rpm -e IBMWebSphere-UDDI` on Unix platforms. This removes the application, but preserves the UDDI Registry database.
4. If you wish to continue using DB2 as the persistence store for the UDDI Registry, and you have any data in the UDDI Registry that you wish to preserve, you should not run the DB2 setup wizard to

create the DB2 version of the UDDI Registry database, but will instead be able to continue using the database that you already have. However, if you do run the wizard, you are prompted to keep the database or overwrite it.

5. Now follow the instructions on installing (or upgrading) IBM WebSphere Application Server and "Installing the UDDI Registry component".
6. After completing the installation procedure, you should edit the `uddi.properties` file to reflect any changes that you require to the configuration properties. You should **not** replace this file with your previous copy from the IBM WebSphere UDDI Registry V1.1 or later refreshes. You can also reapply any other configuration changes as necessary.
7. If you are migrating from Version 1.1 of the IBM WebSphere UDDI registry, then there have been a few minor changes to the EJB interface which means that you may need to modify your EJB client applications. If you are migrating from later refreshes of the IBM WebSphere UDDI Registry (such as Version 1.1.1), then you should not need to make any changes to your EJB clients.

The changes for Version 1.1 relate to saving a new service through the EJB interface either using **saveBusiness** or **saveService**. You should not set the **serviceKey** before calling **saveBusiness** or **saveService**.

In the IBM WebSphere UDDI Registry V1.1 the term 'service type' was used to refer to a 'technical model' or 'tModel', for example, in various of the panels in the UDDI user console. This term has now been replaced by the term 'technical model'.

### 5.1+ Migrating from IBM WebSphere Network Deployment V5.0x - federated nodes - to Version 5.1

For a Network Deployment configuration with federated nodes, IBM WebSphere Application Server supplies facilities to migrate to Version 5.1 from Version 5.0x either as part of the installation process, or as a post installation procedure. For instructions on how to do this refer to "Migrating to Network Deployment" in the Information Center.

As part of the migration process, IBM WebSphere Application Server will automatically install the new UDDI version supplied in Version 5.1, but will migrate the `uddi.properties` (from your previous Version 5.0x system) for use in your new setup. If you are using DB2 as your persistence store, the same database used in Version 5.0x can be used in Version 5.1. Ensure your version of DB2 is supported by IBM WebSphere Application Server Version 5.1.

If you are using Cloudscape as your persistence store, you can also use the Version 5.0x database in Version 5.1 but you must review the Cloudscape instructions elsewhere in this Information Center for guidance on upgrading to a supported Cloudscape version.

By default, the newly migrated Application Server contains a JDBC provider that points to your 'old' pre-migration UDDI20 Cloudscape database (which is in your pre-migration WebSphere filing system). This is acceptable, however you may wish to copy your old UDDI20 database to the newly migrated Application Server filing system (in `<NewAppServer-install-dir>/bin/UDDI20`

In either case you will also need to make some updates to your JDBC provider to complete the migration, before starting the new Application Server. This can be done via the administration console.

- Update the JDBC provider resource as follows:
  - update the Classpath to point to the new location for `db2j.jar` which is `<NewAppServer-install-dir>/cloudscape/lib/db2j.jar`
- update the version 4 datasource for this
  - update the 'database name' path to point to the new location in the new Application Server, but only if you have moved it.
- update the custom properties
  - update the property 'database name' to point to the new location in the new Application Server, but only if you have moved it.

- add the new custom property 'connectionAttributes' with a value of 'upgrade=true'.

If you have made other configuration changes to the UDDI user console style sheets for example, or other SOAP interface properties, you will have to manually reapply them.

### **5.1 + Migrating from IBM WebSphere Application Server Version 5.0x to IBM WebSphere Application Server 5.1 in a single application server only environment**

In contrast with the Network Deployment migration, which is mostly automatic, some manual steps are required to upgrade from a WebSphere 5.0x single application server configuration to a WebSphere 5.1 single application server configuration.

In this case it is assumed that you have installed WebSphere Network Deployment to obtain the UDDI application and have installed UDDI into a standalone application server. It is assumed you wish to migrate your 5.0x application server only.

Refer to the migration instructions elsewhere in this Information Center (see "Migrating to Network Deployment") but here are the general steps you will need to follow:

- Stop the WebSphere 5.0x application server containing the UDDI
- Install IBM WebSphere Application Server Version 5.1 Network Deployment on to your system of choice. This will be needed to obtain the new UDDI application and associated files.
- Install IBM WebSphere Application Server Version 5.1 Application Server selecting the migration option. Once completed you will have a new 5.1 Application Server, with your configuration (other applications) migrated. This will include the UDDI application from your old 5.0x system.
- Copy across the new UDDI application and associated files from the **new** Version 5.1 Network Deployment to your new 5.1 Application Server. This is effectively following the same instructions as supplied in Installing and setting up a UDDI Registry, but in summary you will need to copy the following files and directories:
  - uddi.ear to **<NewAppServer-install-dir>\installableApps**
  - uddiresourcebundles.jar to **<NewAppServer-install-dir>\lib**
  - setupuddimessages.jar to **<NewAppServer-install-dir>\lib**
  - uddicloudscapeuserfunc.jar to **<NewAppServer-install-dir>\lib**
  - the UDDIReg/scripts directory to **<NewAppServer-install-dir>**

The uddi.properties file, including any modifications you have made are copied across by the migration process and requires no further action.

- **Database migration consideration**
  - **DB2 users.** If you are using DB2 as your persistence store, the same database used in Version 5.0x can be used in Version 5.1, but you must review the supporting software information to confirm your DB2 version is a supported level for IBM WebSphere Application Server Version 5.1
  - **Cloudscape users.** If you are using Cloudscape as your persistence store and want to continue to use the database (and the data in it) from your old WebSphere, copy your old UDDI20 to the newly migrated Application Server filing system (<NewAppServer-install-dir>/bin/UDDI20).
  - Start the new application server and run the appropriate appserversetupuddi.jacl command (for DB2 or Cloudscape) ensuring the paths refer to your new Version 5.1 Application Server. This installs the new Version 5.1 UDDI into your server. For details of the syntax of the appropriate commands see Setting up the UDDI Registry to use Cloudscape in a single Application Server or Setting up the UDDI Registry to use DB2 in a single Application Server and then return to this point.
- If you have made other configuration changes, to the UDDI user console style sheets for example or other SOAP interface properties, manually reapply them.
- Restart, and use, the new Application Server.

---

## Installing and setting up a UDDI Registry

If you wish to use the UDDI User Console using Internet Explorer as your Web browser, and using SSL, you must use Internet Explorer V5.5 with SP2 and security fix Q321232 (which must be applied in that order), or later.

If you are migrating from IBM WebSphere UDDI Registry running on an earlier version of WebSphere , read Migrating from a previous version of IBM WebSphere before installing the new product.

### Choice of database product to be used as the persistence store

The UDDI Registry application can use either DB2 or Cloudscape as the persistence store for the registry data.

- If you plan to use the UDDI Registry in production you must use DB2 as your persistence store.
- If you plan to use the UDDI Registry for development and testing purposes, you can also choose to use Cloudscape as your persistence store. Note that Cloudscape is not intended for production purposes.

### **Cloudscape Restriction**

Cloudscape Network Server Version 5.1 requires a WebSphere Version 5 datasource to utilize the multiple connection features. As IBM WebSphere UDDI Registry uses a WebSphere Version 4 datasource, this precludes other connections to the Cloudscape database when the UDDI Registry application is in the started state.

### Steps for this task

As part of the installation of the IBM WebSphere Application Server with Network Deployment option, you are given the option to install the "UDDI Registry", which is shown under Web Services. Having selected the UDDI Registry and installed the various files that make up the application, you have two choices as to the environment in which you run it:

1. Install the UDDI Registry application into the deployment manager cell using DB2 or Cloudscape as the database in which the UDDI Registry data will be held, selecting one of the application servers within the cell in which to run the UDDI Registry.
2. Install the UDDI Registry application directly into an application server using DB2 or Cloudscape as the database in which the UDDI Registry data will be held. If you choose this option, the application server on which you run the UDDI Registry must not be added into a deployment manager cell, as this would cause the file synchronization within the cell to remove the application.
3. It is also recommended that you execute `setupCmdline.bat` on Windows, or `./setupCmdline.sh` on Unix platforms, prior to executing any WebSphere commands.

In most cases you will probably choose option 1, and install the UDDI Registry into a deployment manager cell, but you might find that option 2, to install the UDDI Registry into a standalone application server, is useful for development or test purposes.

### **Note:**

1. Several WebSphere commands are used during the following procedures, some of which must execute on the DeploymentManager and some of which must execute on the target Application server. The instructions distinguish which is appropriate for each command. The WebSphere commands are in the bin subdirectory of the appropriate WebSphere install tree. To ensure correct operation of these commands, do one of the following:
  - Ensure that the appropriate bin subdirectory is in your path prior to executing the command
  - Change directory to the appropriate bin subdirectory
  - Fully qualify the path to the commands
2. It is recommended that you use the version of Java shipped with WebSphere and found in the `java/bin` subdirectory.

- It is also recommended that you execute `setupCmdline.bat` (on Windows) or `./setupCmdline.sh` (on Unix platforms) prior to executing any WebSphere commands.

The following table lists the UDDI Registry files, and the locations into which they are placed by the installation. The Location column shows the subdirectory under the WebSphere DeploymentManager install directory. For example, if you had installed IBM WebSphere Application Server with Network Deployment option onto a machine running Windows, and had used the default directory, then a location of `installableApps` would mean that the file had been placed into the `C:\Program Files\IBM\WebSphere\DeploymentManager\installableApps` directory. For Windows platforms, read the “/” directory separator in the location column as a “\” directory separation character.

Files	Purpose	Location
<code>uddi.ear</code>	The UDDI Registry application itself, which is packaged and runs as an enterprise application	<code>installableApps</code>
<code>uddi.properties</code>	Provides configuration properties for the UDDI Registry application	<code>properties</code>
<code>uddiresourcebundles.jar</code>	Contains system messages for the UDDI Registry application	<code>lib</code>
<code>uddicloudscapeuserfunc.jar</code>	Contains functions that are used by Cloudscape if the Cloudscape database is used with the UDDI Registry	<code>lib</code>
<code>setupuddi.jacl</code>	Administrative script to create a JDBC driver and datasource for the UDDI Registry, and to install the UDDI Registry application in a DeploymentManager Cell	<code>UDDIReg/scripts</code>
<code>setupuddimessages.jar</code>	Contains setup and install messages for the UDDI Registry application	<code>lib</code>
<code>removeuddi.jacl</code>	Administrative script to undo the effects of <code>setupuddi.jacl</code>	<code>UDDIReg/scripts</code>
<code>appserverremoveuddi.jacl</code>	Administrative script to undo the effects of <code>appserversetupuddi.jacl</code>	<code>UDDIReg/scripts</code>
<code>appserversetupuddi.jacl</code>	Administrative script to create a JDBC driver and datasource for the UDDI Registry, and to install the UDDI Registry application in a single, stand-alone, application server	<code>UDDIReg/scripts</code>
<code>SetupDB2UDDI.jar</code>	The 'UDDI DB2 Setup Wizard', to create and pre-load the UDDI Registry database if DB2 is to be used as the persistence store	<code>UDDIReg/scripts</code>
<code>UDDI20</code> (directory)	Cloudscape directory containing the UDDI Registry tables and pre-loaded data	<code>bin</code>
<code>uddiejbclient.jar</code>	Class library for use when writing an EJB client to access the UDDI Registry	<code>UDDIReg/ejb</code>
Various javadoc files	JAVADOC to describe the EJB interface to the UDDI Registry	<code>UDDIReg/ejb/javadoc</code>
<code>UDDITaxonomyTools.jar</code>	Provides tools for supporting custom taxonomies with the UDDI Registry	<code>UDDIReg/scripts</code>
<code>CustomTaxonomy.properties</code>	Provides configuration properties to be used the <code>UDDITaxonomyTools</code>	<code>UDDIReg/scripts</code>
<code>UDDIUtilityTools.jar</code>	Provides support for import/export of UDDI entities	<code>UDDIReg/scripts</code>
<code>UDDIUtilityTools.properties</code>	Provides configuration properties for the UDDI Utility Tools	<code>UDDIReg/scripts</code>

If you intend to run in a Deployment Manager Cell then complete the following task - **Installing the UDDI Registry into a deployment manager cell**

If you intend to run in a single WebSphere Application server, then complete the following task - **Installing the UDDI Registry into a single WebSphere Application Server**

Continue with Configuring the UDDI Registry.

## Installing the UDDI Registry into a deployment manager cell

The diagram following shows the configuration used for the Deployment Manager example configurations

that follow:

In this configuration, several nodes are federated to the Deployment Manager (dmgr) on myhome.headoffice.xyz.com, from which UDDI is deployed to the host myriad.headoffice.xyz.com.

These instructions assume that the installation has been performed into a clean environment. If you are installing into an existing deployment manager cell skip to step 6.

1. Install the WebSphere Application Server for Network Deployment package, and select Deployment Manager and UDDI Registry options (under Web Services).
2. Install one or more base application servers which will form the cell of servers. One of these should be the application server in which you plan to run an instance of the UDDI Registry. You can run more than one instance of the UDDI Registry within a cell of servers: the UDDI Registry application name is suffixed with the target node and server names to make it unique within the cell (See also "Advanced use of setupuddi.jacl"), but you can only run one UDDI instance within each application server.
3. Ensure that the target application server is stopped.
4. Run startManager (startManager.sh on Unix and Linux platforms) on the deployment manager node to start the deployment manager.
5. Run addNode (addNode.sh on Unix and Linux platforms) on each of the baseapplication server(s) to add it as a node into the cell. (How to run addNode is described elsewhere in the Information Center - see addNode command). For example: addnode myhome- where myhome is the IP name of your deployment manager host.
6. Copy the *uddiejbclient.jar* file and the EJB javadoc directory tree from the UDDIReg/ejb subdirectory of the deployment manager install tree onto any machine(s) where you will be creating EJB clients to access the UDDI Registry.
7. If you have any global configuration properties that are common to any UDDI Registries that you install into this cell, you can edit the *uddi.properties* file in the properties subdirectory of the

deployment manager install tree to set them up. (See the section on Configuring global UDDI properties for more details about the global configuration properties).

8. If required, edit the security permissions for the UDDI Registry application. You should only do so if you have a thorough understanding of Java 2 security issues, and the way in which security permissions are used by WebSphere. The permissions for the UDDI Registry application are set within the *was.policy* file, which is part of the *uddi.ear*. To see and change the contents of this file you should:

- a. On the deployment manager, copy the **uddi.ear** file from the installableApps subdirectory of the deployment manager install tree into a temporary directory.
- b. Un-jar the *uddi.ear* file (that is unpack *uddi.ear* using the 'jar -x' command).

For example:

```
jar -x uddi.ear
```

(This uses the jar command in the <DeploymentManager-install-dir>\java\bin subdirectory of the deployment manager, so you might need to fully qualify the path to the jar command.)

- c. You will find the *was.policy* file under the META-INF subdirectory that is created.

This will allow you to see the permissions which have been granted to the UDDI Registry application, and to make any changes that are necessary. Please note that if you make any errors in changing this file, then the UDDI Registry application might either fail to start, or will encounter errors when trying to execute UDDI requests.

- d. Re-jar the *uddi.ear* file using the jar command.

For example:

```
jar -cf uddi.ear .
```

**Note:** NOTE the space and the dot after *uddi.ear*)

(This uses the jar command in the <DeploymentManager-install-dir>\java\bin subdirectory of the deployment manager, so you might need to fully qualify the path to the jar command.)

- e. Copy the new *uddi.ear* back to the installableApps directory.
9. Note that if the target application server is running, this step will stop and restart it. If you are planning to use Cloudscape for the database in which the UDDI Registry will be held, please read the section "Setting up the UDDI Registry to use Cloudscape within a deployment manager cell" and then return to this point. If however, you plan to use DB2, then please refer to the section "Setting up the UDDI Registry to use DB2 within a deployment manager cell" and then return to this point.
10. Ensure that the UDDI Registry is configured appropriately for your installation, as described in the section on Configuring the UDDI Registry.
11. Start, or stop and restart, the target application server. This should also start the UDDI Registry application. If not, use the administrative console on the deployment manager to do so.  
On Unix and Linux platforms run the *db2profile* script before issuing the *startServer.sh* server1 command. This script is located within the DB2 instance's home directory under *SQLLIB* and you can invoke it by typing:

```
". /home/db2inst1/sqllib/db2profile"
```

**Note:** In the above example, notice that the '.' is followed by a single space character.

**Note:** On Unix and Linux platforms the DB2 user **must** have a *db2profile* at *\$HOME/sql/lib/db2profile*.

12. Your UDDI application is now ready to use. Go to the User Console section within this Information Center or any of the API sections.

### **Advanced use of setupuddi.jacl**

A number of symbols are defined at the top of the setupuddi.jacl script. These allow you to control the amount of logging that is performed, and to install multiple instances of the UDDI Registry within the same cell.

The symbols that you can edit are as follows:

- **logEnabled** - default setting is 1, which causes the progress of the script to be logged. Setting this symbol to 0 causes information logging to be suppressed, with only error messages being output.
- **overwriteExisting** - default setting is 1 which causes any existing installation of the UDDI Registry application to be overwritten. Setting this symbol to 0 would cause the existing installation to be left as is, but would allow other files used by the UDDI Registry to be updated. You are recommended to only change this setting under the guidance of IBM Service.
- **appName** - default setting is UDDIRegistry, which is the first part of the name used for the UDDI Registry application installed into the target server. To ensure uniqueness of application names within the cell, the full application name that will be used is `<appName>.<nodeName>.<server>`, where `<nodeName>` is the name of the target node and `<server>` is the name of the target server. You can change the first part of this (the `<appName>`) portion by changing the setting of this symbol before running setupuddi.jacl, although it is generally recommended that you do not change this value.

Continue with Configuring the UDDI Registry.

## Setting up the UDDI Registry to use Cloudscape within a deployment manager cell

If you plan to use Cloudscape for the database in which the UDDI Registry data will be held, perform this task to setup and install the UDDI Registry database to use the supplied Cloudscape database.

See "Choice of database product to be used as the persistence store" to decide which database product you should use as your persistence store before proceeding further with this task.

This task is part of a parent task: Installing the UDDI Registry into a deployment manager cell. You should complete this task at the appropriate step in the parent task.

This task configures Cloudscape on the host where you want to run the UDDI Registry. Cloudscape is supplied with WebSphere Application Server.

In this task you will invoke a script called setupuddi.jacl, specifying the target node and application server into which the UDDI Registry is to be deployed. If the target application server is running when you invoke setupuddi.jacl, the script stops the server and restarts the server after it has completed its operations.

1. Copy the UDDI20 directory tree from the bin subdirectory of the deployment manager tree into the bin subdirectory of the target application server's installation tree.
2. Create a JDBC driver and datasource to provide access to the UDDI20 Cloudscape database, and install the UDDI Registry application. This is done using the wsadmin tool, using as input the setupuddi.jacl script from the UDDIReg/scripts subdirectory of the Deployment Manager. Note that this script must be run on the deployment manager node.

You should either run this script from the UDDIReg/scripts subdirectory where it is located, or copy it to some other suitable directory. Note that the wsadmin command is located in the bin subdirectory of the deployment manager node. The syntax for calling this script for Cloudscape is:

```
wsadmin -f setupuddi.jacl
 deploymgrpath
 servername
 nodename
 discoveryURLprefix
 pathtdb
 > setupuddi.log
```

where

- *deploymgrpath* is the fully qualified pathname of the deployment manager install directory, specified using forward slashes regardless of platform; for example for Windows, this might be C:/Progra~1/WebSphere/DeploymentManager for Windows, or, for Unix platforms it might be /opt/WebSphere/DeploymentManager.
- *servername* is the name of the target server on which you wish to deploy the UDDI Registry, such as server1. Note the the server name entered is case sensitive.
- *nodename* is the name of the WebSphere node on which the target server runs. Note the the node name entered is case sensitive.
- *discoveryURLprefix* is the URL prefix to be used for discovery URLs. Typically this will be of the form http://<ip-address>:9080/uddisoap/ - an example of a discoveryURLprefix value might be http://mynode.mylocation.mycompany.com:9080/uddisoap/
- *pathtodb* is the path to the UDDI20 database within the bin subdirectory of your WebSphere AppServer installation, specified using forward slashes regardless of platform; for example for Windows, this might be C:/Progra~1/WebSphere/AppServer/bin/UDDI20 and for Unix platforms: /opt/WebSphere/AppServer/bin/UDDI20
- > *setupuddi.log* is an optional parameter to direct the output to a log file as opposed to the default (which is to the screen)

For example on Windows (shown here on multiple lines for publication):

```
wsadmin -f setupuddi.jacl "C:/Progra~1/WebSphere/DeploymentManager/" server1 myriad
"http://myriad.headoffice.xyz.com:9080/uddisoap/" "C:/Progra~1/WebSphere/Appserver/bin/UDDI20"
```

or, on Unix platforms (shown here on multiple lines for publication):

```
./wsadmin.sh -f setupuddi.jacl "/opt/WebSphere/DeploymentManager/" server1 myriad
"http://myriad.headoffice.xyz.com:9080/uddisoap/" "/opt/WebSphere/Appserver/bin/UDDI20"
```

installs the UDDI Registry application into the server server1 running on node myriad, and sets it up to access the Cloudscape UDDI20 database located in the bin subdirectory of the application server.

The setupuddi.jacl script:

- Creates a JDBC driver named *UDDI.JDBC.Driver.<nodeName>.<server>* and a datasource named *UDDI.Datasource.<nodeName>.<server>* (where *<nodeName>* is the name of the target node and *<server>* is the name of the target server, and will replace any existing driver and datasource of that name.
- Checks whether the UDDI Registry application is already installed and, if so, stop it and uninstall it.
- Updates the uddi.properties configuration property file to configure the discoveryURLprefix value that you have specified and set the persister property as 'Cloudscape', and place this file into the location *config/cells/<currentcell>/nodes/<nodename>/servers/<servername>/uddi.properties*.
- Places a number of files that are needed by the UDDI Registry into the WebSphere configuration repository, and updates the ws.ext.dirs list to reference these files.
- Installs the UDDI Registry.

This script deploys the UDDI Registry into the configuration under the deployment manager, and then do a Synchronization to install it into the specified server.

**Note:** The setup script, setupuddi.jacl, cannot be used to install the UDDI Registry application into a clustered application server. It is possible to cluster the UDDI Registry application by installing UDDI into an unclustered application server using the setup script, and then cluster that application server.

Return to the next step in the parent task Installing the UDDI Registry into a deployment manager cell.

## Setting up the UDDI Registry to use DB2 within a deployment manager cell

To decide which database product you should use as your persistence store, see "Choice of database product to be used as the persistence store".

This task is part of a parent task: Installing the UDDI Registry into a deployment manager cell. You should complete this task at the appropriate step in the parent task.

If you plan to use DB2 for the database in which the UDDI Registry will be held, ensure that the correct prerequisite fix packs have been applied as listed at <http://www-3.ibm.com/software/webservers/appserv/doc/latest/prereq.html> otherwise the startup of the UDDI DB2 setup wizard will fail.

If you plan to use DB2 for the database in which the UDDI Registry data will be held, use this task to create and load the UDDI Registry database using DB2, and to setup and install the UDDI Registry application to use the DB2 database.

This task uses the UDDI DB2 Setup Wizard to configure DB2 on the system where you want to run the UDDI Registry. Before starting this task, ensure that DB2 is installed and running on that system.

Copy the UDDIReg directory tree from the deployment manager to the target application server where DB2 will run.

The following steps should be carried out on the system on which the target application server is located (referred to as the 'target system').

In this task you will invoke a script called `setupuddi.jacl`, specifying the target node and application server into which the UDDI Registry is to be deployed. If the target application server is running when you invoke `setupuddi.jacl`, the script stops the server and restarts the server after it has completed its operations.

Before starting this task, ensure that you have created an appropriate DB2 userid and password. This same userid and password must be used throughout the following steps where the DB2 userid and password is requested.

1. On Windows, and if using DB2 Version 7, ensure that since installing DB2 you have run the `usejdbc2.bat` command file. For more information about this, see "Application Building Guide" in the DB2 documentation.
2. Create and load the UDDI Registry database, called UDDI20.

**Note:** If you are migrating from an earlier version of the UDDI Registry, and your UDDI20 DB2 database already exists, skip this step unless you want to replace the existing database with a new UDDI20 DB2 database. If you do choose to replace an existing database, all of your existing UDDI data will be lost. **Important:** if you do choose to replace the existing UDDI20 database, there must not be any applications or users accessing the database at the time that you run the UDDI DB2 setup wizard.

**Note:** It is recommended you use the `SetupDB2UDDI.jar` command from IBM WebSphere Application Server Version 5.0.1 or later. This is essential for non-English users.

**Note:** If you have a copy of the file `SetupDB2UDDI.jar` in your application server directory, then the application of the base and Network Deployment PTFs will not update `SetupDB2UDDI.jar` in your application server directory. You must apply the PTF for Network Deployment to your DeploymentManager file structure to update the `SetupDB2UDDI.jar` located there (in the `/UDDIReg/scripts` subdirectory), and then manually copy this jar file to any application server you may wish to run it on.

If you are planning to use a remote DB2 system on another host machine, copy the `SetupDB2UDDI.jar` file to the remote system and run it on that system to create and load the UDDI Registry database following the instructions within this step and continue with the next step (which states "If using a remote DB2 system on another host machine..") on the local host.

The UDDI DB2 Setup Wizard used in this task will prompt you to provide the DB2 userid and password under which the UDDI Registry database will be created and subsequently accessed.

Information on how to do this and where to obtain the PTF can be found in "Installing interim fixes, cumulative fixes, and fix packs" in the Information Center.

On Windows this should be a userid and password with administrative privileges. On Unix platforms, you should supply the userid and password of the DB2 instance in which you wish the database to be created.

To create the database you use the UDDI DB2 setup wizard, which is supplied as a jar file called SetupDB2UDDI.jar in the UDDIReg/scripts subdirectory, by following these steps:

- a. Change directory to the directory containing the file SetupDB2UDDI.jar (that is, either the UDDIReg/scripts directory in which it is supplied, or a directory on the target system into which you have copied it).
- b. To run the wizard, first ensure that you have access from your command line to the JVM supplied with WebSphere:

- On Windows, in a command window, a user with administrative privileges should type the following command:

```
<AppServer-install-dir>\bin\setupcmdline.bat
```

For example,

```
C:\Program Files\WebSphere\AppServer\bin\setupcmdline.bat
```

- On Unix platforms, at a command line type one of the following commands:

- If you are using bash, then as the root user run

```
. <AppServer-install-dir>/bin/setupCmdLine.sh
```

- If you are using csh, then as the root user run

```
source . <AppServer-install-dir>/bin/setupCmdLine.sh
```

- c. Temporarily set your path by typing:

- On Windows:

```
set path=%WAS_PATH%;%path%
```

- On Unix or Linux platforms:

```
export PATH=$WAS_PATH:$PATH
```

- d. In the same command window, start the UDDI DB2 setup wizard by entering one of the following commands:

- To start a graphical user interface, type

```
java -jar SetupDB2UDDI.jar
```

- To start a text mode interface, type:

```
java -jar SetupDB2UDDI.jar -console
```

**Note:** The above commands will fail unless your DB2 installation has the correct fix packs applied as listed on the prerequisite page found at <http://www-3.ibm.com/software/webservers/appserv/doc/latest/prereq.html>

- e. Follow the prompts to work through the wizard panels or command prompts.

- f. If necessary, check the log files for the wizard. A log file called UDDIloadDB.log is written to the directory from which the wizard is run (but note that on Windows platforms, if you have decided not to overwrite an existing UDDI20 database, then this fact is not logged, and the log file is not be created).

3. If using a remote DB2 system on another host machine, refer to "Use of a remote DB2 database" and then return to this point and continue with the following instructions.
4. Create a JDBC driver and datasource to provide access to the UDDI20 DB2 database, and install the UDDI Registry application. This is done using the wsadmin tool, using as input the setupuddi.jacl script from the UDDIReg/scripts subdirectory of the deployment manager. This script must be run on the deployment manager node.

Either run this script from the UDDIReg/scripts subdirectory where it is located, or copy it to some other suitable directory. Note that the wsadmin command is located in the bin subdirectory of the deployment manager node. The syntax for this script for DB2 is:

```
wsadmin -f setupuddi.jacl
 deploymgrpath
 servername
```

```

nodename
discoveryURLprefix
dbname
db2userid
db2password
db2ziplocation
> setupuddi.log

```

where:

- *deploymgrpath* is the fully qualified pathname of the deployment manager install directory, specified using forward slashes regardless of platform; for example for Windows, this might be `c:/Progra~1/WebSphere/DeploymentManager` and, for Unix platforms it might be `/opt/WebSphere/DeploymentManager/`
- *servername* is the name of the target application server on which you wish to deploy the UDDI Registry, such as `server1`. The server name is case sensitive.
- *nodename* is the name of the WebSphere node on which the target application server runs. Typically, this is the same as the machine name. The node name is case sensitive.
- *discoveryURLprefix* is the URL prefix to be used for discovery URLs. Typically this will be of the form `http://<ip-address>:9080/uddisoap/` so an example of a *discoveryURLprefix* value might be `http://mynode.mylocation.mycompany.com:9080/uddisoap/`
- *dbname* is the name of the UDDI Registry database under DB2. For this parameter, you should specify `UDDI20`.

**Note:** If a remote DB2 system is being used the *dbname* stated here must be the alias created when access to the remote database was set up on the local system

- *db2userid* and *db2password* are a valid DB2 userid and password with administrative privileges
- *db2ziplocation* is the path to the `db2java` zip file on your system, specified using forward slashes regardless of platform; for example for Windows, this might be `C:/Progra~1/SQLLIB/java/db2java.zip` or, for Unix platforms it might be `/home/db2inst1/sqllib/java12/db2java.zip`
- `> setupuddi.log` is an optional parameter to direct the output to a log file as opposed to the default (which is to the screen)

For example:

On Windows the command is (shown here on multiple lines for publication):

```

wsadmin -f setupuddi.jacl "C:/Progra~1/WebSphere/DeploymentManager/" server1 myriad
"http://myriad.headoffice.xyz.com:9080/uddisoap/" UDDI20 db2admin secretpwd
"C:/Progra~1/SQLLIB/java/db2java.zip" > setupuddi.log

```

On Unix platforms the command is (shown here on multiple lines for publication):

```

wsadmin.sh -f setupuddi.jacl "/opt/WebSphere/DeploymentManager/" server1 myriad
"http://myriad.headoffice.xyz.com:9080/uddisoap/" UDDI20 db2admin secretpwd
"/home/db2inst1/sqllib/java12/db2java.zip" > setupuddi.log

```

This installs the UDDI Registry application into the server `server1` running on node `myriad`, and set it up to access the DB2 `UDDI20` database using the userid `'db2admin'` and password `'secretpwd'`.

The `setupuddi.jacl` script:

- Creates a JDBC driver named `UDDI.JDBC.Driver.<nodeName>.<server>` and a datasource named `UDDI.Datasource.<nodeName>.<server>` (where `<nodeName>` is the name of the target node and `<server>` is the name of the target server), and replaces any existing driver and datasource of that name.
- Checks whether the UDDI Registry application is already installed and, if so, stop it and uninstall it.
- Updates the `uddi.properties` configuration file to configure the `discoveryURLprefix` value that you have specified, and to set the `persist` property as `'DB2'`, and places this file into the location `config/cells/<currentcell>/nodes/<nodename>/servers/<servername>/uddi.properties`.
- Places a number of files that are needed by the UDDI Registry into the WebSphere configuration repository, and update the `ws.ext.dirs` list to reference these files.
- Installs the UDDI Registry.

**Note:** The setup script, `setupuddi.jacl`, cannot be used to install the UDDI Registry application into a clustered application server. It is possible to cluster the UDDI Registry application by installing UDDI into an unclustered application server using the setup script, and then cluster that application server.

Return to the next step in the parent task Installing the UDDI Registry into a deployment manager cell.

## Installing the UDDI Registry into a single appserver

If you intend to run in a single WebSphere Application server, then complete the following task.

When you select the UDDI Registry option, then the installation will place all files that are needed to run a UDDI Registry onto the deployment manager install tree on the machine on which you are installing IBM WebSphere Application Server for Network Deployment.

To be able to run the UDDI Registry in a single application server instance in your network space you must copy these files over to the application server and then deploy the UDDI Registry. You can do this as follows:

1. Stop the application server on which you plan to run the UDDI Registry; for example, using the command `stopServer server_name` (`stopServer.sh` on Unix and Linux Platforms)
2. Copy the `uddi.ear` file from the `installableApps` subdirectory of the deployment manager install tree into the `installableApps` subdirectory of the target application server's install tree.
3. Copy the `uddi.properties` file from the `properties` subdirectory of the deployment manager install tree into the `properties` subdirectory of the target application server's install tree. In a subsequent step, you configure the UDDI Registry using the properties in the `uddi.properties` file.
4. Copy both the `uddiresourcebundles.jar` and the `setupuddimessages.jar` files from the `lib` subdirectory of the deployment manager install tree into the `lib` subdirectory of the target application server's install tree.
5. Optionally, if you are going to write or run code that uses the EJB interface to UDDI on another machine, then copy the `uddiejbclient.jar` file and the EJB javadoc directory tree from the `UDDIReg/ejb` subdirectory of the deployment manager install tree onto a location of your choice on any machines where you will be creating EJB clients to access the UDDI Registry.
6. Configure database support for the UDDI Registry database, in which the UDDI Registry will be held. To do this, complete one of the following tasks then return this point:
  - Setting up the UDDI Registry to use Cloudscape in a single AppServer
  - Setting up the UDDI Registry to use DB2 in a single AppServer

**Note:** If you set up the UDDI Registry application with a JDBC driver and datasource that reference Cloudscape, but set the `persist` property in `uddi.properties` to specify DB2, **or vice versa**, then some unexpected behavior will result, such as a fatal error on deleting an entity. If this happens, you should check that the above details are not in conflict. This only applies to a UDDI Registry installation on a single appserver.

7. Ensure that the UDDI Registry is configured appropriately for your installation, as described in the section on Configuring the UDDI Registry.
8. Stop and then restart the application server. On Unix and Linux platforms you must remember to run the `db2profile` script before issuing the `startServer.sh` command. This script is located within the DB2 instance's home directory under `SQLLIB` and can be invoked, for example, by typing:

```
. /home/db2inst1/sqllib/db2profile
```

**Note:** In the above example, it should be noticed that the `'.'` is followed by a single space character.

**Note:** On Unix and Linux platforms the DB2 user **must** have a `db2profile` at `$HOME/sqllib/db2profile`.

Continue with Configuring the UDDI Registry.

## Setting up the UDDI Registry to use Cloudscape in a single application server

To decide which database product you should use as your persistence store, see "Choice of database product to be used as the persistence store".

If you plan to use Cloudscape for the database in which the UDDI Registry data is held, use this task to set up and install the UDDI Registry application to use the supplied Cloudscape database.

This task configures Cloudscape on the host where you want to run the UDDI Registry.

This task, to configure Cloudscape for the UDDI Registry database, is part of a parent task Installing and Setting up a UDDI Registry. You should complete this task at the appropriate step in the parent task.

1. Copy the UDDI20 directory tree from the bin subdirectory of the deployment manager tree into the bin subdirectory of the target application server's install tree.
2. Copy the `uddicloudscapeuserfunc.jar` file from the lib subdirectory of the deployment manager install tree to the lib subdirectory of the target application server's install tree.
3. Ensure that the `persist` property in the `uddi.properties` file is set to `persist=Cloudscape`
4. Copy the `appserversetupuddi.jacl` script from the `UDDIReg/scripts` subdirectory of the deployment manager install tree to the WebSphere Application Server bin subdirectory.
5. Change directory to the WebSphere Application Server bin subdirectory.
6. Start the application server on which the UDDI Registry is to run.

For example, enter:

```
startServer server1 for Windows
. /startServer.sh server1 for Unix platforms
```

7. Create a JDBC driver and datasource to provide access to the UDDI20 Cloudscape database, and install the UDDI Registry application. To do this run the `wsadmin` tool with the script `appserversetupuddi.jacl` as input, on the target application server, using the following command syntax: (You should either run this script from the `UDDIReg/scripts` subdirectory where it is located, or copy it to some other suitable directory. Note that the `wsadmin` tool is located in the WebSphere bin subdirectory.)

```
wsadmin -f appserversetupuddi.jacl
 uddi-ear-location
 servername
 nodename
 WebSphere-lib-subdirectory
 cloudscapedbname
 > setupuddi.log
```

Where:

- `uddi-ear-location` is the fully-qualified path to the `uddi.ear` file in the `installableApps` subdirectory, specified **using forward slashes regardless of platform**. For example, on Windows:  
C:/Progra~1/WebSphere/AppServer/installableApps/uddi.ear  
and on Unix platforms:  
/opt/WebSphere/AppServer/installableApps/uddi.ear
- `servername` is the name of the application server on which the UDDI registry is to run; for example: `server1`. Note that the server name entered is case sensitive.
- `nodename` is the name of the WebSphere node on which the application server, `servername`, is running. Typically this is the machine name. Note that the node name entered is case sensitive.
- `WebSphere-lib-subdirectory` is the fully-qualified path to the WebSphere Application Server lib subdirectory, specified using forward slashes regardless of platform. For example on Windows:  
C:/Progra~1/WebSphere/AppServer/lib  
and on Unix platforms:

- `/opt/WebSphere/AppServer/lib`
- *cloudscapedbname* is the fully-qualified path to the UDDI20 database within the bin subdirectory of your WebSphere AppServer installation, specified using forward slashes regardless of platform. For example on Windows:
  - `C:/Program~1/WebSphere/AppServer/bin/UDDI20`
 and on Unix platforms
  - `/opt/WebSphere/AppServer/bin/UDDI20`
- `> setupuddi.log` is an optional parameter to direct the output to a log file as opposed to the default (which is to the screen)

The `appserversetupuddi.jacl` script completes the following actions:

- a. Creates a JDBC driver named `UDDI.JDBC.Driver.<nodeName>.<server>` and a datasource named `UDDI.Datasource.<nodeName>.<server>` (where `<nodeName>` is the name of the target node and `<server>` is the name of the target server, and will replace any existing driver and datasource of that name.
- b. Checks whether the WebSphere UDDI Registry application is already installed and, if so, stop the application and uninstall it.
- c. Installs the WebSphere UDDI Registry, then starts it.

**Note:** The setup script, `appserversetupuddi.jacl`, cannot be used to install the UDDI Registry application into a clustered application server. It is possible to cluster the UDDI Registry application by installing UDDI into an unclustered application server using the setup script, and then clustering that application server.

Return to the next step in the parent task Installing the UDDI Registry into a single appserver.

## Setting up the UDDI Registry to use DB2 in a single application server

To decide which database product you should use as your persistence store, see "Choice of database product to be used as the persistence store".

This task is part of a parent task Installing and setting up a UDDI Registry. You should complete this task at the appropriate step in the parent task.

If you plan to use DB2 for the database in which the UDDI Registry is held, ensure that the correct prerequisite fix packs have been applied as listed at <http://www-3.ibm.com/software/webservers/appserv/doc/latest/prereq.html> otherwise the startup of the UDDI DB2 setup wizard will fail.

If you plan to use DB2 for the database in which the UDDI Registry data will be held, use this task to create and load the UDDI Registry database using DB2, and to setup and install the UDDI Registry application to use the database.

This task uses the UDDI DB2 setup wizard to configure DB2 on the system where you want to run the UDDI Registry. Before starting this task, ensure that DB2 is installed and running on that system.

Copy the UDDIReg directory tree from the deployment manager to the target application server where DB2 will run.

The following steps should be carried out on the system on which the target application server is located (referred to below as the 'target system').

1. On Windows, if you are using DB2 Version 7, ensure that since installing DB2 you have run the `usejdbc2.bat` command file. For more information about this, see "Application Building Guide" in the DB2 documentation.
2. Create and load the UDDI Registry database, called UDDI20.

**Note:** If you are migrating from an earlier version of the UDDI Registry, and your UDDI20 DB2 database already exists, you should skip this step unless you want to replace the existing database with a new UDDI20 DB2 database. If you do choose to replace an existing database all of your existing UDDI data will be lost. **Important:** If you do choose to replace the existing UDDI20 database, then there must not be any applications or users accessing the database at the time that you run the UDDI DB2 setup wizard.

**Note:** It is recommended you use the `setupDB2UDDI.jacl` command from IBM WebSphere Application Server Version 5.0.1 or later. This is essential for non-English users.

**Note:** If you have a copy of the file `SetupDB2UDDI.jar` in your application server directory, then the application of the base and Network Deployment PTFs will not update `SetupDB2UDDI.jar` in your application server directory. You must apply the PTF for Network Deployment to your `DeploymentManager` file structure to update the `SetupDB2UDDI.jar` located there (in the `/UDDIReg/scripts` subdirectory), and then manually copy this jar file to any application server you may wish to run it on.

If you are planning to use a remote DB2 system on another host machine, copy the `SetupDB2UDDI.jar` file to the remote system and run it on that system to create and load the UDDI Registry database following the instructions within this step and continue with the next step (which states "If using a remote DB2 system on another host machine ....") on the local host.

The UDDI DB2 setup wizard used in this task prompts you to provide the DB2 userid and password under which the UDDI Registry database is created and subsequently accessed. Before starting this task, ensure that you have created an appropriate DB2 userid and password. This same userid and password must be used throughout the following steps where the DB2 userid and password is requested.

On Windows this should be a userid and password with administrative privileges. On Unix platforms, you should supply the userid and password of the DB2 instance in which you wish the database to be created.

To create the database you use the UDDI DB2 setup wizard:

- a. Change directory to the directory containing the file `SetupDB2UDDI.jar` (that is, either the `UDDIReg/scripts` directory in which it is supplied, or a directory on the target system into which you have copied it).
- b. To run the wizard, you need to first ensure that you have access from your command line to the JVM supplied with WebSphere. This is done as follows:
  - On Windows, in a command window, a user with administrative privileges should type the following command:

```
<AppServer-install-dir>\bin\setupcmdline.bat
```

For example, `C:\Progra~1\WebSphere\AppServer\bin\setupcmdline.bat`
  - On Unix platforms, enter one of the following commands as the root user:
    - If you are using bash:

```
. <AppServer-install-dir>/bin/setupCmdLine.sh
```
    - If you are using csh:

```
source /<AppServer-install-dir>/bin/setupCmdLine.sh
```
- c. Temporarily set your path by typing:
  - On Windows:

```
set path=%WAS_PATH%;%path%
```
  - On Unix or Linux platforms:

```
export PATH=$WAS_PATH:$PATH
```
- d. In the same command window, start the UDDI DB2 setup wizard by issuing one of the following commands:
  - To start a graphical user interface, enter:

```
java -jar SetupDB2UDDI.jar
```

- To start a text mode interface, enter:

```
java -jar SetupDB2UDDI.jar -console
```

**Note:** The above commands will fail unless your DB2 installation has the correct fix packs applied as listed on the prerequisite page found at <http://www-3.ibm.com/software/webservers/appserv/doc/latest/prereq.html>

- e. Follow the prompts to work through the wizard panels or command prompts.
- f. If necessary, check the log files for the wizard. A log file called UDDIloadDB.log is written into the directory from which the wizard is run (but note that, on Windows platforms, if you have decided not to overwrite an existing UDDI20 database, this fact is not logged, and the log file is not created).
3. If using a remote DB2 system on another host machine, refer to "Use of a remote DB2 database" and then return to this point and continue with the next step.
4. Ensure that the persist property in the uddi.properties file is set to persist=DB2.
5. On Unix, run the db2profile script to set up the environment for the DB2 instance that the UDDI Registry is using:
 

```
./home/db2inst1/sqllib/db2profile
```
6. Start the application server on which the UDDI Registry is to run. For example:
 

On Windows:

```
startserver server1
```

On Unix platforms:

```
./startServer.sh server1
```
7. Copy the *appserversetupuddi.jacl* script from the UDDIReg/scripts subdirectory of the deployment manager install tree to the WebSphere Application Server bin subdirectory (for example, on Windows, C:\Progra~1\WebSphere\AppServer\bin).
8. Change directory to the WebSphere Application Server bin subdirectory.
9. Create a JDBC driver and datasource to provide access to the UDDI20 database, and install the UDDI Registry application. To do this run the wsadmin tool with the script *appserversetupuddi.jacl* as input, on the target application server, using the following command syntax. (Either run this script from the UDDIReg/scripts subdirectory where it is located, or copy it to some other suitable directory. Note that the wsadmin tool is located in the WebSphere bin subdirectory.)

```
wsadmin -f appserversetupuddi.jacl
 uddi-ear-location
 servername
 nodename
 WebSphere-lib-subdirectory
 dbname
 db2userid
 db2pwd
 db2ziplocation
 > setupuddi.log
```

where

- *uddi-ear-location* is the fully-qualified path to the uddi.ear file in the installableApps subdirectory, specified **using forward slashes regardless of platform**.

For example, on Windows:

```
C:/Progra~1/WebSphere/AppServer/installableApps/uddi.ear
```

and on Unix platforms

```
/opt/WebSphere/AppServer/installableApps/uddi.ear
```

- *servername* is the name of the application server on which the UDDI registry is to run; for example: server1. Note that the name of the server is case sensitive.
- *nodename* is the name of the WebSphere node on which the application server, *servername*, is running. Typically, this will be the same as the machine name. Note that the name of the node is case sensitive. Typically this is the machine name.

- *WebSphere-lib-subdirectory* is the fully-qualified path to the WebSphere Application Server lib subdirectory, specified **using forward slashes regardless of platform**. For example:
  - On Windows: C:/Progra~1/WebSphere/AppServer/lib
  - On Unix: /opt/WebSphere/AppServer/lib
- *dbname* is the name of the UDDI Registry database under DB2. You should specify UDDI20 for this parameter

**Note:** If a remote DB2 system is being used the *dbname* must be the alias created when access to the remote database was set up on the local system.

- *db2userid* and *db2pwd* are a valid DB2 userid and password with administrative privileges, as specified in an earlier step.
- *db2ziplocation* is the path under which you have installed DB2, specified **using forward slashes regardless of platform..** For example, for Windows, this might be C:/Progra~1/SQLLIB/java/db2java.zip or, for Unix platforms it might be /opt/SQLLIB/java/db2java.zip.
- *> setupuddi.log* is an optional parameter to direct the output to a log file as opposed to the default (which is to the screen)

The appserversetupuddi.jacl completes the following actions:

- a. Creates a JDBC driver named *UDDI.JDBC.Driver.<nodeName>.<server>* and a datasource named *UDDI.Datasource.<nodeName>.<server>* (where *<nodeName>* is the name of the target node and *<server>* is the name of the target server), and will replace any existing driver and datasource of that name.
- b. Checks whether the WebSphere UDDI Registry application is already installed and, if so, stop the application and uninstall it.
- c. Installs the WebSphere UDDI Registry, then starts it.

**Note:** The setup script, appserversetupuddi.jacl, cannot be used to install the UDDI Registry application into a clustered application server. It is possible to cluster the UDDI Registry application by installing UDDI into an unclustered application server using the setup script, and then clustering that application server.

Return to the next step in the parent task Installing and Setting up a UDDI Registry.

---

## Reinstalling the UDDI Registry application

If you wish to reinstall the UDDI Registry, follow the appropriate section below.

### Reinstalling into a deployment manager cell

If you wish to reinstall the UDDI Registry into the target application server, for example because you wish to alter certain aspects of its configuration using AAT, rerun the setupuddi.jacl script (described in the appropriate link as follows):

- "Setting up the UDDI Registry to use Cloudscape within a deployment cell"
- "Setting up the UDDI Registry to use DB2 within a deployment cell"

**Note:** If you decide to change from using Cloudscape as your persistence store to DB2, or vice versa, first remove UDDI from the application server using removeuddi.jacl. You can then run setupuddi.jacl to reinstall UDDI with the new type of persistence store.

If you make such a change, then any data that you had previously stored is no longer be accessible.

### Reinstalling into a single appserver

Remove the UDDI Registry application in the same manner as any other Enterprise Application and then install as described in the appropriate link:

- Setting up the UDDI Registry to use Cloudscape in a single AppServer
- Setting up the UDDI Registry to use DB2 in a single AppServer

**Note:** If you decide to change from using Cloudscape as your persistence store to DB2, or vice versa, first remove UDDI from the application server using `appserverremoveuddi.jacl`. You can then run `appserversetupuddi.jacl` to reinstall UDDI with the new type of persistence store.

If you make such a change, then any data that you had previously stored is no longer accessible.

---

## Applying Service updates to the UDDI Registry in a Network Deployment and single application server environment

When applying service to your WebSphere and UDDI Registry, you need to be aware of the following.

If you are running in a Network Deployment cell, and you apply service to the UDDI Registry (on the deployment manager), the updates are automatically sent to all nodes running UDDI that are federated to that cell.

If, however, you are running in a stand-alone single application server (which is not known to the deployment manager), the updates are not automatically sent out. In this case, you must read the PTF Release Notes for instructions on how to do this.

In addition, there are some updates to files and scripts that may not automatically be sent to the application servers in either a Network Deployment or single application server environment. Please read the PTF Release Notes for details

---

## Using a remote DB2 database for UDDI

The WebSphere Application Server UDDI Registry can use a remote UDDI DB2 database installed on a DB2 system running on another machine.

It is possible to connect a DB2 system on one host to use a DB2 database on a remote host. Refer to the DB2 Information Center which supplies information on using the Client Configuration Assistant to achieve this. For the documentation below, the term *'local system'* refers to the system running the WebSphere Application Server on which the UDDI Registry is installed and the term *'remote system'* refers to another system on which the UDDI DB2 database exists. The UDDI DB2 database is created by running `SetupDB2UDDI.jar` on the remote system as described within "Setting up the UDDI Registry to use DB2 within a deployment manager cell" or "Setting up the UDDI Registry to use DB2 in a single appserver" and referred to in the last task in the list below. Refer to the DB2 specific version documentation for details.

Here is an example for DB2 Version 8:

1. On the remote host, define the UDDI Registry by entering: `java -jar SetupDB2UDDI.jar` and following the prompts. The `DB2userid` and `DB2password` specified here will be the ones that are used when `setupuddi.jacl` (or `appserversetupuddi.jacl`) are run further in these instructions.
2. Use DB2's Client Configuration Assistant. When you receive the message "Welcome to the Assistant - would you like to add a database now?" - select "yes"
3. On the next screen, click the radio button to "Manually configure a connection to a database" and click on "Next".
4. Click TCP/IP on the next screen, and select "The database physically resides on a host or OS/400 system. Click the radio button "Connect directly to the server" and then click "Next".

5. The next screen defines the TCP/IP host name and Port Number of the remote system. For the Port Number the use of 50000 is recommended. You are also asked for the service name (for example db2c\_db2inst1). Click "Next" when completed.
6. The next screen identifies the name of the UDDI database on the remote system and the alias name to be used on the local system. This alias can be anything suitable, including UDDI20 providing there is not a local database of that name.
7. The next screen shows "Register this database for ODBC". Leave this as is and click "Next".
8. The next screen asks for the Operating System (for example AIX or Windows) and the Remote Instance Name (for example db2inst1). Click "Next" when completed.
9. It is not necessary to go any further on this assistant. Click on "Finish" to define the remote database to DB2.
10. Another windows displays stating "Test the Connection". Enter the db2userid and db2password for the remote instance in the appropriate fields and click "Test Connection".
11. Click "Cancel" and the alias is now correctly set up.

**Note:** If the user is running a DB2 Client only, and has not got the DB2 Client Configuration Assistant available there are two options available:

- Obtain and install DB2 Administration Server (which contains the Client Configuration Assistant).
- Run the commands from the command line:
  1. Find the port number used by the remote instance you are trying to connect to:  
On the remote host as the DB2 instance user:
    - a. Enter the command: *"db2 get dbm cfg"*
    - b. Find the line containing *".....(SVCENAME) = <service\_name>"* Make a note of *<service\_name>*
    - c. There is a services file on each supported DB2 platform that changes location depending of the OS. For UNIX platforms this file might typically be found in */etc/services*, and on Windows this file might be found in *C:\WINNT\system32\drivers\etc\services*
    - d. Search this file and find the line for the *<service\_name>* discovered above. Use this port number for the catalog node command. For instance, the service may be *"db2c\_db2inst1"* and the port 50000, depending on the DB2 configuration.
  2. The following commands catalog a node and database alias (on the local host) to allow remote connectivity:
    - a. *db2 catalog tcpip node <nodename> remote <remote\_hostname> server <port>*  
Where *<nodename>* is a node identifier that you choose, *remote\_hostname* is the hostname of the remote host, and *port* is the port number discovered above
    - b. *db2 catalog db UDDI20 at node <nodename>*  
Where *UDDI20* is the name of the UDDI Registry database on the remote system and *<nodename>* is the identifier you chose in the previous step.
  3. You can now to the remote database. Test this by:
    - a. *db2 connect to uddi20 user <db2userid> using <db2password>*  
Where *<db2userid>* is the userid of the DB2 instance on the remote host and *<db2password>* is the password for the DB2 instance on the remote host.

Run the *setupuddi.jacl* (or *appserversetupuddi.jacl*) command on the local system as described in "Setting up the UDDI Registry to use DB2 within a deployment manager cell" or "Setting up the UDDI Registry to use DB2 in a single appserver", ensuring that you specify the alias on the local system as the UDDI database parameter, and the DB2 userid and password on the remote host as the userid and password parameters.

## IP Addressing

If you are experiencing problems accessing the remote host, one of the possible causes might be IP addressing. Refer to the "UDDI Troubleshooting Tips" section for a possible solution.

The remote database is now ready for use. Continue with your next task.

---

## Removing the UDDI Registry application from a deployment manager cell

To completely remove the UDDI Registry application from the target application server in the deployment manager cell, run the *wsadmin* (*wsadmin.sh* on Unix Platforms) script *removeuddi.jacl*, which is located in the UDDIReg/scripts directory of the deployment manager install tree.

If the target server specified on invoking *removeuddi.jacl* is running at the same time, the script stops the server and restarts the server when it has completed its operations.

At a command prompt enter:

```
wsadmin -f removeuddi.jacl
 servername
 nodename
 > removeuddi.log
```

Where *servername* and *nodename* are the server and node where you have deployed the UDDI Registry application. By default output will go to the screen, but, optionally, you can specify '> *removeuddi.log*' to direct output to a log file. For example,

```
wsadmin -f removeuddi.jacl server1 myriad
```

will remove the UDDI Registry application and related files from server *server1* running in node *myriad*, and will send any messages to the screen.

---

## Removing the UDDI Registry application from a single application server

To completely remove the UDDI Registry application from a stand-alone application server run the *wsadmin* script *appserverremoveuddi.jacl*, which was installed into the UDDIReg/scripts directory when you installed the UDDI Registry as part of a Network Deployment install.

At a command prompt enter:

```
wsadmin -f appserverremoveuddi.jacl
 servername
 nodename
 > removeuddi.log
```

where

- *servername* and *nodename* are the name of the stand-alone application node in which it runs (these are the names that you specify when you run *appserversetupuddi.jacl* to install the UDDI Registry application).
- by default output will go to the screen, but, optionally, you can specify '> *removeuddi.log*' to direct the output to a log file.

For example:

```
wsadmin -f appserverremoveuddi.jacl server1 monolith
```

will remove the UDDI Registry application and related files from server *server1* running in node *monolith*, and will send any messages to the screen.

---

## Configuring the UDDI Registry

The UDDI Registry is supplied as a J2EE application file, `uddi.ear`. This is installed into the WebSphere Application Server during installation. If you want to change any of its configuration properties using Assembly Toolkit see [Configuring SOAP properties with the Assembly Toolkit](#).

You can configure the following aspects of the UDDI Registry:

- Configuring global UDDI properties
- Modifying the database userid and password
- Configuring security properties
- Configuring the UDDI User Console (GUI) for multiple language encoding support
- Customizing the UDDI User Console (GUI)
- Configuring SOAP interface properties
- **5.1+** Configuring SOAP properties with the Assembly Toolkit
- Configuring SOAP properties in the deployment descriptor

### Configuring global UDDI properties

To modify any of the global UDDI properties, edit the file called `uddi.properties`. More than one version of this file exists and the version you need to edit depends on:

- whether you are in the installation phase or are updating the properties as a post installation step
- whether you are configured for a deployment manager or base application server environment

The location of the file you should edit will be one of the following:

#### **Deployment Manager Configurations**

1. If you are in the process of installing the UDDI Registry application for the first time into a deployment manager cell and wish to make some generic changes before deploying it in the cell, the `uddi.properties` file will be located in the `<DeploymentManager-install-dir>/properties` directory. If you are reinstalling the UDDI Registry application into a deployment manager cell, then you should edit the file in the location described in step 2.

**Note:** In a deployment manager configuration some properties (such as `persist` and `getServletURLprefix`) are dynamically set up in the `uddi.properties` file, during subsequent installation processing.

2. If the UDDI Registry is already configured into an application server within a Deployment Manager cell (that is you are undertaking post installation configuration changes), the `uddi.properties` file you should edit is located in the configuration repository, under the deployment manager filing system; that is in `<DeploymentManager-install-dir>config/cells/<cellname>/nodes/<nodename>/servers/<servername>`, where `<cellname>` is the name of the deployment manager cell, `<nodename>` is the name of the node in which the application server is installed, and `<servername>` is the name of the application server in which you have installed the UDDI Registry.

#### **Application Server Configurations**

1. If you are in the process of installing the UDDI Registry application into an application server only environment you will be advised during the installation process when to make changes to the `uddi.properties` file.

**Note:** In contrast with the deployment manager configuration, UDDI properties are not dynamically set during installation processing.

2. If the UDDI Registry is already configured into a single application server that is **not** part of a deployment manager cell (i.e. you are undertaking post installation configuration changes), then the

*uddi.properties* file will be located in the properties subdirectory of the WebSphere Application Server in which you have installed the UDDI Registry application, that is <ApplicationServer-install-dir>/properties directory.

The properties that can be changed within *uddi.properties* are as follows:

- The `dbMaxResultCount`, which is the limit on the number of rows of information that should be returned on Find requests, and will apply if the request does not specify a `maxRows` limit itself (or if it specifies a limit that exceeds this value). The initial value for this in *uddi.properties* is 100.
- The `persist`, which indicates what database is to be used as the persistence store for the UDDI Registry database. If you have installed the UDDI Registry into an application server within a deployment manager cell, then the `persist` property will have been set to the correct value for you. If you change this value, you must also ensure that you have a UDDI Registry database created using the chosen database product (for more details about the UDDI Registry database, refer to the section on "Installing the UDDI Registry"). You should also be aware that any data published to the UDDI Registry with one setting of the `persist` property will **not** be accessible when running the UDDI Registry application with a different setting for the `persist` property. The valid values for the `persist` property are:
  - `persist=DB2`  
indicating that DB2 is to be used as the persistence store
  - `persist=Cloudscape`  
indicating that Cloudscape is to be used as the persistence store

The initial value for this in *uddi.properties* is Cloudscape.

**Note:** This property is dynamically set by the `setupuddi.jacl` script when installing into a deployment manager cell so in this case you should not need to modify it.

- The default language to be used on a publish request as the `xml:lang` attribute when one is not specified. The initial value for this in *uddi.properties* is en-US. This property must contain one of the valid `xml:lang` values.
- The UDDI site operator name. This is a string that is stored in every registry object, to indicate the operator of the UDDI Registry. The initial value for this in *uddi.properties* is `www.mycompany.com/uddi`. This property does not have any particular functional use, so its value can be set to any string that you feel is suitable.
- The maximum number of search keys that can be used on find API requests. The initial value for this in *uddi.properties* is 5.
- The `getServletURLprefix` and `getServletname` name, used to build up the discovery URL. The initial values for these are `http://localhost:9080/uddisoap/` and `get`. If you have installed the UDDI Registry into an application server within a deployment manager cell, then the `getServletURLPrefix` property will have been set for you using the value you specified as a parameter to the setup script. You are recommended to set suitable values for these properties before you first use the UDDI Registry.

**Note:** This property is dynamically set by the `setupuddi.jacl` script when installing into a deployment manager cell so in this case you should not need to modify it.

### **Applying these changes to your system**

For your changes to take effect, you must do one of the following:

- If you are in the process of installing the UDDI Registry application for the first time, return to the original topic and complete the installation steps. Any changes you have made are picked up during this subsequent processing.
- If you have made post installation changes in a base application server only environment, you should stop and restart the UDDI Registry application using the WebSphere administrative console.
- If you have made post installation changes in a deployment manager environment you should:
  1. Run a Full Resynchronization for the node where the UDDI Registry runs. This can be done from the WebSphere Network Deployment Administrative Console under section Systems Administration ==> Nodes. Select your node, and then click 'Full Resynchronization'.

- It is important that you do a 'Full Resynchronization' and not just a 'Synchronize'.
2. Stop and restart the UDDI Registry application using the WebSphere administrative console

## Modifying the database userid and password

If you use DB2 as the persistence store for the UDDI Registry, and you need to change the database userid and/or password, alter the user and password values in the custom properties of the 'UDDI Datasource', which can be edited from the WebSphere administrative console. The UDDI.Datasource is under WAS40 datasources within the UDDI.JDBC.Driver, which is itself found under JDBC Providers under Resources. Do not alter the databaseName.

## Configuring security roles

Each interface to the UDDI Registry (either through SOAP, EJB or the GUI) is supplied with two roles:

### Publish role

mapped to AllAuthenticatedUsers. By default, this is configured to use SSL (that is HTTPS), but this only applies when WebSphere security is enabled.

### Inquiry role

mapped to Everyone. By default, this is configured to use HTTP (that is not SSL).

The security roles and use of SSL can be altered by users through the Administration Console.

Authentication uses the standard WebSphere facilities and there is no separate registration function for the Registry. If WebSphere security is enabled, the you will need to supply your WebSphere userid and password for Publish functions (unless you have changed the supplied Publish role).

You will need to set up WebSphere security configuration to be used by UDDI. For information on achieving this, refer to "Configuring Secure Sockets Layer" in the Information Center. It is expected that, for development use, security will be disabled and security will be enabled for production environments.

The SOAP interface also supports the UDDI API for get\_authToken and discard\_authToken API but use of this is optional.

- If security is disabled and get\_authToken is not called, the default user, UNAUTHENTICATED, is used.
- If security is disabled and get\_authToken is called, the specified userid is used (but the password is not checked).
- If WebSphere security is enabled, it takes priority over UDDI authentication, but if the Publish role is mapped to Everyone, get\_authToken must be used and the userid and password will be checked by WebSphere.

The Security Roles provided with the UDDI Registry are as follows:

- GUI\_Publish\_User
- GUI\_Inquiry\_User
- SOAP\_Publish\_User
- SOAP\_Inquiry\_user
- EJB\_Inquiry\_Role
- EJB\_Publish\_Role

## Configuring the UDDI User Console (GUI) for multiple language encoding support

If you want to use multiple language encoding support in the User Console (GUI), you must configure the application server into which the UDDI Registry application is installed with UTF-8 encoding enabled. To do this, refer to "Configuring application servers for UTF-8 encoding" in the WebSphere Information Center.

## Customizing the UDDI User Console (GUI)

The look and feel of the UDDI console is determined by the styles defined in the *uddi\_gui.css* file which is located in the `/gui.war/theme` directory of the installed UDDI Registry application directory. The UDDI Registry application directory will be one of the following, depending on where you have installed the UDDI Registry:

- If you have installed the UDDI Registry into an application server within a deployment manager cell, the directory is `<AppServer-install-dir>/installedApps/<currentcell>/UDDIRegistry.<nodename>.<servername>.ear/gui.war`
- If you have installed the UDDI Registry into a single application server which is not part of a deployment manager cell, the directory is `UDDIRgistry.ear` under the `installedApps` directory of the WebSphere Application Server in which you have installed the UDDI registry application as shown in the example below.

The contents of this file can be edited to change the colors, fonts and font sizes according to the user's preference.

The content and layout of the UDDI User Console is provided by Java Server Pages (JSP), which can be customized by a programmer who is familiar with JSPs. The JSP pages are found in the `uddi.ear` enterprise application, which is under the `installedApps` subdirectory of the WebSphere AppServer installation. To locate the JSPs, expand the `UDDI_Registry.ear`, open the `gui.war`, and they are located under `WEB-INF` in the `pages` subdirectory. So, on a Windows system that has WebSphere installed in the default location, the JSP files will be found in

```
<AppServer-install-dir>\installedApps\<nodename>\UDDI_Registry.ear\gui.war\WEB-INF\pages
```

These JSP pages also contain some application logic (as opposed to presentation logic) that should not be changed.

## Configuring SOAP interface properties

You can configure the following SOAP interface properties:

- *defaultPoolSize* - the number of SOAP parsers with which to initialize the parser pool for the SOAP interface. You can set this independently for the Publish (`uddipublish`) and Inquiry (`uddi`) APIs. For example, if you expect more inquiries than publish requests via the SOAP interface, you can set a larger pool size for the Inquiry API. The default initial size for both APIs is 10.
- The *context root* used for the Publish and Inquiry APIs, which forms a part of the URL by which they are accessed. By default this is `/uddisoap`.
- Whether the API is to be secure (via HTTPS) or insecure (via HTTP). The default is to use HTTPS.

To configure the following SOAP interface properties, use either of the following methods:

- Configuring SOAP properties with the Assembly Toolkit (the recommended option, especially for a production environment)
- Configuring SOAP properties in the deployment descriptor for the SOAP module in the UDDI application directly. This option is faster and may be the preferred method in a test environment.

## Configuring SOAP properties with the WebSphere Assembly Toolkit

To configure SOAP properties by using the WebSphere Assembly Toolkit, complete the following steps:

- Select *Update* and click on the Application icon.
- Select the *uddi.ear* file (this is placed, by the UDDI installation, into the UDDI install directory (e.g. *C:\WebSphere\installableApps\uddi.ear*).
- Expand the *uddi.ear* icon on the left-hand pane in the AAT.
- Expand the *Web Modules* tree.
- Expand the *uddi Soap* tree
- To change the *defaultPoolSize*, expand Web Components and then *uddipublish* (for the publish API) or *uddi* (for the inquiry API).
  - Click on *Initialization Parameters* which will show the *defaultPoolSize* parameter in the upper right-hand pane. This can be edited in the lower right-hand pane.
- To change the *context root*, click on *UDDI Soap* which displays general information about the SOAP module in the lower right-hand pane in Assembly Toolkit. The *context root* can be edited in this pane.
- To change the publish API to use HTTP (instead of HTTPS), click on *Security Constraints* and change the *Transport Guarantee* from Confidential to none.
- Having made any changes above, you must now save them. To do this, click on *File -> Save (or Save As)* to save your changes.
- Redeploy the *uddi.ear* to WebSphere, by first removing it and reinstalling it via the Administrator's Console.

## Configuring SOAP properties in an application that is already deployed

To configure SOAP properties after the UDDI application has been installed:

1. Edit the deployment descriptor for the SOAP module (*web.xml*). This file is located in the *WEB-INF* subdirectory of the *uddi.ear* application in the installed applications within the WebSphere install directory (for example, *<WebSphere-install-dir>\installableApps\uddi.ear\soap.war\WEB-INF*).
2. Stop and restart the application server for the changes to take effect.

---

## Administering the UDDI Registry

Perform the following tasks to administer the UDDI Registry:

- Running the UDDI Registry
- Backing up and restoring the UDDI Registry database

## Running the UDDI Registry

### Starting the WebSphere Application Server in which the UDDI Registry is deployed

After a reboot, or at any time required, the server can be started by running *startServer* (on Windows) or *startServer.sh* (on Unix and Linux platforms).

On Unix and Linux platforms run the *db2profile* script before issuing the *startServer.sh server1* command. This script is located within the DB2 instance home directory under *sqllib* and is invoked by typing:

```
. /home/db2inst1/sqllib/db2profile
```

**Note:** In the above example, notice that the *'.'* is followed by a single space character.

**Note:** On Unix and Linux platforms the DB2 user **must** have a *db2profile* at *\$HOME/sqllib/db2profile*

By default, the UDDI Registry is started automatically when the application server is started. In order to stop and restart it, use the administrative console.

You can also use the administrative console to change this default behavior.

## Backing up and restoring the UDDI Registry database

If you want to protect the data in your UDDI Registry database, you can back up and restore the database using the facilities of the database product. For DB2, you can do this by using the export and import utilities of the DB2 Control Center. For Cloudscape you can simply use operating system tools to copy the database directory. Refer to the database product information for more details.

DB2 allows for dynamic backup, but, if you are using static backup, stop any UDDIReg applications beforehand.

The UDDI Registry database is called UDDI20, and the tables that should be backed up are:

- ADDRESS
- ADDRLINE
- BSERVICE
- BTEMPLATE
- BUSINESS
- CATEGORY
- CATEGORYBAG
- CONTACT
- DESCR
- DISCOVERYURL
- EMAIL
- EXTCATEGORY
- IDENTIFIERBAG
- INSTANCEDetail
- NAMEELEMENT
- OVERVIEWDOC
- PHONE
- PUBLISHERASSERTION
- SERVICEPROJECTION
- TMODEL
- VALIDATIONCACHE
- VALIDATIONSERVICES

---

## UDDI4J programming interface

The following considerations are specific to the support for UDDI4J specification provided by WebSphere Application Server:

- **UDDI4J class libraries provided.**

WebSphere Application Server provides two UDDI4J class libraries:

**uddi4jv2.jar**

This class library contains classes which support Version 2 of the UDDI specification.

**uddi4j.jar**

This class library is provided for compatibility with WebSphere Application Server and supports Version 1 of the UDDI specification. The classes in this library are deprecated.

- **UDDI4J error handling**

When invoking UDDIProxy inquiry methods, UDDIException is thrown if errors are received from the UDDI proxy. UDDIException can contain a DispositionReport with information about the error. APIs that do not return a data object, provide the disposition report. SOAPException is thrown if a communication error occurs or if the resulting data cannot be parsed as a valid SOAP message.

See the article [Web services: Resources for Learning](#), to learn more about the use of SOAP, Universal Description, Discovery and Integration (UDDI) Registry, UDDI4J, programming specifications and examples.

---

## UDDI user console

This topic describes the layout of the UDDI user console (also referred to as the Graphical User Interface (GUI)), which you can use to interact with the IBM WebSphere UDDI Registry.

For information about how to display the UDDI user console, see [Displaying the user console](#).

If you will be using the UDDI console, it is recommended that you configure the application server into which you have installed the UDDI Registry for UTF-8 encoding support: see ["Configuring the UDDI User Console for multiple language encoding support"](#).

- The user console provides a graphical user interface to the majority of the UDDI Version 2 API. It is not intended to support the full API set: there is some focus on inquiry operations, as the main purpose of the UDDI user console is to allow users to issue inquiry requests and to familiarize themselves with general UDDI concepts. This section documents those areas for which support through the user console is not provided, together with other known restrictions to the user console.
  - General
    - Help is provided in the form of explanatory text on the screens.
    - Maximum rows cannot be specified on finds. The single maximum rows value for the registry can be set through the *dbMaxResultCount* global configuration property. For more information on setting this property see [Configuring global UDDI properties](#)
  - Find business
    - The business identifier feature is not supported.
  - Find service type
    - The business identifier feature is not supported.
  - Add business
    - You must supply the business contact as a name and role (no other information is supported).
  - Add service type
    - You can enter the overview URL, but only with one description in English.
  - Add service
    - There is no support for entering a Hosting Redirector, nor for adding an overviewURL.
- **Note:** The UDDI Version 2 specification states that when a tModel is deleted, it should not be physically deleted. This allows the tModel to be reinstated. One effect of this is that, if you delete a tModel using the UDDI user console, the tModel is still visible through the Show Owned Entities display.

The UDDI user console is split into three distinct areas. At the top of the screen are buttons that activate various functions in the areas below this bar. These buttons are:

**Home** Returns you to the IBM WebSphere UDDI Registry welcome page

**Find** Activates the Find tab on the frame below to the left

**Publish**

Similarly activates the Publish tab on the frame below to the left

Below the WebSphere UDDI Registry banner the screen is split into two parts. On the left are the two tabs mentioned above, the Find and Publish tabs.

### Find tab

The Find tab is in two parts. At the top, a **Quick Find** service is provided. There are three radio buttons to enable a choice of 'service', 'business' and 'technical model' finds. Below these radio buttons is a text entry box for entering the name to search for and, beneath this, a 'Find' link to start the search. Comments are provided to show the user the wildcard character. The results of clicking on the 'Find' link are shown in the detail frame to the right.

Beneath the Quick Find is a section for **Advanced Find** functions which enables the user to choose which entity they want to perform an advanced search on. There are three links: Find services, Find businesses and Find technical models. Clicking one of these links displays the corresponding advanced search form in the frame to the right, which the user may use to enter search criteria. To initiate a Find, the user must first enter a search path (the % wildcard may be used) and then click the blue Add link to enter the search. Then click on the 'Find Services' (or 'Find Businesses/Find technical models) link below to initiate the Find operation. The **Locator** section has a link (marked in blue with the words "**Show category tree**") which displays the tree from which the user can select categories (or taxonomies). This is shown in the left-hand frame. In the advanced search form there are two links to start the search (mid-way down and at the bottom).

The results of clicking either of the two links to start the search are displayed in the same detail frame.

## **Publish tab**

The *Publish* link on the top banner activates the Publish tab in the navigation frame to the left. The Publish tab is split into three distinct sections.

### **1. Quick Publish Function**

The top part is a **Quick Publish** section to allow the user to publish a business or technical model by name only. There are two radio buttons to enable a choice of 'business' or 'technical model'. Below these radio buttons is a text entry box for entering the name to assign to the selected entity and, beneath this, a blue 'Publish now' link to publish the entity. The results of clicking on the **Publish now** link are shown in the detail frame to the right.

### **2. Advanced Publish Functions**

To publish an entity with more detail, such as with multiple names, descriptions and categories, use the **Advanced Publish** section below this. The comments below each link ('Add a business' and 'Add a technical model') describe individual functions. Clicking one of these links displays the corresponding advanced publish form in the detail frame where the user may enter details about the entity they want to publish. As in the Advanced Find functions described above, there are two links to publish a business or technical model (one towards the top of the form and the other at the bottom). Similarly the **Locator** section allows taxonomies to be shown in the left frame from which the user can select categories.

Following entry of the relevant details on the **Advanced Publish** section, the user must click on the **Publish Business** bar in order for the business to be published to the UDDI Registry.

### **3. Registered Information**

Below the Advanced Publish section is a **Registered Information** section which has a link to **Show Owned Entities** in order to show the businesses, services and technical models registered to the individual user, and pending business relationships. Clicking the **Show Owned Entities** link displays the **Show Owned Entities** page in the detail frame at the right. The **Show Owned Entities** page is organized in three sections: **Registered Businesses**, **Pending Business Relationships** and **Registered Technical Models**. Each section shows the number of registered items.

#### **Edit and Delete Businesses**

Users can **Edit** or **Delete** businesses owned by them by clicking the appropriate links in the **Actions** column.

After an **Edit** or **Delete** function has been completed, the user **must** click on the **Update Business** bar in order to publish the changes to the UDDI Registry.

After Deleting a Business the user must confirm the deletion by clicking on the 'Delete this Business' link.

#### **Adding a Service to a Business**

Services are added to a business by clicking the **Add a Service** link in the **Services** column of the **Registered Businesses** section.

After the **Add a Service** function is complete, users **must** click on the **Publish Service** bar in order to publish the service to the UDDI Registry.

## Referencing a Service from a Business

Services can also be 'referenced' by a business as if the business was the owner of the service. This 'service projection' is performed by clicking the **Reference a service** link in the **Services** column. Services associated with a business, whether they are owned or referenced, can be displayed by clicking the **Show services** link. This acts as a toggle between displaying services available for editing or deleting, and hiding them.

## Adding a relationship to another Business

A business can be associated with another business in the UDDI Registry and this function is performed by clicking the **Add a relationship** link in the **Actions** column of the Registered Businesses section. Clicking the **Show related businesses** link in the **Actions** column displays a list of any completed business relationships.

The **Pending Business Relationships** section shows all incomplete publisher assertions, where only one party has asserted a relationship and is waiting for the other party to make the same assertion. This section reminds the user of any relationships that involve their businesses. Once both parties have asserted the same relationship between two businesses, the relationship moves from the **Pending Business Relationships** section and appears in the list of relationships displayed after clicking the **Show related businesses** link in the **Registered Businesses** section.

## Technical Models

Technical Models owned by the user are shown in the bottom **Registered Technical Models** section. As for businesses, users can Edit or Delete technical models owned by them by clicking the appropriate links in the **Actions** column.

**Note:** Users should take note that deletion of Technical Models (tModels) does **not** cause them to be physically deleted, but hidden. This is in accordance with the UDDI Registry V2.0 specifications. After deletion Technical Models are shown under the "**Shown Owned Entities**" link on the publish page but not via the Find links on the Find page. ALL other entities are deleted from the UDDI Registry in the normal way.

## Example of publishing a Business, Service and tModel with the User Console

For the example, here, we will assume a business called Mondeo Cars that sells used cars

### 1. Add the Business

Click on the Publish tab in the left hand navigation frame. Then click on 'Add a business' in the Advanced Publish in the left pane. This takes you to a 'Publish Business' pane on the right. Start by adding your Business Name in the text field labelled (Mondeo Cars in this example) and select a language and then click on the blue Add link to the right. This adds the business name (but the business is not yet published - more about which is explained later). Below the Business Name is an area called Descriptions - it allows free text to be added to describe the business - if you enter anything here you must click on the blue Add link to the right to insert the description.

The next section/area is the Locator area which can be used to describe the business according to what categories it falls into. This example uses a Used car dealership. Within the NAICS taxonomy (which you may view by clicking on 'Show category tree' and then expanding NAICS) this is a Retail Trade [44] entry which, on expansion, has Motor Vehicle and Parts Dealers [441] and, again on expansion, has automobile Dealers [4411] and Used Car Dealers [44112]. This fits the Business perfectly, so clicking on Used Car Dealers will enter the Key Name and Key Value into the business. For Checked Categorizations (such as NAICS) the Key name is not checked but the Key Value is checked. It should be noticed that for unchecked categorizations (such as 'other' or unspsc') the Key value is not checked either. If the locator field has been added, then the blue Add link must be clicked. The final area is Contacts, which can have names and role information added if required. Again, the blue Add link must be clicked after adding the relevant information.

Once all the fields are filled in to the required level, the final action is to click on the Publish Business at the bottom of the form or at the top. This causes the business to be published to the UDDI Registry and a page is displayed showing the business details.

### 2. Add a Service

From the Publish tab, there is a 'Show owned entities' link. This shows the businesses owned by the current user in the Registry and the language to be used for a particular user. For Mondeo Cars, the user will see a 'Add service' button. Clicking this button shows the Publish Service form. The top part of the form is the Service Name field. After adding this name, the user must click on the blue Add link to enter the name. As in the Adding the Business form, each subsequent part must end with the blue Add link being clicked to add that part of the information to the service. The sections are (from top to bottom, Description (a free text area), Access Points (to add link points to the Service), Locator (to add references to taxonomies to the service), and Technical Models (to associate existing tModels to the Service). After completion of those areas required, clicking on the 'Publish Service' button will Publish the service to the UDDI Registry with the current form contents.

### 3. **Adding a new technical model**

Clicking on the 'Add a technical model' link in the left frame opens up the Publish Technical Model form on the right. A tModel can only have one name - hence the lack of a blue Add link next to the Technical Model Name field. Beneath this field are other fields - Description (a free text area to describe the technical model), Locator (to describe the technical model with taxonomies, and an Overview URL (which gives a URL pointing to an overview document, a description of the document and a Language field). For each of these fields there is a blue Add link which must be clicked to add the relevant data. At the bottom of the form is a 'Publish Technical Model' link which will create the technical model in the UDDI Registry.

There is a Publish link at the top of the frame in each case also - after the Name section.

- Displaying the user console

## Displaying the user console

### Access without authentication enabled

This topic describes how to display the UDDI Registry user console (also referred to as the GUI). By default two URLs are supplied, one for inquiry (non-SSL) and one for publish (via SSL). This section describes the default behavior.

- For inquiry you can access the UDDI User Console by using the following URL in your Web browser:

`http://<hostname>:9080/uddigui`

- For publish you can access the UDDI user console by using the following URL in your Web browser:

`https://<hostname>:9443/uddigui`

**Note:** With WebSphere security disabled, all the publish operations are performed using a userid of UNAUTHENTICATED. Also, if you select a publish action on the GUI you will automatically be redirected to the SSL port.

### Access with authentication enabled.

If you have WebSphere security enabled, you can access the UDDI User Console through the two URLs as above, however, for publish request, you will be prompted for a WebSphere uid and password.

The user console displays the default frameset containing the header frame, navigation frame showing find options, and details frame. When you click the link to show the publish options in the navigation frame, you are challenged for a userid and password.

If WebSphere security is enabled and you try to access a publish action via an unsecured link, e.g. clicking the publish link on the navigation frame where the user console was opened with:

`http://<hostname>:9080/uddigui`

you are redirected to a secure logon screen. Inquire functions work as expected.

The uDDI Registry supports a number of security roles, including two for the user console. See [Configuring Security Roles](#) within this Information Center for more details on this topic.

## Custom Taxonomy Support in the UDDI Registry

The IBM WebSphere UDDI Registry is supplied with six published taxonomies (or categorization schemes) in the taxonomy data. Taxonomies can be either checked or unchecked, and this is indicated via a keyedReference in the categoryBag of the tModel that represents a taxonomy (a "categorization tModel"). These keyedReferences have the tModel key for uddi-org:types and are added to the categoryBag to further describe the behavior of the categorization tModel, as follows:

### checked

Marking a tModel with this classification asserts that it represents a categorization, identifier, or namespace tModel that has a validation service to check that category values are present in a specified value set.

### unchecked

Marking a tModel with this classification asserts that it represents a categorization, identifier, or namespace tModel that does not have a validation service.

Of these six published taxonomies, four are checked.

In the IBM WebSphere UDDI Registry and also in the IBM UDDI Business Registry (UBR), the validation of categories in checked taxonomies is performed against locally managed taxonomy data. The published taxonomies are:

Taxonomy name	Checked	Description	tModel key
ntis-gov:naics:1997	Yes	Business Taxonomy: NAICS (1997 Release)	uuid:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2
uddi-org:iso-ch:3166-1999	Yes	ISO 3166-1:1997 and 3166-2:1998. Codes for names of countries and their subdivisions. Part 1: Country codes. Part 2: Country subdivision codes. Update newsletters include ISO 3166-1 V-1 (1998-02-05), V-2 (1999-10-01), ISO 3166-2 I-1 (1998)	uuid:4E49A8D6-D5A2-4FC2-93A0-0411D8D19E88
unspsc-org:unspsc	Yes	Product Taxonomy: UNSPSC	uuid:CD153257-086A-4237-B336-6BDCBDCC6634
unspsc-org:unspsc:3-1	No	Product Taxonomy: UNSPSC (Version 3.1)	uuid:DB77450D-9FA8-45D4-A7BC-04411D14E384
uddi-org:types	Yes	UDDI Type Taxonomy	uuid:C1ACF26D-9672-4404-9D70-39B756E62AB4
uddi-org:general_keywords	No	Special taxonomy consisting of namespace identifiers and the keywords associated with the namespaces	uuid:A035A07C-F362-44DD-8F95-E2B134BF43B4

Taxonomy data is provided in the IBM WebSphere UDDI Registry for all the above taxonomies, apart from the general keywords taxonomy (which is unchecked). The UDDI User Console (GUI) provided with the IBM WebSphere UDDI Registry uses a shortened label for taxonomies when displayed in the taxonomy tree view, or in a pull-down list of available taxonomies as follows:

Taxonomy Name (published)	Taxonomy name (as displayed in the UDDI user console)
ntis-gov:naics:1997	naics
uddi-org:iso-ch:3166-1999	geo
unspsc-org:unspsc	unspsc7
unspsc-org:unspsc:3-1	unspsc
uddi-org:types	udditype
uddi-org:general_keywords	other

This release of IBM WebSphere UDDI Registry (included with IBM WebSphere Application Server, Version 5.0.2) introduces the ability to add user-defined taxonomies, with available allowed values presented in the existing GUI taxonomy tree display. IBM WebSphere Studio Application Developer, Version 5.1 has a Web Services Explorer user interface that also allows addition and display of custom checked taxonomies. The publisher of a custom taxonomy's categorization tModel may specify a 'display name' for use in GUI implementations.

### Procedure for adding a Custom taxonomy

To add a custom taxonomy to the IBM WebSphere UDDI Registry requires you to perform two tasks: load the custom taxonomy data and publish a categorization tModel. Only when both are complete will the checked taxonomy be of practical use. Taxonomy data must be provided for validating checked taxonomies.

Taxonomy data *may* also be used by GUIs for unchecked taxonomies, but it is not a requirement and is usually only used for presentation of deprecated taxonomies, such as unspsc-org:unspsc.

If the taxonomy is checked, then any publish requests that have a categoryBag containing keyedReferences with the new categorization tModel will be validated. If there is taxonomy data corresponding to the categorization tModel in the registry database then only valid values will be accepted. If there is no taxonomy data in the database then **all** values will be rejected, and the publish request will fail. If the categorization tModel is unchecked, all values will be allowed, regardless of whether there is corresponding taxonomy data present in the UDDI Registry database.

### Suggested approach

The suggested way of introducing a new taxonomy is to:

1. Load custom taxonomy data into the UDDI Registry database using the UDDITaxonomyTools.jar utility (described below)
2. Publish the categorization tModel with a keyedReference of type 'general keywords' with keyname of 'customTaxonomy:key' and a keyValue matching the taxonomy name in the taxonomy data file (described below also)

**Note:** the SOAP and EJB interfaces will be able to make use of categorization tModels as soon as they are published. However, the UDDI Registry GUI will currently require a restart of the UDDI application because it currently gathers its list of categorizations for use in the taxonomy tree display when the application starts.

## Loading Custom Taxonomy Data

### Custom Taxonomy Data File Format

Taxonomy data is identified by a common taxonomy name, a unique code value, an optional description and a parent code that specifies its relationship with other code values. Taxonomy data must adhere to this format:

Column name	Maximum length	Description of use
<b>name</b>	8	Uniquely identifies the taxonomy within the registry
<b>code</b>	32	Unique value within the taxonomy used for validation
<b>description</b>	128	Typically used by GUIs and optionally in the keyedReference as the keyName value
<b>parentcode</b>	32	Indicates which existing <b>code</b> is the logical parent of this one, and is used in tree displays

Typically columns are delimited in the taxonomy data file by '#' characters as in this example:

```
food#00#Food#00
food#10#Fruit#00
food#101#Apples#10
food#102#Oranges#10
food#103#Pears#10
food#1031#Anjou#103
food#1032#Conference#103
food#1033#Bosc#103
food#104#Pomegranates#10
food#20#Vegetables#00
food#201#Carrots#20
food#202#Potatoes#20
food#203#Peas#20
food#204#Sprouts#20
```

In the example, 'Food' is the description for the root node with child nodes of 'Fruit' and 'Vegetables' (both of these have parentcode values the same as the code value for 'Food').

The taxonomy data in the example file could then be rendered in a tree like this:

```
Food
 Fruit
 Apples
 Oranges
 Pears
 Anjou
 Conference
 Bosc
 Pomegranates
 Vegetables
 Carrots
 Potatoes
 Peas
 Sprouts
```

The file must be saved in UTF-8 format.

The following taxonomy names are reserved within the IBM WebSphere UDDI Registry and should not be used for custom taxonomy files: **naics**, **geo**, **unspsc**, **unspsc7**, **other**, **udditype**. Any attempts to publish a categorization tModel using these values for a customTaxonomy:key are rejected. If these names are used in custom data files and the data is imported it is indistinguishable from taxonomy data with the same name.

## UDDITaxonomyTools.jar

A utility is provided to load taxonomy data into the IBM WebSphere UDDI Registry, rename existing taxonomy data and remove existing taxonomy data, for both IBM DB2 and Cloudscape databases. The usage for each database and platform is identical:

Usage: java -jar UDDITaxonomyTools.jar {function} [options]

function:

```
-load <path> Load taxonomy data from specified file
-rename <old> <new> Rename existing taxonomy
-unload <name> Unload existing taxonomy
```

options:

```
-properties <path> Specify location of configuration file
```

**Note:** Ensure that the command window from which the UDDITaxonomyTools.jar is run is using a suitable codepage and font for displaying the characters contained in the taxonomy name.

Use of an incorrect codepage/font may result in unclear messages on a successful load, and create difficulty using the -unload and -rename options.

UDDITaxonomyTools.jar is located, by default, in the <DeploymentManager-install-dir>/UDDIReg/scripts directory.

The following section explains in more detail how to use the utility's commands and parameters. The configuration file, if specified by the optional properties parameter, determines the database driver, authentication information and delimiters. The contents are as follows (typical data for DB2 installation shown):

Property and example data (for DB2)	Comments
classpath= "c:/program files/sqllib/java12/db2java.zip; c:/tools/UDDITaxonomyTools.jar"	Classpath including database driver <i>and</i> the UDDITaxonomyTools.jar*
database.driver.className=COM.ibm.db2.jdbc.app.DB2Driver	Fully qualified classname of the database driver class
database.url=jdbc:db2:UDDI20	JDBC URL of the database
database.userName=db2admin	Database userid (DB2 only)
database.password=db2admin	Database password (DB2 only)
column.delimiter=#	Column delimiter used in taxonomy data files
string.delimiter=\"	Field delimiter (must be different to the column.delimiter value)

\* the classpath needs to be enclosed in quotes if the path includes space characters. Also, the UDDITaxonomyTools.jar filepath itself must be appended to the classpath (if the working directory is the same as the location of the UDDITaxonomyTools.jar then just the name is sufficient)

Filepath names should include the use of the forward-slash character (/) for all platforms.

For Cloudscape database users, the values of the following properties would be likely to be:

- classpath=c:/websphere/appserver/lib/db2j.jar; UDDITaxonomyTools.jar
- database.driver.className=com.ibm.db2j.jdbc.DB2jDriver
- database.url=jdbc:db2j:c:/ websphere/appserver/bin/uddi20

The string.delimiter is typically used where a description value contains the same character as the column delimiter character. For example, if the column.delimiter was set to ',' (comma), and there was a taxonomy

description value of 'Fruits, citrus', you could include this in the taxonomy data file by setting the string.delimiter to "(double quote) and enclosing the description in quotes: 'Fruits, citrus'. Note that the quote character is escaped with a backslash to indicate the literal character is to be used.

If a properties parameter is not specified, the utility looks for and uses configuration data set in a file called customTaxonomy.properties. This file is located, by default, in the <DeploymentManager-install-dir>/UDDIReg/scripts directory.

**Note:** to make updates to taxonomy data in a Cloudscape database, the IBM WebSphere Application Server must be stopped to release the connection to the database.

**Note:** There is currently a limitation with UDDITaxonomyTools.jar when used with a DB2 UDDI database and multi-byte characters such as Chinese, Japanese and Korean. The maximum number of multi-byte characters is the maximum value specified earlier for name, code, description and parentcode divided by 3. For example, name can only contain values up to 8 characters in length so the maximum number of Korean characters is 2. If the taxonomy file is found to have values that exceed the limits, a message is displayed by the tool indicating the line number and column where the problem occurs. This limitation does not affect use with a Cloudscape UDDI database.

### Publishing a Checked Categorization tModel

This section describes how to publish a checked categorization tModel with the 'customTaxonomy' keyedReferences to specify which custom taxonomy data to use and a display name.

**Note:** to specify an unchecked categorization substitute the 'checked' keyValue with 'unchecked' or, more simply, omit the keyedReference.

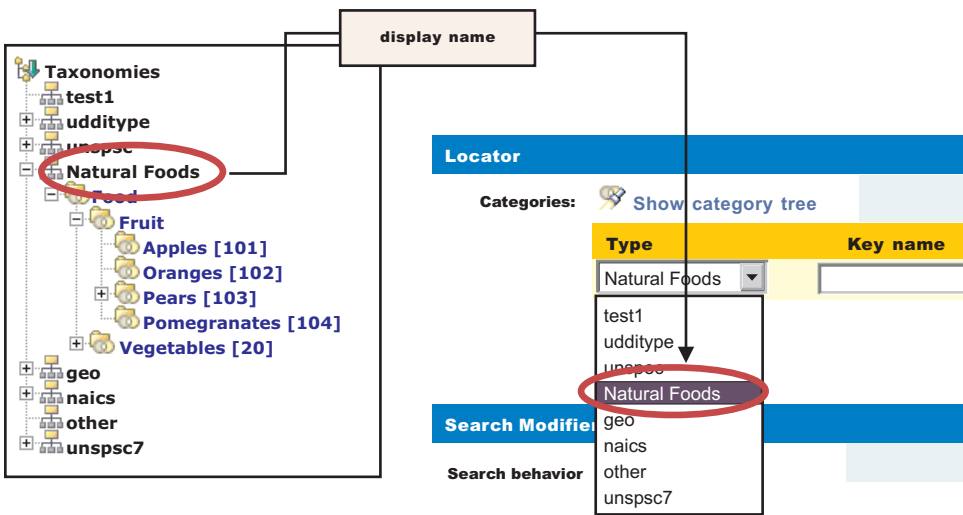

Publish a tModel to the IBM WebSphere UDDI Registry with a categoryBag containing keyedReferences as follows:

Note	tModelKey	KeyName	KeyValue
1	(uddi-org:types)	<optional>	categorization
2	(uddi-org:types)	<optional>	checked
3	(general keywords)	urn:x-ibm:uddi:customTaxonomy:key	<custom taxonomy name>
4	(general keywords)	urn:x-ibm:uddi:customTaxonomy:displayName	<custom taxonomy displayName>

1. Indicates this tModel is a categorization tModel (required)
2. Indicates use of the tModel will be checked against a list of valid data (required). (Omitting this keyedReference, or explicitly specifying a value of 'unchecked' will indicate this categorization is unchecked).
3. Indicates special use of the general keywords taxonomy, with a proprietary urn as the keyName value, defines the value used by the UDDI Registry to look up taxonomy data in its database. The value must be 1-8 (inclusive) characters long and corresponds directly with the name value in the custom taxonomy data file. Therefore, it must be unique within the registry.
4. Indicates special use of the general keywords taxonomy, with a proprietary urn as the keyName value, defines a name for the custom taxonomy that is intended for use in GUI implementations where the full tModel name might be too long\*. The value can be 1-255 characters (inclusive) long. If this keyedReference is not supplied, the name of the tModel should be used by the GUI implementation.

\* The displayName is intended to provide a way to label a taxonomy such that, when the UDDI GUI displays it in a taxonomy tree or in a pull-down list of available taxonomies, the meaning is clear to the user without being restricted to 8 characters and without needing to be the same as the published

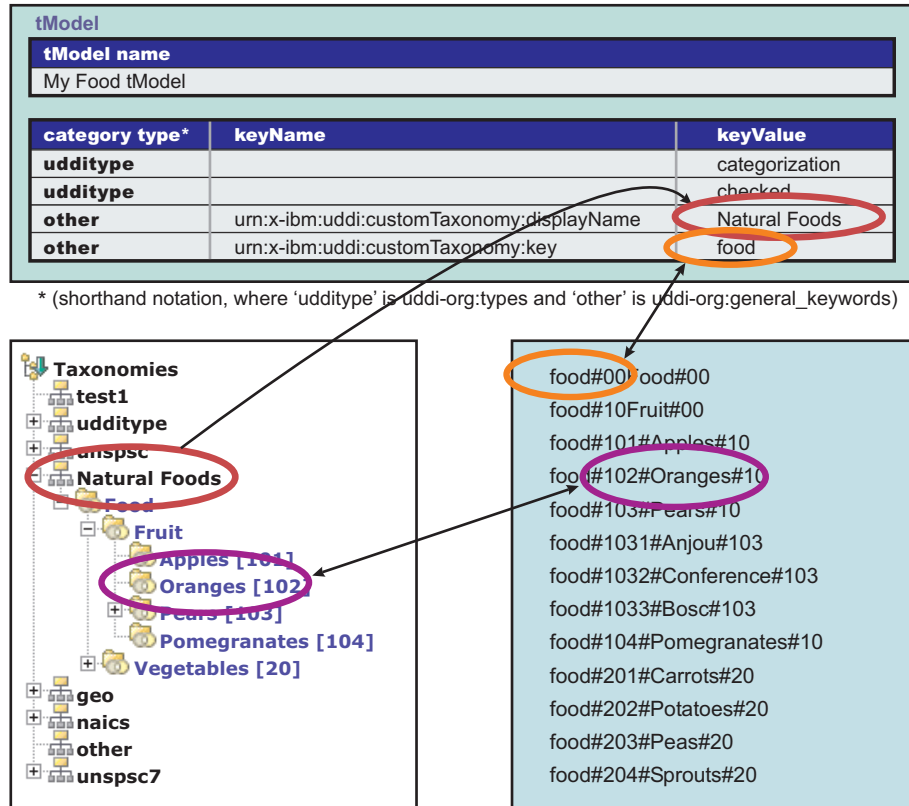

tModelName, which could be as long as 255 characters. An example is shown:

Uniqueness of the urn:x-ibm:uddi:customTaxonomy:key value is validated at the time a categorization tModel is published. If it is not unique, a UDDIInvalidValueException is returned. If using a GUI to publish the tModel, an appropriate message is displayed indicating the likely cause of the problem.

The urn:x-ibm:uddi:customTaxonomy:displayName should be unique if only to avoid confusion when displayed in GUIs but this is not validated.

The relationship between the various keyedReferences, the custom taxonomy data files and use in GUIs for a categorization tModel is shown below:

As a further example, to display the label 'Delicious Victuals' in GUI displays, the categorization tModel would have a keyedReference like this:

type	keyName	keyValue
other	urn:x-ibm:uddi:customTaxonomy:displayName	Delicious Victuals

And to link a categorization tModel to a custom taxonomy datafile with a taxonomy name of 'goodfood' the tModel's categoryBag must have a keyedReference like this:

type	keyName	keyValue
other	urn:x-ibm:uddi:customTaxonomy:key	goodfood

To publish a new categorization tModel using SOAP, the message would be:

```
<save_tModel generic="2.0" xmlns="urn:uddi-org:api_v2">
 <authInfo></authInfo>>
 <tModel tModelKey="">
 <name>Natural Foods tModel</name>
 <categoryBag>
 <keyedReference tModelKey="uuid:C1ACF26D-9672-4404-9D70-39B756E62AB4"
 keyValue="categorization"/>
 <keyedReference tModelKey="uuid:C1ACF26D-9672-4404-9D70-39B756E62AB4"
 keyValue="checked"/>
 <keyedReference tModelKey="uuid:A035A07C-F362-44DD-8F95-E2B134BF43B4"
 keyName="urn:x-ibm:uddi:customTaxonomy:key" keyValue="food"/>
 <keyedReference tModelKey="uuid:A035A07C-F362-44DD-8F95-E2B134BF43B4"
```

```

 keyName="urn:x-ibm:uddi:customTaxonomy:displayName" keyValue="Natural Foods"/>
 </categoryBag>
</tModel>
</save_tModel>

```

**Note:** 'uuid:C1ACF26D-9672-4404-9D70-39B756E62AB4' is the tModel key for uddi-org:types and 'uuid:A035A07C-F362-44DD-8F95-E2B134BF43B4' is the tModel key for uddi-org:general\_keywords.

## Validation and Error Handling

For a DB2-based IBM WebSphere UDDI Registry, custom taxonomy data can be loaded, removed and renamed using the provided utility without restarting the application (if you are using Cloudscape the application server must be stopped to make database updates). Removing data for which there is a corresponding checked categorization tModel will cause any use of that categorization's data to be reported as invalid.

**Note:** If an attempt is made to add data with a name that matches any of the 'internal' taxonomies, such as naics, geo, and so on, the request is rejected. If an attempt is made to rename or remove one of the internal taxonomies, a warning message is returned. Likewise if the user tries to rename a taxonomy to one of the reserved taxonomies, that is rejected.

The UDDI Registry user console performs validation while a save tModel request is being built, that is, before the publish occurs. For example, if a categorization tModel with a customTaxonomy:key keyValue of 'food' already exists (in a published categorization tModel), and the user tries to add a keyedReference with the same value to the current list of keyedReferences, the following message is displayed:

```
Advice: The 'urn:x-ibm:uddi:customTaxonomy:key' value of 'food' is already in use
by another categorization tModel. Enter a unique value
```

Similarly, only one of each of the customTaxonomy:key and customTaxonomy:displayName keyedReferences are allowed. For example, if the user tries to add two customTaxonomy:displayName keyedReferences the following message is displayed:

```
Advice: Only one 'urn:x-ibm:uddi:customTaxonomy:displayName' key name is allowed for the
'Other' taxonomy
```

If the customTaxonomy:key keyedReference is valid and unique at the time it is added to the save\_tModel request, the keyedReference is further validated when the user makes the publish request, to ensure that another session has not successfully published a categorization tModel with the same customTaxonomy:key. In this case, the user is returned to the Publish Technical Model page.

If a keyedReference containing a keyName value that starts with 'urn:x-ibm:uddi:customTaxonomy:' is followed by anything other than 'key' or 'displayName', the following message is displayed:

```
Advice: Only key name values of 'urn:x-ibm:uddi:customTaxonomy:displayName' and
'urn:x-ibm:uddi:customTaxonomy:key' are supported.
```

For SOAP, UDDI4J, and EJB initiated requests where the save\_tModel message may have multiple tModels, if any one of the tModels is a categorization tModel and it fails validation, the request fails with a UDDIInvalidValueException (plus additional information explaining the likely cause), and none of the tModels is published. For example, if a publish request includes a customTaxonomy:key keyedReference with a keyValue that matches the customTaxonomy:key keyValue of an existing categorization tModel, the following UDDIInvalidValueException is thrown, with the message:

```
E_invalidValue (20200) A value that was passed in a keyValue attribute did not pass validation.
This applies to checked categorizations, identifiers and other validated code lists. The error
text will clearly indicate the key and value combination that failed validation. Invalid
'customTaxonomy:dbKey' keyValue [naics] in keyedReference. KeyValue already in use by
tModelKey[UUID:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2]
```

The customTaxonomy:key and customTaxonomy:displayName keyValue values are validated. For example, a publish categorization tModel request with a keyedReference including a customTaxonomy:key of 'toolongdbkey' was attempted, the following UDDIInvalidValueException is thrown, with the message:

```
E_invalidValue (20200) A value that was passed in a keyValue attribute did not pass validation.
This applies to checked categorizations, identifiers and other validated code lists. The error
text will clearly indicate the key and value combination that failed validation. Invalid
'customTaxonomy:key' keyValue [toolongdbkey] in keyedReference. tModelKey[]
```

If a categorization tModel is edited in the user console, or republished via SOAP, UDDI4J or EJB, such that it is no longer a categorization tModel (ie the categorization keyedReference is removed), then that tModel is removed from the internal store of categorization tModels, and its customTaxonomy:key value, if present, is available for use by new categorization tModels.

---

## UDDI Utility Tools

The UDDI Utility Tools is a suite of functions to help manage entities in a UDDI Registry. The functions allow users to:

- Search and select entities from a source UDDI Registry by specifying keys or search criteria
- Copy selected entities to a target UDDI Registry, while keeping the same entity key, and any child entities
- Delete selected entities from a target UDDI Registry
- Persist UDDI entities in an intermediate XML representation that can be used to customize and copy those entities to multiple target UDDI Registries
- Create new entities such as canonical tModels in a target UDDI Registry, including child entities
- Update existing entities in a target UDDI Registry, including child entities
- Automatically identify any entities referenced by an entity and import those into a target UDDI Registry first

UDDI Utility Tools can be used by running the UDDIUtilityTools.jar file, or from a batch file that invokes a specific Java class in the JAR file. UDDIUtilityTools.jar is located in the <DeploymentManager-install-dir>/UDDIReg/scripts directory. Alternatively, all of the functions of UDDI Utility Tools can be invoked through the supplied public Java API.

There are five main functions in UDDI Utility Tools:

### Export

Given an entity type and key, or a list of entity types and keys, UDDI Utility Tools gets the UDDI entities from the specified registry and writes them to the UDDI Entity Definition File. The entity type for each key can be one of business, service, bindingTemplate or tModel. The Entity Definition File contains XML that exactly describes each of the specified entities, according to the UDDI Utility Tools schema (which includes the UDDI V2 schema). The UDDI Entity Definition File separates entities by type, and automatically detects and records tModels referenced by the specified entities. You can use the 'referenced tModels' section of the file to ensure a target registry includes any referenced tModels before you try to import new entities to that registry.

### Import

Given a list of UDDI entities (which can be supplied using the UDDI Entity Definition File generated by the export function, possibly with additional editing, or programmatically in a container object), the import function detects if the entities already exist in the target registry and, if they do not, creates a minimal entity ("stub") with the specified key. The entities are then published updating the stubs with the supplied data and overwriting, or ignoring, existing entities as specified by the user. Note that the original key is maintained throughout.

### Promote

Combines the export and import steps such that the specified entities are extracted (by key) from the source registry and then imported into the target registry in a single logical step. The generation of a UDDI Entity Definition File is optional for this function.

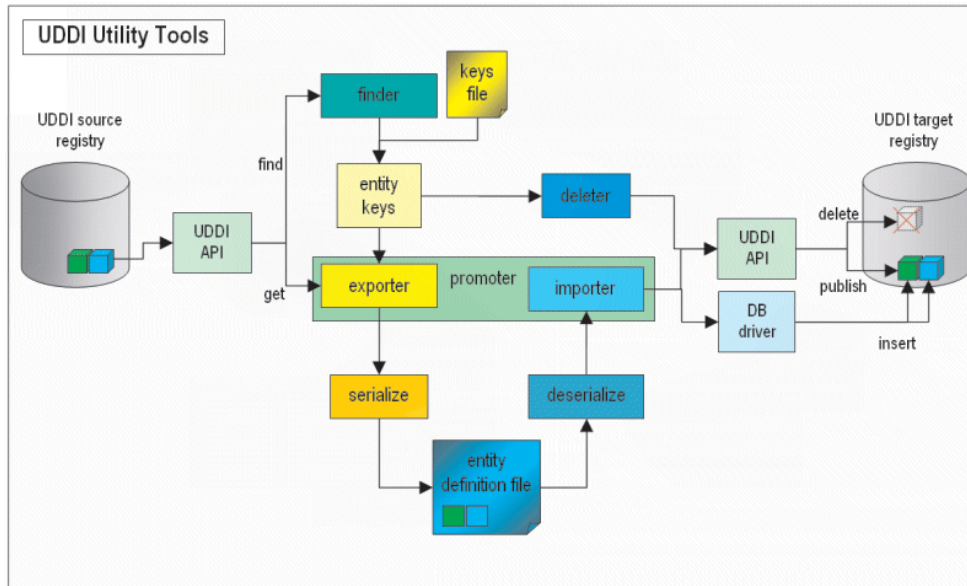

**Delete** Deletes the specified entities from the target UDDI Registry. The entities to delete are specified as an entity type, or a list of entity types, and keys, in the same way as for the export function.

**Find Matching Entities**

Takes as input search criteria in the form of UDDI Inquiry API objects for each of the various entity types. The set of entities that match the search criteria are used to generate a list of entity keys, and this in turn can be used as input to the export, promote and delete functions.

**Note:** This function is available only through the programmatic API.

The relationship between the functions, their input and output, and the source and target UDDI Registries is shown in this conceptual overview diagram:

**Setting up the configuration file**

Configuration data for UDDI Utility Tools resides in a configuration properties file, which describes the runtime environment, UDDI and database locations and access information, logging information, security configuration, entity definition file location, and other flags to control whether referenced entities are to be imported and/or overwritten.

UDDI Utility Tools is distributed with a sample configuration properties file (UDDIUtilityTools.properties) and this is searched for by default in the current directory if no properties path is specified. By default, this file is located in the <DeploymentManager-install-dir>/UDDIReg/scripts directory.

The most important property to set is the classpath, and this should include the current directory (.) and the UDDIUtilityTools.jar itself, plus all the dependent jars, most of which are located in the WebSphere AppServer lib directory. The classpath must include the database driver jar (for example db2java.zip). The other properties are well commented in the example properties file.

Below is an example properties file as distributed:

```
#####
Runtime environment
(if invoking via java -jar...)
"X Y" required around paths with spaces
#####
classpath=.;c:/Progra~1/WebSphere/utilitytools/UDDIUtilityTools.jar;
C:/WebSphere/AppServer/lib/soap.jar;C:/WebSphere/AppServer/java/jre/lib/ext/mail.jar;
C:/WebSphere/AppServer/java/jre/lib/ext/ibmjsse.jar;
```

```
C:/WebSphere/AppServer/java/jre/lib/ext/activation.jar;
C:/promoter/uddi4jv2.jar;C:/WebSphere/AppServer/lib/xerces.jar;
C:/WebSphere/AppServer/lib/j2ee.jar;"C:/Program Files/SQLLIB/java12/db2java.zip"
```

(ALL the above is on ONE line - shown here as broken for clarity)

```
#####
SOAP entry points for source UDDI
#####

```

```

Miscellaneous Options
#####
indicates if existing entities are overwritten (import/promote)
overwrite=false

indicates if referenced entities will be imported (import/promote)
importReferencedEntities=true

location of entity definition file, used for (export/import)
UddiEntityDefinitionFile=C:/definitions/entities01.xml

namespace prefix to use in definition file (export)
namespacePrefix=promote

```

## Prerequisites

UDDI Utility Tools must have the following jar files available. Their locations should be specified in the classpath property in the UDDI Utility Tools properties file:

### UDDIUtilityTools.jar

This is the tools jar itself. It MUST appear on the classpath.

### uddi4jv2.jar

This is the UDDI4J classes and can be found in <WAS\_HOME>/lib.

### db2java.zip

This is the DB2 JDBC driver classes jar which is provided with DB2.

### j2ee.jar

This contains some required J2EE classes.

### soap.jar

This is the Apache SOAP implementation.

### xerces.jar

This is the xerces XML parser.

Apache SOAP, and therefore UDDI Utility Tools, has a requirement of having activation.jar and mail.jar java extensions available. These should NOT be placed on the classpath but rather the ext folder of the JRE that is used to run the tool. If SSL is needed then ibmjssse.jar must also be in the ext folder. If you are using the JRE as supplied with IBM WebSphere Application Server then these extensions will already be in place and no further action is necessary.

The Security provider configuration section in the above properties file shows the location of the default DummyClientTrustFile.jks file. If you are using your own truststore, ensure that the location is placed here.

## The UDDI Entity Definition File

You generate this file by the export and promote functions, or you can choose to create it (either by hand, or by modifying a version of the file output by UDDI Utility Tools specifying the export function). It is the input to the import function.

**Note:** The extension to the uddi:tModel type to add a 'deleted' attribute is not currently used in UDDI Utility Tools.

The file is validated for well formedness and that it complies with the UDDI Utility Tools schema, shown here.

```

<?xml version="1.0" encoding="UTF-8" ?>
<xsd:schema id="uddiPromote" attributeFormDefault="unqualified" elementFormDefault="qualified"

</xsd:complexType>
</xsd:schema>

```

## UDDI Entity Definition File example for canonical tModels

The example Entity Definition File following shows the five main sections for tModels, businesses, services, bindings and referencedTModels:

UDDI Utility Tools can be used to create new UDDI entities in a target UDDI Registry. A typical example of this is to introduce a new canonical tModel, which has a publicly known tModel key.

```

<?xml version="1.0" encoding="UTF-8"?>
<promote:uddiEntities xmlns="urn:uddi-org:api_v2"
 xmlns:promote="http://www.ibm.com/xmlns/prod/WebSphere/UDDIUtilityTools">

 <!-- tModels -->
 <promote:tModels>

 <tModel tModelKey="uuid:ee3966a8-faa5-416e-9772-128554343571" >
 <name>http://schemas.xmlsoap.org/ws/2002/07/policytmodel</name>
 <description>WS-PolicyAttachment policy expression</description>
 </tModel>

 <tModel tModelKey="uuid:ad61de98-4db8-31b2-a299-a2373dc97212" >
 <name>uddi-org:wSDL:address</name>
 <description xml:lang="en">
This tModel specifies the URL fact that the address obtains from the WSDL deployment file.
 </description>
 <overviewDoc>
 <overviewURL>
http://www.oasis-open.org/committees/uddi-spec/doc/tn/uddi-spec-tc-tn-wsdl-v2.htm#Address
 </overviewURL>
 </overviewDoc>
 </tModel>

 </promote:tModels>

 <!-- businesses -->
 <promote:businesses>
</promote:businesses>

 <!-- services -->
 <promote:services>
</promote:services>

 <!-- bindings -->
 <promote:bindings>
</promote:bindings>

 <!-- referenced tModels -->
 <promote:referencedTModels>
</promote:referencedTModels>

</promote:uddiEntities>

```

## Starting UDDI Utility Tools at a command prompt

Ensure the correct level of java is appropriate by setting the PATH statement to the level of java supplied with WebSphere. For example, from the command line, type:

On Windows:

```
set PATH=c:\Progra~1\WebSphere\AppServer\java\bin;%PATH%
```

On Unix and Linux platforms:

```
export PATH=/opt/WebSphere/AppServer/java/bin:$PATH
```

On Unix and Linux platforms run the db2profile script before issuing the java command to start UDDI Utility Tools. This script is located within the DB2 instance home directory under sqllib and is invoked by typing:

```
. /home/db2inst1/sqllib/db2profile
```

**Note:** In the above example, notice that the '.' is followed by a single space character.

**Note:** On Unix and Linux platforms the DB2 user **must** have a db2profile at \$HOME/sqllib/db2profile.

UDDI Utility Tools can be started using:

**java -jar UDDIUtilityTools.jar <function> [options]**

using a specified properties file that sets up classpath and other parameters, or it can be called using:

**java CommandLineProcessor**

where CommandLineProcessor is the class which processes command line arguments for UDDI Utility Tools, sets up configuration and invokes the appropriate function.

The usage is as follows:

```
Usage: java -jar UDDIUtilityTools.jar {function} [options]
```

function:

```
-promote <entity source> Promote entites between registries
-export <entity source> Extract entities from registry to XML
-delete <entity source> Delete entities from registry
-import Create entities from XML to registry
```

where <entity source> is one of:

```
-tmodel|-business|-service|-binding <key> Specify single entity type and key
-keysFile | -f <filename> Specify file containing entity types and keys
```

options:

```
-properties <filename> Specify path to configuration file
-overwrite | -o Overwrite an entity if it already exists
-log | -v Output verbose messages
-definitionFile <filename> Specify path to UDDI entity definition file
-importReferenced Import entities referenced by source entities
```

The following options override property settings in configuration file:

```
-overwrite
-log
-definitionFile
-importReferenced
```

```
Example: java -jar UDDIUtilityTools.jar -promote -keysFile C:/uddikeys.txt
```

Below are a set of UDDI Utility Tools command line examples:

To export a single business to the EDF file specified in a properties file in the current directory.

```
java -jar UDDIUtilityTools.jar -export -business 28B8B928-2B2E-4EC9-A647-1E40651E4752
```

As above but this time using a keys file to specify the entities to be exported

```
java -jar UDDIUtilityTools.jar -export -keysFile c:/myKeyFiles/keyFile01.txt
```

As above but also specifying verbose output to appear on the command line.

```
java -jar UDDIUtilityTools.jar -export -keysFile c:/myKeyFiles/keyFile02.txt -v
```

To import the contents of the default EDF specified in a UDDIUtilityTools.properties file in the current directory.

```
java -jar UDDIUtilityTools.jar -import
```

As above but also specifying that referenced tModels should be imported into the target registry.

```
java -jar UDDIUtilityTools.jar -import -importReferenced
```

To import the entities from an EDF at the specified location. Note the use of forward slashes even though this is an example on a windows file system.

```
java -jar UDDIUtilityTools.jar -import -definitionFile c:/myEDFs/entities01.xml
```

To import the entities from the default EDF including referenced tModels. Overwrite specifies that any entities excluding referenced tModels that are found in the target registry should be overwritten.

```
java -jar UDDIUtilityTools.jar -import -overwrite -importReferenced
```

To promote a single service from a source to a target registry using the properties file at a specified location.

```
java -jar UDDIUtilityTools.jar -promote -service 67961D67-330F-4F14-8210-E74A58E710F3
-properties c:/UUT/myUUTProps.properties
```

To promote a set of entities specified in a keys file.

```
java -jar UDDIUtilityTools.jar -promote -keysFile c:/myKeyFiles/keyFile03.txt
```

As above but specifying that existing entities in the target registry get overwritten.

```
java -jar UDDIUtilityTools.jar -promote -keysFile c:/myKeyFiles/keyFile04.txt -overwrite
```

To promote a set of entities specified in a keys file including referenced tModels.

```
java -jar UDDIUtilityTools.jar -promote -keysFile c:/myKeyFiles/keyFile05.txt -importReferenced
```

To promote a set of entities specified in a keys file but also create an EDF containing the promoted entities.

```
java -jar UDDIUtilityTools.jar -promote -keysFile c:/myKeyFiles/keyFile06.txt
-definitionFile c:/myEDFs/entities02.xml
```

To logically delete a single tModel. Note that it is not possible to physically delete tModels.

```
java -jar UDDIUtilityTools.jar -delete -tModel UUID:1E2B9D1E-E53D-4D36-9D46-6CCC176C466A
```

To delete all the entities specified in the keys file. Note that with the exception tModels all other entities will be physically deleted from the target registry.

```
java -jar UDDIUtilityTools.jar -delete -keysFile c:/myKeyFiles/keyFile04.txt
```

## A keys file example

Below is an example of the keys that are to be exported, promoted or deleted from the target registry:

```

Keys of entities to be exported, promoted from source registry or deleted from target registry

Note: keys must be comma separated and on SAME line
Note: property names are case sensitive. ('tmodels=' will be ignored)

businesses=97C77097-AC6C-4CA0-A6C4-452F7045C470, 4975E949-581F-4FCA-AD5F-E08280E05F9F
services=BB3864BB-1578-4833-8179-14391F14791F
bindings=
tModels=273F1727-7BFF-4FB5-A1FD-BA5C45BAFD9C
```

**Note:** If the importReferenced property is set to true, the list of tModels in the referencedTModels section is imported to the target registry. Minimal entities are created if the referencedTModel is new. If the referencedTModel already exists it is never overwritten, regardless of the overwrite property value. This is so that commonly referenced tModels such as categorization tModels do not keep being updated unnecessarily.

Should you need to update a referencedTModel, you must manually move the referencedTModel definition to the tModels section in the entity definition file and set overwrite to true.

## Content of the log files

Below shows examples of contents of two of the log files produced by running the tool. Note that some comments have been added in square brackets and in italic to highlight important points within the log file. The first is the messages.log which shows successful and unsuccessful operations for export, import and delete functions:

```
[18/09/03 22:57:24:684 BST] UDUT0002I: ***** Starting UDDI Utility Tools *****

```

## Starting UDDI Utility Tools through the API

UDDI Utility Tools provides a public API to functions for exporting, importing, promoting, finding and deleting UDDI entities. All of these functions can be invoked by using the PromoterAPI class. Usage of this class to perform these functions is typically to:

1. Create a Configuration object and populate it from a Properties object or from a configuration properties file.
2. Create a PromoterAPI object passing the Configuration in the constructor.
3. For keys based functions (export, delete and promote), set the keys by supplying a UDDIEntityKeys object, the location of the keys file, or, for one entity, by specifying an entity type and a key value.
4. Invoke the corresponding method for the function required: exportEntities, promoteEntities(boolean), importEntities, deleteEntities or extractKeysFromInquiry(FindTModel, FindBusiness, FindService, FindBinding, FindRelatedBusinesses).

The PromoterAPI classes should be sufficient for most users, but for users who want more specific control, classes are available for invoking lower level functions directly. See the Javadocs for more information on the interfaces.

Below are nine sets of sample code for UDDI Utility Tools demonstrating usage of the API classes. These are:

- TestEntityExporter.java
- TestEntityImporter.java
- TestEntityPromoter.java
- TestEntityFinder.java
- TestEntityDeleter.java
- TestUddiSerializer.java
- TestUddiDeserializer.java
- TestStubManager.java

- TestCreateMinimalEntity.java

## Known limitations with UDDI Utility Tools and workarounds

There are some known limitations with UDDI Utility Tools and a workaround for each. See UDDI troubleshooting tips for more information.

### Cloudfscape Restriction

The 'export' function when referencing a source registry with a Cloudfscape database is supported. However, the 'import', 'promote' and 'delete' functions are not supported when referencing a target registry because of a limitation with the UDDI Registry when working with a Cloudfscape database.

## SOAP application programming interface for the UDDI Registry

Access to the SOAP API will by default be available at:

<http://localhost:9080/uddisoap/inquiryapi>

or

<https://localhost:9443/uddisoap/publishapi>

Where 'localhost' is the address by which your WebSphere server is known. If security is enabled on your WebSphere server, the publishapi will also be protected by basic-authentication. By default, when security is enabled, the publishapi is restricted to HTTPS, this is to ensure the confidentiality and security of your data whilst in transit to UDDI. If you do not wish to use SSL, when security is enabled, modify the jar file using AAT Assembly Toolkit to remove the CONFIDENTIAL restriction placed upon the publish URLs. For more information about this topic, see the section on **Configuring SOAP properties with the Application Assembly Tool** **Assembly Toolkit**. If you normally access your WebSphere server via a Web server, ensure the plugin configuration for the WebSphere plugin on the Web server has been updated since installing UDDI. This allows access to the UDDI SOAP API through the URLs :

<http://localhost/uddisoap/inquiryapi>

or

<https://localhost/uddisoap/publishapi>

Where 'localhost' is the address by which your Web server is accessed. Note that if you plan on accessing UDDI via a Web server in this manner, that the samples will require modification to inform them of the SSL certificates used by your Web server, so that the samples can make SSL connections to the Web server. It is beyond the scope of this document to cover the many variants available on Web server/WebSphere/java SSL configurations

- Using the SOAP API
- Handling Errors as a User of the SOAP API

## Programming the SOAP API

To use the SOAP API construct a properly formed UDDI message within the body of a SOAP request, and send it using HTTP POST to the URL of the API that the request relates to. The response is returned within the body of the HTTP reply. Although the samples are written in Java, you can use other programming languages to create your SOAP client, providing you still send requests compliant to the SOAP specification. Valid UDDI requests should conform to the UDDI schema, and be as detailed within the UDDI standard documentation:

<http://www.uddi.org/>

For more information on using the SOAP API, refer to "The UDDI Registry application programming interface".

## SOAP API error handling tips in the UDDI Registry

When using the SOAP API there are three main categories that can cause an error to be returned:

- An incorrect request being sent to the SOAP API., for example:
  - incorrectly formed XML
  - badly formed UDDI requests
  - non-schema compliant requests
- Incorrect business logic within a SOAP API request, for example attempting to delete a business that does not exist.
- Problems occurring while processing a valid request., for example server connection to database failure.

In each of these cases, an error is returned to the client that made the request, which attempts to explain further what the problem was.

---

## UDDI Registry Application Programming Interface

The IBM WebSphere UDDI Registry fully supports the application programming interface (API) specification, which can be viewed by visiting [http://www.uddi.org/pubs/ProgrammersAPI\\_v2.pdf](http://www.uddi.org/pubs/ProgrammersAPI_v2.pdf). Any changes from this specification are documented within the IBM WebSphere UDDI Registry information.

- The Inquiry API
- The Publish API

### Inquiry API for the UDDI Registry

The Inquiry API provides four forms of query that follow broadly used conventions that match the needs of software traditionally used within registries.

- The browse pattern
- The drill-down pattern
- The invocation pattern
- Inquiry API functions

### Browse pattern for the UDDI Registry

Software that allows people to explore and examine data - especially hierarchical data - requires browse capabilities. The browse pattern characteristically involves starting with some broad information, performing a search, finding general result sets and then selecting more specific information for drill-down.

The UDDI API specifications accommodate the browse pattern by way of the *find\_xx* API calls. These calls form the search capabilities provided by the API and are matched with summary return messages that return overview information about the registered information that is associated with the inquiry message type and the search criteria specified in the inquiry.

A typical browse sequence might involve finding whether a particular business you know about has any information registered. This sequence would start with a call to *find\_business*, perhaps passing the first few characters of a business name that you already know. This returns a *businessList* result. This result is overview information (keys, names and descriptions) derived from the registered *businessEntity* information, matching on the name fragment that you provided. If you spot the business you are looking for within this list, you can drill down into the corresponding *businessService* information, looking for particular technical models (for example purchasing, shipping, and so on) using the *find\_service* API call. Similarly, if you know the technical *fingerprint* (tModel signature) of a particular software interface and want to see if the business you have chosen provides a Web service that supports that interface, you can use the *find\_binding* inquiry message.

## Drilldown pattern for the UDDI Registry

When you have a key for one of the four main data types managed by a UDDI registry, you can use that key to access the full registered details for a specific data instance. The UDDI data types are `businessEntity`, `businessService`, `bindingTemplate` and `tModel`. You can access the full registered information for any of these structures by passing a relevant key type to one of the `get_xx` API calls.

Continuing the example from the Browse pattern for the UDDI Registry, one of the data items returned by all of the `find_x` return sets is key information. In the case of the business we were interested in, the `businessKey` value returned within the contents of a `businessList` structure can be passed as an argument to `get_businessDetail`. The successful return to this message is a `businessDetail` message containing the full registered information for the entity whose key value was passed. This will be a full `businessEntity` structure.

## Invocation pattern for the UDDI Registry

To prepare an application to take advantage of a remote Web service that is registered within the UDDI registry by other businesses or entities, you must prepare that application to use the information found in the registry for the specific service being invoked.

The `bindingTemplate` data obtained from the UDDI registry represents the specific details about an instance of a given interface type, including the location at which a program starts interacting with the service. The calling application or program should cache this information and use it to contact the service at the registered address whenever the calling application needs to communicate with the service instance. In previously popular remote procedure technologies tools have automated the tasks associated with caching (or hard coding) location information. Problems arise however when a remote service is moved without any knowledge on the part of the callers. Moves occur for a variety of reasons, including server upgrades, disaster recovery, and service acquisition and business name changes.

When a call fails using cached information previously obtained from a UDDI Registry, the proper behavior is to query the UDDI Registry for fresh `bindingTemplate` information. If the data returned is different from the cached information, the service invocation should automatically retry the invocation using the fresh information. If the result of this retry is successful, the new information should replace the cached information.

By using this pattern with Web services, a business using a UDDI Registry can automate the recovery of a large number of partners without undue communication and coordination costs. For example, if a business has activated a disaster recovery site, most of the calls from partners fail when they try to invoke services at the failed site. By updating the UDDI information with the new address for the service, partners who use the invocation pattern automatically locate the new service information and recover without further administrative action.

## Inquiry API functions in the UDDI Registry

These messages represent inquiries that can be made of the UDDI Registry. These messages all behave synchronously.

The queries available are:

### **find\_binding**

Locates specific bindings within a registered `businessService`. Returns a `bindingDetail` message that contains zero or more `bindingTemplate` structures matching the criteria specified in the argument list.

### **find\_business**

Locates information about one or more businesses. Returns a `businessList` message that matches the conditions specified in the arguments.

**find\_relatedBusinesses**

Locates information about businessEntity registrations that are related to a specific business entity whose key is passed in the inquiry. The Related Businesses feature is used to manage registration of business units and subsequently relate them based on organizational hierarchies or business partner relationships. Returns a relatedBusinessList message containing results that match the conditions specified in the arguments.

**find\_service**

Locates specific services within a registered businessEntity. Returns a serviceList message that matches the conditions specified in the arguments.

**find\_tModel**

Locates a list of tModels that match a set of specified criteria. The response will be a list of abbreviated information about registered tModel data that matches the criteria specified. The result will be returned in a tModelList message.

**get\_bindingDetail**

Requests the run-time bindingTemplate information for the purpose of invoking a registered business API. Returns a bindingDetail message.

**get\_businessDetail**

Returns complete businessEntity information for one or more specified businessEntity registrations matching on the businessKey values specified. Returns a businessDetail message.

**get\_businessDetailExt**

Returns extended businessEntity information for one or more specified businessEntity registrations. This message returns exactly the same information as the get\_businessDetail message, but may contain additional attributes if the source is an external registry with the API specification.

**get\_serviceDetail**

Requests full information about a known businessService structure. Returns a serviceDetail message.

**get\_tModelDetail**

Gets full details for a given set of registered tModel data. Returns a tModelDetail message.

## Publish API for the UDDI Registry

The messages in this section represent commands that are used to publish, delete and update information contained in a UDDI registry. The messages defined in this section all behave synchronously.

The Publishing API calls defined that UDDI operators support are:

**add\_publisherAssertions**

Causes one or more publisherAssertions to be added to an individual publisher's assertion collection.

**delete\_binding**

Causes one or more instances of bindingTemplate data to be deleted from the UDDI registry.

**delete\_business**

Removes one or more business registrations and all direct contents from a UDDI registry.

**delete\_publisherAssertions**

Causes one or more publisherAssertion elements to be removed from a publisher's assertion collection.

**delete\_service**

Removes one or more businessService elements from the UDDI registry and from its containing businessEntity parent.

**delete\_tModel**

Logically deletes one or more tModel structures. Logical deletion hides the deleted tModels from find\_tModel result sets but does not physically delete them, so they are returned on a get\_registeredInfo request.

**discard\_authToken**

Informs an operator site that the authentication token is to be discarded, effectively ending the

session. Subsequent calls that use the same authToken will be rejected. This message is optional for operator sites that do not manage session state or that do not support the get\_authToken message.

#### **get\_assertionStatusReport**

Provides administrative support for determining the status of current and outstanding publisher assertions that involve any of the business registrations managed by the individual publisher account. Using this message, a publisher can see the status of assertions that they have made, as well as see assertions that others have made that involve businessEntity structures controlled by the calling publisher account.

#### **get\_authToken**

Obtains an authentication token. Authentication tokens are opaque values that are required for all other publisher API calls. This message is not required for operator sites that have an external mechanism defined for users to get an authentication token. This API is provided for implementations that do not have some other method of obtaining an authentication token or certificate, or that choose to use userid and password based authentication.

#### **get\_publisherAssertions**

Obtains the full set of publisher assertions that are associated with an individual publisher account. Publisher assertions are used to control publicly visible business relationships.

#### **get\_registeredInfo**

Gets an abbreviated list of all businessEntity and tModel data that are controlled by the individual associated with the credentials passed.

#### **save\_binding**

Saves or updates a complete bindingTemplate element. This message can be used to add or update one or more bindingTemplate elements as well as the container/contained relationship that each bindingTemplate has with one or more existing businessService elements.

#### **save\_business**

Saves or updates information about a complete businessEntity element. This API has the broadest scope of all the save\_xx API calls in the publisher API, and can be used to make sweeping changes to the published information for one or more businessEntity elements controlled by an individual.

#### **save\_service**

Adds or updates one or more businessService elements exposed by a specified businessEntity.

#### **save\_tModel**

Adds or updates one or more registered tModel elements.

#### **set\_publisherAssertions**

Manages all of the tracked relationship assertions associated with an individual publisher account.

For full details of the syntax of the above queries, refer to the API specification at [http://www.uddi.org/pubs/ProgrammersAPI\\_v2.pdf](http://www.uddi.org/pubs/ProgrammersAPI_v2.pdf).

---

## **UDDI EJB Interface for the UDDI Registry**

This section describes how to use the EJB application programming interface (API) of the IBM WebSphere UDDI Registry component to publish, find and delete UDDI entries.

The necessary client classes are contained in the *uddiejbclient.jar* file in the *ejb* subdirectory of the UDDIReg directory under the WebSphere application server directory tree.

The Javadoc for the EJB API is contained in the javadoc directory tree under the *ejb* subdirectory of the UDDIReg directory under the WebSphere appserver directory tree.

The EJB API is contained in two stateless session beans, one for the Inquiry API (*com.ibm.uddi.ejb.InquiryBean*) and one for the Publish API (*com.ibm.uddi.ejb.PublishBean*), whose public methods form an EJB interface for the UDDI Registry. All the public methods on the *InquiryBean* correspond to UDDI Inquiry API functions, and all the public methods on the *PublishBean* correspond to

UDDI Publish API functions. (Not all UDDI API functions are implemented, for example get\_authToken, discard\_authToken, get\_businessDetailExt, and so on) For Version 1 of the UDDI registry, the EJB component supports only UDDI v2.0.

The two EJBs use container-managed transactions. The transaction attribute for the methods of the InquiryBean is NotSupported, and for the methods of the PublishBean it is Required. You must not change the transaction attributes as this could result in undesirable behavior.

Within each interface there are groups of overloaded methods that correspond to the operations in the UDDI 2.0 specification. There is a separate method for each major variation in function. For example, the single UDDI 2.0 operation find\_business is represented by 10 variations of findBusiness methods, with different variations for finding by name, finding by categoryBag and so on.

The arguments for the EJB interface methods are java objects in the package com.ibm.uddi.datatypes. Roughly speaking, there is a one-one correspondence between classes in this package and elements of the UDDI V2.0 XML schema. Exceptions to this are, for example, where UDDI XML elements can be represented by a single String. (See Package com.ibm.uddi.datatypes below for more information.)

### Enabling an EJB Client

This section is written on the assumption that WebSphere Application Server V5.0, a supported database and the IBM WebSphere UDDI Registry have already been installed.

#### Classpaths

Add the following jar files and folders to your CLASSPATH:

##### For Windows

<WebSphere-install-dir>\lib\j2ee.jar
<WebSphere-install-dir>\lib\naming.jar
<WebSphere-install-dir>\lib\namingclient.jar
<WebSphere-install-dir>\lib\ecutils.jar
<WebSphere-install-dir>\lib\sas.jar
<WebSphere-install-dir>\properties

##### For Unix Platforms, and also including z/OS

<WebSphere-install-dir>/lib/j2ee.jar
<WebSphere-install-dir>/lib/naming.jar
<WebSphere-install-dir>/lib/namingclient.jar
<WebSphere-install-dir>/lib/ecutils.jar
<WebSphere-install-dir>/lib/sas.jar
<WebSphere-install-dir>/properties

In addition to these jars, there is also the jar file that contains all of the UDDI specific API for the EJB interface, which can be found at:

##### For Windows

<DeploymentManager-install-dir>\UDDIReg\ejb\uddiejbclient.jar
---------------------------------------------------------------

where <DeploymentManager-install-dir> is the install location for WebSphere Application Server for Network Deployment, which by default is C:\Progra~1\WebSphere\DeploymentManager.

### For Unix Platforms, and also including z/OS

```
<DeploymentManager-install-dir>/UDDIReg/ejb/uddiejbclient.jar
```

where <DeploymentManager-install-dir> is the install location for WebSphere Application Server for Network Deployment, which by default is /opt/WebSphere/DeploymentManager for Linux/Solaris systems or /usr/WebSphere/DeploymentManager for AIX systems.

### The Path

Ensure that your PATH statement starts with <WebSphere-install-dir>\java\bin

### Creating an EJB Client

If you want to read about creating EJB Clients in more detail, then please read the "Sun Microsystems Enterprise JavaBeans™ Specification Version 2.0"

### Finding the EJB Reference

An EJB Client can be a stand-alone Java application, an applet, servlet or a JSP. This document only covers writing a stand-alone Java application. In order to invoke an enterprise java bean (EJB) that has been deployed into WebSphere on the server side, the Client must do two things: find the EJB on the server, and then create a Client side reference to that EJB. When this Client side reference has been created, the Client can invoke methods upon the EJB as if it was a local object. Clients cannot reference, or invoke, and EJB directly. Any calls made to the EJB must be made through the interfaces that the EJB provides. The interface that is used to create a local reference to the EJB is called the *home interface*. When an EJB is deployed in WebSphere, this home interface is made available to Clients by means of a searchable namespace. This means that a Client can look up an address on the namespace. If there is a home interface at that address, and it is the home interface to the EJB that they were looking for, then the Client can create a local instance of that home interface, and then, from that, a local reference to the EJB can be created.

### What code is needed in the Client?

The following code fragment illustrates how to Find and Create a local instance of the Inquiry EJB only. The same must be done to Find and Create a local copy of the Publish EJB.

```
private com.ibm.uddi.ejb.Inquiry inquiry = null;
// This private variable, "inquiry" is going to be the local reference to the EJB in WebSphere
// declaring it outside the scope of a method means that this same reference can be
// used throughout the client, without having to query the namespace again.
public void homeLookup()
{
 // These variables simply determine the address of the JNDI namespace, and the address
 // of the home interface within that namespace.

 // String naming_factory = "com.ibm.ejs.ns.jndi.CNInitialContextFactory";
 //WAS 4.0.2 Naming Factory
 String naming_factory = "com.ibm.websphere.naming.WsnInitialContextFactory";
 //WAS 5.0 Naming Factory

 String namespace_address = "iiop://localhost:2809/"; //The address of the namespace
 String home_address = "com/ibm/uddi/ejb/InquiryHome";
 //The address of the home interface within the JNDI namespace

 java.util.Hashtable environment = new java.util.Hashtable();
```

```

environment.put(javax.naming.Context.INITIAL_CONTEXT_FACTORY, naming_factory);
environment.put(javax.naming.Context.PROVIDER_URL, namespace_address];

try
{
 javax.naming.InitialContext ic = new javax.naming.InitialContext(environment);
 // Create a context using the details above to connect to the namespace

 Object o = ic.lookup(home_address);
 // Do a lookup to see if there is an ejb_home at the address specified above

 // Now create a valid home instance for the EJB type we want to create
 com.ibm.uddi.ejb.InquiryHome home =
 (com.ibm.uddi.ejb.InquiryHome)(javax.rmi.PortableRemoteObject.narrow(o,
 com.ibm.uddi.ejb.InquiryHome.class));

 inquiry = home.create();
 // Now create a local reference of the EJB, by using the home.create() method.
 // Any business method that is intended for the EJB in WebSphere
 // must me invoked against this inquiry object.
}
catch (javax.naming.NamingException ne) {ne.printStackTrace();}
// This is thrown if there was a problem connecting to the namespace, or finding the
// home_address in the namespace
catch (java.rmi.RemoteException re) {re.printStackTrace();}
// This usually indicates some sort of system failure, either WebSphere is not running,
// or there is a communications problem
catch (javax.ejb.CreateException ce) {ce.printStackTrace();}
// This is thrown if the EJB reference cannot be created from the home instance.
}

```

## Writing Client code to use the EJB API

When the reference to the EJB has been created (the Inquiry Object, in the code shown in the previous paragraph), then the reference can be treated like any other Java object. This is an example method using the UDDI EJB API - the only important point to remember is that, although the Inquiry Object has been created as a local reference, it is still referring to a remote EJB Object in a different server, possibly even in a different country. This means that at the very least a `javax.rmi.RemoteException` must be caught on each method call that is made to the EJB.

```

public void findBusiness()
{
 System.out.println("Find Business:");
 NameList names = new NameList();
 names.add(new Name("IBM Corporation"));
 //Create the list of names to find in the UDDI Registry, here just one is used,
 // "IBM Corporation"
 try
 {
 BusinessList list = inquiry.findBusiness(names);
 //This is the call to the inquiry EJB that searches through the UDDI Registry

 //Now display the amount of business found, and for each one, get the BusinessKey,
 // the BusinessName and the amount of Services that Business has
 System.out.println(
 "There are "+list.getBusinessInfos().size()+" matching Businesses in this registry");
 for (int i=0;i<list.getBusinessInfos().size();i++)
 {
 BusinessInfo business = list.getBusinessInfos().get(i);
 System.out.println("\nBusinessKey = "+business.getBusinessKey());
 System.out.println("BusinessName = "+business.getNames().get(0).getNameString());
 System.out.println(
 "This Business Has "+business.getServiceInfos().size()+" Services\n");
 }
 }
}

```

```

// This is a UDDI specific exception, and will be thrown if for example an invalid name
// was used as the search criteria
catch (com.ibm.uddi.datatypes.DispositionReportException e) {
 this.handleDispositionReportException(e);}

 catch (java.rmi.RemoteException re) {re.printStackTrace();}
// This is the RemoteException that is thrown if there has been a system failure or a
// connection problem.
}

```

### What new code is needed on the client?

Just as each EJB has an interface listed on the JNDI namespace, the `javax.transaction.UserTransaction` class also has an interface listed. This means that the same method used to get a local instance of an EJB can be applied to get a local instance of the `UserTransaction` class. Again, this code can be used to find the `UserTransaction` reference on the namespace, in addition to the code required to find the `Inquiry` EJB and the `Publish` EJB, or, alternatively, there is a slightly more elegant method used in the `TransactionEJBClientSample.java`.

```

public void txLookup()
{
 private javax.transaction.UserTransaction tx = null;
 // This is the private variable that will be used to hold the UserTransaction Object
 // declaring it outside the scope of a method means that this same reference can be
 // used throughout the client, without having to query the namespace again.

 // These variables simply determine the address of the JNDI namespace, and the address
 // of the home interface within that namespace.

 // String naming_factory = "com.ibm.ejs.ns.jndi.CNInitialContextFactory";
 //WAS 4.0.2 Naming Factory
 String naming_factory = "com.ibm.websphere.naming.WsnInitialContextFactory";
 //WAS 5.0 Naming Factory

 String namespace_address = "iiop://localhost:2809/"; //The address of the namespace
 String transaction_address = "jta/usertransaction";
 //The address of the UserTransaction interface within the JNDI namespace

 java.util.Hashtable environment = new java.util.Hashtable();
 environment.put(javax.naming.Context.INITIAL_CONTEXT_FACTORY, naming_factory);
 environment.put(javax.naming.Context.PROVIDER_URL, namespace_address);

 try
 {
 javax.naming.InitialContext ic = new javax.naming.InitialContext(environment);
 // Create a context using the details above to connect to the namespace
 Object remote_object = ic.lookup(transaction_address);
 // Do a lookup to see if there is a UserTransaction Object at the address specified above
 tx = (javax.transaction.UserTransaction)remote_object;
 //Convert the remote object found into a UserTransaction Object, and assign to the private variable
 }
 catch (javax.naming.NamingException ne) {ne.printStackTrace();}
 // This is thrown if there was a problem connecting to the namespace, or finding the
 // transaction_address in the namespace
}

```

### Writing Client code to use the EJB API with a Client transaction

To perform an `Inquiry`, a `Publish` or a `Delete` upon the IBM WebSphere UDDI Registry with client-side transactional support requires very little additional code compared to doing the same operations without client side transactional support. Using the same code that is listed previously (in "Writing Client Code to use the EJB API"), this example illustrates how easy client side transactions are to implement.

The additional lines of code needed are in bold type. This code also assumes that there is a variable called *tx* that has been declared at the class scope.

```
public void findBusiness()
{
//Just as there are UDDI and RMI specific exceptions thrown, 5 more exceptions need to be caught.
try
{
tx.begin(); //This begins the transaction context
System.out.println("Find Business:");
NameList names = new NameList();
names.add(new Name("IBM Corporation"));
//Create the list of names to find in the UDDI Registry, here just one is used, "IBM Corporation"
try
{
BusinessList list = inquiry.findBusiness(names);
//This is the call to the inquiry EJB that searches through the UDDI Registry

//Now display the amount of business found, and for each one, get the BusinessKey,
// the BusinessName and the amount of Services that Business has
System.out.println("There are "+list.getBusinessInfos().size()+" matching Businesses in this registry");
for (int i=0;i<list.getBusinessInfos().size();i++)
{
BusinessInfo business = list.getBusinessInfos().get(i);
System.out.println("\nBusinessKey = "+business.getBusinessKey());
System.out.println("BusinessName = "+business.getNames().get(0).getNameString());
System.out.println("This Business Has "+business.getServiceInfos().size()+" Services\n");
}
}
// This is a UDDI specific exception, and will be thrown if for example an invalid name was
// used as the search criteria
catch (com.ibm.uddi.datatypes.DispositionReportException e) {
this.handleDispositionReportException(e);}
catch (java.rmi.RemoteException re) {re.printStackTrace();}
// This is the RemoteException that is thrown if there has been a system failure or a
// connection problem.

tx.commit(); //This ends the transaction context
}

- The datatypes package
- Methods in the EJB Interface

## Datatypes package in the UDDI Registry

The following table lists the classes in the com.ibm.uddi.datatypes package, the elements in the UDDI v2.0 XML schema, and the correspondence between the two.

com.ibm.uddi.datatypes Class	Corresponding UDDIv2.0 XML Schema Element	Notes on DatatypeClass
AccessPoint	accessPoint	
Address	address	
	String addressLine	
AdressLineList		Encapsulates a vector of addressLine Strings
AddressList		Encapsulates a vector of Address objects
AssertionStatusItem	assertionStatusItem	

AssertionStatusItemList		Encapsulates a vector of AssertionStatusItem objects
AssertionStatusReport	assertionStatusReport (response message)	
	String authInfo	
AuthToken		Object containing authInfo String and operator name
	String bindingKey	
BindingDetail	bindingDetail (response message)	
BindingTemplate	bindingTemplate	
BindingTemplateList	bindingTemplates	Encapsulates a vector of Bindingtemplate objects
BusinessDetail	businessDetail (response message)	
BusinessDetailExt	businessDetailExt (Response message)	**
BusinessEntity	businessEntity	
BusinessEntityExt	businessEntityExt	**
BusinessEntityExtList		Encapsulates a vector of BusinessEntityExt objects **
BusinessEntityList		Encapsulates a vector of BusinessEntity objects
BusinessInfo	businessInfo	
BusinessInfoList	businessInfo	Encapsulates a vector of businessInfo objects
	String businessKey	
BusinessList	businessList (response message)	
BusinessService	businessService	
BusinessServiceList	businessServices	Encapsulates a Vector of BusinessService objects
CategoryBag	categoryBag	
	String completionStatus	
Contact	contact	
ContactList	contacts	Encapsulates a vector of Contact objects
Description	description	
DescriptionList		Encapsulates a vector of Description objects
DiscoveryUrl	discoveryURL	
DiscoveryUrlList	discoveryURLs	Encapsulates a vector of DiscoveryURL objects
DispositionReport	dispositionReport	
DispositionreportException		Exception thrown by EJB interface functions when an error occurs
Email	email	
EmailList		Encapsulates a vector of Email objects
EndPoint		Used as baseclass for AccessPoint and HostingRedirector providing mutual exclusivity
ErrInfo	errInfo	
	findQualifier	
FindQualifier	findQualifiers	
	String fromKey	

HostingRedirector	hostingRedirector	
IdentifierBag	identifierbag	
InquiryOptions		Encapsulates a FindQualifiers object and a maxrows field. Used in find_* API calls to specify search options
InstanceDetails	instanceDetails	
	String instanceParms	
	String keyValue	
KeyedReference	keyedReference	
keysOwned	keysOwned	
LanguageString		Abstract class, extended by some of the datatypes, which represents a string that can optionally be tagged with xml:lang.
Name	name	
NameList		Encapsulates a vector of Name objects
OverviewDoc	overviewDoc	
	String overviewURL	
	String personName	
Phone	phone	
PhoneList		Encapsulates a vector of Phone objects
PublisherAssertion	publisherAssertion	
PublisherAssertionList		Encapsulates a vector of Publisher Assertion objects
PublisherAssertions	publisherAssertions (response message)	
RegisteredInfo	registeredInfo (response message)	
	relatedBusinessInfo	Not used
	relatedBusinessInfos	Not used
RelatesBusinessesList	relatedBusinessesList	
RelatedBusinessInfo	relatedBusinessInfo	
RelatedBusinessInfos	relatedBusinessInfos	
Result	result	
ResultList		Encapsulates a Vector of Result objects
ServiceDetail	serviceDetail (response message)	
ServiceInfo	serviceInfo	
ServiceInfoList	serviceInfos	Encapsulates a vector of serviceInfo objects
	String serviceKey	
ServiceList	serviceList (response message)	
	sharedRelationships	Not used
SharedRelationships	sharedRelationships	
Tmodel	tModel	
TModelBag	tModelBag	

TModelDetail	tModelDetail (response message)	
TModelInfo	tModelInfo	
TModelInfoList	tModelInfos	Encapsulates a vector of TModelInfo objects
TModelInstanceInfo	tModelInstanceInfo	
TModelInstanceInfoList	tModelInstanceDetails	Encapsulates a vector of TModelInstanceInfo objects
	String tModelKey	
TModelList	tModelList (response message)	
TModels		Encapsulates a vector of TModel objects
	String toKey	
	String uploadRegister	
UploadRegisterList		Encapsulates a vector of uploadRegister strings

\*\* Used in UDDI API functions relating to BusinessDetailExtension. These UDDI API functions are not implemented in Version 1 of the IBM WebSphere UDDI Registry.

In general, a datatype called *DatatypeList* contains a vector of *Datatype* objects. Often these correspond to XML schema elements with plural names. (For example the datatype *Contact* corresponds to XML element *contact*, and *ContactList* corresponds to *contacts*.) Where there is no "plural" XML schema element for a particular *Datatype*, often there is still a *DatatypeList* where it is useful to have one, for example *AddressList*.

The exceptions to this naming convention occur when there is an existing XML schema element ending in "List". The exceptions are: *TModelList*, *ServiceList*, *BusinessList*. In these cases, the corresponding datatypes are given the same names as the XML schema elements, and the datatypes that would have had these names are called: *TModels*, *BusinessServiceList*, *BusinessEntityList*.

## EJB interface methods in the UDDI Registry

### Inquiry

```
findBinding
findBusiness
findRelatedBusinesses
findService
findTModel
getBindingDetail
getBusinessDetail
getServiceDetail
getTModelDetail
```

### Publish

```
addPublisherAssertions
deleteBinding
deleteBusiness
deletePublisherAssertions
deleteService
deleteTModel
getAssertionStatusReport
getRegisteredInfo
getPublisherAssertions
saveBinding
```

```
saveBusiness
saveService
saveTModel
setPublisherAssertions
```

Each method is overloaded and can take various combinations of arguments. The Javadoc information contains detailed information about each method.

Note that the `get_authToken` and `discard_authToken` methods are not implemented, as WebSphere security is used instead.

---

## UDDI troubleshooting tips

When the IBM WebSphere UDDI Registry is running, it might issue messages to report events or errors. You can use these messages, described in Messages as your first aid to problem determination. If you need more details about the causes of a problem, you can turn on tracing for UDDI, as described in:

- Turning on UDDI trace

- **Common causes of errors**

Below are a few of the common causes of errors that might be found and their suggested solutions.

- If you set up the UDDI Registry application with a JDBC driver and datasource that reference Cloudscape, but set the `persist` property in `uddi.properties` to specify DB2, **or vice versa**, then some unexpected behavior results, such as a fatal error on deleting an entity. If this happens, you should check that the above details are not in conflict. This only applies to a UDDI Registry installation on a single appserver.
- If you get a message "The application failed to initialize" when trying to access the UDDI User console and you are using DB2 as the persistence store for the UDDI Registry, a likely cause of the problem is that you specified the wrong userid and/or password when you ran the script to install the UDDI Registry application. If this occurs rerun the script ensuring you use the correct userid and password.

Alternatively, on Unix platforms, you may not have run the `db2profile` before deploying the UDDIReg application or before starting the application server.

- You might find that, after uninstalling and reinstalling the UDDI Registry, you get errors from the UDDI User Console of the form:

```
"Error 500: JSPG0059E: Unable to compile class for JSP".
```

If this occurs, then you should clear out the temp directory of the WebSphere AppServer.

- When running one of the UDDI setup scripts `setupuddi.jacl` or `removeuddi.jacl`, if you get an error such as:

```
WASX7017E: Exception received while running file "setupuddi.jacl";
exception information: com.ibm.bsf.BSFException:
error while eval'ing Jacl expression:
java.util.MissingResourceException:
```

```
Can't find resource for bundle java.util.PropertyResourceBundle, key ErrMsgIncorrectNumArgs
```

ensure that the file `setupuddimessages.jar` is located in the `lib` subdirectory of the WebSphere deployment manager or application server under which you are running the script.

- When running the DB2 Setup Wizard, if you get an error stating "Invalid userid and password", it could be caused by any of the following situations:
  - You have supplied an invalid userid or password - re-enter with a valid userid and password.
  - The supplied userid does not have the necessary privileges - retry with a userid that has appropriate privileges.
  - DB2 is stopped when you run the wizard - start DB2 and retry the wizard.
  - The UDDI20 database already exists and has been removed previously and, as such, is not catalogued. The DB2 wizard does not recognize this situation and gives the error. You now have two options.
    1. To use the existing database, catalogue it, and there is no need to rerun the Wizard.

2. To create a new database, recatalog the database and re-run the DB2 wizard and choose the option to overwrite the database. (Any existing data **WILL** be lost.)
  - Catalog the database by:

- **On Windows:**

```
>db2cmd
>db2cat -d uddi20
```

- **On Unix platforms**

```
>su db2inst1 (or name of your db2 instance)
>db2 CATALOG DATABASE UDDI20
```

- ensure that, if you are using a non-English installation of DB2, you have applied PTF501.

**Note:** If you have a copy of the file SetupDB2UDDI.jar in your appserver directory, the application of the base and Network Deployment PTFs will not update SetupDB2UDDI.jar in your appserver directory. You must apply the PTF for Network Deployment to your DeploymentManager file structure to update the SetupDB2UDDI.jar located there (in the /IDDIReg/scripts subdirectory), and then manually copy this jar file to any application server you may wish to run it on.

- There is a limitation concerning URL rewriting causing JavaScript syntax errors on several Web pages in the UDDI User Console. Because of this, cookies must be enabled in client browsers, the application server must have cookies enabled as the session tracking mechanism, and URL rewriting must be disabled.
- If you have an existing DB2 version of the UDDI Registry database, and you use the UDDI DB2 setup wizard to replace this database with a new one, and if the database is in use at the time that you run the UDDI DB2 setup wizard, then the existing database is not overwritten.
- When running the UDDI DB2 setup wizard, as part of the installation step "Setting up the UDDI Registry to use DB2 within a deployment manager cell" or "Setting up the UDDI Registry to use DB2 in a single application server", in addition to running the *was\_install\bin\setupcmdline.bat* directory, you should also enter either **set PATH=%WAS\_PATH%** (for Windows platforms) or **export PATH=/opt/WebSphere/AppServer/java/bin:\$PATH** (for Unix platforms) to ensure that you have access to Java.
- UDDI user console "Page cannot be displayed" errors with Internet Explorer.
 

If you use Internet Explorer with the option "Show friendly HTTP error messages" enabled and you have WebSphere Application Server security enabled (user ID and password authentication enabled), you might experience intermittent errors on the browser, such as "Page cannot be displayed", when navigating the UDDI user console. This might be particularly noticeable when accessing the publish actions.

To avoid such errors, disable the "Show friendly HTTP error messages" option on Internet Explorer. This option is found under **Tools > Internet options > Advanced Tab > Browsing Section**
- When using SOAP or UDDI4J, it is sometimes necessary to call `setServiceKey("")` before saving your changes, except with the EJB interface where this might result in an error.
- There are known problems with inquiries issued against the UDDI Registry if IBM Cloudscape is used as the persistence store for the registry data. Certain complex inquiries might produce unexpected results, or could fail. If your application needs to make inquiries of this nature, consider using DB2 as the persistence store. Note: DB2 must be used for production purposes. The IBM Cloudscape support is only provided for development and test use.
- You might see errors if you specify requests that specify more than 5 category values, more than 5 identifier values, or more than 5 technical model (tModel) values.
- If you stop and restart the UDDI Registry application from the administrative console, and then try to access the Registry through the user console, an "Error 500 - object is not an instance of a declaring class" displays on the user console, and the error message "SRVE0026E" displays in the system log. You cannot access the UDDI Registry until you restart the WebSphere Application Server. To avoid this problem when restarting the UDDI Registry, you should set **Prefer WEB-INF classes** on the panel navigated to by the following steps: **Applications > Manage Applications > UDDIRegistry > Web Modules defined for this Application > gui.war**.
- It is possible that a scripting error displays when you are running the **wsadmin appserversetupuddi.jacl** command.

During installation, if you see the following error at the end of running the **appserversetupuddi.jacl** command, you can safely ignore the error. It is recommended that you start (or stop and restart) the application server and then continue.

Here is an example of the error:

```
UDIN2041I: Starting UDDI application. UDIN8019E: startApplication command for
 appname caught exception Exc. Values are: appname=UDDIRegistry,
 Exc=com.ibm.ws.scripting.Scripting
 Exception: com.ibm.websphere.management.exception.Connector
 Exception: ADMC0009E: Failed to make the SOAP RPC call: invoke
```

- If you find that the UDDI user console is giving unexpected results, in particular if you have installed a FixPack but are not seeing all of the fixes, then you should clear out the compiled UDDI JSP files from the temp directory of the WebSphere Application Server. These files will be in a directory identified by the name of the UDDI Registry located beneath the temp directory.
- If attempting to use a remote DB2 database and you are experiencing problems attaching to the remote system, one of the possible causes might be IP addressing. You should not have this problem if the remote system is using a static IP address. If, however, the remote system is using DHCP, the two systems must be aware of each others subnet mask.

For Windows, the subnet mask can be found by starting a Command Prompt and entering "*ipconfig*" on the remote system. On the host system, the WINS might need to be edited to add the remote subnet mask. To do this on Windows go to the following commands:

1. START => Network and Dial-up Connections => Local Area Network Connection 2 => Internet Protocol (TCP/IP) and click on Properties
2. Click on "*Advanced*".
3. Click on the WINS tab and add the new subnet mask
4. Move the new subnet mask to the top of the list by highlighting it and pressing the "*Up*" arrow until it is the top of the list of WINS addresses

On Unix platforms, you can use *ifconfig* to determine the subnet mask.

- **Known limitations with UDDI Utility Tools and workarounds**

There are known limitations with the UDDI Utility Tools and a workaround for each:

- Referenced businesses in service projections are not added automatically to the EDF in the same manner as referenced tModels.

**Workaround:** Add the referenced business that will 'own' the projected service to the EDF. If the business is not present in the target registry, it should be placed before the service's owning business in the EDF.

- Cycle detection for service projections are not detected in the same manner as for referenced tModels.

**Workaround:** If a circular reference is present between two or more service projections, break the cycle by removing one of the projections temporarily, perform the import and update the changed entity to reestablish the cycle in the target registry.

- tModels that were deleted (in the logical sense) in the source registry are imported and promoted as undeleted in the target registry. This is because, in the UDDI Version 2 specification, the deleted state of tModels is not exposed as API calls.

**Workaround:** After importing the tModel, perform a delete. This is done using the UDDI Utility Tools delete function, or any other UDDI Registry API access method.

- BindingTemplates referenced by hostingRedirectors are not added automatically to the EDF in the same manner as referenced tModels.

**Workaround:** Add the referenced bindingTemplate to the EDF.

- Businesses referenced by an 'owningBusiness' keyedReference are not automatically added to the EDF.

**Workaround:** Import the referenced business into the target registry before importing the tModel that references it.

- The JSSE provider class, when security is enabled, is not configurable. It must be `com.ibm.jsse.IBMJSSEProvider`.
- A few combinations of command line arguments are not validated and prevented, for example, it is possible to specify `-import with -keysFile <path to file>` in the same command, although the `&#8209;keysFile` is ignored.

## Turning on UDDI trace

You enable UDDI-specific trace in the same way as you enable other tracing in the WebSphere Application Server.

The following is a list of trace strings that you can use:

- `com.ibm.uddi.api`
- `com.ibm.uddi.config`
- `com.ibm.uddi.datatypes`
- `com.ibm.uddi.dom`
- `com.ibm.uddi.ejb`
- `com.ibm.uddi.exception`
- `com.ibm.uddi.exceptions`
- `com.ibm.uddi.gui`
- `com.ibm.uddi.gui.inquire`
- `com.ibm.uddi.gui.publish`
- `com.ibm.uddi.persistence`
- `com.ibm.uddi.persistence.jdbc`
- `com.ibm.uddi.persistence.jdbc.cloudscape`
- `com.ibm.uddi.persistence.jdbc.db2`
- `com.ibm.uddi.ras`
- `com.ibm.uddi.security`
- `com.ibm.uddi.soap`
- `com.ibm.uddi.uuid`
- `com.ibm.uddi.validation`
- `com.ibm.uddi.xml`

For example, to trace the UDDI user console:

```
'com.ibm.uddi.gui=all=enabled'
```

This enables all types of trace for the gui. Please refer to "Enabling trace" in the Information Center for more information about using the administrative console to enable or disable trace.

---

## Messages

When the IBM WebSphere UDDI Registry is running, it issues messages to report events or errors. The messages are in the form `UDxxnnnns` where:

- xx** is a two character descriptor identifying which component is involved
- nnnn** is the error code
- s** is either I (Information) or E (Error)

The prefix `UDxxnnnns`: is followed by text that describes the event or error. For some messages, the first word of the text is one of the form `(MSN=SSSS)`. The SSSS provides a message sequence number (or MSN), which identifies the unique circumstance in which the message was issued, and is of use where the same message can be issued in more than one circumstance.

To help you diagnose problems and minimize the need to enable trace in any of the above components, view the messages table. You can view the messages by prefix or component, whichever is easiest for you to find in the table. All messages are documented with user/system action and explanation.

The text for the UDDI messages is contained in a file *uddiresourcebundles.jar* which is placed, by the installation process, into the `\lib` subdirectory (Windows) of the WebSphere application server into which the UDDI Registry was installed. If you will be running a console or log analyzer from another process; for example, to analyze the activity log, you must place a copy of *uddiresourcebundles.jar* into a directory that is within the classpath of that process. Otherwise, the message lookup for the UDDI messages will fail.

## UDAI (Web Services UDDI) messages

There are no messages issued by this component.

## UDCF (Web Services UDDI) messages

**UDCF0001E: Exception occurred while getting int value of configuration property "<property>", exception: "<exception>"**

**Explanation:** This message is issued when an attempt to read the value of a configuration property from the `uddi.properties` file and convert it to integer has failed with the indicated exception.

**User Response:** Check that the `uddi.properties` file contains a value for the indicated configuration property, and that the value is valid. Check also that the indicated configuration property is a legal property. Refer to the Information Center for further information about global configuration properties and the `uddi.properties` file.

**UDCF0002E: Exception occurred while getting long value of configuration property "<property>", exception: "<exception>"**

**Explanation:** This message is issued when an attempt to read the value of a configuration property from the `uddi.properties` file and convert it to long has failed with the indicated exception.

**User Response:** Check that the `uddi.properties` file contains a value for the indicated configuration property, and that the value is valid. Check also that the indicated configuration property is a legal property. Refer to the Information Center for further information about global configuration properties and the `uddi.properties` file.

**UDCF0003E: Exception occurred while getting boolean value of configuration property**

"<property>", exception: "<exception>"

**Explanation:** This message is issued when an attempt to read the value of a configuration property from the uddi.properties file and convert it to boolean has failed with the indicated exception

**User Response:** Check that the uddi.properties file contains a value for the indicated configuration property, and that the value is valid. Check also that the indicated configuration property is a legal property. Refer to the Information Center for further information about global configuration properties and the uddi.properties file.

**UDCF0004E: Failed to load UDDI global properties file.**

**Explanation:** This message is issued when the UDDI global configuration properties file, uddi.properties, cannot be loaded. Default values for the global configuration properties will be set, but these defaults may not be adequate for many of the properties, so you should investigate and resolve this problem.

**User Response:** Check that the uddi.properties file exists and is in the correct directory. Refer to the Information Center for further information about global configuration properties and the uddi.properties file.

**UDCF0005E: Exception occurred while loading UDDI global configuration properties, exception:**

"<exception>"

**Explanation:** This message is issued when an attempt to load the UDDI global configuration properties from the uddi.properties has failed with the indicated exception. Default values for the global configuration properties will be set, but these defaults may not be adequate for many of the properties, so you should investigate and resolve this problem.

**User Response:** Check that the uddi.properties file exists and contains valid values for each of the configuration properties. Refer to the Information Center for further information about global configuration properties and the uddi.properties file.

**UDDA (Web Services UDDI) messages**

There are no messages issued by this component.

**UDDM (Web Services UDDI) messages**

There are no messages issued by this component.

**UDEJ (Web Services UDDI) messages**

There are no messages issued by this component.

**UDEX (Web Services UDDI) messages**

There are no messages issued by this component.

**UDIN (Web Services UDDI) messages****UDIN0001I: Assuming hard coded defaults.**

**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.

**User Response:** None..

**UDIN0002I: Cloudscape classpath is clpath. Value is:**

**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.

**User Response:** None.

**UDIN0003I: Looking for childtype childname under parenttype parentname. Values are:**

**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.

**User Response:** None.

**UDIN0004I: Looking for childtype childname under parenttype parentname and parenttype2 parentname2. Values are:**

**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.

**User Response:** None.

**UDIN0005I: Conflict found with existing childtype childname. Values are:**

**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.

**User Response:** None.

**UDIN0006I: Not creating requested childtype. Value is:**

**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.

**User Response:** None.

**UDIN0007I: Seeking parenttype with requested id of parentname. Values are:**

**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.

**User Response:** None.

**UDIN0008I: Seeking parenttype with requested id of parentname under parenttype2 parentname2. Values are:**

**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.

**User Response:** None.

**UDIN0009I: Attempting to create childtype under parenttype of parentID. Values are:**

**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.

**User Response:** None.

**UDIN0010I: Create command that will be issued is:**

**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.

**User Response:** None.

**UDIN0011I: childtype childid was successfully created. Values are:**

**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.

**User Response:** None.

**UDIN0012I: Looking for builtin\_rra.**

**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.

**User Response:** None.

**UDIN0013I: List for J2CResourceAdapter returned N members. Value is:**

**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.

**User Response:** None.

**UDIN0014I: Hunting J2CResourceAdapter associated with Node nodename. Value is:**

**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.

**User Response:** None.

**UDIN0015I: Using rraID as builtin\_rra. Value is:**

**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.

**User Response:** None.

**UDIN0016I: Using provider class of implclass with a classpath of clpath. Values are:**

**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.

**User Response:** None.

**UDIN0017I: Installing to server servename, node nodename using database type of dbtype. Values are:**

**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.

**User Response:** None.

**UDIN0018I: Attempting to create UDDI JDBCProvider.**

**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.

**User Response:** None.

- UDIN0019I: Attempting to create UDDI Datasource.**  
**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.  
**User Response:** None.
- UDIN0020I: Application Manager appmgr found. Value is:**  
**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.  
**User Response:** None.
- UDIN0021I: Attempting to install UDDI Registry application.**  
**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.  
**User Response:** None.
- UDIN0022I: Checking for installed UDDI Registry application of name appname. Value is:**  
**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.  
**User Response:** None.
- UDIN0023W: Application of name appname is not present. Value is:**  
**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.  
**User Response:** None.
- UDIN0024I: ApplicationManager not running, so application will not need to be stopped.**  
**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.  
**User Response:** None.
- UDIN0025I: Stopping application of name appname. Value is:**  
**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.  
**User Response:** None.
- UDIN0026W: stopApplication command for application appname caught exception Exc. Application might not have been running on this server. Values are:**  
**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.  
**User Response:** None.
- UDIN0027I: Application appname stopped successfully. Value is:**  
**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.  
**User Response:** None.
- UDIN0028I: Removing application appname. Value is:**  
**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.  
**User Response:** None.
- UDIN0029I: Application appname removed successfully. Value is:**  
**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.  
**User Response:** None.
- UDIN0030I: Adding resource bundles to repository.**  
**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.  
**User Response:** None.
- UDIN0031I: Adding Cloudscape user functions to repository.**  
**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.  
**User Response:** None.
- UDIN0032I: UDDI configuration properties file already exists. Only the persister and getServletURLPrefix properties will be overwritten.**  
**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.  
**User Response:** None.
- UDIN0033I: Editing UDDI configuration properties file propsfile. Value is:**  
**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.  
**User Response:** None.

**UDIN0034I: Url prefix found. Updating it to discoveryURL. Value is:**  
**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.  
**User Response:** None.

**UDIN0035I: Persister property found. Updating it to dbtype. Value is:**  
**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.  
**User Response:** None.

**UDIN0036I: Adding UDDI configuration properties file to repository for cell cellname under target node and server. Value is:**  
**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.  
**User Response:** None.

**UDIN0037I: ws.ext.dir processing starting.**  
**Explanation:** This is an informational message issued by the UDDI setup script setupuddi.jacl.  
**User Response:** None.

**Explanation:** This is an informational message issued by the UDDI setup script appserverremoveuddi.jacl.

**User Response:** None.

**UDIN3102I: Changes to remove UDDI Registry have been saved successfully.**

**Explanation:** This is an informational message issued by the UDDI setup script appserverremoveuddi.jacl.

**User Response:** None.

**UDIN3103I: Attempting to save new configuration.**

**Explanation:** This is an informational message issued by the UDDI setup script appserverremoveuddi.jacl.

**User Response:** None.

**UDIN3104I: Changes saved successfully.**

**Explanation:** This is an informational message issued by the UDDI setup script appserverremoveuddi.jacl.

**User Response:** None.

**UDIN3105I: Attempting final save of new configuration.**

**Explanation:** This is an informational message issued by the UDDI setup script appserverremoveuddi.jacl.

**User Response:** None.

**UDIN3106I: Changes saved successfully.**

**Explanation:** This is an informational message issued by the UDDI setup script appserverremoveuddi.jacl.

**User Response:** None.

**UDIN6001E: This script must be run in a Deployment Manager environment.**

**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6002E: To install in a standalone application server, use appserversetupuddi.jacl.**

**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6003E: Incorrect number of arguments passed to script.**

**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6004E: Usage is:**

**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl. The text following 'Usage is:' gives the syntax for calling setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6005E: (<db2userid> <db2password> <db2ziplocation> are only required if setting up to use DB2).** **Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6006E: Use all forward (/) slashes to avoid problems with escaping back (\) slashes.**

**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6007E: Removal of childtype childname caught exception Exc. Values are:**

**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6008E: An exception Exc occurred while creating childtype. Values are:**

**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6009E: Unable to find requested parenttype of parentname. Values are:**

**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6010E: List command for J2CResourceAdapter caught exception Exc. Value is:**

**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6011E: No J2CResourceAdapter objects available.**

**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6012E: An error occurred during execution of setupuddi.jacl. Please check the parameters and try again.**

**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6013E: Uninstall of application appname caught exception Exc. Values are:**  
**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6014E: Install of UDDI application caught exception Exc. Value is:**  
**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6015E: Could not get JVM.**  
**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6016E: Cannot find nodeSync MBean.**  
**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6017E: nodeSync failed. UDDI Application may not be fully installed.**  
**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6018E: stopServer command for server servername caught exception Exc. Values are:**  
**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6019E: startServer command for server servername caught exception Exc. Values are:**  
**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6101E: Error saving configuration, changes not saved due to exception Exc. Value is:**  
**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6102E: Error saving configuration, changes not saved due to exception Exc. Value is:**  
**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6103E: Error saving configuration, changes not saved due to exception Exc. Value is:**  
**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN6104E: Error saving configuration, changes not saved due to exception Exc. Value is:**  
**Explanation:** This is an error message issued by the UDDI setup script setupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN7001E: This script must be run in a Deployment Manager environment.**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN7002E: To remove from a standalone application server, use appserverremoveuddi.jacl.**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN7003E: Incorrect number of arguments passed to script.**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN7004E: Usage is:**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl. The text following 'Usage is:' gives the syntax for calling removeuddi.jacl.

**User Response:**This message is self-explanatory.

- UDIN7005E: stopServer command for server servername caught exception Exc. Values are:**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN7006E: Removal of resource bundles caught exception Exc. Value is:**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN7007E: Removal of Cloudscape user functions caught exception Exc. Value is:**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN7008E: Uninstall of application appname caught exception Exc. Values are:**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN7009E: Removal of UDDI datasource caught exception Exc. Value is:**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN7010E: Removal of UDDI JDBC driver caught exception Exc. Value is:**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN7011E: Removal of configuration properties file caught exception Exc. Value is:**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN7012E: Cannot find nodeSync MBean.**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN7013E: nodeSync failed. UDDI Application may not be fully uninstalled.**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN7014E: startServer command for server servername caught exception Exc. Values are:**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN7015E: Could not get JVM.**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN7101E: Error saving configuration, changes not saved due to exception Exc. Value is:**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN7102E: Error saving configuration, changes not saved due to exception Exc. Value is:**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN7103E: Error saving configuration, changes not saved due to exception Exc. Value is:**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN7104E: Error saving configuration, changes not saved due to exception Exc. Value is:**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN7105E: Error saving configuration, changes not saved due to exception Exc. Value is:**  
**Explanation:** This is an error message issued by the UDDI setup script removeuddi.jacl.  
**User Response:**This message is self-explanatory.

- UDIN8001E: This script must be run on a standalone application server.**  
**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN8002E: To install in a Deployment Manager Environment, use setupuddi.jacl.**  
**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN8003E: Incorrect number of arguments passed to script.**  
**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN8004E: Usage is:**  
**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.  
The text following 'Usage is:' gives the syntax for calling appserversetupuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN8005E: (<db2userid> <db2password> <db2ziplocation> are only required if setting up to use DB2).** **Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN8006E: Use all forward (/) slashes to avoid problems with escaping back (\) slashes.**  
**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN8007E: List command for type parenttype caught exception Exc. Values are:**  
**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN8008E: No objects of type parenttype available. Value is:**  
**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN8009E: List command for childtype caught exception Exc. Values are:**  
**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN8001E: This script must be run on a standalone application server.**  
**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN8010E: Error during remove of existing childtype, exception Exc caught. Values are:**  
**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN8011E: Create command for childtype caught exception Exc. Values are:**  
**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN8012E: Unable to find requested parenttype of parentname. Values are:**  
**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN8013E: List command for J2CResourceAdapter caught exception Exc. Value is:**  
**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.  
**User Response:**This message is self-explanatory.
- UDIN8014E: No J2CResourceAdapter objects available.**  
**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.  
**User Response:**This message is self-explanatory.

**UDIN8015E: An error occurred during execution of appserversetupuddi.jacl. Please check the parameters and try again.**

**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN8016E: List command for Applications caught exception Exc. Value is:**

**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN8017E: Uninstall of application appname caught exception Exc. Values are:**

**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN8018E: Install of UDDI application caught exception Exc. Value is:**

**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN8019E: startApplication command for appname caught exception Exc. Values are:**

**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN8101E: Error saving configuration, changes not saved due to exception Exc. Value is:**

**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN8102E: Error saving configuration, changes not saved due to exception Exc. Value is:**

**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN8103E: Error saving configuration, changes not saved due to exception Exc. Value is:**

**Explanation:** This is an error message issued by the UDDI setup script appserversetupuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN9001E: This script must be run on a standalone application server.**

**Explanation:** This is an error message issued by the UDDI setup script appserverremoveuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN9002E: To remove from a deployment manager environment, use removeuddi.jacl.**

**Explanation:** This is an error message issued by the UDDI setup script appserverremoveuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN9003E: Incorrect number of arguments passed to script.**

**Explanation:** This is an error message issued by the UDDI setup script appserverremoveuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN9004E: Usage is:**

**Explanation:** This is an error message issued by the UDDI setup script appserverremoveuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN9005E: List command for Applications caught exception Exc. Value is:**

**Explanation:** This is an error message issued by the UDDI setup script appserverremoveuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN9006E: Uninstall of application appname caught exception Exc. Values are:**

**Explanation:** This is an error message issued by the UDDI setup script appserverremoveuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN9007E: Removal of UDDI datasource caught exception Exc. Value is:**

**Explanation:** This is an error message issued by the UDDI setup script appserverremoveuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN9008E: Removal of UDDI JDBC driver caught exception Exc. Value is:**

**Explanation:** This is an error message issued by the UDDI setup script appserverremoveuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN9101E: Error saving configuration, changes not saved due to exception Exc. Value is:**

**Explanation:** This is an error message issued by the UDDI setup script appserverremoveuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN9102E: Error saving configuration, changes not saved due to exception Exc. Value is:**

**Explanation:** This is an error message issued by the UDDI setup script appserverremoveuddi.jacl.

**User Response:**This message is self-explanatory.

**UDIN9103E: Error saving configuration, changes not saved due to exception Exc. Value is:**

**Explanation:** This is an error message issued by the UDDI setup script appserverremoveuddi.jacl.

**User Response:**This message is self-explanatory.

## UDLC (Web Services UDDI) messages

There are no messages issued by this component.

## UDPR (Web Services UDDI) messages

There are no messages issued by this component.

## UDRS (Web Services UDDI) messages

**UDRS0001E: Exception "<exception>" occurred while attempting to get UDDI Message Logger.**

**Explanation:** This message is issued to stderr when an attempt to get the UDDI Message Logger fails with the indicated exception. Since the attempt to get the message logger failed, the message cannot be logged. No messages can be logged by this instance of the IBM WebSphere UDDI Registry.

**User Response:** Restart the UDDI registry. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then please contact the IBM Customer Service Center.

**UDRS0002E: Exception "<exception>" occurred while attempting to get UDDI Trace Logger for "<component>".**

**Explanation:** This message is logged when an attempt to get the UDDI Trace Logger for the specified component (or package) fails with the indicated exception. No trace entries can be logged for this component or package of the IBM WebSphere UDDI Registry.

**User Response:** Restart the UDDI registry. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then please contact the IBM Customer Service Center.

## UDSC (Web Services UDDI) messages

There are no messages issued by this component.

## UDSP (Web Services UDDI) messages

**UDSP0001E: ParserPool found empty whilst attempting to process request. Request unsatisfied**

**Explanation:** A SOAP request was received, but was unable to be dealt with, as there were no free Parsers within the ParserPool.

**User Response:** Consider increasing the number of Parsers within the ParserPool by modifying the Init Parameter on the SOAP servlets.

**UDSP0002E: Error locating schemas required for UDDI processing. SOAP Servlets unworkable.**

**Explanation:** The SOAP servlet was unable to locate the schemas it requires in order to process SOAP requests. Without these, the servlet cannot process SOAP requests.

**User Response:** Check installation of UDDI was performed correctly. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then please contact the IBM Customer Service Center.

**UDSP0003W: Servlet unable to locate init parameter 'defaultPoolSize'. Using internal defaults.**

**Explanation:** The SOAP servlet was unable to locate the init parameter which sets the default size of the ParserPool. It will fall back to an internal default.

**User Response:** If this message occurred after attempting to make changes to the defaultPoolSize init parameter, ensure the changes were correct. If this message has appeared after installed, ensure installation was performed correctly.

**UDSP0004W: Servlet unable to understand init parameter 'defaultPoolSize'. Using internal defaults.**

**Explanation:** The SOAP servlet was unable to parse the init parameter which sets the default size of the ParserPool. It will fall back to an internal default.

**User Response:** If this message occurred after attempting to make changes to the defaultPoolSize init parameter, ensure the changes were correct. If this message has appeared after installed, ensure installation was performed correctly.

**UDSP0005E: Error occurred during parser creation.**

**Explanation:** An unspecified error occurred during the creation of a SOAP parser

**User Response:** Restart the UDDI registry. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then please contact the IBM Customer Service Center.

**UDSP0006E: Internal configuration error.**

**Explanation:** This error may occur if there was a failure creating a Parser, with accompanying message UDSP0005. It may also occur if there was a problem acquiring the Persistence layer.

**User Response:** Restart the UDDI registry. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then please contact the IBM Customer Service Center.

**UDSP0007E: Error during servlet acquisition of persistence layer.**

**Explanation:** The SOAP servlet was unable to acquire the persistence layer required for it to communicate with the UDDI datasource

**User Response:** Restart the UDDI registry. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then please contact the IBM Customer Service Center.

**UDSP0008E: Error during servlet release of persistence layer.**

**Explanation:** The persistence layer reported a problem when the SOAP servlet attempted to release it.

**User Response:** Restart the UDDI registry. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then please contact the IBM Customer Service Center.

**UDSP0009E: Error during sending of response to client.**

**Explanation:** An error occurred when sending a SOAP response message back to a client. The client may not have received the response

**User Response:** This error is recorded to enable logging of failed responses to clients. The error may be the fault of the client disconnecting before the reply could be sent, or may indicate a network problem. Examine the WebSphere logs for more information on its cause.

## **UDUC (Web Services UDDI) messages**

**UDUC0001I: IBM WebSphere UDDI Registry user console starting initialization.**

**Explanation:** The user console control servlet is starting.

**User Response:** None.

**UDUC0002I: IBM WebSphere UDDI Registry user console finished initialization.**

**Explanation:** The user console control servlet has completed startup.

**User Response:** None.

**UDUC0003I: Reading init parameters.**

**Explanation:** The user console control servlet has started reading external parameters in its init method

**User Response:** None.

**UDUC0004I: Finished reading init parameters.**

**Explanation:** The user console control servlet has finished reading external parameters in its init method. This message indicates the user console is ready to accept client requests.

**User Response:** None.

**UDUC0005E: A serious error has occurred. Error message: <Message> error: <Throwable>. More information: <Additional information>.**

**Explanation:** This error message indicates an unexpected error has occurred. The <Message> describes the error that has occurred and the <Throwable> is the type of error that was caught. <Additional information> may provide further information, if available.

**User Response:** A trace of the gui component is recommended. Contact IBM support with this information.

**UDUC0006E: A persistence error has occurred. Error message: <Message> error: <Throwable>. More information: <Additional information>.**

**Explanation:** An error occurred while performing a database operation. The <Message> describes the error that occurred and the <Throwable> is the type of error that was caught. <Additional information> may provide further information, if available.

**User Response:** Check database connections and state. Please provide IBM support with a trace, including the gui and persistence components.

**UDUC0007E: A User mismatch error has occurred. Error message: <Message> error: <Throwable>. More information: <Additional information>.**

**Explanation:** The user id provided does not match the user id required or expected whilst performing an operation that requires authentication. The <Message> describes the error that occurred and the <Throwable> is the type of error that was caught. <Additional information> may provide further information, if available.

**User Response:** Check the user has authority for the operation being requested. If necessary, contact IBM support detailing the actions taken to recreate the problem.

**UDUC0008E: An invalid key was passed. Error message: <Message> error: <Throwable>. More information: <Additional information>.**

**Explanation:** The requested operation is trying to retrieve information about an entity with a key that is invalid. This may occur if the entity has been deleted by another session. The <Message> describes the error that occurred and the <Throwable> is the type of error that was caught. <Additional information> may provide further information, if available.

**User Response:** Ask the client to close existing sessions and attempt the operation in a new browser session. If the problem persists, please provide IBM support with a trace of the gui and api components.

**UDUC0009E: An invalid value was supplied. Error message: <Message> error: <Throwable>. More information: <Additional information>**

**Explanation:** An invalid value was passed to an API call. The >Message> describes the error that occurred and the <Throwable> is the type of error that was caught. <Additional information> may provide further information, if available.

**User Response:** Contact IBM support with a trace of the gui and api components.

**UDUC0010E: Failed to introspect ActionForm properties. Exception: <Exception>.**

**Explanation:** String properties of a form object could not be introspected which means that the form contents cannot be checked for invalid characters.

**User Response:** Please contact IBM support with details of the Exception and a trace of the gui component.

**UDUC0011E: Failed to invoke reflected methods in ActionForm. Exception: <Exception>.**

**Explanation:** A form object's declared public method for setting or getting a String value could not be invoked. This method is required to check for invalid characters.

**User Response:** Please contact IBM support with details of the Exception and a trace of the gui component.

**UDUC0012E: User console initialization failed to connect to UDDI database. Exception: <Exception>.**

**Explanation:** During user console initialization, connection to the database failed, and threw the exception specified.

**User Response:** Check the connection to the UDDI database. The included exception message may yield some clues to help you resolve the problem. If unresolved, please contact IBM support with a trace of the gui component during startup.

**UDUC0013E: User console initialization failed to initialize tModels. Exception: <Exception>.**

**Explanation:** Indicates that an error has occurred during initialization of ActionServlet, specifically when reading tModels (invoking init method in class TModelNames).

**User Response:** Check the state of the UDDI database. Visually inspect the TMODEL table and confirm it is populated with valid data. The included exception message may yield some clues to help you resolve the problem. If unresolved, please contact IBM support with a trace of the gui component during startup.

**UDUC0014E: User console initialization failed to initialize taxonomies. Exception: <Exception>.**

**Explanation:** Indicates that an error has occurred during initialization of ActionServlet, specifically when reading taxonomy data (invoking init method of CategoryTaxonomyTree).

**User Response:** Check the state of the UDDI database. The included exception message may yield some clues to help you resolve the problem. If unresolved, please contact IBM support with a trace of the gui component during startup.

## UDUT UDDI Utility Tools messages

**UDUT0001I: Usage: java -jar UDDIUtilityTools.jar {'function'} [options]**

**function:**

<code>-promote <i>entity source</i></code>	Promote entities between registries
<code>-export <i>entity source</i></code>	Extract entities from registry to XML
<code>-delete <i>entity source</i></code>	Delete entities from registry
<code>-import</code>	Create entities from XML to registry

**where *entity source* is one of:**

<code>-tmodel</code>	Specify single entity type and key
<code>-business</code>	Specify single entity type and key
<code>-service</code>	Specify single entity type and key
<code>-binding <i>key</i></code>	Specify single entity type and key
<code>-keysFile   -f <i>filename</i></code>	Specify file containing entity types and keys

**options:**

<code>-properties <i>filename</i></code>	Specify path to configuration file
<code>-overwrite   -o</code>	Overwrite an entity if it already exists
<code>-log   -v</code>	Output verbose messages
<code>-definitionFile <i>filename</i></code>	Specify path to UDDI entity definition file
<code>-importReferenced</code>	Import entities referenced by source entities

**The following options override property settings in configuration file:**

<code>-overwrite</code>
<code>-log</code>
<code>-definitionFile</code>
<code>-importReferenced</code>

**Example:** `java -jar UDDIUtilityTools.jar -promote -keysFile C:/uddikeys.txt`

**Explanation:** This is the usage message displayed at the command line when the user has entered an invalid combination of arguments or options.

**User Response:** Enter the command according to the usage message..

**UDUT0002I: \*\*\*\*\* Starting UDDI Utility Tools \*\*\*\*\***  
**Explanation:** This message is used as a marker in the message log file to indicate tool start points.

**User Response:** None.

**UDUT0003I: Promoting entityType<entity type> key<entity key>...**  
**Explanation:** Indicates which entity type (business, tModel and so on) is being promoted, and it's key value.

**User Response:** None.

**UDUT0004I: Bad entityType: received<incorrect entity type>, expected <tModel|business|service|binding>**  
**Explanation:** The user entered an incorrect entity type.

**User Response:** Use an entity type of tModel, business, service or binding.

**UDUT0005I: Promotion successful.**  
**Explanation:** Indicates the promote function completed successfully.

**User Response:** None.

**UDUT0006I: Import successful.**  
**Explanation:** Indicates the import function completed successfully.

**User Response:** None.

**UDUT0007I: Export successful.**  
**Explanation:** Indicates the export function completed successfully.

**User Response:** None.

**UDUT0008I: Delete successful.**  
**Explanation:** Indicates the delete function completed successfully.

**User Response:** None.

**UDUT0009I: Exporting entities ...**  
**Explanation:** Indicates the export function has started.

**User Response:** None.

**UDUT0010I: Exporting business, businessKey[<business key>].**  
**Explanation:** Indicates that the businessEntity with the specified key is being exported.

**User Response:** None.

**UDUT0011I: Exporting service, serviceKey[<service key>].**  
**Explanation:** Indicates that the businessService with the specified key is being exported.

**User Response:** None.

**UDUT0012I: Exporting binding, bindingKey[<binding key>].**  
**Explanation:** Indicates that the bindingTemplate with the specified key is being exported.

**User Response:** None.

**UDUT0013I: Exporting tModel, tModelKey[<tModel key>].**  
**Explanation:** Indicates that the tModel with the specified key is being exported.

**User Response:** None.

**UDUT0014I: Exporting referenced tModel, tModelKey[<tModel key>].**  
**Explanation:** Indicates that the referenced tModel with the specified key is being exported.

**User Response:** None.

**UDUT0015I: Exported <entity count> entities.**  
**Explanation:** Indicates that the export function completed, and shows the number of entities exported.

**User Response:** None.

**UDUT0016I: Importing entities ...**  
**Explanation:** Indicates the import function has started.

- User Response:** None.
- UDUT0017I: Importing business, businessKey[<business key>].**  
**Explanation:** Indicates that the businessEntity with the specified key is being imported.
- User Response:** None.
- UDUT0018I: Importing service, serviceKey[<service key>].**  
**Explanation:** Indicates that the businessService with the specified key is being imported.
- User Response:** None.
- UDUT0019I: Importing binding, bindingKey[<binding key>]**  
**Explanation:** Indicates that the bindingTemplate with the specified key is being imported.
- User Response:** None.
- UDUT0020I: Importing tModel, tModelKey[<tModel key>].**  
**Explanation:** Indicates that the tModel with the specified key is being imported..
- User Response:** None.
- UDUT0021I: Importing referenced tModel, tModelKey[<tModel key>].**  
**Explanation:** Indicates that the referenced tModel with the specified key is being imported.
- User Response:** None.
- UDUT0022I: Imported <entity count> entities.**  
**Explanation:** Indicates that the import function completed, and shows the number of entities imported.
- User Response:** None.
- UDUT0023I: Deleting entities ...**  
**Explanation:** Indicates the delete function has started.
- User Response:** None.
- UDUT0024I: Deleting business, businessKey[<business key>].**  
**Explanation:** Indicates that the businessEntity with the specified key is being deleted.
- User Response:** None.
- UDUT0025I: Deleting service, serviceKey[<service key>].**  
**Explanation:** Indicates that the businessService with the specified key is being deleted.
- User Response:** None.
- UDUT0026I: Deleting binding, bindingKey[<binding key>].**  
**Explanation:** Indicates that the bindingTemplate with the specified key is being deleted.
- User Response:** None.
- UDUT0027I: Deleting tModel, tModelKey[<tModel key>].**  
**Explanation:** Indicates that the tModel with the specified key is being deleted.
- User Response:** None.
- UDUT0028I: Deleted <entity count> entities.**  
**Explanation:** Indicates that the delete function completed, and shows the number of entities deleted.
- User Response:** None.
- UDUT0029I: Serializing ...**  
**Explanation:** Indicates that generation of the Entity Definition File has started.
- User Response:** None.
- UDUT0030I: Serialized entities.**  
**Explanation:** Indicates that generation of the Entity Definition File completed successfully.
- User Response:** None.
- UDUT0031I: Deserializing ...**  
**Explanation:** Indicates that reading of the Entity Definition File and creation of UDDI entities has started.

- User Response:** None.
- UDUT0032I: Deserialized entities.**  
**Explanation:** Indicates that reading of the Entity Definition File and creation of UDDI entities completed successfully.
- User Response:** None.
- UDUT0033I: Function '<function>' completed successfully.**  
**Explanation:** Indicates the requested function completed successfully.
- User Response:** None.
- UDUT0034W: Function '<function>' did not complete successfully. See message log for further information.**  
**Explanation:** Indicates the requested function did not complete successfully.
- User Response:** The message log may yield further information if the verbose option is on. Check the configuration properties file setting are correct. If that does not identify the problem, try running with trace logging enabled. If that does not yield a solution, contact your IBM support center.
- UDUT0035W: Parser error: <warning description>**  
**Explanation:** The XML parser reports a warning about the content of the Entity Definition File.
- User Response:** Based on the context of the warning message, check the validity of the Entity Definition File.
- UDUT0036E: Parser error <error description>**  
**Explanation:** The XML parser reports an error about the content of the Entity Definition File.
- User Response:** Based on the context of the error message, check the validity of the Entity Definition File.
- UDUT0037E: Unrecognized parser feature: <feature description>**  
**Explanation:** A parser feature set by the UDDI Utility Tools is not recognized by the parser.
- User Response:** Check you are using the correct type and level of XML parser. If correct, contact your IBM support center.
- UDUT0038E: Unsupported parser feature: <feature description>**  
**Explanation:** A parser feature set by the UDDI Utility Tools is not supported by the parser.
- User Response:** Check you are using the correct type and level of XML parser. If correct, contact your IBM support center.
- UDUT0039E: Unrecognized parser property: <property description>, value: <value>**  
**Explanation:** A parser property set by the UDDI Utility Tools is not recognized by the parser.
- User Response:** Check you are using the correct type and level of XML parser. If correct, contact your IBM support center.
- UDUT0040E: Unsupported parser property: <property description>, value: <value>**  
**Explanation:** A parser property set by the UDDI Utility Tools is not supported by the parser.
- User Response:** Check you are using the correct type and level of XML parser. If correct, contact your IBM support center.
- UDUT0041I: <message>**  
**Explanation:** This is a placeholder message used during development only.
- User Response:** None.
- UDUT0042E: Unable to find the configuration file: <filepath>**  
**Explanation:** UDDI Utility Tools cannot locate the specified configuration file.
- User Response:** UDDI Utility Tools looks for a default configuration properties with the file name 'UDDIUtilityTools.properties' in the current directory. Check that the configuration file has this name, or that the argument value supplied with the '-properties' option is pointing at a file that exists.
- UDUT0043E: An Exception occurred trying to read the configuration file.**  
**Explanation:** The configuration file could not be read.

**User Response:** Check the file path points to a valid file and that the file does not have the 'hidden' attribute set.

**UDUT0044W: Configuration file is missing the '<property name>' property.**

**Explanation:** A required property is missing from the configuration file.

**User Response:** Add the missing property name and value to the configuration file. Check that the property name is not misspelled.

**UDUT0045W: Property: '<property name>' has value '<property value>'. It must be either 'true' or 'false'.**

**Explanation:** A value was given to a property other than 'true' or 'false'.

**User Response:** Set the property value to 'true' or 'false'.

**UDUT0046W: Property: '<property name>' has value '<property value>'. It must be an integer value.** **Explanation:** A value was given to a property other than an integer value.

**User Response:** Set the property value to an integer value.

**UDUT0047E: Unable to find the keyFile file: <keys file path>**

**Explanation:** The keys file could not be located at the specified path.

**User Response:** Check the file name and path and correct and that the file exists.

**UDUT0048E: Unable to read the keyFile file: <keys file path>**

**Explanation:** The keys file could not be read due to an IO error.

**User Response:** Check the file's hidden attribute is not set.

**UDUT0049E: Unable to write to entity definition file: <entity definition file path>**

**Explanation:** During initialization, the Entity Definition File could not be written to.acl.

**User Response:** Check the file's read only attribute is not set.

**UDUT0050E: Unable to find UDDI Entity definition file: <entity definition file path>**

**Explanation:** The Entity Definition File could not be found at the specified file path.

**User Response:** Check the file path is correct and that the file exists.

**UDUT0051E: Unable to read UDDI Entity definition file: <entity definition file path>**

**Explanation:** The Entity Definition File could not be read due to an IO error.

**User Response:** Check the file's hidden attribute is not set.

**UDUT0052E: Unable to close the message file: <file path>**

**Explanation:** The attempt to close the message file failed.

**User Response:** The disk might be full. If so, clear some space or direct log output to a different disk.

**UDUT0053E: Unable to close the trace file: <file path>**

**Explanation:** The attempt to close the trace log file failed.

**User Response:** The disk might be full. If so, clear some space or direct log output to a different disk.

**UDUT0054E: The logger was unable to find the file: <file path>**

**Explanation:** The UDDI Utility Tools logger could not find the specified file.

**User Response:** None.

**UDUT0055E: ERROR OCCURRED ...**

**Explanation:** General purpose error message used in development only.

**User Response:** None.

**UDUT0056E: Exception:**

**Explanation:** General purpose message prefix used for reporting exceptions.

**User Response:** None.

**UDUT0057W: Only one function may be specified on the command line.**

**Explanation:** Multiple function commands were entered on the command line.

**User Response:** Specify one function in accordance with the usage message.

**UDUT0058W: No function was specified.**

**Explanation:** UDDI Utility Tools was invoked with no function specified.

**User Response:** Specify one function in accordance with the usage message.

**UDUT0059W: The function: <function> was not recognized.**

**Explanation:** The function value did not match any of the allowed functions.

**User Response:** Specify one function in accordance with the usage message.

**UDUT0060W: The argument '<argument>' was not recognized.**

**Explanation:** The argument value does not match any of the allowed arguments.

**User Response:** Specify arguments in accordance with the usage message.

**UDUT0061W: There was a missing value for <argument> argument.**

**Explanation:** An expected value for the specified argument was not supplied.

**User Response:** Specify a value for the argument in accordance with the usage message.

**UDUT0062W: Unexpected argument: <argument> (entity key file is already specified).**

**Explanation:** The entity type argument cannot be specified if the keysFile argument is already specified.

**User Response:** Specify arguments in accordance with the usage message.

**UDUT0063W: Unexpected argument: <argument> (entity key is already specified).**

**Explanation:** The keysFile argument cannot be specified if an entity type argument and key value has already been specified.

**User Response:** Specify arguments in accordance with the usage message.

**UDUT0064W: Argument: <argument> cannot be specified more than once.**

**Explanation:** An argument was specified twice in the same command.

**User Response:** Specify arguments in accordance with the usage message.

**UDUT0065E: No entity keys were specified.**

**Explanation:** A keys file or an entity type and key value must be specified for functions using keys.

**User Response:** Specify arguments in accordance with the usage message.

**UDUT0066E: Could not load Database driver: dbDriver<database driver>.**

**Explanation:** The specified database driver could not be loaded.

**User Response:** Check the database driver value in the configuration file is valid, and the driver's class is present in the classpath property.

**UDUT0067E: Could not create Database connection: dbUrl, dbUser, (dbPasswd not shown).**

**Explanation:** A connection could not be established with the database at the specified URL with the specified userid.

**User Response:** Check the database URL, userid and password values are correct in the configuration file, and that the database manager is running.

**UDUT0068E: Could not close the database connection.**

**Explanation:** An attempt to close the database connection failed.

**User Response:** If the problem persists, contact your IBM support center.

**UDUT0069E: Could not create minimal entity for tModel.**

**Explanation:** The minimal data necessary for a valid tModel could not be inserted in the target UDDI registry database.

**User Response:** Check the database URL, userid and password values are correct in the configuration file, and that the database manager is running.

**UDUT0070E: Could not create minimal entity for Service.**

**Explanation:** The minimal data necessary for a valid businessService could not be inserted in the target UDDI registry database.

**User Response:** Check the database URL, userid and password values are correct in the configuration file, and that the database manager is running.

**UDUT0071E: Could not create minimal entity for Business.**

**Explanation:** The minimal data necessary for a valid businessEntity could not be inserted in the target UDDI registry database.

**User Response:** Check the database URL, userid and password values are correct in the configuration file, and that the database manager is running.

**UDUT0072E: Could not create minimal entity for Binding.**

**Explanation:** The minimal data necessary for a valid bindingTemplate could not be inserted in the target UDDI registry database.

**User Response:** Check the database URL, userid and password values are correct in the configuration file, and that the database manager is running.

**UDUT0073E: There was an error while trying to create an XML Document.**

**Explanation:** An attempt to create the Entity Definition File failed.

**User Response:** Check the file path specified in the configuration file for the Entity Definition File is valid and is not set to read only.

**UDUT0074E: There was an error parsing the entity definition file.**

**Explanation:** An unspecified error occurred when parsing the Entity Definition File.

**User Response:** Check the entity definition file content is valid according to the UDDI Utility Tools schema file, promoter.xsd.

**UDUT0075E: One or more errors occurred while parsing the entity definition file. See message log for details.**

**Explanation:** Errors occurred when parsing the Entity Definition File.

**User Response:** Check the entity definition file content is valid according to the UDDI Utility Tools schema file, promoter.xsd.

**UDUT0076W: One or more warnings were raised while parsing the entity definition file. See message log for details.**

**Explanation:** Warnings occurred when parsing the Entity Definition File.

**User Response:** Check the entity definition file content is valid according to the UDDI Utility Tools schema file, promoter.xsd.

**UDUT0078E: Unable to obtain authinfo.**

**Explanation:** AuthInfo could not be obtained from the UDDI registry with the given userid and password.

**User Response:** Check the userid and password property values are correct in the configuration file.

**UDUT0079E: The inquiryURL is malformed: <inquiry URL>.**

**Explanation:** The inquiry URL specified in the configuration file is not valid.

**User Response:** Correct the value for the inquiry URLs (fromInquiryURL and toInquiryURL) in the configuration file.

**UDUT0080E: The publishURL is malformed: <publish URL>**

**Explanation:** The publish URL specified in the configuration file is not valid.

**User Response:** Correct the value for the publish URL (toPublishURL) in the configuration file.

**UDUT0081E: Could not get tModel detail for tModelKey[<tModel key>].**

**Explanation:** The get tModel operation failed on the source registry.

**User Response:** Check the key exists in the source registry.

**UDUT0082E: Could not get service detail for serviceKey[<service key>].**

**Explanation:** The get service operation failed on the source registry.

**User Response:** Check the key exists in the source registry.

**UDUT0083E: Could not get business detail for businessKey[<business key>].**

**Explanation:** The get business operation failed on the source registry.

**User Response:** Check the key exists in the source registry.

**UDUT0084E: Could not get binding detail for bindingKey[<binding key>].**

**Explanation:** The get binding operation failed on the source registry.

**User Response:** check the key exists in the source registry.

**UDUT0085E: Could not save tModel for tModelKey[<tModel key>].**

**Explanation:** The publish operation failed at the target registry.

**User Response:** Check the tModel is not referencing another entity (such as a tModel) that is not present in the target registry. This may occur if the 'importReferenced' property is set to false. Specify referenced tModels in the referencedtModels section of the Entity Definition File and set 'importReferenced' property in the configuration file to 'true'.

**UDUT0086E: Could not save business for businessKey[<business key>].**

**Explanation:** The publish operation failed at the target registry.

**User Response:** Check the businessEntity is not referencing another entity (such as a tModel) that is not present in the target registry. This may occur if the 'importReferenced' property is set to false. Specify referenced tModels in the referencedtModels section of the Entity Definition File and set 'importReferenced' property in the configuration file to 'true'.

**UDUT0087E: Could not save service for parent businessKey[<business key>].**

**Explanation:** The publish operation failed at the target registry.

**User Response:** Check the businessEntity specified as the parent of the businessService exists in the target registry.

**UDUT0088E: Could not save binding for parent serviceKey[<service key>].**

**Explanation:** The publish operation failed at the target registry.

**User Response:** Check the businessService specified as the parent of the bindingTemplate exists in the target directory.

**UDUT0089W: Did not save service for serviceKey[<service key>].**

**Explanation:** The parent business for the specified businessService does not exist.

**User Response:** Check the key value for the parent entity is correct in the Entity Definition File, and that the entity exists in the target registry.

**UDUT0090W: Did not save binding for bindingKey[<binding key>].**

**Explanation:** The parent service for the specified bindingTemplate does not exist.

**User Response:** Check the key value for the parent entity is correct in the Entity Definition File, and that the entity exists in the target registry.

**UDUT0091E: Could not delete business for businessKey[<business key>] because parent service did not exist.**

**Explanation:** The UDDI4J operation to delete the businessEntity with the specified key failed.

**User Response:** Check the userid and password property values in the configuration file and that the entity exists in the target UDDI registry.

**UDUT00921E: Could not delete service for serviceKey[<tModel key>].**

**Explanation:** The UDDI4J operation to delete the businessService with the specified key failed.

**User Response:** Check the userid and password property values in the configuration file and that the entity exists in the target UDDI registry.

**UDUT0093E: Could not delete binding for bindingKey[<binding key>].**

**Explanation:** The UDDI4J operation to delete the bindingTemplate with the specified key failed.

**User Response:** Check the userid and password property values in the configuration file and that the entity exists in the target UDDI registry.

**UDUT0094E: Could not delete tModel for tModelKey[<tModel key>].**

**Explanation:** The UDDI4J operation to delete the tModel with the specified key failed.

**User Response:** Check the userid and password property values in the configuration file and that the entity exists in the target UDDI registry.

**UDUT0096W: <entity type><key value> is not a valid UUID.**

**Explanation:** The key value entered does not comply with the format specified for a UUID in the UDDI specification.

**User Response:** Enter a valid UUID key.

**UDUT0097W: Did not save tModel for tModelKey[<tModel key>] as it already exists. Use the -overwrite argument to overwrite the tModel.**

**Explanation:** The tModel was not saved because the overwrite property is false

**User Response:** If the desired action is to overwrite existing entities, specify -overwrite on the command line or set the overwrite property in the configuration file to true.

**UDUT0098W: Did not save business for businessKey[<business key>] as it already exists. Use the -overwrite argument to overwrite the tModel.**

**Explanation:** The businessEntity was not saved because the overwrite property is false

**User Response:** If the desired action is to overwrite existing entities, specify -overwrite on the command line or set the overwrite property in the configuration file to true.

**UDUT0099W: Did not save service for serviceKey[<service key key>] as it already exists. Use the -overwrite argument to overwrite the tModel.**

**Explanation:** The businessService was not saved because the overwrite property is false

**User Response:** If the desired action is to overwrite existing entities, specify -overwrite on the command line or set the overwrite property in the configuration file to true.

**UDUT0100W: Did not save binding for bindingKey[<binding key key>] as it already exists. Use the -overwrite argument to overwrite the tModel.**

**Explanation:** The bindingTemplate was not saved because the overwrite property is false

**User Response:** If the desired action is to overwrite existing entities, specify -overwrite on the command line or set the overwrite property in the configuration file to true.

**UDUT0101W: Bad entity type: received<entity type>, expected<tModel|business|service|binding>.**

**Explanation:** The entered entity type was not recognized.

**User Response:** Specify arguments in accordance with the usage message.

**UDUT0102E: Promotion failed.**

**Explanation:** The promote function failed to complete.

**User Response:** Check the configuration properties file has correct settings.

**UDUT0106E: Unable to commit transaction.**

**Explanation:** The insertion of minimal entity data during the import function failed to commit to the database.

**User Response:** Check the database configuration. If necessary, turn on trace logging and look for the SQLException that is recorded.

**UDUT0107E: Unable to set auto-commit off on the database connection.**

**Explanation:** UDDI Utility Tools needs to control commits of data changes, however the attempt to turn off auto-commit failed.

**User Response:** Check the database configuration. If necessary, turn on trace logging and look for the SQLException that is recorded.

**UDUT0109E: The import function requires a UDDI entity definition file to be specified.**

**Explanation:** A required argument value was not specified.

**User Response:** Specify -definition <path to Entity Definition File> on the command line, or set the value of the UDDIEntityDefinitionFile property in the configuration file to the path to the Entity Definition File.

**UDUT0110E: A cyclic dependency exists in the referenced tModels. The reference from tModel with key [<tModel key>] to the tModel with key [<tModel key>] completes the detected cycle.**

**Explanation:** A cycle has been detected such that a tModel is being referenced by a tModel that it directly or indirectly references. This would cause the UDDI Utility Tools to enter an infinite loop trying to import referenced tModels, so the process is halted.

**User Response:** Edit the Entity Definition File and temporarily remove the reference to the tModel in the cycle, taking a note of the referenced details. After the import has successfully completed, update the tModel in the target registry to reintroduce the reference you previously removed. This can be done using the UDDI User Console, UDDI4J, or by creating a new Entity Definition File with just the tModel to be updated, and running the UDDI Utility Tools with the import function.

**UDUT0112E: An unexpected exception has occurred: <Exception message>.**

**Explanation:** An unexpected error occurred.

**User Response:** Check configuration file settings and all registries and databases are active. If necessary, contact your IBM support center.

**UDUT0113E: Could not get a response from UDDI registry at URL: <URL>.**

**Explanation:** A TransportException occurred while performing an UDDI4J operation on the UDDI registry at the specified URL.

**User Response:** Check configuration properties for the UDDI registry in question and ensure the UDDI registry is active.

**UDUT0114E: An IOException occurred trying to invoke 'java'.**

**Explanation:** When UDDI Utility Tools was invoked using the java -jar syntax, the invocation of the second JVM failed.

**User Response:** Check configuration property 'classpath' value is correct, and that Java is configured to run from the command line.

**UDUT0115I: Imported <entity count> entities and <referenced entity count> referenced entities.**

**Explanation:** Indicate that the import step of the import or promote function has completed, showing the number of entities imported.

**User Response:** None.

**UDUT0116W: Not all minimal entities could be removed. The following remain in the database:**

**Explanation:** A publish step was not successful which may have left one or more minimal entities in the target registry database. UDDI Utility Tools attempts to remove these minimal entities but in this case, the removal has failed. Following messages will indicate which minimal entities are left in the target registry.

**User Response:** You can attempt to remove the minimal entities using normal methods, such as the user console, UDDI4J, or using the delete function of the UDDI Utility Tools.

**UDUT0117W: Business minimal entities with businessKey [<business key>] has not been removed from the database.**

**Explanation:** A business minimal entity was orphaned in the target registry database and attempts to remove it failed.

**User Response:** Identify the orphaned minimal entity in the target and attempt to remove using normal UDDI methods, or by using the delete function of the UDDI Utility Tools.

**UDUT0118W: Service minimal entity with serviceKey [<service key>] has not been removed from the database.**

**Explanation:** A service minimal entity was orphaned in the target registry database and attempts to remove it failed.

**User Response:** Identify the orphaned minimal entity in the target registry and attempt to remove using normal UDDI delete methods, or by using the delete function of the UDDI Utility Tools.

**UDUT0119W: Binding Template minimal entity with bindingKey [<binding key>] has not been removed from the database.**

**Explanation:** A binding minimal entity was orphaned in the target registry database and attempts to remove it failed.

**User Response:** Identify the orphaned minimal entity in the target registry and attempt to remove using normal UDDI delete methods, or by using the delete function of the UDDI Utility Tools.

**UDUT0120W: TModel minimal entity with tModelKey [<tModel key>] has not been removed from the database.**

**Explanation:** A tModel minimal entity was orphaned in the target registry database and attempts to remove it failed.

**User Response:** Identify the orphaned minimal entity in the target registry and attempt to remove using normal UDDI delete methods, or by using the delete function of the UDDI Utility Tools.

**UDUT0121I: Created business minimal entity with businessKey [<business key>].**

**Explanation:** Indicates the minimal data required for a businessEntity has successfully been inserted in the target UDDI registry database.

**User Response:** None.

**UDUT0122I: Created service minimal entity with serviceKey [<service key>].**

**Explanation:** Indicates the minimal data required for a businessService has successfully been inserted in the target UDDI registry database.

**User Response:** None.

**UDUT0123I: Created binding template minimal entity with bindingKey [<binding key>].**

**Explanation:** Indicates the minimal data required for a bindingTemplate has successfully been inserted in the target UDDI registry database.

**User Response:** None.

**UDUT0124I: Created tModel minimal entity with tModelKey [<tModel key>].**

**Explanation:** Indicates the minimal data required for a tModel has successfully been inserted in the target UDDI registry database.

**User Response:** None.

**UDUT0125I: Deleted business minimal entity with businessKey [<business key>].**

**Explanation:** Indicates the minimal data inserted for a businessEntity was successfully removed from the target UDDI registry database. This would normally happen after a publish operation has failed.

**User Response:** None.

**UDUT0126I: Deleted service minimal entity with serviceKey [<service key>].**

**Explanation:** Indicates the minimal data required for a businessService was successfully removed from the target UDDI registry database. This would normally happen after a publish operation has failed.

**User Response:** None.

**UDUT0127I: Deleted binding template minimal entity with bindingKey [<binding key>].**

**Explanation:** Indicates the minimal data required for a bindingTemplate was successfully removed from the target UDDI registry database. This would normally happen after a publish operation has failed.

**User Response:** None.

**UDUT0128I: Deleted tModel minimal entity with tModelKey [<tModel key>].**

**Explanation:** Indicates the minimal data required for a tModel was successfully removed from the target UDDI registry database. This would normally happen after a publish operation has failed.

**User Response:** None.

**UDUT0129E: Find related businesses failed.**

**Explanation:** The UDDI4J find related businesses operation did not complete.

**User Response:** Check the configuration properties for the source registry, such as fromInquiryURL.

**UDUT0130E: Find businesses failed.**

**Explanation:** The UDDI4J find businesses operation did not complete.

**User Response:** Check the configuration properties for the source registry, such as fromInquiryURL.

**UDUT0131E: Find services failed.**

**Explanation:** The UDDI4J find services operation did not complete.

**User Response:** Check the configuration properties for the source registry, such as fromInquiryURL.

**UDUT0132E: Find tModels failed.**

**Explanation:** The UDDI4J find tModels operation did not complete.

**User Response:** Check the configuration properties for the source registry, such as fromInquiryURL.

**UDUT0133E: Find bindings failed.**

**Explanation:** The UDDI4J find bindings operation did not complete.

**User Response:** Check the configuration properties for the source registry, such as fromInquiryURL.

**UDUT0134I: Performing inquiry request ...**

**Explanation:** Indicated the find operation for selecting keys has started.

**User Response:** None.

**UDUT0135I: Extracted keys from inquiry results.**

**Explanation:** Indicates the find operation to select keys has completed successfully.

**User Response:** None

## UDUU (Web Services UDDI) messages

There are no messages issued by this component.

---

## Running the UDDI samples

The UDDI samples, and documentation on how to use them, are available through the Web Services UDDI samples link on the Samples Central page of the IBM WebSphere Developer Domain Web site.

---

## Installation Verification Program (IVP)

There are some samples available on the WebSphere Developer Domain (WSDD) web site (at <http://www7b.software.ibm.com/wsdd/library/samples/AppServer.html>) that are intended to provide an optional Installation Verification test, or IVP, for the UDDI Registry component.

This topic describes how to run these installation verification programs (IVPs) to verify that the IBM UDDI Registry has been installed correctly.

There are two IVP SOAP samples: SOAPSampleIVPa and SOAPSampleIVPb. They are intended to verify the successful installation of the product, and should be used in conjunction with the UDDI Users Console (GUI). SOAPSampleIVPa saves some data to the registry which you can then find using the GUI. Finally you can delete the data by running SOAPSampleIVPb.

The IVP samples are installed into the same target directory as the other SOAP samples and they use the same XML files as the basic Java SOAP samples.

SOAPSampleIVPa saves three businesses, six services (2 per business) and three tModels. The data structures are very basic and consist only of a name. The keys returned by the save\_\* UDDI API calls are then written to a file, SOAPSamp1eIVPa.out. SOAPSampleIVPb then reads in these keys from the file to delete the saved data from the UDDI registry.

**Note:** Each time you run SOAPSampleIVPa, it overwrites the output file SOAPSamp1eIVPa.out so, if you wish to use SOAPSampleIVPb to delete the data, you must run this before you next run SOAPSampleIVPa.

**Note:** As supplied, the IVP programs are written to work on a system without authentication. It is possible to configure the IVPs to work with authentication (see

<http://www7b.software.ibm.com/wsdd/library/samples/AppServer.html>), however, if possible it is recommended you run them on a non-authenticated system.

### Steps for this task

Perform the following steps on the same system as the UDDI Registry:

1. Ensure that DB2 and the WebSphere Administrative Server are started.
2. Start the WebSphere Administrator's Console and ensure the default server is started and the UDDI Registry Application is started.
3. For SOAP samples to work, you need to ensure that the Client Developer Kit for Java is either the one shipped with IBM WebSphere Application Server or a later IBM Developer Kit for Java.:
  - For Windows - ensure that <WebSphere-install-dir>\java\bin is present in the PATH statement before any other Developer Kits for Java
  - For Unix Platforms - ensure that <WebSphere-install-dir>/java/bin is present in the PATH statement before any other Developer Kits for Java

**Note:** You **must** use the IBM WebSphere supplied Developer Kit for Java or a later level of the IBM Developer Kit for Java.

For Windows, the default system path can be set via **Control Panel ...-> Settings ...-> System ...-> Advanced Properties ...-> Environment Variables**

Alternatively, this can be accomplished just for the shell where you plan to run the samples by modifying the path within the shell:

- For Windows - set path=<WebSphere-install-dir>\java\bin;%path%
  - For Unix Platforms - export PATH=<WebSphere-install-dir>/java/bin:\$PATH
4. Copy the samples and \*.xml files to a directory
  5. Compile both SOAPSsampleIVPa and SOAPSsampleIVPb by entering (from a command prompt):

```
'javac SOAPSsampleIVPa.java'
```

and

```
'javac SOAPSsampleIVPb'
```

6. Run SOAPSsampleIVPa by entering 'java SOAPSsampleIVPa'. This should publish a number of businesses and services and technical models into the registry.
7. Start your Web browser on the same system as the UDDI Registry.
8. To display the UDDI GUI home page, enter the following URL:
  - <http://localhost:9080/uddigui>
9. On the find page, complete the following steps:
  - a. Select the business radio button
  - b. In the data entry field, enter % (the wild card symbol)
  - c. Click **Find**

You should get a results page returned with three businesses (mybusiness1, mybusiness2, and mybusiness3). This demonstrates that the API and the UDDI user console are working correctly.
10. To see the services that are available for a business, click the "Show Services" option next to the business.
11. To delete all of the IVP data, run SOAPSsampleIVPb (from the command prompt as before - by entering 'java SOAPSsampleIVPb')
12. On the find page, complete the following steps:
  - a. Select the business radio button
  - b. In the data entry field, enter % (the wild card symbol)
  - c. Click **Find**

You should get an empty results page returned.

---

## Reporting problems with the IBM WebSphere UDDI Registry

If you report a problem with the IBM WebSphere UDDI Registry component to IBM, supply the following information:

1. A detailed description of the problem.
2. The build date and time of the version you are using. This can be obtained as follows:
  - In the installedApps subdirectory of the WebSphere installation location, you will find a subdirectory called UDDI\_Registry.<nodename>.<servername>.ear, where <nodename> is the name of the node into which the UDDI Registry application is installed, and <servername> is the name of the server. Within that subdirectory, you will find a file called version.txt. Include the contents of this file as part of your information.
  - If the UDDI Registry has been started with tracing enabled for the UDDI component, you should find a trace entry in the WebSphere trace log that includes the strings "getUDDIMessageLogger" and "UDDI Build : " followed by the build date and time, and the build system. Also include this information.
3. Any relevant log files and trace files.
  - If the problem occurred while setting up and installing the UDDI Registry application using one of the setup scripts, setupuddi.jacl or appserversetupuddi.jacl, supply the log output from running the script. (If you did not redirect the output from the script file to a log file, rerun the script, this time redirecting the output as described in the section 'Installing and Setting up a UDDI Registry'.) The log file is written to the directory from which you ran the setup script.
  - If the problem occurred while removing the UDDI Registry application using one of the remove scripts, removeuddi.jacl or appserverremoveuddi.jacl, supply the log output from running the script. (If you did not redirect the output from the script file to a log file, rerun the script, this time redirecting the output as described in the section 'Removing the UDDI Registry from a deployment manager cell' or 'Removing the UDDI Registry application from a single appserver'.) The log file is written to the directory from which you ran the remove script.
  - If the problem occurred while creating the UDDI Registry database using the UDDI DB2 Setup Wizard, supply the log file UDDIloadDB.log, which is written to the directory from which the wizard was run.
  - If the problem occurred while running the UDDI Registry, enable UDDI tracing (if not already enabled) and supply the trace log from the logs directory of the application server on which the UDDI Registry was running. See 'Turning on UDDI Trace' for details on how to enable UDDI tracing.
  - Also supply the WebSphere log files system.out and system.err.
  - Supply details of the version of IBM WebSphere Application Server you are running by executing the command versioninfo (Windows) or versioninfo.sh (Unix platforms) on both the application server and deployment manager nodes and directing the output to a log file.
4. If appropriate, any application code that you are using and the output produced by the application code.

In addition to the above, it is useful to run the WebSphere collector tool and send the resulting jar file(s) (two files if run from base application server AND DeploymentManager) to IBM. See "Running the collector tool" in the Information Center.

---

## Feedback

See the section on "Obtaining help from IBM" in the Information Center for details on seeking assistance.

---

## Chapter 12. Web services gateway: Enabling Web services

You use the Web services gateway to handle Web service invocations between Internet and intranet environments. You use it to make your internal Web services available externally, and to make external Web services available to your internal systems.

With the Web services gateway you administer the following resources:

- Web services.
- Channels.
- Filters.
- **5.1+** JAX-RPC handlers.
- Security bindings.
- UDDI references.

To make the Web services gateway files available for you to install, you select the gateway option when you install WebSphere Application Server (either by accepting the “typical install” option, or by choosing the “custom install” option **Web services > Web services gateway**). Note that when you install WebSphere Application Server, or an upgrade or fix pack, the installation program does *not* install the gateway. The installation program copies the gateway files into directories within your application server directory structure, then you install the gateway into your application server as a separate task.

When you install the gateway into your application server, any previously configured gateway is replaced with an upgraded but empty gateway. If you want to preserve an existing gateway configuration, you need to save the configuration before you install the upgrade, then restore the configuration after the upgrade is installed. To save your gateway configuration before you complete the installation of an upgraded gateway, see Preserving an existing gateway configuration.

To install the gateway into your application server, see Completing the installation.

Detailed instructions on how to enable Web services through the gateway are provided in the following tasks:

- Backing up and restoring a gateway configuration.
- Administering the Web services gateway.
- Running the Web services gateway samples.
- Passing SOAP messages with attachments through the Web services gateway.
- Developing Web services gateway extensions.
- Scaling the Web services gateway.
- Securing the Web services gateway.
- Tuning the Web services gateway.
- Troubleshooting the Web services gateway.

For a brief overview of the gateway and how it works, see [Web services gateway - frequently asked questions](#).

For a list of the major changes since the AlphaWorks preview version of the gateway, see [Web services gateway - What is new in this release](#).

For additional technical details of the Web services gateway, see the [gateway Javadoc](#).

For more information about working with Web services, visit the Web sites referenced in [Web services: Resources for Learning](#).

---

## Web services gateway - frequently asked questions

This topic provides answers to a set of frequently asked questions about the Web services gateway.

- What are Web services?
- What is the IBM Web services gateway?
- How does the Web services gateway work?
- What problems are solved by the Web services gateway?
- Who should use the Web services gateway?
- What is the difference between the Apache SOAP channel and the SOAP over HTTP channel?

### What are Web services?

Web services are modular applications that interact with one another across the Internet. Web services are based on shared, open and emerging technology standards and protocols (such as SOAP, UDDI, and WSDL) and can communicate, interact, and integrate with other applications, no matter how they are implemented.

### What is the IBM Web services gateway?

The gateway is a middleware component that bridges the gap between Internet and intranet environments during Web service invocations. You use the gateway to manage:

- Web services.
- Channels that carry requests to and responses from the services.
- Filters that act upon the services.
- **5.1 +** JAX-RPC handlers that act upon the services.
- References to UDDI registries in which services can be registered.
- Security bindings.

### How does the Web services gateway work?

The gateway builds upon the Web Services Description Language (WSDL) and the Web Services Invocation Framework (WSIF) for deployment and invocation.

You deploy a Web service to the gateway by deploying a WSDL file that describes how the gateway accesses the service. You deploy the WSDL file to a UDDI registry or to a Web address. You can send requests through the gateway to a Java class, an enterprise bean, a SOAP server or a SOAP over JMS server (including another gateway).

A request to the Web services gateway arrives through a channel, is translated into an internal form, then passes through any filters that are registered for the requested service, and finally sent on to the service implementation. Responses follow the same path in reverse.

### What problems are solved by the Web services gateway?

The gateway solves the following problems:

- **Securely “externalizing” Web services:** Business applications that are exposed as Web services can be used by any Web service-enabled tool, regardless of the implementation details. To better integrate your business processes, you might want to expose these assets to business partners, customers and suppliers who are outside the firewall. The gateway lets clients from outside the firewall use Web services that are hosted within your enterprise. Using the gateway, you can control access to each of these services.
- **Better return on investment:** Any number of partners can reuse a process that you develop as a Web service.
- **Use of existing infrastructure:** With the gateway, you can use your existing messaging infrastructure to make Web service requests, and use your existing Web services for external process integration.

- **Protocol transformation:** You might use one particular messaging protocol to invoke Web services, while your partners use some other protocol. Using the Web services gateway, you can trap the request from the client and transform it to another messaging protocol.

### Who should use the Web services gateway?

Any enterprise that chooses to share its resources selectively with its business partners and customers. IT managers and developers, who deploy resources, can also benefit from this technology.

### What is the difference between the Apache SOAP channel and the SOAP over HTTP channel?

The Apache SOAP channel and the SOAP over HTTP channel both support SOAP applications that are SOAP 1.1 compatible (for example Apache SOAP 2.3 and Axis SOAP 1.0). Therefore if you have an application that uses a production-supported Axis 1.0 SOAP stack that is generating SOAP 1.1, then this application can use either channel. However the Apache SOAP channel is deprecated and wholly superseded by the SOAP over HTTP channel.

If you use the Apache SOAP channel, then the SOAP message format must be RPC style. The SOAP over HTTP channel has all the functionality of the Apache SOAP channel, and also supports:

- Document style SOAP message format.
- SOAP messages with attachments.
- **5.1+** Java API for XML-based Remote Procedure Call (JAX-RPC) handlers.
- **5.1+** Selective SOAP parsing.

---

## Web services gateway - What is new in this release

The Web services gateway was first released on AlphaWorks on 21 December 2001. Here is a list of the main differences between the AlphaWorks edition and this version:

- The gateway is now built using enterprise beans. This new construction supports the Web services gateway only in an application server that has an EJB container. The gateway no longer runs in the Tomcat server.
- The gateway includes UDDI integration, therefore you can deploy and remove Web services to a UDDI registry as well as to a Web address.
- In addition to the Apache SOAP channel, the following channels now exist:
  - A SOAP over HTTP channel.
 

This channel supersedes the Apache SOAP channel. It has all the functionality of the Apache SOAP channel, and also supports:

    - RPC style and Document style SOAP message formats.
    - SOAP messages with attachments.
    - **5.1+** Java API for XML-based Remote Procedure Call (JAX-RPC) handlers.
    - **5.1+** Selective SOAP parsing.
  - **5.1+** A synchronous SOAP over Java Messaging Service (JMS) channel.
- The gateway supports bidirectional interactions (that is, both inbound and outbound requests) directly, by deploying two instances of each type of channel. To achieve this configuration with the AlphaWorks version, you deployed two instances of the Web services gateway; one for inbound communication and one for outbound communication.

### Note:

- Interceptors have been renamed as filters.
- Channels, filters and UDDI references are deployed to the Web services gateway, then associated with individual Web services. When you configure a Web service, you choose the following entities:
  - The channels on which the Web service is available.
  - Any filters that apply.

- **5.1+** Any JAX-RPC handlers that apply.
- Any UDDI references to which the Web service is deployed.
- Any security bindings that apply.
- You can change the channels, filters, handlers and UDDI references that are associated with a deployed service without removing the service.
- You can deploy multiple targets for a single service (that is, more than one implementation of a service that has the same service interface).
- You can back up and restore a gateway configuration.
- You can scale the Web services gateway.
- You can configure the gateway for secure transmission of SOAP messages using tokens, keys, signatures and encryption in accordance with the emerging Web Services Security (WS-Security) specification.
- You can set security (basic authorization) on the individual methods of a Web service, and on the whole gateway.
- The gateway can invoke Web services over HTTPS.
- You can configure the gateway to work with authenticating proxies.

---

## Web services gateway - Completing the installation

This task assumes that when you installed WebSphere Application Server you selected the Web services gateway either by accepting the “typical install” option, or by choosing the “custom install” option **Web services > Web services gateway**.

When you install WebSphere Application Server, or apply an upgrade or fix pack, the installation program does not install the gateway enterprise applications. When you run the installation program, and select the Web services gateway component, the files that are required for running the gateway are copied into directories under *WebSphere\_DeployMgr\_root*, where *WebSphere\_DeployMgr\_root* is the deployment manager root directory (by default WebSphere/DeploymentManager ). For example, if you install WebSphere Application Server and accept the default directory names, then the location of the `installableApps` directory is `WebSphere/DeploymentManager/installableApps` .

When you install the gateway into your application server (by completing the steps described in this topic), any previously configured gateway is replaced with an upgraded but empty gateway. If you want to preserve an existing gateway configuration, you need to save the configuration before you install the upgraded gateway, then restore the configuration after the upgrade is installed. To save your gateway configuration before you complete the installation of an upgraded gateway, see [Preserving an existing gateway configuration](#).

The following table lists the gateway files, and the locations into which they are placed. The **Location** column shows the subdirectory under *WebSphere\_DeployMgr\_root*.

File name	Purpose	Location
wsgw.ear	The Web services gateway application	/installableApps
wsgwsoap1.ear	The Apache SOAP channel 1 application	/installableApps
wsgwsoap2.ear	The Apache SOAP channel 2 application	/installableApps
wsgwsoaphttp1.ear	The SOAP over HTTP channel 1 application	/installableApps
wsgwsoaphttp2.ear	The SOAP over HTTP channel 2 application	/installableApps

File name	Purpose	Location
wsgwsoapjms1.ear	The synchronous SOAP over Java Messaging Service (JMS) channel 1 application	/installableApps
wsgwsoapjms2.ear	The synchronous SOAP over JMS channel 2 application	/installableApps
wsgwauth.ear	The Web service operation-level security application	/installableApps
WSGWResourceBundles.jar	System messages for the Web services gateway	/lib
Installation scripts	Installation of the Web services gateway	/WSGW/scripts/install
Authorization scripts	Generation of authorization beans for Web service operation-level security	/WSGW/scripts/auth

To complete the gateway installation, you have two choices:

- Install into an application server that is part of a deployment manager cell.
- Install into a stand-alone application server (that is, an application server that is not part of a deployment manager cell).

The gateway functions identically in either environment, but if you install the gateway into an application server that is part of a deployment manager cell, then you can use the deployment manager tooling for that cell to complete the gateway installation on any server within the cell, irrespective of where the server is physically hosted. Note however that the gateway is not fully integrated into the WebSphere Application Server Network Deployment tooling:

- You cannot use the full power of the deployment manager tooling to automatically install or update a set of gateways across all application servers in a cell. You must follow the more manual steps for each server that are described in this topic.
- You cannot install the gateway into an application server that is part of a WebSphere Application Server Network Deployment cluster. See "Setting up a multinode environment" in the Information Center.

To achieve high availability and load balancing, follow the steps described in *Scaling the Web services gateway*. The gateways that you include in your load-balancing group can be hosted on stand-alone application servers, or application servers that are members of a deployment manager cell, or a mixture of the two.

To finish the Web services gateway installation, complete the following steps:

1. Confirm that your system configuration complies with the Web services gateway prerequisites and constraints.
2. Optional: Preserve an existing gateway configuration.
3. Optional: Enable security.
4. Either Install the gateway into a deployment manager cell, or Install the gateway into a stand-alone application server.
5. Test the installation.

## Web services gateway - prerequisites and constraints

WebSphere Application Server Network Deployment is not a stand-alone product for running enterprise applications. If you want to deploy the gateway you also need to install the base WebSphere Application Server product. Although it is not installed by default, a copy of the base WebSphere Application Server product is packaged with WebSphere Application Server Network Deployment.

The gateway is not fully integrated into the WebSphere Application Server Network Deployment tooling:

- When you install WebSphere Application Server, or an upgrade or fix pack, the installation program does *not* install the gateway. The installation program copies the gateway files into directories within your application server directory structure, then you install the gateway into your application server as a separate task.
- You cannot use the full power of the deployment manager tooling to automatically install or update a set of gateways across all application servers in a cell.
- You cannot install the gateway into an application server that is part of a WebSphere Application Server Network Deployment cluster. See "Setting up a multinode environment" in the Information Center

For more information about these restrictions, see [Completing the installation](#).

If you want to enable gateway-level security, you must do so before you install the gateway.

This version of the Web services gateway is also subject to the following constraints:

- WSDL definitions for target services must use XML Schema Version 2001. For more information, see [Troubleshooting the Web services gateway](#).
- Install the gateway application (wsgw.ear) before you install channel and filter applications. If you need to reinstall the gateway application, uninstall all channels and filters first, then reinstall them after the gateway application.
- If the WSDL for your service contains <soap:header> elements within the <wsdl:definition> element, then the gateway passes the SOAP headers through. This behavior is correct. However, you also see the following effects:
  - The SOAP headers are not included in the WSDL that the gateway generates.
  - If you set the "must understand" flag on the SOAP message, then you get an error message.
- The Apache SOAP channel is deprecated and wholly superseded by the SOAP over HTTP channel.
- If you are using the Apache SOAP channel, then the SOAP message format must be RPC style. To handle Document style SOAP messages, use the SOAP over HTTP channel, which supports both RPC style and Document style SOAP messages.

You might also find it useful to enable trace for all gateway components:

1. Set the WebSphere Application Server trace string to `com.ibm.wsgw.*=all=enabled`
2. Write trace, stdout and stderr for the application server to a well-known location.

For more information, see ["Enabling trace"](#) in the Information Center.

## Preserving an existing gateway configuration

When you install WebSphere Application Server, or an upgrade or fix pack, the installation program does *not* install the gateway. The installation program copies the gateway files into directories within your application server directory structure, then you install the gateway into your application server as a separate task.

When you install the gateway, any previously configured gateway is replaced with an upgraded but empty gateway. If you want to preserve an existing gateway configuration, you need to save the configuration before you install the upgraded gateway into your application server, then restore the configuration after the upgrade is installed.

To preserve your existing gateway configuration, complete the following steps:

1. Back up the existing configuration.
2. Complete the installation of the upgraded gateway.
3. Restore the previously-saved configuration.

## Installing the gateway into an application server that is part of a deployment manager cell

Use this task to install the gateway into an application server that is part of a node of an existing deployment manager cell.

This topic assumes that you have completed the pre-installation steps described in [Completing the installation](#) and that the gateway application files are therefore available in directories under *WebSphere\_DeployMgr\_root*, where *WebSphere\_DeployMgr\_root* is the deployment manager root directory (by default *WebSphere/DeploymentManager*). This topic also assumes that you have already created or selected an application server that is part of a node in a deployment manager cell, and that this application server is not also part of a cluster.

When you install the gateway into your application server (by completing the steps described in this topic), any previously configured gateway is replaced with an upgraded but empty gateway. If you want to preserve an existing gateway configuration, you need to save the configuration before you install the upgraded gateway, then restore the configuration after the upgrade is installed. To save your gateway configuration before you complete the installation of an upgraded gateway, see [Preserving an existing gateway configuration](#).

**5.1** When you run the `jacl` script to install the gateway upgrade (as described in this topic), the previous versions of the gateway applications are not automatically uninstalled. The `jacl` script attempts to uninstall the previous gateway applications before it installs the new ones, but the script assumes that the previous applications have the same installed application names as the new ones. However, the default names used for the installed gateway applications were changed between WebSphere Application Server Version 5.0.2 and Version 5.1. Therefore you must manually uninstall the previous versions of the gateway applications after you have saved the configuration (optional), and before you use the `jacl` script to install the upgrade.

To install the gateway into an application server that is part of a node in a deployment manager cell, complete the following steps:

1. Start the application server.
2. Clear your class path. You can use the following command:
  - (Windows systems): `set CLASSPATH=`
  - (UNIX and Linux systems): `unset CLASSPATH`
3. Navigate to the *WebSphere\_DeployMgr\_root*/WSGW/scripts/install directory.
4. Enter the command: *WebSphere\_DeployMgr\_root*/bin/wsadmin.ext -f setupWSGW.jacl *parm1* ... *parmN* where:
  - *parm1* is the *WebSphere\_DeployMgr\_root* directory
  - *parm2* is the server name
  - *parm3* is the node name (this is case sensitive)

For example (Windows systems, shown on multiple lines for publication):

```
C:\Progra~1\WebSphere\DeploymentManager\bin\wsadmin.bat -f setupWSGW.jacl
C:/Progra~1/WebSphere/DeploymentManager server1 PHJ2
```

**Note:** The use of forward slashes (/) is compulsory for this command, even on Windows systems.

**Tip:** If you create a symbolic link to the `wsadmin.sh` file, then you need not type the directory path to the `wsadmin.sh` file in the previous command. To create this symbolic link, issue the following command from within the *WebSphere\_DeployMgr\_root*/WSGW/scripts/install directory:

```
ln -s WebSphere/V5R1M0/DeploymentManager/bin/wsadmin.sh wsadmin.sh
```

After you run the `setupWSGW.jacl` command, system messages are displayed confirming that the following initial set of gateway applications have installed successfully:

- The gateway (wsgw.ear).
- Apache SOAP channel 1 (wsgwsoap1.ear).
- SOAP over HTTP channel 1 (wsgwsoaphttp1.ear).

**Note:** **5.1+** In some circumstances, the “installed successfully” system messages are immediately followed by error messages saying that these same applications are *not* installed. These error messages should not appear, and you should ignore them, because the installation of the applications has succeeded.

5. Install additional gateway applications. For example:
  - Apache SOAP channel 2 (wsgwsoap2.ear)
  - SOAP over HTTP channel 2 (wsgwsoaphttp2.ear)

To install additional gateway applications, complete the following steps:

**Note:**

- If you prefer, you can install these EAR files using the WebSphere Application Server administrative console, as described in the final step of Enabling operation-level authorization.
- **5.1+** Before you install the synchronous SOAP over JMS channel, see the additional information in Installing the synchronous SOAP over JMS channel.

- a. Navigate to the *WebSphere\_DeployMgr\_root/bin* directory.
- b. Start the application server.
- c. Start the WebSphere administration program (by entering the command *wsadmin.ext*).
- d. For each additional Web services gateway enterprise application that you install, enter the following commands at the *wsadmin>* prompt:

```
$AdminApp install path_to_ear_file {-appname application
 -server your_server -node your_node_name}
$AdminConfig save
```

where:

- *application* is the name of the enterprise application
- *path\_to\_ear\_file* is the name and location of the enterprise application EAR file
- *your\_node\_name* is the node name (this value is case sensitive)

For example (Windows systems):

```
$AdminApp install
 C:/Progra~1/WebSphere/DeploymentManager/installableApps/wsgwsoap2.ear
 {-appname wsgwsoap2 -server server1 -node PHJ2}
$AdminConfig save
```

- e. After you install all your additional Web services gateway enterprise applications, close the WebSphere administration program by entering *quit* or *exit* at the *wsadmin>* prompt.

6. Stop then restart the application server.

If you want more than one gateway installation (for example, to scale the Web services gateway), repeat the steps in this topic for another application server that is part of a node in a deployment manager cell.

You are now ready to test the installation. Run the test on every application server on which you installed the gateway.

## Installing the gateway into a stand-alone application server

Use this task to install the gateway into an individual application server instance in your network space.

A stand-alone application server is an application server that is not part of a deployment manager cell. Before you install the gateway into a stand-alone application server, you should consider whether you might subsequently want to add the machine on which the application server is hosted as a node of a cell.

If you do subsequently add the machine to a cell, then the installed gateway application will be deleted by the node synchronization process. You cannot install the gateway into a stand-alone application server that is part of a cluster. See "Setting up a multinode environment" in the Information Center.

When you install the gateway into your application server (by completing the steps described in this topic), any previously configured gateway is replaced with an upgraded but empty gateway. If you want to preserve an existing gateway configuration, you need to save the configuration before you install the upgraded gateway, then restore the configuration after the upgrade is installed. To save your gateway configuration before you complete the installation of an upgraded gateway, see Preserving an existing gateway configuration.

**5.1** When you run the `jacl` script to install the gateway upgrade (as described in this topic), the previous versions of the gateway applications are not automatically uninstalled. The `jacl` script attempts to uninstall the previous gateway applications before it installs the new ones, but the script assumes that the previous applications have the same installed application names as the new ones. However, the default names used for the installed gateway applications were changed between WebSphere Application Server Version 5.0.2 and Version 5.1. Therefore you must manually uninstall the previous versions of the gateway applications after you have saved the configuration (optional), and before you use the `jacl` script to install the upgrade.

This topic assumes that you have completed the pre-installation steps described in Completing the installation and that the gateway application files are therefore available in directories under `WebSphere_DeployMgr_root`, where `WebSphere_DeployMgr_root` is the deployment manager root directory (by default `WebSphere/DeploymentManager`). Before you can install and run the gateway in a stand-alone application server, you must copy these files over to the application server by completing the following steps:

- Stop the application server into which you plan to install the Web services gateway.
- Copy all the EAR files with file names that begin `wsgw` from the `WebSphere_DeployMgr_root/installableApps` directory of the machine on which you installed WebSphere Application Server Network Deployment into the `stand-alone_install_root/installableApps` directory of the target application server install tree, where `stand-alone_install_root` is the root directory for the installation of your target application server (by default `WebSphere/AppServer`).
- Copy the `WebSphere_DeployMgr_root/lib/WSGWResourceBundles.jar` file into the `stand-alone_install_root/lib` directory.
- Copy the `WebSphere_DeployMgr_root/WSGW` directory and all files and directories within it into the `stand-alone_install_root/WSGW` directory.

To install the gateway into your stand-alone application server, complete the following steps:

1. Start the application server.
2. Clear your class path. You can use the following command:
  - (Windows systems): `set CLASSPATH=`
  - (UNIX and Linux systems): `unset CLASSPATH`
3. Navigate to the `stand-alone_install_root/WSGW/scripts/install` directory.
4. Enter the command: `stand-alone_install_root/bin/wsadmin.ext -f setupWSGW.jacl parm1 ... parmN` where
  - `parm1` is the `stand-alone_install_root` directory
  - `parm2` is the server name
  - `parm3` is the node name (this is case sensitive)

For example (Windows systems, shown on multiple lines for publication):

```
C:\Progra~1\WebSphere\AppServer\bin\wsadmin.bat -f setupWSGW.jacl
C:/Progra~1/WebSphere/AppServer server1 PHJ2
```

**Note:** The use of forward slashes (/) is compulsory for this command, even on Windows systems. When you run the `setupWSGW.jac1` command, the following initial set of gateway applications is installed:

- The gateway (`wsgw.ear`).
  - Apache SOAP channel 1 (`wsgwsoap1.ear`).
  - SOAP over HTTP channel 1 (`wsgwsoaphttp1.ear`).
5. Install additional gateway applications. For example:
- Apache SOAP channel 2 (`wsgwsoap2.ear`)
  - SOAP over HTTP channel 2 (`wsgwsoaphttp2.ear`)

To install additional gateway applications, complete the following steps:

**Note:**

- If you prefer, you can install these EAR files using the WebSphere Application Server administrative console, as described in the final step of Enabling operation-level authorization.
  - **5.1+** Before you install the synchronous SOAP over JMS channel, see the additional information in Installing the synchronous SOAP over JMS channel.
- a. Navigate to the `stand-alone_install_root/bin` directory.
  - b. Start the application server.
  - c. Start the WebSphere administration program (by entering the command `wsadmin.ext`).
  - d. For each additional Web services gateway enterprise application that you install, enter the following commands at the `wsadmin>` prompt:

```
$AdminApp install path_to_ear_file {-appname application
 -server your_server -node your_node_name}
$AdminConfig save
```

where

- *application* is the name of the enterprise application
- *path\_to\_ear\_file* is the name and location of the enterprise application EAR file
- *your\_node\_name* is the node name (this value is case sensitive)

For example (Windows systems):

```
$AdminApp install
 C:/Progra~1/WebSphere/AppServer/installableApps/wsgwsoap2.ear
 {-appname wsgwsoap2 -server server1 -node PHJ2}
$AdminConfig save
```

- e. After you install all your additional Web services gateway enterprise applications, close the WebSphere administration program by entering `quit` or `exit` at the `wsadmin>` prompt.
6. Stop then restart the application server.

If you want more than one gateway installation (for example, to scale the Web services gateway), repeat the steps provided in this topic for another stand-alone application server.

You are now ready to test the installation. Run the test on every application server on which you installed the gateway.

## Testing the Web services gateway installation

Use this task to test that the Web services gateway is installed correctly.

This topic assumes that you have completed the steps described in Completing the installation.

To test the basic installation of the Web services gateway, complete the following steps:

1. In a Web browser, go to `http://host:port/wsgw` where *host* and *port* are the host name and port number on which your HTTP server is listening. The browser displays the following message:

## IBM Web services gateway

What do you want to do?

- [Run the admin client](#)
  - [View the product ID](#)
2. Test the Apache SOAP channels by using your Web browser to display the Web page at `http://host:port/wsgwengine/soaprpcrouter`, where *engine* is either *soap1* or *soap2*. The browser displays the following message: Sorry, I don't speak via HTTP GET - you have to use HTTP POST to talk to me.
  3. Test the SOAP over HTTP channels by using your Web browser to display the Web page at `http://host:port/wsgwengine/soaphttpengine`, where *engine* is either *soaphttp1* or *soaphttp2*. The browser displays the message: And now... Some Services, followed by a list of the Web services that are currently deployed to the channel.

If you do not see these messages, your server is not configured correctly - in which case, see [Troubleshooting the Web services gateway](#).

---

## Backing up and restoring a gateway configuration

There are two situations in which you might want to back up a gateway configuration:

- To preserve an existing gateway configuration.
- To scale the Web services gateway.

The **Back up** options save the deployment details for all the Web services and associated resources (channels, filters, UDDI references and so on) that are currently deployed to the gateway. There are two backup options: **Save Gateway Configuration > Private** and **Save Gateway Configuration > Shared**. For an explanation of these terms, and detailed steps for this task, see [Backing up a gateway configuration](#).

The **Restore** option uses a previously-saved gateway configuration to populate an empty installation of the gateway with the same deployment details. For detailed steps for this task, see [Restoring a gateway configuration](#).

## Backing up and restoring UDDI publication links

When you save a gateway configuration, the deployment details through which a deployed Web service has been published to UDDI by the gateway are not saved. Here are the reasons for not backing up these details:

- When a gateway is upgraded, or otherwise removed without first using the gateway administrative console to un-publish each Web service from UDDI, then the associated entries in UDDI registries are not removed.
- When a gateway is restored, if the UDDI publication details are also restored, then the Web services are re-published to UDDI by the gateway.
- When a gateway publishes the same service twice to a UDDI registry, the registry does not overwrite the initial publication. The registry creates a second copy of the TModel and Service Definition.
- When a gateway removes a service from a UDDI registry, it only removes the last one published. This means that it can leave behind outdated TModels and Service Definitions.

To preserve the integrity of the UDDI registries, restoring the gateway does not automatically re-publish any Web services to UDDI. But if you know that a service has been un-published from UDDI (for example because you removed it manually before backing up the gateway configuration) then you can safely re-publish it to UDDI after the configuration is restored.

## Backing up a gateway configuration

The **Back up** options write out, to a single file, the deployment details for all the Web services and associated resources (channels, filters, UDDI references and so on) that are currently deployed to the gateway.

There are two situations in which you might want to back up a gateway configuration:

- To preserve an existing gateway configuration.
- To scale the Web services gateway.

When you install a gateway upgrade, any previously configured gateway is replaced with an upgraded but empty gateway. Use the **Save Gateway Configuration > Private** option to preserve an existing gateway configuration before you complete the installation of an upgraded gateway. This saved configuration contains deployment details (for example URIs) that are specific to a given instance of the gateway, so you should only use it to save a configuration that you intend to re-apply to the same gateway instance.

When you want to scale the gateway, use the **Save Gateway Configuration > Shared** option to save a shareable version of your gateway configuration. This saved configuration does not include machine-specific values, and therefore can be shared by all the gateways in your scaled gateway deployment group.

To back up your gateway configuration, complete the following steps:

1. Display the Web services gateway administrative user interface.
2. Optional: If you are backing up to preserve your gateway configuration before you install a gateway upgrade, and any of your deployed Web services are also published by the gateway to UDDI registries, use the Listing and managing gateway-deployed Web services option to un-publish them from UDDI. Make a note of the UDDI deployment details so that you can re-publish them to UDDI after you restore the gateway configuration (the reasons why this manual step is necessary are explained in Backing up and restoring UDDI publication links).
3. In the gateway administrative user interface navigation pane, click the following link:  
**Gateway**
  - [Back Up](#)The Save Gateway Configuration window opens.
4. In the **Location** field, type the path to your configuration file. The path to your configuration file must point to a local drive on the machine on which the gateway is currently running. The file name for the configuration file can be any valid Java file name.
5. If you are backing up to preserve the configuration of a gateway before you install a gateway upgrade, select **Private**. If you are backing up to create a scaled gateway deployment, select **Shared**.
6. Click **OK**.

Your gateway configuration is saved to the location you specified.

## Restoring a gateway configuration

This topic assumes that you have already completed the following tasks:

1. Back up your gateway configuration.
2. Complete the installation of an upgraded gateway.

The **Restore** option uses the information contained in a previously-saved file to populate an empty installation of the gateway with the same deployment details for those Web services and associated resources.

The **Restore** option automatically detects whether the configuration file that it is restoring contains a **Private** or a **Shared** gateway configuration (for an explanation of these terms, see Backing up a gateway configuration).

To restore a gateway configuration, complete the following steps:

1. Check that the target gateway is empty. Remove any Web services and associated resources that are deployed to the gateway. If you have just completed the installation of an upgraded gateway, then the installed gateway is empty.
2. In the gateway administrative user interface navigation pane, click the following link:

**Gateway**

- [Restore](#)

The Restore Gateway Configuration window opens.

3. In the **Location** field, type the path to your configuration file.

The path to your configuration file must point to a local drive on the machine on which the gateway is currently running. The saved file is not specific to a given version of the gateway.

If you are restoring a file that was backed up using the **Save Gateway Configuration > Private** option, then the backup contains deployment details (for example URIs) that are specific to a given gateway instance. If you restore this type of backup file to a different instance (for example a gateway on a host with a different network identity), then the restore succeeds but you have to use the gateway administrative user interface to correct any errors in the deployment details.

4. Click **OK**.

Your gateway configuration is restored to the gateway that you are currently administering.

If you have just restored a configuration after installing an upgraded gateway, and any of the deployed Web services were previously published to UDDI registries, use the Listing and managing gateway-deployed Web services option (and the notes you made when you backed up the configuration) to re-publish these Web services to UDDI. The reasons why this manual step is necessary are explained in Backing up and restoring UDDI publication links.

---

## Administering the Web services gateway

If you have just completed the installation of an upgraded gateway, your gateway configuration is currently empty. If you want to restore a saved configuration, you must do so before you add any new channels, filters, handlers, UDDI references or Web services.

You should not make changes to a gateway that is part of an unlocked configuration load-balancing group unless you are making changes, under controlled conditions, to all members of the group.

To administer the Web services gateway, complete the following steps:

1. Start the WebSphere Application Server Administrative Server.
2. Open the following Web page: `http://host:port/wsgw/admin/index.html` where *host* and *port* are the host name and port number on which your HTTP server is listening. For example, `localhost:8080` or `localhost:9080`. The main administration page is displayed:

# IBM Web Services Gateway

## Gateway

- **Configure**
- **Security**
- **Back Up**
- **Restore**
- **About**

## Services

- **List**
- **Deploy**
- **Remove**

## Channels

- **List**
- **Deploy**
- **Remove**

## Filters

- **List**
- **Deploy**
- **Remove**

## Handlers

- **List**
- **Deploy**
- **Remove**

## UDDI References

- **List**
- **Deploy**
- **Remove**

## Welcome to the IBM Web Services Gateway systems administration console

To begin, please make a selection from the options to the left

To modify features after initial deployment, first select "list" under the feature and then select the item you want to modify

The gateway administration options are listed in the left-hand panel. The order in which these options are listed is significant, for the following reasons:

- If you change the namespace URI or WSDL URI (using the **Gateway > Configure** option), you break the link back to the gateway for every Web service that you have already deployed. You must therefore set these URIs before you deploy any Web services.
- When you deploy a Web service to the gateway, you choose the following entities:
  - The channels on which it is available.
  - Any filters that apply to it.
  - **5.1+** Any JAX-RPC handlers that apply to it.
  - Any UDDI references to which it is deployed.

Each of these choices is made from a list of resources that are already deployed to the gateway. Therefore you might want to deploy your channels, filters, handlers and UDDI references to the gateway before you deploy the Web services that use them.

3. Use the gateway administration options to configure the gateway as described in the following topics:
  - Setting the namespace URI and WSDL URI for the Web services gateway
  - Working with channels
  - Working with filters
  - **5.1+** Working with JAX-RPC handlers
  - Working with UDDI references
  - Working with Web services

In all of the gateway administration panels, fields marked with asterisks are required. After you deploy a channel, filter, handler or UDDI reference, refresh all other open browser windows to ensure that current lists are displayed.

## Setting the namespace URI and WSDL URI for the Web services gateway

Initial values for the namespace URI and WSDL URI are automatically configured when you install the Web services gateway.

When you change these URIs, you break the link back to the Web services gateway for every Web service that you have already deployed, so you must set these URIs before you deploy any Web services to the gateway.

You should not make changes to these URIs for a gateway that is part of an unlocked configuration load-balancing group.

When you deploy a Web service to the gateway, these two URIs are used in the following ways:

- The **Namespace URI for services** is used as the namespace for the gateway services in exported WSDL documents.
- The **WSDL URI for exported definitions** is used to generate the Web address in import statements within exported WSDL documents.

To set the namespace URI and WSDL URI for the Web services gateway, complete the following steps:

1. Display the Web services gateway administrative user interface.
2. In the navigation pane, click the following link:

### **Gateway**

- [Configure](#)

The gateway configuration form is displayed:

# IBM Web Services Gateway

## Gateway

- **Configure**
- Security
- Back Up
- Restore
- About

## Services

- List
- Deploy
- Remove

## Channels

- List
- Deploy
- Remove

## Filters

- List
- Deploy
- Remove

## Handlers

- List
- Deploy
- Remove

## UDDI References

- List
- Deploy
- Remove

## Configure Gateway

Namespace URI for services

WSDL URI for exported definitions

## Proxy Configuration

Enable proxy authentication

Proxy user

Proxy password

Use Gateway proxy credentials for invoking WebServices

3. In the **Namespace URI for services** field, type the new name.

There is no fixed syntax for the namespace URI, but whatever name you choose is likely to be more effective if it observes the following guidelines:

- The name begins with urn:

See the guidance on Internet standards for the syntax of Uniform Resource Names (URNs) at <http://www.ietf.org/rfc/rfc2141.txt>.

- The name is globally unique.
- The name reflects your company name.

4. In the **WSDL URI for exported definitions** field, type the new name.

The initial value is the gateway best guess at the right value, but you probably want to overwrite it with a new value. For example it might guess a local URI such as `http://h1dswrth:9080/wsgw`, and because you are giving the WSDL to people in other companies, you modify this value to `http://h1dswrth.your_company.com/wsgw`. Note that only the *host* and *port* parts of the initial value are modified. This URI must always start with `http://` and end with `/wsgw`.

5. Click **Apply Changes**.

You are now ready to deploy your channels, filters, handlers and UDDI references to the gateway.

You might also want to enable proxy authentication for the gateway.

## Working with channels

Before you can work with a channel, you must install the channel application in WebSphere Application Server as described in *Installing the gateway-supplied channels*.

You should not make changes to the channel deployment settings for a gateway that is part of an unlocked configuration load-balancing group unless you are making changes, under controlled conditions, to all members of the group.

Two versions of each type of channel are supplied so that, for each channel type, you can set up separate channels for inbound and outbound requests. For more information, see *Channels - entry points to the Web services gateway*.

From the navigation pane of the Web services gateway administrative user interface, you can choose the following actions for **Channels**:

- **List** to list the deployed channels, and modify their deployment details.
- **Deploy** to deploy a channel.
- **Remove** to remove channels.

### Channels - Entry points to the Web services gateway

Channels form entry points to the Web services gateway and carry requests and responses between Web services and the Web services gateway.

A request to the Web services gateway arrives through a channel, is translated into a WSIF message, then passed through any filters that are registered for the requested service, and finally sent on to the service implementation. Responses follow the same path in reverse.

Before you can use a channel, you must install the channel application in WebSphere Application Server then deploy the channel to the Web services gateway. A deployed channel is not used until you deploy a Web service that uses the channel.

Two versions of each type of channel are supplied with the gateway. This is so that, for each channel type, you can set up separate channels for inbound and outbound requests. This provides a simple mechanism for giving different access rights to users from outside your organization from the rights you give to users within your organization:

- To ensure that users outside your organization can only access those internal services that you choose to publish externally, you deploy those services on the inbound channel.
- To give users inside your organization access to the full range of internal and external services, you deploy those services on the outbound channel.

### Installing the gateway-supplied channels

There are different installation criteria and procedures for installing each of the gateway-supplied channels. The steps to take in each case are referenced in this topic.

- Install the Apache SOAP channel 1 application (wsgwsoap1.ear) when you install the gateway application, as described in Installing the gateway into an application server that is part of a deployment manager cell and Installing the gateway into a stand-alone application server.
- Install the Apache SOAP channel 2 application (wsgwsoap2.ear) as described in the step “Install additional gateway applications” in Installing the gateway into a deployment manager cell and Installing the gateway into a stand-alone application server.
- Install the SOAP over HTTP channel 1 application (wsgwsoaphttp1.ear) when you install the gateway application, as described in Installing the gateway into an application server that is part of a deployment manager cell and Installing the gateway into a stand-alone application server.
- Install the SOAP over HTTP channel 2 application (wsgwsoaphttp2.ear) as described in the step “Install additional gateway applications” in Installing the gateway into an application server that is part of a deployment manager cell and Installing the gateway into a stand-alone application server.
- **5.1+** Install the synchronous SOAP over Java Messaging Service (JMS) channel applications (wsgwsoapjms1.ear and wsgwsoapjms2.ear) as described in Installing the synchronous SOAP over JMS channel.

### ***Installing the synchronous SOAP over JMS channel:***

The synchronous SOAP over Java Messaging Service (JMS) channels use a JMS provider (either the JMS provider that is embedded in WebSphere Application Server, or another provider such as WebSphere MQ) to pass SOAP messages over JMS. To install and configure the JMS provider, then install the synchronous SOAP over JMS channels, complete the following steps:

1. Install a JMS provider. You might have already installed a JMS provider when you installed WebSphere Application Server. If not, install one now as described in Installing and configuring a JMS provider.
2. Use the administrative console to create and configure queue connection factories and queue destinations as described in Configuring JMS provider resources. Create two connection factories (one for each channel) and two destinations. The JMS resources and JNDI names that the synchronous SOAP over JMS channels expect by default are provided in the following table. If you use different resources and names in this step, then change the defaults when you subsequently install the channel EAR files.

<b>JMS resource</b>	<b>default JNDI name (channel 1)</b>	<b>default JNDI name (channel 2)</b>
connection factory	jms/SOAPJMSFactory1	jms/SOAPJMSFactory2
destination	jms/SOAPJMSQueue1	jms/SOAPJMSQueue2

3. Optional: If you are using embedded messaging, use the administrative console to add the two new destinations to the list of JMS Server destination names for your application server as described in Managing WebSphere internal JMS servers. Ensure that the Initial State is started.
4. Use the administrative console to create and configure listener ports in the message listener service for your application server as described in Adding a new listener port. Create two listener ports (one for each channel). The default JMS resources and associated names that the synchronous SOAP over JMS channels expect are provided in the following table. If you use different resources and names in this step, then change the defaults when you subsequently install the channel EAR files.

<b>JMS resource</b>	<b>default name (for use with SOAP over JMS channel 1)</b>	<b>default name (for use with SOAP over JMS channel 2)</b>
listener port	SOAPJMSPort1	SOAPJMSPort2
connection factory	jms/SOAPJMSFactory1	jms/SOAPJMSFactory2
destination	jms/SOAPJMSQueue1	jms/SOAPJMSQueue2

5. Use the administrative console to create a new URL provider for your application server as described in "URL provider settings" in the online help and the Information Center. Enter the property values provided in the following table:

URL provider property	value
Name	JMSHandler
Stream Handler Class Name	com.ibm.ws.protocol.Handler
Protocol	jms

6. Install the synchronous SOAP over JMS channel applications (wsgwsoapjms1.ear and wsgwsoapjms2.ear) as described in the next to last step of Installing the gateway into an application server that is part of a deployment manager cell and Installing the gateway into a stand-alone application server.
7. Optional: If you want to change the default values for listener port and connection factory for the synchronous SOAP over JMS channel applications, modify the installed applications by completing the following steps for each channel application:
  - a. In the administrative console navigation pane, click **Applications > Enterprise Applications**. A list of all installed enterprise applications is displayed.
  - b. Click the name of the channel application (for example SOAPJMSChannel1). Configuration details for the application are displayed.
  - c. Scroll down through the configuration details to the Additional Properties pane, then click Provide Listener Ports for Messaging Beans. The Binding Enterprise Beans to Listener Port Name pane is displayed.
  - d. Change the listener port value from (for example) SOAPJMSPort1 to the value that you configured in the message listener service in a previous step, then click **OK** to return to the Additional Properties pane.
  - e. In the Additional Properties pane, click Map resource env entry references to resources. The Mapping Resource Environment References to Resources pane is displayed.
  - f. Change the connection factory value from (for example) jms/SOAPJMSFactory1 to the value that you configured in the message listener service in a previous step, then click **OK** to return to the Additional Properties pane.
  - g. Scroll up through the configuration details to the Messages pane, then click **Save**. The Save to Master Configuration pane is displayed.
  - h. In the Save to Master Configuration pane, click **Save**. The changes have been committed and installed.
  - i. Stop then restart the application server.

You are now ready to Deploy the synchronous SOAP over JMS channels to the gateway.

**Web services gateway - Channel deployment details:** Here are the deployment details for the channels supplied with the Web services gateway:

- **Apache SOAP channel 1**

**Note:** The Apache SOAP channel is deprecated and wholly superseded by the SOAP over HTTP channel.

- **Channel Name:** ApacheSOAPChannel1
- **Home Location:** ApacheSOAPChannel1Bean
- **End Point Address:**
  - **Application server not within an unlocked configuration deployment:**  
http://domain\_name/wsgwsoap1
  - **Application server within an unlocked configuration deployment:**  
http://domain\_name/wsgwsoap1, http://host\_name:port\_number/wsgwsoap1

where *host\_name* and *port\_number* are the host name and port number for this application server.

- **Async Reply Context Name:** Leave blank. This function is not supported by this channel.
- **Async Reply Context Value:** Leave blank. This function is not supported by this channel.

- **Apache SOAP channel 2**

**Note:** The Apache SOAP channel is deprecated and wholly superseded by the SOAP over HTTP channel.

- **Channel Name:** ApacheSOAPChannel2
- **Home Location:** ApacheSOAPChannel2Bean
- **End Point Address:**

- **Application server not within an unlocked configuration deployment:**

- `http://domain_name/wsgwsoap2`

- **Application server within an unlocked configuration deployment:**

- `http://domain_name/wsgwsoap2, http://host_name:port_number/wsgwsoap2`

- where *host\_name* and *port\_number* are the host name and port number for this application server.

- **Async Reply Context Name:** Leave blank. This function is not supported by this channel.
- **Async Reply Context Value:** Leave blank. This function is not supported by this channel.

- **SOAP over HTTP channel 1**

- **Channel Name:** SOAPHTTPChannel1
- **Home Location:** SOAPHTTPChannel1Bean

- **5.1 End Point Address:**

- **Application server not within an unlocked configuration deployment:**

- `http://domain_name/wsgwsoaphttp1`

- **Application server within an unlocked configuration deployment:**

- `http://domain_name/wsgwsoaphttp1, http://host_name:port_number/wsgwsoaphttp1`

- where *host\_name* and *port\_number* are the host name and port number for this application server.

- **Async Reply Context Name:** Leave blank. This function is not supported by this channel.
- **Async Reply Context Value:** Leave blank. This function is not supported by this channel.

- **SOAP over HTTP channel 2**

- **Channel Name:** SOAPHTTPChannel2
- **Home Location:** SOAPHTTPChannel2Bean

- **5.1 End Point Address:**

- **Application server not within an unlocked configuration deployment:**

- `http://domain_name/wsgwsoaphttp2`

- **Application server within an unlocked configuration deployment:**

- `http://domain_name/wsgwsoaphttp2, http://host_name:port_number/wsgwsoaphttp2`

- where *host\_name* and *port\_number* are the host name and port number for this application server.

- **Async Reply Context Name:** Leave blank. This function is not supported by this channel.
- **Async Reply Context Value:** Leave blank. This function is not supported by this channel.

- **5.1+ Synchronous SOAP over Java Messaging Service (JMS) channel 1**

- **Channel Name:** SOAPJMSChannel1
- **Home Location:** SOAPJMSChannel1Bean
- **End Point Address:**

- Specify the properties of the synchronous SOAP over JMS channel 1 endpoint, using the following syntax:

- `jms:/queue or topic indicator?property_name=property_value` and so on, separating each property using the & character.

- For example, if you use the default values for queue destination and queue connection factory when you install the synchronous SOAP over JMS channels, then the first part of the end point address is:

- `jms:/queue?destination=jms/SOAPJMSQueue1&connectionFactory=jms/SOAPJMSFactory1`

- For each of the synchronous SOAP over JMS channels, here is the full list of properties that can be specified in the end point address:

Property name	Property description
<b>Destination-related Properties (required)</b>	
connectionFactory	The JNDI name of the queue or topic connection factory.
destination	The JNDI name of the destination queue or topic.
<b>JNDI-related Properties (optional)</b>	
initialContextFactory	The name of the initial context factory to use (this is mapped to the <code>java.naming.factory.initial</code> property).
jndiProviderURL	The JNDI provider Web address (this is mapped to the <code>java.naming.provider.url</code> property).
<b>JMS-related Properties (optional)</b>	
deliveryMode	An indication as to whether or not the request message is persistent. The valid values are 1 (non persistent) and 2 (persistent). The default value is 1.
timeToLive	The lifetime (in milliseconds) of the request message. A value of 0 indicates an infinite lifetime.
priority	The JMS priority associated with the request message. Valid values are 0 - 9. The default value is 4.
userid	The User ID that is used to gain access to the connection factory.
password	The password that is used to gain access to the connection factory.

- **Async Reply Context Name:** Leave blank. This function is not supported by this channel.
- **Async Reply Context Value:** Leave blank. This function is not supported by this channel.

- **5.1+ Synchronous SOAP over JMS channel 2**

- **Channel Name:** SOAPJMSChannel2
- **Home Location:** SOAPJMSChannel2Bean
- **End Point Address:**

Specify the properties of the synchronous SOAP over JMS channel 2 endpoint, using the following syntax:

`jms:/queue or topic indicator?property_name=property_value` and so on, separating each property using the & character.

For example, if you use the default values for queue destination and queue connection factory when you install the synchronous SOAP over JMS channels, then the first part of the end point address is:

`jms:/queue?destination=jms/SOAPJMSQueue2&connectionFactory=jms/SOAPJMSFactory2`

For the full list of properties that can be specified in the end point address for synchronous SOAP over JMS channel 2, see the list of properties detailed above for Synchronous SOAP over JMS channel 1.

- **Async Reply Context Name:** Leave blank. This function is not supported by this channel.
- **Async Reply Context Value:** Leave blank. This function is not supported by this channel.

## Listing and managing gateway-deployed channels

To list the channels that are currently deployed to the Web services gateway, and to view and modify their deployment details, complete the following steps:

1. Display the Web services gateway administrative user interface.
2. In the navigation pane, click the following link:

### Channels

- [List](#)

The main pane is updated with a list of all the channels that are deployed to the Web services gateway.

3. Click the name of a channel in the list. A form is displayed that you can use to view and modify the current deployment details for this channel.

4. Modify the following deployment details:

**Home Location**

Type the name of the new home for this channel.

**End Point Address**

Type the new address on which the channel is to listen.

**5.1** For an Apache SOAP or SOAP over HTTP channel running on an application server that is not part of an unlocked configuration deployment, this address is used to access the channel through the associated HTTP server. For either of these types of channel running on an application server that is part of an unlocked configuration deployment, this address is in two parts (separated by a comma):

- The address for accessing the channel through the associated HTTP server.
- The address for accessing the channel through the particular application server on which the channel application is running.

5. If the channel supports asynchronous messaging, type the values provided in the deployment documentation for the channel into the following two fields. Otherwise leave them blank.

**Async Reply Context Name**

**Async Reply Context Value**

6. To start this channel, click **YES**. To stop this channel, click **NO**.

7. Click **Apply changes**.

If the processing completes successfully, the list of deployed channels is redisplayed. Otherwise, an error message is displayed.

## Deploying channels to the Web services gateway

Before you can deploy a channel, you must install the channel application in WebSphere Application Server as described in Installing the gateway-supplied channels.

If you want to deploy the channels supplied with the Web services gateway, see the deployment details listed in Web services gateway - channel deployment details.

To deploy a channel, complete the following steps:

1. Display the Web services gateway administrative user interface.
2. In the navigation pane, click the following link:

**Channels**

- [Deploy](#)

A form is displayed that you can use to specify the deployment details.

3. Type the following channel deployment details:

**Channel Name**

Type the name by which the channel is known within the Web services gateway and by which it is listed using the **Channels > List** option. This name must be unique within the gateway.

**Home Location**

Type the name of the home for this channel.

**End Point Address**

Type the address on which the channel is to listen.

**5.1** For an Apache SOAP or SOAP over HTTP channel running on an application server that is not part of an unlocked configuration deployment, this address is used to access the

channel through the associated HTTP server. For either of these types of channel running on an application server that is part of an unlocked configuration deployment, this address is in two parts (separated by a comma):

- The address for accessing the channel through the associated HTTP server.
  - The address for accessing the channel through the particular application server on which the channel application is running.
4. If the channel supports asynchronous messaging, type the values provided in the deployment documentation for the channel into the following two fields. Otherwise leave them blank.  
**Async Reply Context Name**  
**Async Reply Context Value**
  5. Click **OK**.

If the processing completes successfully, the list of deployed channels is updated to include the new channel. Otherwise, an error message is displayed.

To use this channel, select it for use with a Web service as described in *Deploying Web services to the Web services gateway and Listing and managing gateway-deployed Web services*.

## Removing channels from the Web services gateway

To remove a channel, complete the following steps:

1. Display the Web Services gateway administrative user interface.
2. In the navigation pane, click the following link:

**Channels**  
• [Remove](#)

The main pane is updated with a list of all the channels that are deployed to the Web services gateway. Next to each entry in the list is a check box, and information on the number of Web services that currently use the channel.

3. Click the name of a channel in the list. A form is displayed that you can use to view the current deployment details for this channel, including a list of the Web services that currently use the channel.
4. Select the check box for every channel that you want to remove.

**Note:** When you remove a channel that is currently used by one or more Web services, the gateway removes the channel from the channel list for each associated Web service.

5. Click **OK**.

If the processing completes successfully, the list of deployed channels is updated. Otherwise, an error message is displayed.

## Working with filters

**Note:** **5.1+** The use of filters is deprecated. However, you can achieve similar results using Java API for XML-based Remote Procedure Call (JAX-RPC) handlers. For more information, see *JAX-RPC handlers - An alternative to gateway filters*.

Before you can work with a filter, you must install the filter application in WebSphere Application Server as described in the next to last step of *Installing the gateway into a deployment manager cell* and *Installing the gateway into a stand-alone application server*.

You should not make changes to the filter deployment settings for a gateway that is part of an unlocked configuration load-balancing group unless you are making changes, under controlled conditions, to all members of the group.

From the navigation pane of the Web services gateway administrative user interface, you can choose the following actions for **Filters**:

- **List** to list the deployed filters, and modify their deployment details.
- **Deploy** to deploy a filter.
- **Remove** to remove filters.

You can also write your own filters for the Web services gateway.

## Filters - Service interceptors for the Web services gateway

Filters are used to intercept service invocations and responses that come into and leave the gateway.

**Note:** **5.1+** The use of filters is deprecated. However, you can achieve similar results using Java API for XML-based Remote Procedure Call (JAX-RPC) handlers. For more information, see JAX-RPC handlers - An alternative to gateway filters.

Filters can perform a wide range of tasks, from logging messages, to transforming the content, to terminating an incoming request. Filters are deployed to the Web services gateway as described in Deploying filters to the Web services gateway, then registered for use with individual Web services as described in Working with Web services.

## Listing and managing gateway-deployed filters

**Note:** **5.1+** The use of filters is deprecated. However, you can achieve similar results using Java API for XML-based Remote Procedure Call (JAX-RPC) handlers. For more information, see JAX-RPC handlers - An alternative to gateway filters.

To list the filters that are currently deployed to the Web services gateway, and to view and modify their deployment details, complete the following steps:

1. Display the Web Services gateway administrative user interface.
2. In the navigation pane, click the following link:

### Filters

- [List](#)

The main pane is updated with a list of all the filters that are deployed to the Web services gateway.

3. Click the name of a filter in the list. A form is displayed that you can use to view and modify the current deployment details for this filter.

4. Modify the following deployment detail:

### Home Location

Type the name of the new home for this filter.

5. Click **Apply changes**.

If the processing completes successfully, the list of deployed filters is redisplayed. Otherwise, an error message is displayed.

## Deploying filters to the Web services gateway

Use this task to deploy a filter to the Web services gateway.

**Note:** **5.1+** The use of filters is deprecated. However, you can achieve similar results using Java API for XML-based Remote Procedure Call (JAX-RPC) handlers. For more information, see JAX-RPC handlers - An alternative to gateway filters.

Before you can deploy a filter, you must install the filter application in WebSphere Application Server as described in the next to last step of Installing the gateway into an application server that is part of a deployment manager cell and Installing the gateway into a stand-alone application server.

**Note:** You can deploy multiple instances of a filter by entering different filter names.

To deploy a filter, complete the following steps:

1. Display the Web services gateway administrative user interface.
2. In the navigation pane, click the following link:

**Filters**

- [Deploy](#)

A form is displayed for you to specify the deployment details.

3. Type the following filter deployment details:

**Filter Name**

Type the name by which the filter is known within the Web services gateway, and by which it is listed using the **Filters > List** option. This name must be unique within the Web services gateway.

**Home Location**

Type the JNDI name for this filter.

4. Click **OK**.

If the processing completes successfully, the list of deployed filters is updated to include the new filter. Otherwise, an error message is displayed.

To use this filter, select it for use with a Web service as described in [Deploying Web services to the Web services gateway](#) and [Listing and managing gateway-deployed Web services](#).

## Removing filters from the Web services gateway

**Note:** **5.1+** The use of filters is deprecated. However, you can achieve similar results using Java API for XML-based Remote Procedure Call (JAX-RPC) handlers. For more information, see [JAX-RPC handlers - An alternative to gateway filters](#).

To remove a filter, complete the following steps:

1. Display the Web Services gateway administrative user interface.
2. In the navigation pane, click the following link:

**Filters**

- [Remove](#)

The main pane is updated with a list of all the filters that are deployed to the Web services gateway. Next to each entry in the list is a check box, and information on the number of Web services that currently use the filter.

3. Click the name of a filter in the list. A form is displayed that you can use to view the current deployment details for this filter, including a list of the Web services that currently use the filter.
4. Select the check box for every filter that you want to remove.

**Note:** When you remove a filter that is currently used by one or more Web services, the gateway removes the filter from the filter lists for each associated Web service.

5. Click **OK**.

If the processing completes successfully, the list of deployed filters is updated. Otherwise, an error message is displayed.

## Working with JAX-RPC handlers

For information about creating JAX-RPC handlers, see the IBM developerWorks article [A developer introduction to JAX-RPC, Part 2: Mine the JAX-RPC specification to improve Web service interoperability](#).

Before you can work with a Java API for XML-based Remote Procedure Call (JAX-RPC) handler, you must make the handler classes available to the application server in one of the following ways:

- Copy the individual class file into a directory structure under *install\_root/classes* that matches the package name of the class, where *install\_root* is the root directory for the installation of your application server (by default WebSphere/AppServer). For example a handler class `com.ibm.jaxrpc.handler.TestHandler` is copied into *install\_root/classes/com/ibm/jaxrpc/handler*.
- Package the class files for all your handlers as a JAR file, then copy it into *install\_root/lib/app*.

You should not make changes to the handler deployment settings for a gateway that is part of an unlocked configuration load-balancing group unless you are making changes, under controlled conditions, to all members of the group.

From the navigation pane of the Web services gateway administrative user interface, you can choose the following actions for **Handlers**:

- **List** to list the deployed handlers, and modify their deployment details.
- **Deploy** to deploy a handler.
- **Remove** to remove handlers.

### JAX-RPC handlers - An alternative to gateway filters

JAX-RPC handlers interact with messages as they pass between the service requester and the gateway, and between the gateway and the target service.

A Java API for XML-based remote procedure call (JAX-RPC) handler is a Java class that performs a similar range of tasks to a gateway filter - from logging messages, to transforming their contents, to terminating an incoming request. For more detailed information about JAX-RPC handlers, see the IBM developerWorks article [A developer introduction to JAX-RPC, Part 2: Mine the JAX-RPC specification to improve Web service interoperability](#).

All new gateway installations should use JAX-RPC handlers rather than gateway filters, for the following reasons:

- JAX-RPC is part of the proposed Java 2 Platform, Enterprise Edition (J2EE) 1.4, and JAX-RPC handlers are emerging as the standard approach in Java for intercepting and filtering service messages.
- JAX-RPC handlers are already being widely implemented - and any JAX-RPC handlers you write for use in other systems can also be deployed to the gateway.
- JAX-RPC handlers are already accepted as the standard approach in Java for managing message-level security as defined by the Web Services Security (WS-Security) specification.

Filters are applied at the level of the gateway service. JAX-RPC handlers are applied to:

- The gateway service and the channel (for messages passing between the service requester and the gateway).
- The target service and the target service port (for messages passing between the gateway and the target service).

JAX-RPC handlers are deployed to the Web services gateway as described in [Deploying handlers to the Web services gateway](#) and [Listing and managing gateway-deployed handlers](#). After you deploy a handler to the gateway you can add it to the handler chain for the gateway service and the channel, or to the handler chain for the target service and the target service port, as described in [Listing and managing gateway-deployed Web services](#).

If you deploy a gateway service to run in proxy mode, then you must also deploy (to the gateway service and the channel) a JAX-RPC handler that can set the target endpoint for the gateway service. For more information, see [JAX-RPC handlers and proxy operation](#).

Use of JAX-RPC handlers is currently supported only by the SOAP over HTTP channel.

## JAX-RPC handlers and proxy operation

You can set the gateway to act purely as a proxy for your service, then use JAX-RPC handlers to set the endpoints for incoming request messages for the service.

When you deploy a service to the gateway and enable proxy operation, the gateway takes no action with regard to that service other than to invoke it as a WSIF service. When you deploy a service to run in proxy mode, you also enable selective SOAP parsing for that service, and deploy a JAX-RPC handler that sets the `transport.url` context property to set the target endpoint for the service.

When the gateway receives a message, it needs to know whether the request being invoked is request and response, or one-way. Because the Gateway is not parsing the SOAP message, it cannot get this information from the message. Therefore the requesting clients append an `operationMode` HTTP query string parameter to the Web address for the gateway service. The value of this parameter is either `oneway` or `requestResponse`. For example, if the Web address of the deployed proxy service is `http://.../wsgwsoap/urn:wsgw::ProxyService`, then requesting clients indicate that they are sending a one-way request by using the following URL:

```
http://.../wsgwsoap/urn:wsgw::ProxyService?operationMode=oneway
```

If the `operationMode` parameter is missing, the gateway assumes that the requested method is `requestResponse`.

A gateway service that runs in proxy mode has no gateway-deployed target services and therefore no WSDL that the gateway can use to configure the WSIF service invocation. A generic template WSDL file is used to configure the basic parameters for the invocation call (for example which WSIF provider to use), but you can override the default by supplying your own equivalent template. The default template WSDL defines a single `portType` with two operations: `oneway` and `requestResponse`. If the operation mode is `oneway`, then the gateway selects the one-way operation from the WSDL. The default template WSDL is located at `http://.../wsgw/admin/ProxyServiceTemplate.wsdl`.

If you want the gateway to use a different template WSDL file, then you specify the Web address of the new template WSDL file when you deploy the service to the Web services gateway. Your new template WSDL must implement the same port type, binding, service, and port names as the default template. The only differences that can exist are in the extension elements used to configure the binding. In your new template WSDL, the value of the `<soap:target address>` tag must be a properly formatted Web address but it does not have to point to a real page. For example, a value of `this.is.a.fake.url` is rejected, whereas a value of `http://this.is.a.fake.url` is accepted. The JAX-RPC handler that sets the `transport.url` property overrides this value at runtime with the real Web address.

**Note:** If the JAX-RPC handler is not deployed, then the gateway attempts to send all requests to the fake url specified in the `<soap:target address>` tag in the template WSDL.

Proxy operation is currently supported only by the SOAP over HTTP channel.

For the detailed steps to take to enable proxy operation for a Web service, see [Deploying a gateway service for proxy operation](#).

## Listing and managing gateway-deployed handlers

To list the handlers that are currently deployed to the Web services gateway, and to view and modify their deployment details, complete the following steps:

1. Display the Web Services gateway administrative user interface.
2. In the navigation pane, click the following link:

### Handlers

- [List](#)

The main pane is updated with a list of all the handlers that are deployed to the Web services gateway.

3. Click the name of a handler in the list. A form is displayed that you can use to view and modify the current deployment details for this handler.
4. Modify the following deployment details. Click the **Add** and **Remove** buttons to the right of each row to add and remove corresponding parameters of the handler (the **Remove** button appears automatically after you add your first parameter).

**Handler Class**

Modify the name of the class that is to be instantiated.

**Init Parameter name/value**

Add or remove up to three initial parameter names and associated values.

**SOAP Header QName**

Add or remove the QName of a SOAP header that will be processed by the handler.

**SOAP role**

Add or remove a SOAP actor definition that the Handler will play as a role. For more information, see the SOAP specification.

5. Click **Apply changes**.

If the processing completes successfully, the list of deployed handlers is redisplayed. Otherwise, an error message is displayed.

## Deploying handlers to the Web services gateway

Use this task to deploy a Java API for XML-based Remote Procedure Call (JAX-RPC) handler to the gateway.

For information about creating JAX-RPC handlers, see the IBM developerWorks article *A developer introduction to JAX-RPC, Part 2: Mine the JAX-RPC specification to improve Web service interoperability*.

Before you can deploy a handler, you must make the handler class available to the application server in one of the following ways:

- Copy the individual class file into a directory structure under *install\_root/classes* that matches the package name of the class, where *install\_root* is the root directory for the installation of your application server (by default WebSphere/AppServer). For example a handler class `com.ibm.jaxrpc.handler.TestHandler` is copied into *install\_root/classes/com/ibm/jaxrpc/handler*.
- Package the class files for all your handlers as a JAR file, then copy it into *install\_root/lib/app*.

**Note:** You can deploy multiple instances of a handler by entering different handler names.

To deploy a handler, complete the following steps:

1. Display the Web services gateway administrative user interface.
2. In the navigation pane, click the following link:

**Handlers**

- [Deploy](#)

A form is displayed for you to specify the deployment details.

3. Type the following required handler deployment details:

**Handler Name**

Type the name by which the handler is known within the Web services gateway, and by which it is listed using the **Handlers > List** option. This name must be unique within the Web services gateway. For example `TestHandler`.

**Handler Class**

Type the name of the class that is to be instantiated. For example `com.ibm.jaxrpc.handler.TestHandler`.

4. Optional: Type the following optional handler deployment details:

**Init Parameter name/value**

Type up to three initial parameter names and associated values.

**SOAP Header QName**

Type the QName of a SOAP header that will be processed by the handler.

**SOAP role**

Type a SOAP actor definition that the Handler will play as a role. For more information, see the SOAP specification.

5. Click **OK**.

If the processing completes successfully, the list of deployed handlers is updated to include the new handler. Otherwise, an error message is displayed.

To use this handler, select it for use with a Web service as described in *Deploying Web services to the Web services gateway and Listing and managing gateway-deployed Web services*.

## Removing handlers from the Web services gateway

Use this task to remove a Java API for XML-based Remote Procedure Call (JAX-RPC) handler from the gateway.

To remove a handler, complete the following steps:

1. Display the Web Services gateway administrative user interface.
2. In the navigation pane, click the following link:

**Handlers**

- [Remove](#)

The main pane is updated with a list of all the handlers that are deployed to the Web services gateway. Next to each entry in the list is a check box, and information on the number of Web services that currently use the handler.

3. Click the name of a handler in the list. A form is displayed that you can use to view the current deployment details for this handler, including a list of the Web services that currently use the handler.
4. Select the check box for every handler that you want to remove.

**Note:** When you remove a handler that is currently used by one or more Web services, the gateway removes the handler from the handler lists for each associated Web service.

5. Click **OK**.

If the processing completes successfully, the list of deployed handlers is updated. Otherwise, an error message is displayed.

## Working with UDDI references

You should not make changes to the UDDI references for a gateway that is part of an unlocked configuration load-balancing group.

A UDDI reference is a pointer to a UDDI registry. This registry can be a private UDDI registry such as the IBM WebSphere UDDI Registry, or a public UDDI registry.

In the UDDI model, Web services are owned by businesses, and businesses are owned by Authorized Names. Each UDDI reference gives access to the Web services that are owned by a single Authorized Name in a single UDDI registry.

From the navigation pane of the Web services gateway administrative user interface, you can choose the following actions for **UDDI References**:

- **List** to list the deployed UDDI references, and modify their deployment details.

- **Deploy** to deploy a UDDI reference.
- **Remove** to remove UDDI references.

For more information about how the gateway works with UDDI registries, see [UDDI registries - Web service directories that integrate with the Web services gateway](#) and [Publishing a Web service to a UDDI registry for deployment to the gateway](#). For more general information about UDDI and UDDI registries, see the UDDI community at [uddi.org](http://uddi.org).

## **UDDI registries - Web service directories that integrate with the Web services gateway**

### **UDDI**

The Universal Description, Discovery and Integration (UDDI) specification defines a way to publish and discover information about Web services.

In this specification:

- Each Web service is owned by one business, and each business (and the Web services it owns) is maintained by one Authorized Name.
- One Authorized Name can own many businesses, and one business can own many Web services.

The UDDI specification also associates Web services with Technical models. Using these models or generic categories, a UDDI registry user can search for a type of service, rather than needing to know the access details for a specific service.

For more general information about UDDI, see the UDDI community at [uddi.org](http://uddi.org).

### **UDDI registries**

UDDI registries use the UDDI specification to publish directory listings of Web services. There are Universal Business Registries (sometimes referred to as public UDDI registries) hosted worldwide, including one hosted by IBM. Enterprises can also host their own internal registries behind their firewalls (sometimes referred to as private UDDI registries) to better manage their internal implementation of Web services. The IBM WebSphere UDDI Registry is an example of a private UDDI registry.

### **How the gateway interacts with UDDI registries**

The gateway interacts with UDDI registries in two ways:

- When you deploy a Web service to the gateway, you specify the location of the internal WSDL file that describes the Web service to be deployed. This WSDL file can be located through a UDDI registry.
- For any gateway-deployed Web service, you can tell the gateway to create entries for the Web service in one or more UDDI registries.

To enable your gateway to interact with a UDDI registry, you create one or more gateway pointers to the registry. The gateway refers to these pointers as UDDI references, and you create them as described in [Deploying UDDI references to the Web services gateway](#). Each UDDI reference includes the following parameters:

- The access points for the UDDI registry (the **Inquiry URL** and the **Publish URL**).
- The Authorized Name (the **User ID** and **Password**) for the owner of one or more businesses in the UDDI registry.

You get the Authorized Name from the target UDDI registry. For more information, see [Publishing a Web service to a UDDI registry for deployment to the gateway](#).

A given UDDI reference can only access the Web services that are owned by the businesses that are owned by a single Authorized Name. Therefore if you need to access two Web services in the same registry, and each service is owned by a different “Authorized Name”, then you need to create two UDDI references.

When you deploy a Web service, and you specify that the internal WSDL file is located through a UDDI registry, you enter the following two parameters:

- The UDDI reference that can access this service.
- The service key that the UDDI registry has assigned to this service.

You get the service key from the target UDDI registry. For more information, see Publishing a Web service to a UDDI registry for deployment to the gateway.

When you tell the gateway to create entries for a deployed Web service in one or more UDDI registries, you enter the following two parameters:

- The UDDI references (one for each registry) that can access the UDDI business category under which you want to publish this service.
- The business key that identifies the UDDI business category.

You get the business key from the target UDDI registry. For more information see Publishing a Web service to a UDDI registry for deployment to the gateway.

Because the gateway only interacts with UDDI registries at the level of specific Web services, the gateway does not use UDDI Technical models.

## Listing and managing gateway-deployed UDDI references

To list the UDDI references that are currently deployed to the Web services gateway, and to view and modify their deployment details, complete the following steps:

1. Display the Web services gateway administrative user interface.
2. In the navigation pane, click the following link:

### UDDI References

- [List](#)

The main pane is updated with a list of all the UDDI references that are deployed to the Web services gateway.

3. Click the name of a UDDI reference in the list. A form is displayed that you can use to view and modify the current deployment details for this UDDI reference.
4. Modify the following deployment details:

#### **Inquiry URL**

Type the new Web address that provides access to this registry for the SOAP inquiry API.

#### **Publish URL**

Type the new Web address that provides access to this registry for the SOAP publish API.

#### **User Name**

Type the new user ID for the Authorized Name that has update access to this registry.

#### **Password**

Type the password for this new user ID.

#### **Confirm Password**

Type again the password for this new user ID.

#### **Note:**

The values you enter here for **User Name** and **Password** must match those of the owner of the corresponding business in UDDI. You can see the owning user ID in UDDI by looking at the business details under the “Authorized Name” field.

If the values you enter here do not match the “Authorized Name” values for the business that owns the service, then the service will not be published or found.

If the business that owns the service has more than one Authorized Name, you might want to set up multiple UDDI references (each with a different user ID) to the same UDDI registry .

5. Click **Apply changes**.

If the processing completes successfully, the list of deployed UDDI references is redisplayed. Otherwise, an error message is displayed.

## Deploying UDDI references to the Web services gateway

To deploy a UDDI reference, complete the following steps:

1. Display the Web services gateway administrative user interface.
2. In the navigation pane, click the following link:

### UDDI References

- [Deploy](#)

A form is displayed for you to specify the deployment details.

3. Type the following UDDI reference deployment details:

#### Reference Name

Type the name by which the UDDI reference is known within the Web services gateway, and by which it is listed using the **UDDI References > List** option. This name must be unique within the gateway. You might need more than one UDDI reference for a given UDDI registry. For more information, see UDDI registries - Web service directories that integrate with the Web services gateway.

#### Inquiry URL

Type the Web address that provides access to this registry for the SOAP inquiry API.

#### Publish URL

Type the Web address that provides access to this registry for the SOAP publish API.

#### User Name

Type the user ID for an “Authorized Name” that has update access to this registry.

#### Password

Type the password for this user ID.

#### Confirm Password

Type again the password for this user ID.

#### Note:

The values you enter here for **User Name** and **Password** must match those of the Authorized Name in the UDDI registry. You can see the owning user ID in UDDI by looking at the business details under the Authorized Name field.

4. Click **OK**.

If the processing completes successfully, the list of deployed UDDI references is updated to include the new UDDI reference. Otherwise, an error message is displayed.

To use this UDDI reference, select it for use with a Web service as described in *Deploying Web services to the Web services gateway and Listing and managing gateway-deployed Web services*.

## Removing UDDI references from the Web services gateway

To remove a UDDI reference, complete the following steps:

1. Display the Web services gateway administrative user interface.
2. In the navigation pane, click the following link:

## UDDI References

- [Remove](#)

The main pane is updated with a list of all the UDDI references that are deployed to the Web services gateway. Next to each entry in the list is a check box, and information on the number of Web services that currently use the UDDI reference.

3. Click the name of a UDDI reference in the list. A form is displayed that you can use to view the current deployment details for this UDDI reference, including a list of the Web services that currently use the UDDI reference.
4. Select the check box for every UDDI reference that you want to remove. When you remove a UDDI reference that is currently used by one or more Web services, the gateway removes the UDDI reference from the UDDI reference list for each associated Web service.
5. Click **OK**.

If the processing completes successfully, the list of deployed UDDI references is updated. Otherwise, an error message is displayed.

## Working with Web services

If you change the namespace URI, you break the link back to the Web services gateway for every Web service that you have already deployed. Therefore you must set the namespace URI before you deploy any Web services.

When you configure a Web service, you associate it with one or more of the following resources:

- The channels on which the service is available.
- Any filters that apply to the service.
- **5.1 +** Any JAX-RPC handlers that apply to the service.
- Any security bindings that apply to the service.
- Any references to UDDI registries in which entries for the service are created.

You choose each of these resources from a list of gateway-deployed resources, so you should (if possible) deploy each resource to the gateway before you deploy a Web service that uses it.

You should not make changes to the Web service deployment settings for a gateway that is part of an unlocked configuration load-balancing group unless you are making changes, under controlled conditions, to all members of the group.

From the navigation pane of the Web services gateway administrative user interface, choose one of the following actions for **Services**:

- **List** to list the deployed Web services, and modify their deployment details.
- **Deploy** to deploy a Web service.
- **Remove** to remove Web services.

## Target services and gateway services

The gateway makes the following distinction between a target service and a gateway service:

- A target service is an actual service that exists outside the gateway, and that you make available to others through the gateway.
- A gateway service is the view of a target service that the gateway gives to service requesters. It is decoupled from the actual target service.

When you deploy a target service to the gateway, the gateway creates an equivalent gateway service. This gateway service is described in a new representation of the target service WSDL that is published to a gateway-controlled URL. This indirection gives the following benefits:

- You can move the target service to a new location, or replace it with a new implementation, and you only need to update the target service information that is held in the gateway. Existing service requesters can still find it and use it, because (as far as they can see) nothing has changed.
- If you have several different implementations of the same service, and you deploy them all to the gateway as multiple target services for a single gateway service, then they appear to service requesters as a single service. You can then use a filter (or similar mechanism) to choose the most appropriate target service for each incoming request.
- You can set, quite independently, the security measures that apply between the service requester and the gateway, and the security measures that apply between the gateway and each target service.

## Listing and managing gateway-deployed Web services

Use this task to list the Web services that are deployed to the Web services gateway, and modify their deployment details.

Do not deploy multiple target services to the same gateway service unless you have a filter (or similar mechanism) that can select the required target service, because without filtering the gateway always picks the first target service in the list.

For information on how to write pluggable filters that can select the target service, see [Writing a filter for the Web services gateway](#) and [Using a filter to select a target service and port](#).

To list the Web services that are currently deployed to the Web services gateway, and to view and modify their deployment details (including adding or removing multiple target services) complete the following steps:

1. Display the Web services gateway administrative user interface.
2. In the navigation pane, click the following link:

### Services

- [List](#)

The main pane is updated with a list of all the Web services that are deployed to the Web services gateway.

3. Click the name of a Web service in the list. A form is displayed that you can use to view and modify the current deployment details for this gateway service, and to add or remove multiple target services.
4. In the **Gateway Service Properties** section you can change the following details. When you have finished making changes, click **Apply Changes**.
  - a. **Authorization Policy - Control access to this service.** Use this check box to enable or disable operation-level authorization for this gateway service.
  - b. **Audit Policy - Log requests to this service.**  
 The Audit policy indicates whether the MessageWarehouse object, if present, is used to log requests and responses for this service. If you have a Message Warehouse implementation, use this check box to enable or disable logging of requests and responses for this Web service.  
 For more information, see [Capturing Web service invocation information](#) and [The MessageWarehouse interface](#).
  - c. In this release of the gateway, the **Annotation URL** field is not used.
  - d. If you want to publish the service to one or more UDDI registries (selected in the subsequent **UDDI References** section), enter the UDDI business key in the field provided under **UDDI Publication Properties**. This key identifies the business category under which you want your service to appear in UDDI. To get a list of valid business keys, look up businesses in a UDDI registry. Here is an example of a UDDI business key: 08A536DC-3482-4E18-BFEC-2E2A23630526.  
 For more information about UDDI business keys, see [Publishing a Web service to a UDDI registry for deployment to the gateway](#).
  - e. If you want to enable or disable **Service Security**, select or clear the **Enable service security** check box. If you choose to enable service security, then you must use the **Edit service security**

**configuration** option to configure secure communication for this gateway service between the service requester (the client) and the gateway. For more information, see Editing the service security configuration.

5. In the **Target Services** section you add, modify or remove services from a list of target services for this single gateway service. Every target service on this list provides exactly the same service, and they are presented by the gateway to the service requesters as a single gateway service. To add a new target service, complete the following steps:
  - a. **WSDL Location and Location Type.** Specify the location, and select the location type, for the internal WSDL file that describes the Web service to be deployed. The WSDL file is either located at a Web address, or through a UDDI registry.

**Note:**

- When the gateway deploys the Web service, it generates a matching external WSDL file that it makes available to gateway users. This external WSDL file also describes the service, but is located at a new Web address and is generated and maintained by the Web services gateway.
- If the service provider makes changes to the internal WSDL file, the gateway does not pick up the changes until the application server on which the gateway is hosted is restarted. For performance reasons, the gateway does not check the service information on each service invocation. The gateway reads the service information when it deploys the Web service, then uses this information for as long as the service remains deployed, or until the application server is restarted.
- If the Web service is also being published to one or more UDDI registries, then the internal WSDL file is required to remove the service from the gateway.

If the location for the internal WSDL file is a Web address, type the Web address. If the binding and service definition for this Web service are held in separate WSDL files, then type the Web address of the WSDL file that defines the binding.

If the WSDL is located through a UDDI registry, type *uddiReference,serviceKey* where

- *uddiReference* is the reference name by which a currently-deployed UDDI reference is known within the gateway, and by which it is listed using the **UDDI References > List** option.
- *serviceKey* is the service key that the UDDI registry has assigned to the service. Here is an example of a UDDI service key: 34280367-0ECF-46CE-B804-14C21D6D0FB1. For more information about UDDI service keys, see Publishing a Web service to a UDDI registry for deployment to the gateway.

- b. **Target Service Name.** If the Web service WSDL contains more than one service, or the WSDL is located through a UDDI registry, type the target service name from the target service WSDL.
- c. **Target Service Namespace.** If the Web service WSDL contains more than one service, or the WSDL is located through a UDDI registry, type the namespace of the target service name from the target service WSDL.
- d. **Target Service Identity Information.** Type the identity by which the target service is known within the Web services gateway. This identity need not be unique.

**Note:** If you are mapping multiple target services, and also writing a filter to select a target service, you might use the Target Service Identity Information to select a particular target service from the set.

- e. Click **add**. The target service is added to a list of target services.

To modify the deployment details for an existing target service, click on the name of the service in the list of target services. A form is displayed, containing the same fields that you filled in when you added the service, and also the following additional fields:

- **Started.** Enable this check box option if you want the gateway to offer this Web service to service requesters.
- **Enable target service security.** Enable this check box if you want the gateway to use secure communication between the gateway and the target service.

- **Edit target service security configuration.** If you choose to enable target service security, then you must use this option to configure secure communication between the gateway and the target service. For more information see Editing the target service security configuration.

**5.1 +** At the bottom of this form is the **Target Service Ports** section. This section contains a list of available ports for this target service. To edit the JAX-RPC handler configuration for a port for this target service, complete the following steps:

- a. Click the link next to the port name. The **Edit Target Service JAX-RPC handler configuration** pane is displayed.
- b. In the **Edit Target Service JAX-RPC handler configuration** pane, use the **add** and **remove** buttons, and the drop-down lists, to modify the chain of handlers for this target service and target service port.
- c. Click the target service name to return to the target service deployment details form.

When you have finished making changes to the target service deployment details, click **Apply Changes**.

6. In the **Channels** section, you can add or remove channels from the list of deployed channels through which this service is available.

**5.1 +** To edit the JAX-RPC handler configuration for a channel for this gateway service, complete the following steps:

- a. Click the link next to the channel name. The **Edit Gateway Service JAX-RPC handler configuration** pane is displayed.
- b. In the **Edit Gateway Service JAX-RPC handler configuration** pane, use the **add** and **remove** buttons, and the drop-down lists, to modify the chain of handlers for this gateway service and channel.
- c. Click the gateway service name to return to the gateway service deployment details form.

7. In the **Request filters** section of the gateway service deployment details form, you can add or remove filters from the list of deployed filters that are applied to the service request message.

**Note:** The filters are executed in the order shown. To add a filter into the list at a particular position, use the **at position** menu.

8. In the **Response filters** section, you can add or remove filters from the list of deployed filters that are applied to the service response message.

**Note:** The filters are executed in the order shown. To add a filter into the list at a particular position, use the **at position** menu.

9. In the **UDDI References** section, you can add or remove UDDI references from the list of deployed UDDI references to UDDI registries in which this service is published. If you select one or more UDDI references in this step, you must also enter a UDDI business key in the field provided under **UDDI Publication Properties** as described in a previous step. For more information about how the gateway works with UDDI registries, see UDDI registries - Web service directories that integrate with the Web services gateway.
10. In the **Exported WSDL definitions** section there are two pairs of WSDL links. Both pairs link to the external WSDL implementation definition, and the external WSDL interface definition.
  - To view the XML source of the associated external WSDL for the service, use the **View external WSDL implementation definition** links.
  - To return the WSDL parsed for use by application programs that need the WSDL definitions for the service, use the pair labelled **External WSDL implementation definition (WSDL only)**.

WSDL documents are XML documents, and two pairs of links are supplied in order to display the same external WSDL in two different document formats. The pair of links labelled **View external WSDL implementation definition** display the XML source for the WSDL, whereas the pair of links labelled **External WSDL implementation definition (WSDL only)** display the WSDL as it appears in a Web browser.

For example, in XML notation the ampersand character (“&”) is reserved for use in encoding special characters such as the quotation mark (“&quot;”). The ampersand character itself is encoded as “&amp;”. When you select either of the **View external WSDL implementation definition** links, you view the literal XML source and the ampersand character is represented as “&amp;”. When you select either of the **External WSDL implementation definition (WSDL only)** links, your Web browser parses the XML source, converts the special characters back into their normal form, and the ampersand character is represented as “&”.

**Note:** The “&amp;” encoding is required only within the WSDL XML source document. You should not use it in any endpoint address that you supply to a service client. If you get the endpoint address from the WSDL programatically, then the XML parser handles the conversion. If you manually copy and paste the address into the properties file, you should copy the address from one of the **External WSDL implementation definition (WSDL only)** links.

If there is an error generating the WSDL then a blank page is returned.

To help your service users locate the WSDL documents for services that are deployed to the Web services gateway, the gateway also supports the WS-Inspection specification. To open a Web services inspection document that contains references to the WSDL documents for all of the gateway-deployed services, you issue an HTTP GET against

`http://host:port/wsgw/wsinspection.wsil`

where *host* and *port* are the host name and port number on which your HTTP server is listening.

**Note:** When you use the Web address provided in Testing the installation to list the services that are deployed to the SOAP over HTTP channel, you see a link labeled **WSDL** next to each service in the list. Do not use these links. To get the WSDL location for your service, open a Web services inspection document.

## Deploying Web services to the Web services gateway

To deploy a Web service, complete the following steps:

1. Display the Web services gateway administrative user interface.
2. In the navigation pane, click the following link:

### Services

- [Deploy](#)

A form is displayed that you use to specify the deployment details.

3. In the **Gateway Service Properties** section, specify the following details:
  - a. **Gateway Service Name.** Type the name by which the Web service is known within the gateway, and by which it is listed using the **Services > List** option. This name must be unique within the gateway and must not contain any spaces.
  - b. **Message part representation.** Choose between **Generic classes** and **Deployed Java classes**, and (if available) choose whether or not **Selective SOAP parsing** is enabled.

You can use either generic classes or deployed Java classes to represent simple, compound and complex data types, subject to the constraints described in Data type representation - Choosing between Generic classes and Deployed Java classes. If your Web service uses complex data types, and there is no other constraint that forces you to use deployed Java classes, then choose generic classes.

**5.1+** If you enable selective SOAP parsing, then the gateway parses only the headers of incoming messages for this service. The message body is passed through unchecked. Choose this option to optimize the speed at which messages pass through the gateway. Selective SOAP parsing is only supported by the SOAP over HTTP channel. For more information, see Selective SOAP parsing.

- c. **5.1+ Operate in Proxy Mode.** Choose whether or not this gateway service runs in proxy mode. If you enable proxy operation, then you must also choose selective SOAP parsing in the previous

step, and deploy a JAX-RPC handler that sets the target endpoint for this gateway service. Proxy operation is only supported by the SOAP over HTTP channel. For more information, see JAX-RPC handlers and proxy operation and Deploying a gateway service for proxy operation.

- d. **5.1+ Proxy Service Template WSDL Override.** If you enable proxy operation in the previous step, and you want to override the default proxy service template WSDL that is supplied with the gateway, then type the location (as a URI) of the replacement template WSDL file. Otherwise, leave this field blank. For more information, see JAX-RPC handlers and proxy operation.
- e. **Authorization Policy - Control access to this service.** If you want to enable operation-level authorization for this Web service, enable this check box.
- f. **Audit Policy - Log requests to this service.**

The Audit policy indicates whether the MessageWarehouse object, if present, is used to log requests and responses for this service. If you have a Message Warehouse implementation, and you want it to log requests and responses for this Web service, enable this check box.

For more information see Capturing Web service invocation information and The MessageWarehouse interface.

- g. In this release of the gateway, the **Annotation URL** field is not used.
- h. Select the deployed resources for the Web service to use, from the following lists:

**Channels**

Select one or more deployed channels through which this service is available.

**Request filters**

Select zero or more deployed filters to apply to the request.

**Response filters**

Select zero or more deployed filters to apply to the response.

**UDDI References**

Select zero or more deployed UDDI references (one for each UDDI registry) that can access the UDDI business category under which you want to publish this service. If you select one or more UDDI references in this step, you must also enter the UDDI business key in step 3h. For more information about how the gateway works with UDDI registries, see UDDI registries - Web service directories that integrate with the Web services gateway.

4. In the **Target Service Properties** section, specify details for the first target service that is represented by this gateway service.

**Note:** **5.1+** If you are deploying a service for proxy operation, do not specify any target service properties.

**Note:** If you have several implementations of the same Web service, you can map them all to the same deployed gateway service. To add more target services to this gateway service, use the Services > List option.

- a. **WSDL Location and Location Type.** Specify the location, and select the location type, for the internal WSDL file that describes the Web service to be deployed. The WSDL file is either located at a Web address, or through a UDDI registry.

**Note:**

- When the gateway deploys the Web service, it generates a matching external WSDL file that it makes available to gateway users. This external WSDL file also describes the service, but is located at a new Web address and is generated and maintained by the Web services gateway.
- If the service provider makes changes to the internal WSDL file, the gateway does not pick up the changes until the application server on which the gateway is hosted is restarted. (For performance reasons, the gateway does not check the service information on each service invocation. The gateway reads the service information when it deploys the Web service, then uses this information for as long as the service remains deployed, or until the application server is restarted.)

- If the Web service is also being published to one or more UDDI registries, then the internal WSDL file is required to remove the service from the gateway.

If the location for the internal WSDL file is a Web address, type the Web address. If the binding and service definition for this Web service are held in separate WSDL files, then type the Web address of the WSDL file that defines the binding.

If the WSDL is located through a UDDI registry, type *uddiReference*, *serviceKey* where:

- *uddiReference* is the reference name by which a currently-deployed UDDI reference is known within the gateway, and by which it is listed using the **UDDI References > List** option.
  - *serviceKey* is the service key that the UDDI registry has assigned to the service. Here is an example of a UDDI service key: 34280367-0ECF-46CE-B804-14C21D6D0FB1. For more information about UDDI service keys, see Publishing a Web service to a UDDI registry for deployment to the gateway.
- Target Service Name.** If the Web service WSDL contains more than one service, or the WSDL is located through a UDDI registry, type the target service name from the target service WSDL.
  - Target Service Namespace.** If the Web service WSDL contains more than one service, or the WSDL is located through a UDDI registry, type the namespace of the target service name from the target service WSDL.
  - Target Service Identity Information.** Type the identity by which the target service is known within the Web services gateway. This identity need not be unique.

**Note:** If you later add more target services to this gateway service, and also write a filter to select a target service, you might use the Target Service Identity Information to select a particular target service from the set.

- If you want to publish this gateway service to one or more UDDI registries (selected in a previous step), enter the UDDI business key in the field provided in the **UDDI Publication Properties** section. This key identifies the business category under which you want your service to appear in UDDI. To get a list of valid business keys, look up businesses in a UDDI registry. Here is an example of a UDDI business key: 08A536DC-3482-4E18-BFEC-2E2A23630526. For more information about UDDI business keys see Publishing a Web service to a UDDI registry for deployment to the gateway.
- Click **OK**.

If the processing completes successfully, the list of deployed Web services is updated to include the new Web service. Otherwise, an error message is displayed.

After deployment, use the list deployed Web services option to add multiple target services for this gateway service, or to change the following resources that the Web service uses:

- Channels.
- Filters
- **5.1 +** JAX-RPC handlers
- UDDI references
- Security bindings.

If you enabled the “Authorization Policy - Control access to this service” check box , you must now enable Web service operation-level authorization.

**Data type representation - Choosing between Generic classes and Deployed Java classes:** When you deploy a Web service, you use the **Message part representation** option to choose between **Generic classes** and **Deployed Java classes**.

As your message passes through the gateway, the message parts are represented as actual Java objects. These are the data type definitions that are used for each part:

- One of the set of XML schema and SOAP supported simple and compound data types, or
- A complex type defined in the WSDL schema section.

A complex type is a data type represented by a Java class (such as a user-written class) that is not part of the native Java language.

**Generic classes** and **Deployed Java classes** can both represent simple, compound and complex data types, subject to the following constraints:

- The gateway only supports the simple and compound types that are listed in Web services gateway - Supported types.
- Only **Deployed Java classes** can represent vectors, enumerations, hashtables and maps (but either **Generic classes** or **Deployed Java classes** can represent arrays).
- If **Deployed Java classes** are used to represent complex types, then the actual Java classes representing these complex types must be deployed to the application server on which the gateway is running.
- If the target service uses Java or EJB WSDL bindings (that is, if the target service is a Java class deployed on the local application server, or it is an enterprise bean) then you must use **Deployed Java classes**, and you must make the bindings available as described in Deploying Web services with Java bindings.

The gateway schema parser determines all top-level types that are defined in the WSDL schema section, and generates mappings to **generic classes** for all of these types. This mapping enables the gateway to forward requests (and responses) containing most complex data type parameters (and return values) to a remote destination without requiring the actual Java classes representing these complex types to be deployed to the application server on which the gateway is running. If your Web service uses complex data types, and there is no other constraint that forces you to use **Deployed Java classes**, then select **Generic classes**.

Performance is the same whether you choose to use **Deployed Java classes** or **Generic classes**.

**Complex data types - Mapping namespaces to packages:** If you write your own WSDL file that describes your Web service (rather than use an automated tool such as WebSphere Studio Application Developer) and the service uses complex data types, then follow these guidelines for mapping namespaces to packages.

For working with complex data types, there is no industry-wide standard way of mapping namespaces to packages (in fact the Java API for XML-based Remote Procedure Call (JAX-RPC) standard states that the tools must make up their own standard). This is the standard used by the gateway:

- Set the namespace of the complex data type to the Java package name of the class.
- Set the complex data type name to the name of the class.

For example, if the Java class you are using for the complex data type is `random.RandomData`, then the namespace of the complex data type is `random`, and the complex data type name is `RandomData`. And if the full package name is `com.ibm.www.random`, then the namespace is `www.ibm.com/random`.

See also the troubleshooting tip about working with Web services that use complex data types.

### **Deploying Web services with Java bindings:**

For Web services deployed with Java bindings (or EJB bindings even where the Web service is on a different server) you must make additional classes available to the gateway.

For **EJB bindings**, make the EJB client JAR file available. If the Web service is deployed on the same server as the gateway, the necessary interfaces and classes are already visible. If not, implement one of the following options:

- Copy the EJB client JAR file into the `install_root/lib` or `install_root/lib/app` directory, where `install_root` is the root directory for your installation of IBM WebSphere Application Server (by default `WebSphere/AppServer`).
- Update the application server class path to include the EJB client JAR file.

For **Java bindings**, make the Java classes for the Web service available by implementing one of the following options:

- Copy the JAR file or class files that contain the Java classes into the *install\_root/lib* or *install\_root/lib/app* directory.
- Update the application server class path to include the JAR file.
- Wrap the Java classes in an enterprise bean and deploy it on the same application server. WebSphere Application Server then makes the classes available to the gateway application.

**Web services gateway - Supported types:** When you deploy a Web service, you use the **Message part representation** option to choose between Generic classes and Deployed Java classes. This topic gives reference information about the data types that are supported in each case.

## Simple types

The following table gives a list of the XML schema (and Java equivalent) simple types that are supported by both **Generic classes** and **Deployed Java classes**:

XML schema (and Java equivalent) simple type
xsd:string
xsd:float
xsd:double
xsd:int
xsd:boolean
xsd:byte
xsd:short
xsd:long
xsd:decimal
xsd:QName
xsd:date
xsd:timeInstant

## Compound types

From a Java perspective, compound types are types with constituent elements. These elements are either identified purely by name (for example, a Java class with several member properties) or by ordinal position (for example, a List data structure like Array or Vector).

The following table gives a list of the SOAP (and Java equivalent) compound types that are supported:

SOAP compound type	Java equivalent compound type	Supported by
Array	Java array	Generic classes and Deployed Java classes
Vector	java.util.Vector	Deployed Java classes
Vector	java.util.Enumeration	Deployed Java classes
Map	java.util.Hashtable	Deployed Java classes
Map	java.util.Map	Deployed Java classes

## Complex types

A complex type is a data type represented by a Java class (such as a user-written class) that is not part of the native Java language.

Complex types can include combinations of simple types, compound types, and other complex types. For example, the children of a complex type might be represented by another complex type, or by any of the simple or compound types.

**Generic classes** and **Deployed Java classes** can both represent complex types, subject to the constraints described in Data type representation - Choosing between Generic classes and Deployed Java classes.

### ***Deploying a gateway service for proxy operation:***

Use this task to set the gateway to act purely as a proxy for your service, and use JAX-RPC handlers to set the endpoints for incoming request messages for the service.

For an overview of proxy operation, see JAX-RPC handlers and proxy operation. To deploy a gateway service for proxy operation, complete the following steps:

1. Create a JAX-RPC handler that sets the `transport.url` context property to set the target endpoint for the service. It is up to you to decide how you want to establish the target endpoint, and to create and configure the `transport.url` JAX-RPC handler. For information about creating JAX-RPC handlers, see the IBM developerWorks article *A developer introduction to JAX-RPC, Part 2: Mine the JAX-RPC specification to improve Web service interoperability*.
2. Deploy the new handler to the gateway.
3. Deploy the SOAP over HTTP channel (if not already deployed). Proxy operation is only supported by this channel.
4. Deploy your Web service. Ensure that you set the following parameters:
  - a. Enable **Selective SOAP parsing**.
  - b. Enable **Operate in Proxy Mode**.
  - c. Optional: If you want to override the default proxy service template WSDL, then type the location of your replacement template WSDL file in the **Proxy Service Template WSDL Override** field.
  - d. Select the SOAP over HTTP channel from the list of available channels.

**Note:** Do *not* set any **Target Service Properties**.

5. List the Web services that are deployed to the Web services gateway, then complete the following steps to add the handler that sets the target endpoint for this service:
  - a. Click the name of your service in the list. A form is displayed that you can use to view and modify the current deployment details.
  - b. Scroll down to **Channels**, then click **Edit JAX-RPC handler configuration**.
  - c. Select the handler that sets the target endpoint for this service, and add it to the handler chain.

Ensure that all service requesters append an `operationMode` HTTP query string parameter to the Web address for the gateway service. The value of this parameter is either `oneway` or `requestResponse`. For example, if the Web address of the deployed proxy service is `http://.../wsgwssoap/urn:wsgw::ProxyService`, then requesting clients indicate that they are sending a one-way request by using the following URL:

```
http://.../wsgwssoap/urn:wsgw::ProxyService?operationMode=oneway
```

### ***Publishing a Web service to a UDDI registry for deployment to the gateway:***

The gateway interacts with UDDI registries as described in UDDI registries - Web service directories that integrate with the Web services gateway. When you deploy a Web service to the gateway, you enable UDDI interaction by entering a UDDI reference, and (depending upon what you are trying to do) either or both of the following pieces of information:

- The service key that the UDDI registry has assigned to this service.
- The business key that identifies the UDDI business category under which you want your service to appear in the UDDI registries.

You get these two keys from the UDDI registry. To help you understand what UDDI service keys and business keys are, and where you find them in a UDDI registry, this topic describes how to publish a Web service to a UDDI registry.

The following description of the UDDI publication process requires that you specify a Technical model. Technical models are generic categories. Using these models, a UDDI registry user can search for a type of service, rather than needing to know the access details for a specific service. The gateway makes no use of Technical model information because it only interacts with UDDI registries at the level of specific Web services.

The following task steps include specific navigation instructions. These instructions describe how you publish a Web service to the IBM WebSphere UDDI Registry. If you are working with a different UDDI registry, then the specific navigation is different but the underlying principles are the same.

1. Specify a business:
  - a. To get a list of valid business keys, look up businesses in the UDDI registry. Here is an example of a UDDI business key: 08A536DC-3482-4E18-BFEC-2E2A23630526.
  - b. If you do not find an appropriate existing business in the UDDI registry, then use the **Add a business** option on the **Advanced Publish** section of the Publish pane to add a new one.
2. Add a technical model:
  - a. Select **Add a technical model** on the **Advanced Publish** section of the Publish pane.
  - b. Enter the name as specified for the target namespace of your binding (or interface) WSDL file, then add a description (if required).
  - c. Add a category of Type unspsc and value wsdlSpec (the Key name field can be left blank).
  - d. Add an overview URL specifying the Web address for your binding WSDL file, then add a description (if required).

**Note:** The binding and the service definition for your Web service might be held in separate WSDL files, therefore be careful to type the Web address of the WSDL file that defines the *binding*.

  - e. Click **Publish Technical Model**.
3. Add a service:
  - a. Select **Show owned entities** on the **Advanced Publish** section of the Publish pane.
  - b. Select **Add a Service** for your business.
  - c. Enter the name as specified for the target service in your WSDL file, then add a description (if required).
  - d. For the **Access point** verify that the correct Web address type is selected (for example http for an HTTP access point), then enter the value of the soap:address location (or its equivalent) from your service definition WSDL file (for example http://yourhost:80/SimpleTest/servlet/rpcrouter).
  - e. For the **Technical model** select **Add**, then find the required Technical model by entering a suitable prefix and selecting **Find technical models**, then enable the check box for the required Technical model and click **Update**.
  - f. Click **Publish Service**.

The UDDI registry assigns a service key to your service, and publishes the service.

## Removing Web services from the Web services gateway

To remove a Web service, complete the following steps:

1. Display the Web services gateway administrative user interface.
2. In the navigation pane, click the following link:

### Services

- [Remove](#)

The main pane is updated with a list of all the Web services that are deployed to the Web services gateway. Next to each entry in the list is a check box.

3. Select the check box for every Web service that you want to remove.
4. Click **OK**.

If the processing completes successfully, the list of deployed Web services is updated. Otherwise, an error message is displayed.

If the Web service that you want to remove is also published to one or more UDDI registries, then the internal WSDL file is required to remove the service from the gateway. Therefore if the service is published to UDDI, and the processing does not complete successfully, check that the WSDL file is still available at the location defined for the service in the **Target Services -> WSDL Location**. For more information, see Listing and managing gateway-deployed Web services.

---

## Running the Web services gateway Samples

The following pre-built Samples are available for use with the Web services gateway:

- The standard Stock Quote service Sample, that requires an Internet connection.
- The Address Book service Sample, that allows the storing and retrieval of names and addresses.

These Samples, and documentation on how to use them, are available through the Web services gateway Samples link on the Samples Central page of the DeveloperWorks WebSphere Web site.

If you want to test the gateway taking service definitions from a private UDDI registry such as the IBM WebSphere UDDI Registry, complete the following additional steps:

1. Publish the WSDL for each of these Samples to UDDI. (For more information, see Publishing a Web service to a UDDI registry for deployment to the gateway and the documentation for your private UDDI registry).
2. Instruct the gateway to locate the service through the UDDI registry, as described in Deploying Web services to the Web services gateway.

---

## Passing SOAP messages with attachments through the Web services gateway

The Web services gateway supports Web services that pass attachments in a MIME message.

This support is included in the SOAP over HTTP channel.

Attachments are carried through the various gateway components and passed to the target service. The content MIME type of each attachment is preserved.

When the target service is deployed to a Java API for XML-based Remote Procedure Call (JAX-RPC) compliant server, you can access the attachments on the target service using the `javax.activation.DataHandler` handler.

The WSDL representing a SOAP messages with attachments service must define the attachment parts in the binding section. The `mime:multipartRelated`, `mime:part` and `mime:content` tags are used to describe the attachment.

For more information, see the following topics:

- SOAP messages with attachments - a definition.
- Writing the WSDL extensions for SOAP messages with attachments.

The following scenarios are not supported:

- Using the Apache SOAP channel.
- Using DIME.
- Using the `mime:mimeXml` WSDL tag.
- Nesting a `mime:multipartRelated` inside a `mime:part`.
- Using arrays or vectors of `DataHandlers`, images, and so on.

The MIME headers from the incoming message are not preserved for referenced attachments. The outgoing message contains new MIME headers for `Content-Type`, `Content-Id` and `Content-Transfer-Encoding` that are created by WSIF.

## SOAP messages with attachments - a definition

From an architecture and external specification viewpoint, SOAP Messages with Attachments is an extension to the SOAP 1.1 Recommendation from the World Wide Web Consortium (W3C).

The W3C SOAP messages with attachments document describes a standard way to associate a SOAP message with one or more attachments in their native format (for example GIF or JPEG) by using a multipart MIME structure for transport. This document defines specific use of the Multipart/Related MIME media type, and rules for the use of URI references to refer to entities bundled within the MIME package. It outlines a technique for a SOAP 1.1 message to be carried within a MIME multipart/related message in such a way that the SOAP processing rules for a standard SOAP message are not changed.

An associated W3C document Web Services Description Language (WSDL) outlines a technique for including bindings to MIME types in a WSDL file.

## Writing the WSDL extensions for SOAP messages with attachments

The following example WSDL illustrates a simple operation that has one attachment called `attch`:

```
<binding name="MyBinding" type="tns:abc" >
 <soap:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/http"/>
 <operation name="MyOperation">
 <soap:operation soapAction=""/>
 <input>
 <mime:multipartRelated>
 <mime:part>
 <soap:body parts="part1 part2 ..." use="encoded" namespace="http://mynamespace"
 encodingStyle="http://schemas.xmlsoap.org/soap/encoding"/>
 </mime:part>
 <mime:part>
 <mime:content part="attch" type="text/html"/>
 </mime:part>
 </mime:multipartRelated>
 </input>
 </operation>
</binding>
```

In this type of WSDL extension:

- There must be a `part` attribute (in this example `attch`) on the input message for the operation (in this example `MyOperation`). There can be other input parts to `MyOperation` that are not attachments.

- In the binding input there must either be a `<soap:body>` tag or a `<mime:multipartRelated>` tag, but not both.
- For MIME messages, the `<soap:body>` tag is inside a `<mime:part>` tag. There must only be one `<mime:part>` tag that contains a `<soap:body>` tag in the binding input and that must not contain a `<mime:content>` tag as well, because a content type of `text/xml` is assumed for the `<soap:body>` tag.
- There can be multiple attachments in a MIME message, each described by a `<mime:part>` tag.
- Each `<mime:part>` tag that does not contain a `<soap:body>` tag contains a `<mime:content>` tag that describes the attachment itself. The type attribute inside the `<mime:content>` tag is not checked or used by the gateway. It is there to suggest to the application using the gateway what the attachment contains. Multiple `<mime:content>` tags inside a single `<mime:part>` tag means that the backend service expects a single attachment with a type specified by one of the `<mime:content>` tags inside that `<mime:part>` tag.
- The `parts="..."` attribute inside the `<soap:body>` tag is assumed to contain the names of all the SOAP parts in the message, but not the attachment parts. If there are only attachment parts, then you must specify `parts=""` (empty string). If you omit the `parts` attribute altogether, then the gateway assumes ALL parts including the attachments - which means the attachments will appear twice.

In your WSDL you might have defined a schema for the attachment (for instance as a `binary[]`). The gateway silently ignores this mapping and treats the attachment as a Data Handler.

You do not need to mention unreferenced attachments in the WSDL bindings.

---

## Developing Web services gateway extensions

Use this task to develop your own extensions for the gateway.

**Note:** **5.1+** The gateway system level interfaces described in this task and its sub-tasks are deprecated. However, you can achieve similar results using Java API for XML-based Remote Procedure Call (JAX-RPC) handlers. For more information, see [JAX-RPC handlers - An alternative to gateway filters](#).

The filters that you create as described in this topic and sub-topics use the gateway `WorkArea` to maintain context. The gateway `WorkArea` is only available with IBM WebSphere Application Server Enterprise Version 5 or WebSphere Business Integration Server Foundation Version 5.1. Therefore you can only deploy these filters on WebSphere Application Server Enterprise Version 5 or WebSphere Business Integration Server Foundation Version 5.1.

To extend the functionality of the gateway, you can write your own Java programs. The gateway does not provide any application programming interfaces, but there are system level interfaces that you can use. Specific guidance on using these interfaces is provided in the following topics:

- [Writing a filter for the Web services gateway.](#)
- [Using a filter to select a target service and port.](#)
- [Capturing Web service invocation information from the Web services gateway.](#)
- [Handling exceptions for the Web services gateway.](#)

For additional technical details of the Web services gateway, see the Javadoc.

## Writing a filter for the Web services gateway

**Note:** **5.1+** Use of the `Filter` interface is deprecated. However, you can achieve similar results using Java API for XML-based Remote Procedure Call (JAX-RPC) handlers. For more information, see [JAX-RPC handlers - An alternative to gateway filters](#).

The filters that you create as described in this topic use the gateway `WorkArea` to maintain context. Specifically, they extend `FilterImpl` which implements this for you:

```

public int getContextVersion() {
 return Filter.CONTEXT_VERSION_WORKAREA;
}

```

The gateway WorkArea is only available on WebSphere Application Server Enterprise Version 5 or WebSphere Business Integration Server Foundation Version 5.1.

To use this information you should be familiar with using a Java 2 platform, Enterprise Edition (J2EE) session bean development environment such as IBM WebSphere Studio Application Developer.

A Web services gateway filter is essentially a J2EE session bean implementing specific Home and Remote interfaces.

To write a filter using IBM WebSphere Studio Application Developer, for deployment on WebSphere Application Server Enterprise Version 5 or WebSphere Business Integration Foundation Version 5.1, complete the following steps. For more detailed information on writing session beans, see the WebSphere Studio documentation topic *Developing enterprise beans - overview*.

1. Open the J2EE perspective.
2. To create a new EJB application project, complete the following steps:
  - a. Select **File > New > Enterprise Application Project**. The Project Creation wizard opens.
  - b. In the Project Creation wizard, complete the following steps:
    - 1) Select the version of the J2EE specification that you want to use, then click **Next**.

**Note:** **5.1+** If you want to enable the local client view (so that the gateway can make local EJB calls to your filter, as described in *Tuning the Web services gateway*) then you must specify J2EE version 1.3 or later.

- 2) Type your project name.
- 3) Create a new module project for the EJB project only. Clear the other **Application Client Project**, **Web Project** and **Connector Project** check boxes as necessary.
- 4) Clear the **Web module** check box.
- 5) Click **Finish**.

Your new EJB application project and associated EAR project are created.

3. To add the extra JAR files that your EJB module needs that are not already in the enterprise application server `/lib` directory, complete the following steps:
  - a. Select **File > Import**.
  - b. In **Select an import source**, select **File system** then click **Next**.
  - c. In the Import window, complete the following steps:
    - 1) Select `wsgw_root/client` as the source directory.  
where `wsgw_root` is the root directory for your installation of the gateway.
    - 2) Select the `wsgwejb.jar` file.
    - 3) Select the root directory of your new EAR project as the **destination for imported resources**.
    - 4) Click **Finish**.

**Note:** You might see one or more instances of the following WebSphere Studio warning message. You should ignore these messages.

```

IWAE0024W The Manifest Class-Path for archive wsgwejb.jar contains
an entry, name.jar, that is not resolveable to a file or module in
the EAR earName.

```

- d. Repeat the previous **File > Import** process to add any other extra JAR files that your EJB module needs.
- e. In the J2EE Hierarchy view, from the pop-up menu for your EJB module, select **Open With > JAR Dependency Editor**.
- f. In the JAR Dependencies window, select all the JAR files listed.

- g. Close the JAR Dependencies window, then click **Yes** in the Save Resource window to save your changes.
- 4. To add extra JAR files to the Java build path for your EJB module, complete the following steps:
  - a. In the J2EE Hierarchy view, select your EJB module **Properties**.
  - b. In the Properties window, verify that the following JAR files are included on the **Java Build Path**:
    - *install\_root/lib/jrom.jar*
    - *install\_root/lib/qname.jar*
    - *install\_root/lib/wsd14j.jar*
    - *install\_root/lib/wsif.jar*
    - *wsgw\_root/client/wsgwejb.jar*

where *install\_root* is the root directory for your installation of IBM WebSphere Application Server Enterprise Version 5 or IBM WebSphere Business Integration Foundation Version 5.1, and *wsgw\_root* is the root directory for your installation of the gateway.

- c. Add any other JAR files or projects that you need for compiling your filter.
- d. Click **OK**.
- 5. To create the session bean, complete the following steps:
  - a. Select **File > New > Enterprise Bean**. The Enterprise Bean Creation wizard opens.
  - b. In the Enterprise Bean Creation wizard, complete the following steps:
    - 1) Select your EJB project, then click **Next**.
    - 2) Verify that **Session Bean** is selected.
    - 3) Enter a name for the bean.
    - 4) Enter a suitable package name for the bean.
    - 5) Click **Next**.
  - c. In the Enterprise Bean Details window, complete the following steps:
    - 1) Accept the defaults offered for **Session type** (Stateless) and **Transaction type** (Container).
    - 2) Accept the defaults offered for **Bean supertype** (<none>), **Bean class** and **EJB binding name**.
    - 3) **5.1 +** If you selected J2EE version 1.3 or later for your enterprise application project, and you want the gateway to make local EJB calls to your filter, then enable the **Local client view** by completing the next two steps.
    - 4) **5.1 +** For the **Local client view: Local Home Interface**, click **Class...** then select the `com.ibm.wsgw.beans.FilterLocalHome` interface.
    - 5) **5.1 +** For the **Local client view: Local Interface**, click **Class...** then select the `com.ibm.wsgw.beans.FilterLocal` interface.

**Note:** When the FilterLocal interface is used, the arguments to the filter methods are passed by reference. You should ensure that the `filterRequest()` and `filterResponse()` methods do not modify their arguments, unless the modification is intended.

    - 6) For the **Remote client view: Remote Home Interface**, click **Class...** then select the `com.ibm.wsgw.beans.FilterHome` interface.
    - 7) For the **Remote client view: Remote Interface**, click **Class...** then select the `com.ibm.wsgw.beans.FilterRemote` interface.
    - 8) Click **Next**.
  - d. In the EJB Java Class window, specify the **Bean superclass** as `com.ibm.wsgw.beans.FilterImpl`, then click **Finish**.

Your new session bean is created.

- 6. The generated Java code for your session bean does not implement the filter. To update the code, complete the following steps:
  - a. In the J2EE Hierarchy view, expand your session bean to show Java code entries for the Home interface, the Remote interface and for the session bean.

- b. In the J2EE Hierarchy view, double-click the entry for the session bean code. In the editor view, the generated code opens for editing.
- c. In the editor view, add the following import statements:

```
import com.ibm.wsgw.*;
import com.ibm.wsgw.beans.*;
import org.apache.wsif.*;
import java.rmi.RemoteException;
```

If you selected J2EE version 1.3 or later for your enterprise application project, then omit the `import java.rmi.RemoteException` statement from the set of import statements added here.

- d. Select **File > Save** to save the file. Ignore any errors.

If you selected J2EE version 1.3 or later for your enterprise application project, then your filter methods must not throw a `java.rmi.RemoteException` exception. For J2EE version 1.3 or later:

- Omit the statement `import java.rmi.RemoteException` from the set of import statements added in the previous step.
- Remove all instances of `throws RemoteException` from your filter methods.
- Code your filter to override the `getContextVersion()` method from `FilterImpl` (to eliminate the `RemoteException` from this method). Specifically, implement a `getContextVersion()` method in your filter to return `Filter.CONTEXT_VERSION_WORKAREA` as shown in the following example:

```
public int getContextVersion()
{
 return Filter.CONTEXT_VERSION_WORKAREA;
}
```

7. To add the unimplemented methods of the `Filter` interface to your session bean, complete the following steps:
  - a. Open the Outline view (select **Window > Show View > Outline**).
  - b. In the Outline view, from the pop-up menu for your session bean, select **Override Methods**.
  - c. In the Override Methods window, select all the `Filter` methods to override then click **OK**.

The methods of the `Filter` interface are added to your session bean.

8. Select **File > Save** to save the file. Any errors from the previous **File > Save** are resolved.
9. Develop your filter.

The exact steps that you take to develop your filter depend upon what you want it to do. However, to develop any filter, you use the following resources:

- The `Filter` interface.
- The gateway Javadoc for the `Filter` interface.
- The additional information on the `Filter` interface that is in *Web services gateway - The Filter interface*
- The gateway message context. (This contains the context values for each message that comes into the gateway. Your filter acts upon these values.)
- The gateway Javadoc for the `GatewayContextNames` class. (To use the gateway message context values, you import the `GatewayContextNames` class.)
- The additional information on the gateway message context values that is in *Web services gateway - The message context values*.
- The gateway `WorkArea`. (Filters use this resource to get and set the message context values, as described in *Web services gateway - The Filter interface*.)
- The WSIF Javadoc for the following WSIF objects:
  - `WSIFRequest`
  - `WSIFResponse`
  - `WSIFMessage`
  - `WSIFException`

(The methods of the `Filter` interface use these objects, as described in *Web services gateway - The Filter interface*.)

- The following example code.

**Note:** You must observe the J2EE programming model, and ensure that any non-gateway services you use are available on all platforms on which the filter might be expected to run. For example, do not use static variables to store state information because on certain platforms, or in certain configurations (such as a scaled gateway deployment), a filter might be invoked in a different Java Virtual Machine (JVM) for each request.

This example shows you how to access the context and get values in the filterRequest method of a filter.

```
import javax.naming.InitialContext;
import javax.naming.NamingException;

import com.ibm.websphere.workarea.UserWorkArea;
import com.ibm.websphere.workarea.WorkAreaException;

import com.ibm.wsgw.GatewayContextNames;

...

try
{
 // Lookup the WorkArea gateway context in JNDI
 InitialContext ctx = new InitialContext();
 UserWorkArea wsgwContext =
 (UserWorkArea)ctx.lookup("services:websphere/WSGW/workarea");

 // Get the currently selected port name
 String Ptype =
 (wsgwContext.get(GatewayContextNames.TARGET_PORT_NAME)).getClass().getName();
 String ThePortname =
 (String) wsgwContext.get(GatewayContextNames.TARGET_PORT_NAME);

 // Get the currently selected target service WSDL location
 String Xtype =
 (wsgwContext.get(GatewayContextNames.TARGET_SERVICE_LOCATION)).getClass().getName();
 TargetServiceLocation WSDLObject =
 (TargetServiceLocation) wsgwContext.get(GatewayContextNames.TARGET_SERVICE_LOCATION);

 String ServiceLocation = WSDLObject.serviceLocation;
 int ServiceLocationType = WSDLObject.serviceLocationType;
 String ServiceName = WSDLObject.serviceName;
 String ServiceNamespace = WSDLObject.serviceNamespace;
}
catch (NamingException e)
{
 // Handle any exceptions thrown by the InitialContext here
}
catch (WorkAreaException e)
{
 // Handle exceptions thrown by UserWorkArea here
}

...
```

After you have developed your filter, you need to generate deployment code and export the enterprise application. To do this using IBM WebSphere Studio Application Developer, complete the following steps:

1. Open the J2EE perspective.
2. In the J2EE Hierarchy view, from the pop-up menu for your EJB module, select **Generate > Deploy and RMIC code**.
3. In the Generate Deploy and RMIC Code window, select the beans for which you want to generate code, then click **Finish**.
4. To configure the deployment descriptor properties for your bean, complete the following steps:
  - a. In the J2EE Hierarchy view, from the pop-up menu for your bean, select **Open With > EJB Deployment Descriptor**.

- b. On the **Beans** tab, set the Java Naming and Directory Interface (JNDI) name to the Filter class name. This name is used as the Home Location when the filter is deployed to the gateway.
  - c. Close the EJB Deployment Descriptor window, then click **Save** to save the changes.
5. To export the enterprise application, complete the following steps:
    - a. In the J2EE Hierarchy view, from the pop-up menu for your project, select **Export ...**.
    - b. In the **Select an export destination:** box, select **EAR file**, then click **Next**.
    - c. In the **What resources do you want to export?** box, type your project name.
    - d. In the **Where do you want to export resources to?** box, type the destination directory.
    - e. Select any other options that you require, then click **Finish**.

You are now ready to install your filter into WebSphere Application Server Enterprise Version 5 or WebSphere Business Integration Server Foundation Version 5.1 (as described in the next to last step of Installing the gateway into a deployment manager cell and Installing the gateway into a stand-alone application server), then deploy your filter.

## Web services gateway - The Filter interface

**Note:** **5.1 +** Use of the Filter interface is deprecated. However, you can achieve similar results using Java API for XML-based Remote Procedure Call (JAX-RPC) handlers. For more information, see [JAX-RPC handlers - An alternative to gateway filters](#).

This topic gives more information on using each of the methods of the Filter interface. It supplements the information provided in the following Javadoc:

- The gateway Javadoc for the Filter interface.
- The WSIF Javadoc for
  - WSIFRequest
  - WSIFResponse
  - WSIFMessage
  - WSIFException

The Filter interface represents an object that is called during service invocation. You can register a bean that implements this interface to be called just before a request invocation, or just after a response is received for a particular service.

Gateway filters use the gateway WorkArea to get and set the gateway message context values. You get the gateway WorkArea partition from `services:websphere/WSGW/workarea` in the Java Naming and Directory Interface (JNDI), then use the UserWorkArea API to get and set data within the message context.

These are the two main methods you use for developing your filter:

- `FilterAction filterRequest(org.apache.wsif.WSIFRequest request, org.apache.wsif.WSIFResponse response)`.
- `FilterAction filterResponse(org.apache.wsif.WSIFRequest request, org.apache.wsif.WSIFResponse response)`.

Another important method that requires a specific value to be returned is `getContextVersion()`.

If you want your filter to change the WSIFResponse and WSIFRequest messages, then note that changes to messages are only recognized if the `setUpdatedRequest` and `setUpdatedResponse` methods are called on the returned FilterAction object. The FilterAction object can also dictate whether or not to continue processing the message by calling the `setContinueProcess` method.

## **filterRequest method**

The filterRequest method is called by the gateway Manager just before a request is sent to a target service. The return value from the method can indicate not to send the request.

The request parameter contains the request WSIFMessage. This consists of a set of named parts. Each part has a value that is encoded as an instance of an appropriate Java object. Filters can change the values of the Java object instances, but should not add or remove parts, or replace the values of parts with ones of a different type.

The Filter interface might decide not to proceed with the request. In that case the interface has three options:

- Throw a FilterException exception. The gateway logs the exception but continues processing filters and the request invocation.
- Throw a WSGWException exception. The gateway logs and rethrows the exception, and processing of filters and the request is stopped. The exception then goes back to the receiving channel, and the channel must determine what to do with the exception (in the case of SOAP-based channels, this results in a Fault message back to the client). This should only be done for unexpected errors in the filter.
- Return a FilterAction object with the continueProcessing flag set to false. In this case the response message in the FilterAction object can also be set, and is sent to the originator of the request. No further filters are invoked.

If the request or response is modified, then it must be returned in an instance of the FilterAction class. If this return is not done, any change to the response is ignored by the gateway.

## **filterResponse method**

The filterResponse method is called by the gateway Manager just after a response is received from a target service. The response parameter contains the response or fault WSIFMessage. This message consists of a set of named parts.

Each part has a value that is encoded as an instance of an appropriate Java object. Filters can change the values of the Java object instances, but should not add or remove parts, or replace the values of parts with ones of a different type.

The Filter interface might decide not to proceed with the response. In that case the interface has three options:

- Throw a FilterException exception. The gateway logs the exception but continues processing filters and the response invocation.
- Throw a WSGWException exception. The gateway logs and rethrows the exception, and processing of filters and the response is stopped. The exception then goes back to the receiving channel, and the channel must determine what to do with the exception (in the case of SOAP-based channels, this results in a Fault message back to the client). This should only be done for unexpected errors in the filter.
- Return a FilterAction object with the continueProcessing flag set to false. In this case the fault WSIF Message is set in the response message in the FilterAction object, and is sent to the originator of the request. No further filters are invoked.

If the response is modified, then it must be returned in an instance of the FilterAction class. If this return is not done, any change to the response is ignored by the gateway.

If the filter throws a FilterException exception, it is logged but the gateway continues to process other filters. If the filter throws a WSGWException exception, processing of the response is stopped.

See also Creating and returning a SOAP fault message from a filterResponse method.

## getVersionString method

The getVersionString method returns a string form of the filter implementation version. The gateway uses this form when logging events relating to the filter so that the exact version of the filter implementation is known.

## getContextVersion method

The getContextVersion method indicates the approach that this filter uses to access context information. To access the message context information for WebSphere Application Server Enterprise Version 5 or WebSphere Business Integration Server Foundation Version 5.1, implement this method to return the value: Filter.CONTEXT\_VERSION\_WORKAREA.

## init method

The init method tells the filter that it is configured with the gateway. This method is called when you deploy a filter to the gateway.

## destroy method

The destroy method tells the filter that it is no longer configured with the gateway. This method is called when you remove a filter from the gateway.

## Creating and returning a SOAP fault message from a filterResponse method

This topic provides an example of how to create and return a SOAP fault message from a GatewayFilter.filterResponse method.

**Note:** **5.1+** Use of the Filter interface is deprecated. However, you can achieve similar results using Java API for XML-based Remote Procedure Call (JAX-RPC) handlers. For more information, see [JAX-RPC handlers - An alternative to gateway filters](#).

```
public FilterAction filterResponse(WSIFRequest wsifRequest, WSIFResponse wsifResponse)
 throws FilterException, WSGWException, RemoteException {
 // Construct the fault message
 WSIFMessage faultMessage = new WSIFDefaultMessage();
 faultMessage.setObjectPart(WSIFConstants.SOAP_FAULT_ACTOR, "mySoapFaultActor");
 faultMessage.setObjectPart(WSIFConstants.SOAP_FAULT_CODE, "mySoapFaultCode");
 faultMessage.setObjectPart(WSIFConstants.SOAP_FAULT_STRING, "mySoapFaultString");
 faultMessage.setObjectPart("stackTrace", "myStackTraceDetails");
 faultMessage.setObjectPart("otherDetails", "myOtherDetails");
 // repeat faultMessage.setObjectPart("aaaa", "bbbb");
 // for each additional detail element
 // Set the fault message into the wsifResponse object
 wsifResponse.setFaultMessage(faultMessage);
 wsifResponse.setIsFault(true);

 // Return the updated response in the filterAction object
 FilterAction filterAction = new FilterAction();
 filterAction.setUpdatedResponse(wsifResponse);
 filterAction.setContinueProcessing(false);
 return filterAction;
}
```

The previous example works with both the Apache SOAP and the SOAP over HTTP channels. If you use the SOAP over HTTP channel, the previous example returns the following SOAP fault response:

```
<?xml version="1.0" encoding="UTF-8"?>
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
 <soapenv:Body>
```

```

<soapenv:Fault>
 <faultcode xmlns:ns1="http://xml.apache.org/axis/">ns1:mySoapFaultCode</faultcode>
 <faultstring>mySoapFaultString</faultstring>
 <faultactor>mySoapFaultActor</faultactor>
 <detail>
 <stackTrace>myStackTraceDetails</stackTrace>
 <otherDetails>myOtherDetails</otherDetails>
 </detail>
</soapenv:Fault>
</soapenv:Body>
</soapenv:Envelope>

```

## Web services gateway - The gateway message context values

The gateway message context holds the contextual information for each incoming message.

In WebSphere Application Server Enterprise Version 5 or WebSphere Business Integration Server Foundation Version 5.1 you can use the **Context Field Constant** values if you import the `com.ibm.wsgw.GatewayContextNames` class.

For basic information on the fields that are available in the context, see the Javadoc for the `GatewayContextNames` class. Additional information on all of these fields except `AUTH_SUBJECT` and copyright is provided in the following table.

Treat all of the context fields as Read only. If your filter attempts to write to a context field, you do not get an error message (because the write does not actually fail) but subsequent system behavior is not readily predictable.

If you want to change the target service location and port name fields, then you can use the Routing interface to get the list of valid target service locations and to select the target service location. For more information see Using a filter to select a target service and port.

Context Field Constant	Description
<code>AUTH_PASSWORD</code>	Read the password from the incoming HTTP request (where available)
<code>AUTH_USER_NAME</code>	Read the user name from the incoming HTTP request (where available).
<code>GATEWAY_SERVICE_NAME</code>	Name of the gateway service for which the request was received.
<code>MESSAGE_ID</code>	A server-unique ID that is set by the channel and used to correlate messages, for example in trace. You can make this ID globally unique by using the host name as a prefix.
<code>RECEIVING_CHANNEL_NAME</code>	Name of the channel on which the request was received.
<code>REQUEST_SOAP_HEADERS</code>	Retrieve the SOAP headers for an inbound SOAP request. SOAP Headers are returned as a vector of nodes.
<code>RESPONSE_SOAP_HEADERS</code>	Retrieve the SOAP headers for an outbound SOAP response. SOAP Headers are returned as an array of nodes.
<code>RETRY_COUNT</code>	Number of retries for the request. This constant is NOT CURRENTLY USED.
<code>SOAP_HEADERS</code>	Retrieve the SOAP headers for an inbound SOAP request. SOAP Headers are returned as a vector of nodes. This constant is deprecated (use the <code>REQUEST_SOAP_HEADERS</code> constant).

Context Field Constant	Description
TARGET_PORT_NAME	Currently selected port name. This constant is set after service invocation, therefore the constant can only be got by response filters. See also Using a filter to select a target service and port.
TARGET_SERVICE_LOCATION	Gives the location of the currently selected target service WSDL, name and namespace.
TIMEOUT_TIME	Time-out value for the response. This constant is NOT CURRENTLY USED.

## Using a filter to select a target service and port

Use this task to write a filter to select a target service and port.

**Note:** **5.1+** Use of the Routing interface, and of filters, is deprecated. However, you can achieve similar results using Java API for XML-based Remote Procedure Call (JAX-RPC) handlers. For more information, see *JAX-RPC handlers - An alternative to gateway filters*.

When a request is received by the gateway, it must determine what the target service really is, and what port to use to access that service.

The gateway represents each target service as a gateway service. Each gateway service can map to one or more target services, but without filters there is no point in mapping multiple targets because the gateway always picks the first one. If you want to map multiple targets, you also need to write pluggable filters that are configured for each gateway service and that can select the target service.

You write a filter as described in *Writing a filter for the Web services gateway*. Your filter can get the list of potential target services from the Routing service. It needs to select the target service, then call the Routing service to set the target service. This selection clears any prior selection of a target service port. Your filter might also use the Routing service to select the target port for the service invocation.

The Routing service provides a non-standard interface which is defined in the topic *The **Routing** interface*. The implementation of the Routing service is not pluggable.

The Home object for this service must implement the `com.ibm.wsgw.beans.RoutingHome` interface and be located in the Java Naming and Directory Interface (JNDI) in the `websphere/WSGW/Routing` directory.

This is the sequence of events for a filter to determine and set the target service:

1. The filter is called with a `WSIFRequest` request.
2. The filter obtains the list of potential target services from the Routing service.
3. The filter selects the target service.
4. The filter calls the Routing service to set the target service.

Each target service is identified by the unique location of the target service definition, and by the target service identity information (which might not be unique). To select the target service, your filter can either get the table of mappings from target service location to identity information, then choose a target service to use; or it can call the `setSelectedTargetServiceIdentity` method with the required identity string (relying on the definition of the target service identity information). The routing service then selects the first target service it finds for the current gateway service that matches the specified identity information (using `String.equals()`).

When you use routing to set the target service or the target port, the Routing service updates the request context. Because the request context has changed, you then need to set the request object in the `FilterAction` object that you return from the `filterRequest` method (see the filter interface).

## Web services gateway - The Routing interface

**Note:** **5.1+** Use of the Routing interface is deprecated. However, you can achieve similar results using Java API for XML-based Remote Procedure Call (JAX-RPC) handlers. For more information, see JAX-RPC handlers - An alternative to gateway filters.

This topic gives more information on using each of the methods of the Routing interface. It supplements the information given for this interface in the gateway Javadoc.

The Routing interface encapsulates a service that manages routing for requests. Filters can use this service to select the target service and port.

The set methods all return a WSIFRequest object that contains the updated context information.

To get information on the currently selected target service, use the following Routing interface methods:

### **getSelectedTargetServiceLocation**

This method returns the currently selected target service location for the request.

### **getTargetPortName**

This method returns the currently selected target port name for the request.

**Note:** In this version of the gateway, this method always returns blank.

### **getTargetServiceDefinition**

This method returns the currently selected target service definition for the request.

To set the target port, use the following Routing interface method:

### **setTargetPortName**

This method sets the selected target port name for the request.

To get information on all potential target services, use the following Routing interface method:

### **getTargetServices**

This method returns the set of target service names that are mapped by the gateway service on which the request was received.

To set the target service, use either of the following Routing interface methods:

### **setSelectedTargetServiceLocation**

This method sets the selected target service location for the request. The selected port name is reset by this call.

### **setSelectedTargetServiceIdentity**

This method sets the selected target service identity for the request. The target service identity does not need to be unique, therefore the first target service found with matching identity information is set. If no service is found that matches, the method throws a WSGWException exception.

## Capturing Web service invocation information from the Web services gateway

**Note:** **5.1+** Use of the MessageWarehouse interface is deprecated. However, you can achieve similar results using Java API for XML-based Remote Procedure Call (JAX-RPC) handlers. For more information, see JAX-RPC handlers - An alternative to gateway filters.

The Web services gateway has not implemented a service that stores operational messages, but the gateway does contain an interface, the MessageWarehouse interface, to encapsulate such a service. This interface is driven by channels on receipt of requests.

If you have your own system for handling (classifying, storing and retrieving) operational messages, you can use this system to log the gateway operational messages through the MessageWarehouse interface.

The Home object for this service must implement the `com.ibm.wsgw.beans.MessageWarehouseHome` interface and be located in the Java Naming and Directory Interface (JNDI) in the `websphere/WSGW/MessageWarehouse` directory.

## Web services gateway - The MessageWarehouse interface

**Note:** **5.1+** Use of the MessageWarehouse interface is deprecated. However, you can achieve similar results using Java API for XML-based Remote Procedure Call (JAX-RPC) handlers. For more information, see [JAX-RPC handlers - An alternative to gateway filters](#).

This topic provides more information on each method of the MessageWarehouse interface. It supplements the information given for this interface in the gateway Javadoc.

The MessageWarehouse interface encapsulates a service which stores messages for archiving. Channels use this interface to log incoming requests for the purposes of non-repudiation.

A default implementation of this interface is not provided by the Web services gateway. If no implementation is present, the interface is not used.

### logRequest

This method stores a request, with information about the channel and the originator of the request.

The channel calls this method when a request is received, after the user is authenticated and the message decrypted. The channel might provide information to identify the originator of the request, and to identify the channel. The request is logged as a `WSIFMessage` message.

You can also log additional information regarding receipt of the request (for example any associated digital certificates) as `Serializable` objects.

### logResponse

This method stores a response, with information about the channel and the destination of the response.

The channel calls this method when a response is about to be sent, before the response is encrypted. The channel might provide information to identify the destination of the response, and to identify the channel. The response is logged as a `WSIFMessage` message.

You can also log additional information regarding sending of the response (for example any associated digital certificates) as `Serializable` objects.

### logException

This method stores a request, with information about the channel and the originator of the request, when an exception is thrown to the channel during request processing. This method allows the exact request and exception information to be logged before the channel decides the actions to take.

You can also log additional information regarding request and exception (for example any associated digital certificates) as `Serializable` objects.

## Handling exceptions for the Web services gateway

Use this task to help you capture information on exception handling activities for the gateway.

**Note:** **5.1+** Use of the `ExceptionHandler` interface is deprecated.

During normal processing of a Web service invocation, the target service might generate a fault message and pass it to the channel for forwarding to the originator. As far as the gateway is concerned there is no difference between processing a normal output message and processing a fault message.

When an exception occurs during processing of a request, the channel needs some way to decide what to do with the exception. A service is needed that provides a pluggable handler that can look at the message, the exception and other information to decide whether to throw the exception back to the originator, or to construct a fault message.

This service is not provided with the Web services gateway, but the gateway does contain an interface to encapsulate such a service. The **ExceptionHandler** interface allows channels to call an exception handling service, and report the exceptions to a third party for analysis.

The Home object for this service must implement the `com.ibm.wsgw.beans.ExceptionHandlerHome` interface and be located through the Java Naming and Directory Interface (JNDI) in the `websphere/WSGW/ExceptionHandler` directory.

## Web services gateway - The ExceptionHandler interface

**Note:** **5.1+** Use of the ExceptionHandler interface is deprecated.

This topic provides more information on using each of the methods of the ExceptionHandler interface. This documentation supplements the information provided in the gateway Javadoc for the ExceptionHandler interface.

The ExceptionHandler interface encapsulates a service that channels use to react to exceptions that occur during request and response processing in the gateway.

### **handleException**

This method is called by a channel when an exception is caught as a result of message processing.

The return value indicates the action for the channel to take. The actions include:

- Re-throw the original exception.
- Throw a new exception (The handler throws this exception).
- Convert the exception into a fault message.

If no exception handler is installed, the MessageWarehouse (if any) logs the exception, then the exception is rethrown.

---

## Scaling the Web services gateway

You cannot install the gateway into an application server that is part of a cluster. However, you can still scale the gateway by installing an identical gateway on several application servers, then using a plug-in to the front-end HTTP server to balance the load.

The servers that you include in the load-balancing group can be stand-alone application servers, or application servers that are members of a deployment manager cell, or a mixture of the two. Each server in the group can be hosted on a separate node, or all the servers can be hosted on one or two nodes.

If you create each application server in the group as a member of a single deployment manager cell (that is, create all the servers on machines that are nodes of a single cell), you can use the deployment manager tooling for the cell to help you install and update the gateway installation on each application server in the group, no matter where each server is physically hosted.

You configure and maintain an instance of the gateway that is separate from your deployment group as the source configuration for every gateway in the group. You use the back up option to save the source configuration as a **Shared** configuration, then you restore the saved configuration to every gateway in the group.

**5.1** To scale the Web services gateway, complete the steps given in *Scaling the Web services gateway* using unlocked configuration deployment.

## Scaling the Web services gateway using unlocked configuration deployment

You scale the gateway by installing an identical gateway on several application servers to create a scaling group, then using a plug-in to the front-end HTTP server to balance the load across the group.

**5.1** If any (or all) of the application servers in your scaling group are hosted on nodes that are members of a deployment manager cell, the cell cannot also contain other gateway servers that are not part of the scaling group.

You configure an instance of the gateway that is separate from the scaling group, then maintain this gateway as the source configuration for every gateway in the group. You use the back up and restore options to save the source configuration as a **Shared** configuration, then restore the saved configuration to every gateway in the group.

To scale the gateway using unlocked configuration deployment, complete the following steps:

1. Select or create each member of your scaling group of application servers. If you install WebSphere Application Server, include the gateway files in the installed configuration either by accepting the “typical install” option, or by choosing the “custom install” option **Web services > Web services gateway**.
2. Optional: Add the nodes for the application servers in the scaling group to a deployment manager cell. (See “Managing nodes” in the Information Center.) Note that the cell cannot also contain other gateway servers that are not part of the scaling group.
3. Install a gateway on every application server in the scaling group.
4. Select and configure the gateway that is the source configuration for every gateway in the scaling group. Ensure that your source configuration meets the following requirements:
  - This gateway is not hosted on an application server that is part of the group.
  - The WSDL URI for exported definitions is set to indicate the HTTP server that is used by the scaling group.
  - The HTTP channels deployed to this gateway have their end point addresses set to indicate the HTTP server that is used by the scaling group.
  - **5.1** The HTTP channels deployed to this gateway have their end point addresses configured as two-part addresses (see *Deploying channels to the Web services gateway*).
5. Use the back up and restore options to save the source configuration as a **Shared** configuration, then restore the saved configuration to every gateway in the scaling group.
6. Use the WebSphere Application Server caching proxy and load balancer in the front-end HTTP server to balance the load by sharing incoming HTTP requests among the application servers in the scaling group. For detailed information see the information center for WebSphere Application Server Edge components. This information center contains complete documentation for the caching proxy and the load balancer in the following PDF online books:
  - *WebSphere Application Server Concepts, Planning, and Installation for Edge Components*.
  - *WebSphere Application Server Caching Proxy Administration Guide*.
  - *WebSphere Application Server Programming Guide for Edge Components*.

7. Apply all subsequent gateway updates only to the source configuration gateway. This is particularly important with regard to Web services that are published to UDDI by the gateway. When you save a gateway configuration, the record of which Web services are gateway-published to UDDI is not saved (for reasons that are explained in Backing up and restoring UDDI publication links). If you change the gateway that you use as the source for configuration updates, you lose this record.

---

## Securing the Web services gateway

The gateway provides facilities for secure communication between the service requester and the gateway, and between the gateway and the target service.

To configure these facilities for each deployed Web service, see [Enabling Web Services Security \(WS-Security\)](#) for the gateway.

The gateway provides basic authentication and authorization facilities based upon the broader security features of WebSphere Application Server. See [Enabling basic authentication and authorization](#) for the gateway.

The gateway can also invoke Web services that include `https://` in their addresses, if you have configured your Java and WebSphere Application Server security properties accordingly. To check your security property settings, see [Invoking Web services over HTTPS](#).

In many installations, the gateway requires access to the Internet for invoking external Web services. To configure the gateway to work with authenticating proxies, see [Enabling proxy authentication](#) for the gateway.

For hints on solving security-related problems, see [Troubleshooting the Web services gateway](#).

## Enabling Web Services Security (WS-Security) for the gateway

You can configure the gateway for secure transmission of SOAP messages using tokens, keys, signatures and encryption in accordance with the Web Services Security (WS-Security) draft recommendation.

For more information on how WS-Security is implemented in WebSphere Application Server Network Deployment, see [Securing Web services](#). For more information on the approach taken by the gateway to implementing this emerging standard, see [The Web services gateway and WS-Security](#).

The gateway sits between the service requester (the client) and the target Web service. You configure the gateway to act as the target service from the point of view of the client, and as the client from the point of view of the target service. You therefore need to get, from the owning parties, the WS-Security configurations for both the client and the Web service. This information is found in the following files on the owners systems:

- Key stores (.ks and .jceks files).
- Certificate stores (.cer files).
- Security settings (the `ibm-webservicesclient-ext.xml` file for the client, and the `ibm-webservices-ext.xml` file for the Web service).
- Binding information - for example the location of a keystore file on the file system (the `ibm-webservicesclient-bnd.xml` file for the client, and the `ibm-webservices-bnd.xml` file for the Web service).

If the client is hosted on WebSphere Application Server, and the Web service security settings are created using IBM Web services tooling (for example WebSphere Studio Application Developer), then the files that contain the security settings and binding information have the exact file names (\*.xml) noted previously. For clients and Web services from other vendors, these files have different file names.

You need to copy the key store and certificate store files to the gateway file system, and to enter and configure for the gateway the security settings that are contained in the .xmi files. The security settings are entered and configured manually using the gateway administrative user interface. There are tools available (for example WebSphere Studio Application Developer) that can parse the .xmi files for you.

You use the **Gateway > Security** option to configure the security bindings (the tokens, keys, signatures and encryption methods) that are available to the gateway, as described in Configuring the gateway security bindings. You then configure the level of security that applies at each stage of the transmission (and note that different levels of security, including no security, can be applied at each stage):

- From the service requester to the gateway.
- From the gateway to the target service.
- From the target service back to the gateway.
- From the gateway back to the service requester.

For information on how to configure the security levels, see the following topics:

- Editing the service security configuration - how to configure secure communication for this gateway service between the service requester (the client) and the gateway.
- Editing the target service security configuration - how to configure secure communication between the gateway and the target service.

### The Web services gateway and WS-Security

You can configure the gateway for secure transmission of SOAP messages using tokens, keys, signatures and encryption in accordance with the emerging Web Services Security (WS-Security) specification.

In a normal (non gateway) WS-Security scenario, the message flows are as shown in the following figure:

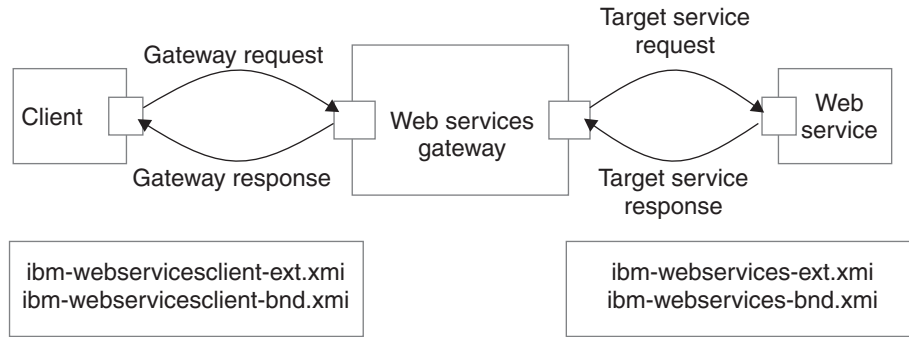

The client generates a request that is handled by the client Web services engine. This engine reads the client security configuration and applies the security defined in the `ibm-webservicesclient-ext.xmi` file to the SOAP message. It gets additional binding information from the `ibm-webservicesclient-bnd.xmi` file (for instance, the location of a keystore on the file system).

On receipt of a SOAP message, the Web services engine on the server refers to the \*.xmi files for the called Web service. In this case, the `ibm-webservices-ext.xmi` file tells the engine what security the incoming message must have (for example, that the body of the message must be signed). If the message does not comply, then it is rejected. The Web services engine verifies any security information, then passes the message on to the Web service that is called.

On the response from server to client, the process is reversed. The Web service \*.xmi files tell the Web services engine what security to apply to the response message, and the client \*.xmi files tell the client engine what security to require in the response message.

When the gateway is introduced, the scenario is more complex. You can think of this scenario as two separate request and response invocations, client to gateway and gateway to target service, as shown in the following figure:

In this scenario, the client application and the Web service are unchanged, and still have the same security settings in their \*.xmi files. However, the gateway is unsecured. Secure SOAP messages cannot travel through the gateway unchanged, and must be processed on receipt. The gateway therefore needs to act as the target service from the point of view of the client, and as the client from the point of view of the target service. In this scenario the security settings for the Web service need to be configured for the view of the service that the gateway presents to the client, and the security settings for the associated gateway target services (remember that there might be multiple target services deployed for a single gateway service) need to be configured with the security settings for the client.

WS-Security settings for the gateway are configured manually using the gateway administrative user interface.

## Configuring the gateway security bindings

You use the **Gateway > Security** option to configure all the security bindings (the tokens, keys, signatures and encryption methods) that are available to the gateway. This information describes the security bindings that are used to secure the SOAP messages that pass between service requesters (clients) and the gateway, and between target services and the gateway.

You receive this security binding information direct from the service requester or target service provider, in the form of an `ibm-webservicesclient-bnd.xmi` file for the client, and an `ibm-webservices-bnd.xmi` file for the Web service. You extract the information from these .xmi files, then manually enter it into the gateway security bindings forms that are described in the following steps.

1. Display the Web services gateway administrative user interface.
2. In the navigation pane, click the following link:

### Gateway

- [Security](#)

The **Configure Gateway Security Bindings** form is displayed.

This form is divided into eight sections, one for each type of security binding. The following comments apply to every section:

- To add a new binding, click **Add new binding type**.
- To amend an existing binding, click on the name of the binding.
- To delete an existing binding, click **remove** next to the name of the binding.
- If you choose to add or amend a binding, then a binding information subform is displayed. Within this form:
  - Help is provided in comments on the subform, and in hover-help next to each field.
  - Fields marked on the subform with an asterisk (\*) are required fields.
  - For some bindings, the fields that are required are different depending on whether you are *adding* or *amending* a binding.
  - Many fields are populated by making a selection from a list.
  - Information entered in one binding information subform often appears in a list in another subform.

- When you have finished entering information for a binding, click **OK**.

3. Add, amend or delete **Signing Information**.

The *signing information* specifies the configuration for digital signature validation and message signing.

If you choose to add or amend a signing information binding, then the **Define Signing Information** form is displayed. In this form you enter a name for the binding (if you are adding a new binding), and the following binding details:

- Signature method
- Digest method
- Canonicalization method
- Signing key name
- Signing Key Locator
- Certificate Path (a choice between trusting *any* certificates, and trusting certificates from a particular *Trust Anchor* and *Certificate Store*).

**Note:** The signing information can also be used for X.509 certificate validation when **Authentication Method** is IDAssertion and **ID Type** is X509Certificate in the gateway service configuration. In such cases, you must fill in the Certificate Path fields only.

4. Add, amend or delete **Encryption Information**.

The *encryption information* specifies the configuration for encrypting and decrypting messages.

If you choose to add or amend an encryption information binding, then the **Define Encryption Information** form is displayed. In this form you enter a name for the binding (if you are adding a new binding), and the following binding details:

- Key locator
- Encryption key name
- Key encryption algorithm
- Data encryption algorithm

5. Add, amend or delete **Trust Anchors**.

A *trust anchor* specifies a list of key store configurations that contain root trusted certificates.

If you choose to add or amend a trust anchor, then the **Define Trust Anchor** form is displayed. In this form you enter a name for the trust anchor (if you are adding a new anchor), and the following details:

- Key store type
- Key store path
- Key store password

**Note:** These configurations are used for certificate path validation of the incoming X.509-formatted security tokens. You create the keystore using the Java command-line tool `keytool`. ( See "Managing digital certificates" in the Information Center.) The `ikeymantool` is not supported.

6. Add, amend or delete **Certificate Stores**.

A *certificate store* specifies a list of untrusted, intermediate certificate files. It is used for certificate path validation of incoming X.509-formatted security tokens.

If you choose to add or amend a certificate store, then the **Define Certificate Store** form is displayed. In this form you enter a name for the certificate store (if you are adding a new store), and the following details:

- Certificate Store Provider

When you amend an existing certificate store, you are given an extra option to add or remove X.509 certificates from the list of certificates that are contained within this store. When you add an X.509 certificate, you specify the full path for the certificate.

7. Add, amend or delete **Key Locators**.

A *key locator* specifies a configuration that is used to retrieve keys for signature and encryption. A key locator class can be customized to retrieve keys from other types of repositories. The default implementation retrieves keys from a keystore.

If you choose to add or amend a key locator, then the **Define Key Locators** form is displayed. In this form you enter a name for the key locator (if you are adding a new key locator), and the following details:

- Classname
- Key store type
- Key store path
- Key store password

When you amend an existing key locator, you are given two extra options:

- Add or remove key entries. For each additional key, you specify:
  - Key name
  - Key alias
  - Key password

**Note:** You do not need to list all the certificate entries as keys; instead, the distinguished name (DN) of the certificate is used as the search key.

- Add or remove additional properties for the configuration. For each additional property, you specify:
  - Property name
  - Property value

8. Add, amend or delete **Trusted ID Evaluators**.

A *trusted ID evaluator* determines whether the identity (ID)-asserting authority is trusted.

If you choose to add or amend a trusted ID evaluator, then the **Define Trusted ID Evaluator** form is displayed. In this form you enter a name for the trusted ID evaluator (if you are adding a new evaluator), and the following details:

- Class name

When you amend an existing trusted ID evaluator, you are given an extra option to add or remove additional properties for the configuration. For each additional property, you specify:

- Property name
- Property value

9. Add, amend or delete **Login Mappings**.

A *login mapping* specifies a configuration for validating security tokens within incoming messages.

If you choose to add or amend a login mapping, then the **Define Login Mapping** form is displayed. In this form you enter a name for the login mapping (if you are adding a new mapping), and the following details:

- Authentication method
- JAAS Configuration name
- Callback handler factory class name
- Token type URI
- Token type local name
- **5.1 +** Nonce maximum age
- **5.1 +** Nonce clock skew

When you amend an existing login mapping, you are given extra options to add or remove additional properties for the *configuration*, and additional properties for the *callback handler factory*. For each additional property, you specify:

- Property name
- Property value

10. Add, amend or delete **Login Bindings**.

A *login binding* specifies a configuration for generating security tokens within outgoing messages.

If you choose to add or amend a login binding, then the **Define Login Binding** form is displayed. In this form you enter a name for the login binding (if you are adding a new binding), and the following details:

- Authentication method
- Callback handler class name
- Token type URI
- Token type local name
- Basic authentication user ID
- Basic authentication password

When you amend an existing login binding, you are given extra options to add or remove additional properties for the *configuration*, and additional properties for the *callback handler*. For each additional property, you specify:

- Property name
- Property value

## Editing the service security configuration

Before you can select the security settings that are applied for an individual Web service, you must configure the gateway security bindings.

For each Web service, you can select the security settings that are applied between the service requester (the client) and the gateway. These settings are specified for each stage of the transmission:

- From the service requester to the gateway (the client request).
- From the gateway back to the service requester (the gateway response).

You receive this security settings information from the service requester and from the target service provider in the following form:

- An `ibm-webservicesclient-bnd.xmi` file for the client, and an `ibm-webservices-bnd.xmi` file for the Web service, from which you process the security bindings information as described in *Configuring the gateway security bindings*.
- An `ibm-webservicesclient-ext.xmi` file for the client, and an `ibm-webservices-ext.xmi` file for the Web service, which contain the information on the levels of security (integrity, confidentiality and identification) that are required when this Web service exchanges messages with a service requester. These levels are also the settings that the gateway needs to apply when it makes the equivalent gateway service available to a service requester.

To set the security settings that are applied between the service requester (the client) and the gateway, complete the following steps:

1. List the gateway-deployed Web services
2. Click the name of a Web service in the list. A form is displayed that you can use to view and modify the current deployment details for this Web service, and add or remove multiple target services.
3. In the **Service Security** section, select the **Edit service security configuration** option.

The service security configuration form is displayed. This form is divided into the following sections:

- **Gateway Security Properties** (the Actor URI)
- **Client Request Security Properties** (integrity, confidentiality and identification settings)
- **Gateway Response Security Properties** (the response Actor URI, and integrity and confidentiality settings)
- **Security bindings** (request bindings and response bindings).

The following comments apply to every section:

- Help is provided in comments on the form, and in hover-help next to each field.
- There are no required fields.
- Many fields are populated by making a selection from a list.

4. In the **Gateway Security Properties** section, set the Actor URI.

If you specify an Actor URI, then only SOAP security headers with this Actor URI are processed.

5. In the **Client Request Security Properties** section, set the following security levels:
  - a. Set the **Integrity** level. Set the parts of the incoming SOAP message that must be signed (the Body, the Timestamp and the Security Token).
  - b. Set the **Confidentiality** level. Set the parts of the incoming SOAP message that must be encrypted (the Body and the Username Token).
  - c. Set the **Identification** level. Set the identification methods that will be accepted (Basic Authentication , Digital Signature, ID Assertion and Lightweight Third Party Authentication (LTPA)). See "Configuring Lightweight Third Party Authentication" in the Information Center.
6. In the **Gateway Response Security Properties** section, set the following security levels:
  - a. Set the Response Actor URI.
 

**Note:** If you specify a Response Actor URI, then the SOAP security header in the response message has this Actor URI.
  - b. Set the **Integrity** level. Set the parts of the response SOAP message that must be signed (the Body and the Timestamp).
  - c. Set the **Confidentiality** level. Set whether or not the Body of the response SOAP message must be encrypted.
7. In the **Security bindings** section, set the Request bindings and the Response bindings to use. You choose these bindings (Signing Information, Encryption Information, Trusted ID Evaluator and Login Mappings) from pull-down lists. The available items in these lists are those that you previously entered, as described in Configuring the gateway security bindings.
8. When you have finished editing the service security configuration, click **Apply changes**.

## Editing the target service security configuration

Before you can select the security settings that are applied for a target Web service, you must configure the gateway security bindings.

For each target Web service, you can select the security settings that are applied between the target Web service and the gateway. These settings are specified for each stage of the transmission:

- From the gateway to the target service (the target service request).
- From the target service back to the gateway (the target service response).

You receive this security settings information from the service requester and from the target service provider - usually in the following form:

- An `ibm-webservicesclient-bnd.xmi` file for the client, and an `ibm-webservices-bnd.xmi` file for the Web service, from which you process the security bindings information as described in Configuring the gateway security bindings.
- An `ibm-webservicesclient-ext.xmi` file for the client, and an `ibm-webservices-ext.xmi` file for the Web service, which contains the information on the levels of security (integrity, confidentiality and identification) that are required when this Web service exchanges messages with a service requester. These settings are also needed by the gateway when it calls the target service on behalf of the service requester.

To set the security settings that are applied between the target service and the gateway, complete the following steps:

1. List the gateway-deployed Web services
2. Click the name of a Web service in the list. A form is displayed that you can use to view and modify the current deployment details for this Web service, and add or remove multiple target services.
3. In the **Target Services** section, click the name of a target Web service in the list. A form is displayed, containing the same fields that you filled in when you added the target service, and also the following additional fields:
  - **Started** (a check box).

- **Enable target service security** (a check box).
  - **Edit target service security configuration.**
4. Select the **Edit target service security configuration** option.  
The target service security configuration form is displayed. This form is divided into the following sections:
    - **Target Service Security Properties** (the Actor URI)
    - **Target Service Request Security Properties** (the Target Actor URI, and the integrity, confidentiality and identification settings)
    - **Target Service Response Security Properties** (integrity and confidentiality settings)
    - **Security bindings** (request bindings and response bindings).
 The following comments apply to every section:
    - Help is provided in comments on the form, and in hover-help next to each field.
    - There are no required fields.
    - Many fields are populated by making a selection from a list.
  5. In the **Target Service Security Properties** section, set the Actor URI.  
If you specify an Actor URI, then only SOAP security headers with this Actor URI are processed.
  6. In the **Target Service Request Security Properties** section, set the following security levels:
    - a. Set the Target Actor URI.  
If you specify a Target Actor URI, then the SOAP security header in the request message has this Actor URI.
    - b. Set the **Integrity** level. Set the parts of the outgoing SOAP message that must be signed (the Body, the Timestamp and the Security Token).
    - c. Set the **Confidentiality** level. Set the parts of the outgoing SOAP message that must be encrypted (the Body and the Username Token).
    - d. Set the **Identification** level. Set the identification methods that will be accepted (None, Basic Authentication, Digital Signature, ID Assertion and Lightweight Third Party Authentication (LTPA)). See "Configuring Lightweight Third Party Authentication" in the Information Center.
  7. In the **Target Service Response Security Properties** section, set the following security levels:
    - a. Set the **Integrity** level. Set the parts of the response SOAP message that must be signed (the Body and the Timestamp).
    - b. Set the **Confidentiality** level. Set whether or not the Body of the response SOAP message must be encrypted.
  8. In the **Security bindings** section, set the Request bindings and the Response bindings to use.  
You choose these bindings (Signing Information, Encryption Information and Login Binding) from pull-down lists. The available items in these lists are those that you previously entered, as described in Configuring the gateway security bindings.
  9. When you finish editing the target service security configuration, click **Apply changes**.

## Enabling basic authentication and authorization for the gateway

In addition to the security options described in Enabling Web Services Security (WS-Security) through the gateway, you can also use the broader security features of WebSphere Application Server to enable basic authentication and authorization.

Basic authentication can be applied at two levels, as described in the following topics:

1. Enabling gateway-level authentication.
2. Enabling Web service operation-level authorization.

For **gateway-level authentication**, you set up a role and realm for the gateway on WebSphere Application Server Web server and servlet container, and define the user ID and password that is used by the gateway to access the role and realm. You also modify the gateway channel applications so that they

only give access to the gateway to service requesters that supply the correct user ID and password for that role and realm. This means that gateway-level authentication must be enabled before you install any channels.

For **operation-level authorization**, you apply security to individual methods in a Web service. To do this, you create an enterprise bean with methods matching the Web service operations. These EJB methods perform no operation and are just entities for applying security. Existing WebSphere Application Server authentication mechanisms can be applied to the enterprise bean. Before any Web service operation is invoked, a call is made to the EJB method. If authorization is granted, the Web service is invoked. Your target Web service is protected by wrapping it in an EAR file, and applying role-based authorization to the EAR file. This process is explained in general terms in *Operation-level security - role-based authorization*.

**Note:**

- If you want to enable operation-level authorization, you must first enable gateway-level authentication.
- After gateway-level authentication is enabled, filters have access to the authentication information for the requester.

The Web services gateway can also invoke Web services that include `https://` in their addresses, if the Java and WebSphere security properties have been configured to allow it. To check your security property settings, see *Invoking Web services over HTTPS*.

For hints on solving security-related problems, see *Troubleshooting the Web services gateway*.

## Enabling gateway-level authentication

A number of default gateway-level authentication settings are included in the gateway. There is a default role of `AuthenticatedUsers` which includes the special group `AllAuthenticatedUsers`. When security is enabled, you must supply a user ID and password to use the gateway administrative interface or invoke a gateway service.

This task covers the three main areas in which you might want to make changes:

- Changing the default gateway-level authentication settings.

If you want to change the default gateway-level authentication settings, you must do so before you install any channels. When you run the script that installs the gateway (*either* into an application server that is part of a deployment manager cell *or* into a stand-alone application server) you also install the following channels:

- Apache SOAP channel 1.
- SOAP over HTTP channel 1.

If you change the default gateway-level authentication settings after you install the gateway, you then need to run the gateway installation program again.

- Enabling gateway-level authentication.

You can enable gateway-level authentication at any time. After gateway-level authentication is enabled, filters have access to the authentication information for the requester.

- Assigning users and groups to roles.

You can assign users and groups to roles at any time.

To enable gateway-level authentication, complete the following steps:

1. To change the default gateway-level authentication settings, choose a tool that is available for your version of WebSphere Application Server:

- **5.1+** The WebSphere Application Server Assembly Toolkit.

Use this tool to complete the following steps:

- a. Set up a role and realm for the gateway on the WebSphere Application Server Web server and servlet container.
  - b. Define the user ID and password that are used by the gateway to access the role and realm.
  - c. Modify the gateway channel applications so that they only give gateway access to service requesters that supply the correct user ID and password for that role and realm.
2. To enable gateway-level authentication, complete the following steps:
    - a. Start the WebSphere Application Server administrative server.
    - b. Start the administrative console.
    - c. In the navigation pane, select **Security > Global Security**.
    - d. In the main pane, on the **Configuration** tab, select the Enabled check box.
    - e. Save the settings.
    - f. Stop then restart the application server.
    - g. Close the administrative console.
  3. To map users to roles using the administrative console, complete the following steps:
    - a. Start the WebSphere Application Server administrative server.
    - b. Start the administrative console.
    - c. In the navigation pane, select **Application > Enterprise Applications > wsgw**. In the main pane, an option to map security roles to users and groups appears in the Additional Properties table.
    - d. Modify the security roles and save the settings.
    - e. Repeat the previous two steps for each enterprise application that you want to modify.
    - f. Stop then restart the application server.
    - g. Close the administrative console.

For more information, see "Assigning users and groups to roles" in the Information Center.

**Note:** The current Jacl installation scripts do not let you assign users to roles as part of installing the gateway into an application server that is part of a deployment manager cell or into a stand-alone application server.

You can now enable operation-level authorization, or install the gateway.

## Enabling operation-level authorization

Use this task to apply security to individual methods in a Web service.

Before you begin this task you must first enable gateway-level authentication.

You can only apply operation-level authorization to a Web service that is already deployed to the gateway with the check box "Authorization Policy - Control access to this service" enabled.

For operation-level authorization you create an enterprise bean with methods matching the Web service operations. These EJB methods perform no operation and are just entities for applying security. You can apply existing WebSphere Application Server authentication mechanisms to the enterprise bean. Before any Web service operation is invoked, a call is made to the EJB method. If authorization is granted, the Web service is invoked.

Your target Web service is protected by wrapping it in an EAR file (*your\_webservice.ear*), then applying role-based authorization to the EAR file. This process is explained in general terms in Operation-level security - role-based authorization. The *your\_webservice.ear* file is then imported into the *wsgwauth.ear* file and the *wsgwauth.ear* file is modified to set the roles and assign them to methods. The modified *wsgwauth.ear* file is then deployed in WebSphere Application Server, and users are assigned to the previously-defined roles.

The wsgwauth.ear file contains an EAR file for each Web service that you protect. The installation version of the wsgwauth.ear file is in *install\_root/installableApps*, where *install\_root* is the root directory for your installation of IBM WebSphere Application Server (by default WebSphere/AppServer). For the first Web service that you protect through operation-level authorization, you copy the installation version of the wsgwauth.ear file and store your copy outside of the application server file system. For each subsequent Web services that you protect, you further modify the same copy of the wsgwauth.ear file.

To enable Web service operation-level authorization, complete the following steps for each Web service that you want to protect:

1. For the first Web service that you protect, make your own copy of the *install\_root/installableApps/wsgwauth.ear* file in a convenient location outside of the application server file system.
2. To create the *your\_webservice.ear* file, complete the following steps:
  - a. Open a command prompt.
  - b. Go to the *install\_root/WSGW/scripts/auth* directory.
  - c. Enter the following command:

```
WSGWAAuthGen location your_webservice
```

where:

- *location* is the Web address for the gateway. This must include the root context.
- *your\_webservice* is the name of the service as deployed in the gateway. This is case-sensitive.

For example

```
WSGWAAuthGen http://host:port/wsgw AddressBook
```

where *host* and *port* are the host name and port number for the application server on which the gateway is installed.

The Web service name and operation name can contain characters (such as a dash (-), period (.) and ampersand (&)) that are disallowed in an EJB class name and method name. Therefore these are translated during the generation process of the *your\_webservice.ear* file. A message appears informing you of any name changes.

The *your\_webservice.ear* file is created in the current directory. There is also a temporary directory *current\_directory/ejb* that you can delete.

3. To finish assigning roles and protecting methods, complete the steps given in the following topics:
  - **5.1+** Using the Assembly Toolkit to enable operation-level authorization.
4. To install the modified copy of the wsgwauth.ear file, complete the following steps:
  - a. Check that the modified wsgwauth.ear file is stored in the convenient location outside of the application server file system that you chose in step 1. Keep the wsgwauth.ear file in this location for subsequent reuse and further modification.
  - b. Start the WebSphere Application Server administrative console.
  - c. In the navigation pane, select **Applications > Install an Application**.
  - d. Use **Install New Application** to install the modified copy of the wsgwauth.ear file. Select the users or groups to assign to the roles when prompted.

**Operation-level security - role-based authorization:** When you build an EAR file, you can define roles and apply them to methods. When you deploy the EAR file, you can assign individual users or groups to roles. You can use this feature of EAR files to add role-based security to your Web service. For example:

1. You have a Web service that controls access to important information, and you want to give read-only access to some users, and write access to others.
2. When you build the EAR file you define two roles: READ and WRITE. You apply the READ role to the getData method and the WRITE role to the writeData method.

3. When you deploy the EAR file in WebSphere Application Server, you assign All Authenticated Users to the READ role and individual users to the WRITE role.
4. When a user tries to access `WebService.getData`, their user name and password is checked by the operating system or by Lightweight Third Party Authentication (LTPA). See "Configuring Lightweight Third Party Authentication" in the Information Center.

**Using the Assembly Toolkit to enable operation-level authorization:**

This task assumes that you have already completed the initial steps for Enabling operation-level authorization.

As is explained in general terms in Operation-level security - role-based authorization, your target Web service is protected by wrapping it in an EAR file and applying role-based authorization to the EAR file. In this task, the EAR file that contains your Web service (*your\_webservice.ear*) is imported into *thewsgwauth.ear* file (which contains all of the protected Web services) and the *wsgwauth.ear* file is modified to set the roles and assign them to methods. This modified *wsgwauth.ear* file is then deployed in WebSphere Application Server and users are assigned to the previously defined roles.

Use the Assembly Toolkit component of the Application Server Toolkit to complete the following steps:

1. Start the Assembly Toolkit then open the J2EE perspective.
2. From the File menu select **File > Import > EAR**, then browse to select your copy of the *wsgwauth.ear* file. Two J2EE projects are created:
  - *wsgwauth*
  - *wsgwauthejb*
3. From the File menu select **File > Import > EAR**, then browse to select the *your\_webservice.ear* file. Two J2EE projects are created:
  - *your\_webservice*
  - *your\_webserviceejb*
4. Select the *your\_webserviceejb* project, then edit the **EJB Deployment Descriptor**. For every security role that you want to create, repeat the following steps:
  - a. On the Assembly Descriptor tab, add the required security role (for example **READER**).
  - b. Follow the on-screen instructions to assign one or more method permissions to the security role.
  - c. Save your changes.
5. To import the *your\_webservice.ear* file into the *wsgwauth.ear* file, complete the following steps:
  - a. Select the *wsgwauth* project, then edit the **EAR Deployment Descriptor**.
  - b. On the Module tab, add the *your\_webserviceejb* enterprise bean from the *your\_webserviceejb* project.
  - c. Save your changes.
6. To ensure that the authorization enterprise bean can reference the newly-imported enterprise bean, complete the following steps to add an EJB reference:
  - a. Select the *wsgwauthejb* project, then edit the **EJB Deployment Descriptor**.
  - b. On the References tab, select **Add EJB Reference**.
  - c. In the Add EJB Reference pane, click **Browse**.
  - d. Select the **Enterprise bean in a different EJB project** radio button, then browse to select the *your\_webserviceejb* enterprise bean.
  - e. Save your changes.
7. To assign users to roles, complete the following steps:
  - a. Select the *wsgwauth* project, then edit the **EAR Deployment Descriptor**.
  - b. On the Security tab, select **Gather**. For every security role that you want to assign, repeat the following steps:

- 1) Select a security role.
- 2) Under **WebSphere Bindings**, select the required access level from the following choices:
  - Everyone
  - All authenticated
  - Users/Groups
8. From the pop-up menu for the wsgwauth project, select **Generate Deploy Code**.
9. Export the wsgwauth project as an EAR file.

You are now ready to install the modified copy of the wsgwauth.ear file as described in the final step of Enabling operation-level authorization.

## Invoking Web services over HTTPS

The Web services gateway can invoke Web services that include `https://` in their addresses, if the Java and WebSphere security properties are configured appropriately. This means that one gateway can send a SOAP over HTTPS message direct to another gateway, rather than exporting services and having clients invoke them using HTTPS.

To enable your gateway to send and receive SOAP/HTTPS messages, confirm that your Java and WebSphere security properties are configured as described in the following steps:

1. Check that there is a copy of the `ibmjssse.jar` file in the `install_root/java/jre/lib/ext` directory where `install_root` is the root directory for your installation of IBM WebSphere Application Server (by default `WebSphere/AppServer`).
2. Edit the `install_root/java/jre/lib/security/java.security` security properties file so that it includes entries for both the Sun security provider and the IBM security provider. For example:

```
security.provider.1=sun.security.provider.Sun
security.provider.2=com.ibm.jsse.IBMJSSEProvider
```

The order is significant. The Sun security provider must come before the IBM provider.

3. Use the WebSphere Application Server administrative console to set up the following equivalent system properties:

```
// truststore location
System.setProperty("javax.net.ssl.trustStore",
 "your_truststore_root_directory/TestSSL/key.jks");
// set truststore password
System.setProperty("javax.net.ssl.trustStorePassword",
 "your_truststore_password");
//use ibm reference implementation
System.setProperty("java.protocol.handler.pkgs",
 "com.ibm.net.ssl.internal.www.protocol");
```

## Enabling proxy authentication for the gateway

The gateway requires access to the Internet for invoking Web services and for retrieval of WSDL files. Many enterprise installations use a proxy server in support of Internet routing, and many proxy servers require authentication before they grant access to the Internet.

This requirement is supported in HTTP messaging by a `Proxy-Authorization` message header that contains encoded user name and password credentials.

For messages passing through the gateway, you can enable and disable proxy authentication, and specify whether the authentication credentials are supplied by the service requester or by the gateway. If you specify *requester-supplied* credentials, the credentials in the HTTP message that the gateway receives are re-instantiated by the gateway in the equivalent message that it sends on to the proxy. If you specify *gateway-supplied* credentials, the gateway ignores any credentials in the incoming HTTP message and supplies its own credentials in the equivalent message that it sends on to the proxy.

In certain circumstances, the gateway also creates and sends its own messages (for example for WSDL retrieval). In these cases the gateway always supplies its own credentials to the authenticating proxy. Therefore even if you enable proxy authentication and specify *requester-supplied* credentials, you must still supply credentials for the gateway.

To enable proxy authentication for the gateway, complete the following steps:

1. Display the Web services gateway administrative user interface.
2. In the navigation pane, click the following link:

**Gateway**

- Configure

The gateway configuration form is displayed:

# IBM Web Services Gateway

## Gateway

- **Configure**
- Security
- Back Up
- Restore
- About

## Services

- List
- Deploy
- Remove

## Channels

- List
- Deploy
- Remove

## Filters

- List
- Deploy
- Remove

## Handlers

- List
- Deploy
- Remove

## UDDI References

- List
- Deploy
- Remove

## Configure Gateway

Namespace URI for services

WSDL URI for exported definitions

## Proxy Configuration

Enable proxy authentication

Proxy user

Proxy password

Use Gateway proxy credentials for invoking WebServices

**Note:** You also use the gateway configuration form to set the namespace URI and WSDL URI for the Web services gateway.

3. Enable the **Enable proxy authentication** check box.
4. In the **Proxy user** field, type the proxy user name for the gateway.

**Note:** If you enable proxy authentication then this field is compulsory, even if you also specify *requester-supplied* credentials as described in a subsequent step.

5. In the **Proxy password** field, type the associated proxy password for the gateway.

**Note:** If you enable proxy authentication then this field is compulsory, even if you also specify *requester-supplied* credentials as described in the next step.

6. To set the **Use Gateway proxy credentials for invoking WebServices** check box, complete one of the following two steps:
  - a. To use *requester-supplied* credentials, clear the **Use Gateway proxy credentials** check box.  
With this setting, each incoming message to the gateway from a service requester is expected to contain a valid Proxy-Authorization HTTP message header. This header is re-instantiated by the gateway in the equivalent message that it sends to the proxy.  
For gateway-initiated messaging, such as WSDL retrieval, the gateway supplies its own credentials in the HTTP messages that it sends to the proxy.
  - b. To use *gateway-supplied* credentials, enable the **Use Gateway proxy credentials** check box.  
With this setting, a trust association is established between the gateway and the authenticating proxy. The gateway supplies its own credentials in all messages that it sends to the proxy, and no user name or password is required from service requesters for invoking Web services.
7. Click **Apply Changes**.
8. To provide the application server in which your gateway is running with machine details for the authenticating proxy and for any internal machines that do not require authentication, set system properties in the Java Virtual Machine (JVM) of WebSphere Application Server by completing the following steps:
  - a. Start the WebSphere Application Server administrative server.
  - b. Start the administrative console.
  - c. In the navigation pane, select **Application Servers > your\_server\_name > Process Definition > Java Virtual Machine > Custom Properties**.
  - d. Set the following properties:
    - **http.proxySet** - Set this to true to tell the application server that it is required to work with an authenticating proxy.
    - **http.proxyHost** - Set this to the machine name of the authenticating proxy.
    - **http.proxyPort** - Set this to the port through which the authenticating proxy is accessed. For example 8080
    - **http.nonProxyHosts** - List the internal machines for which authentication is not required for routing through the proxy. Separate each machine name in the list with a vertical bar (|).
    - This list must include the machine on which the gateway is installed.
  - e. Save the settings.
  - f. Stop then restart the application server.
  - g. Close the administrative console.

---

## Tuning the Web services gateway

For information on tuning the application server, see "Tuning performance" in the Information Center.

To tune the gateway, implement as appropriate the performance enhancements described in the following list:

- **Using the file:///filename notation for locally-stored WSDL files**

If you are passing an address for a WSDL file into the gateway, and the WSDL is stored locally, then use the `file:///filename` notation rather than `drive letter:/filename` because `file:///filename` is more performant.

- **Reviewing the gateway storage requirements**

The amount of storage (memory) that the gateway occupies depends upon the number of resources defined (channels, services, filters and so on). The complexity of the WSDL also affects the storage requirements for each Web service. If the resources you deploy to the gateway grow over time, you should review the heap size accordingly.

Although the Java heap storage requirement for each gateway-deployed service is small, if you deploy a large number of services or services with a large number of targets then you can significantly increase the heap space required to run the gateway efficiently. As well as the heap space required for the resource definitions, a large amount of additional heap space is occupied by resource objects instantiated when each service is invoked. The more deployed services or targets that are invoked, the more heap space is required by the gateway for the reusable elements of those services or targets.

The measurements in the following table estimate the Java heap storage space used by the gateway. These measurements were taken for a heap with these settings:

- **-Xms=256**
- **-Xmx=256**

The Web service defined was a simple case with one operation and no complex types.

Resource	Storage space
Java heap requirements for the gateway with the following resources defined: <ul style="list-style-type: none"> <li>• SOAP over HTTP Channel</li> <li>• One Web service</li> <li>• One basic routing filter</li> </ul>	200KB
Java heap requirements for each additional Web service target defined.	1KB
Java heap requirements for each Web service at runtime (that is, those components that are cached for future use and not eligible for garbage collection).	1.2MB for first invocation 100KB for each additional target invoked

These measurements are provided for illustrative purposes only. To review the gateway storage requirements for your environment, you should take your own measurements for that environment according to the formula described in the next paragraph.

For each Web service defined to the gateway, and for each service subsequently invoked, the Java heap working set is increased. The increase in heap occupancy is a function of base gateway requirements, plus the number of Web services defined, plus the number of unique Web services invoked during the lifetime of the gateway. This can be expressed as:

$$gateway\_server\_storage + n*def + rdef1 + n2*rdef2$$

where:

- *gateway\_server\_storage* is the start-up footprint of the gateway server (not measured in the preceding table), plus any basic deployments of channels, filters and so on (200KB in the preceding table). This startup storage requirement varies depending upon factors such as the initial configuration of the server, and whether or not any other applications are running.
- *n* is the number of Web services (or targets) defined.
- *def* is the number of bytes used for each definition.
- *rdef1* is the number of bytes used for the first invocation of the Web service.
- *n2* is the number of unique Web services (or targets) executed during the lifetime of the gateway.
- *rdef2* is the number of bytes used for each additional invocation of a unique Web service target (that is, those objects for each target that are cached for future use and not eligible for garbage collection).

• **5.1+ Setting application class-loader policy to enable local EJB calls**

Every request that arrives at a channel is passed by the channel to the gateway. This communication is made through either a remote or a local EJB call. If you set the application class-loader policy for the application server to MULTIPLE, then this forces a remote EJB call and the request has to be serialized then de-serialized. If you set the application class-loader policy to SINGLE, then the channel makes a local call and passes the request by reference.

If you set the application class-loader policy to SINGLE, then the gateway can also call a filter through a local EJB call, provided that the filter has been written to provide the local interfaces.

For information on how to write a filter that can be called through a local EJB call, see [Writing a filter for the Web services gateway](#).

- **5.1+** **Enabling selective SOAP parsing**

When you enable selective SOAP parsing for a specific Web service, the gateway only parses the headers of an incoming message for that service. The message body is passed through unchecked. Enable this option, as described in [Deploying Web services to the Web services gateway](#), if you need to optimize the speed at which messages pass through the gateway. For selective SOAP parsing to work, the application class-loader policy for the application server must be set to SINGLE.

For more information, see [Selective SOAP parsing](#).

## Selective SOAP parsing

By default, the gateway parses the whole of every SOAP message that it receives. However, you can speed up the passage of messages through the gateway by choosing selective SOAP parsing.

When you enable selective SOAP parsing for a specific Web service, the gateway only parses the headers of incoming messages for that service. The message body is passed through unchecked.

You enable this option if you need to optimize the speed at which messages pass through the gateway, or if SOAP parsing is already being carried out by another process before the message reaches the gateway (because, with selective SOAP parsing enabled, you can send in a SOAP message that contains an illegal body and it will pass through the gateway without stopping the process or causing an error to be reported).

Even with selective SOAP parsing enabled, you can still use gateway filters that act upon the message body (provided that the message body is legal), because the body is still passing through the gateway even though it is not being parsed.

You enable or disable the selective SOAP parsing option, for each deployed gateway service, as described in [Deploying Web services to the Web services gateway](#).

For selective SOAP parsing to work, you must set the application class-loader policy to SINGLE. For more information, see [Tuning the Web services gateway](#).

Selective SOAP parsing is only supported by the SOAP over HTTP channel. If incoming messages are received on any other channel, they are fully parsed whether or not you have enabled selective SOAP parsing.

---

## Troubleshooting the Web services gateway

This topic provides hints to help you resolve problems you experience when using the Web services gateway.

For information on resolving WebSphere-level problems, see ["Diagnosing and fixing problems"](#) in the Information Center.

For current information available from IBM Support on known problems and their resolution, see the [IBM Support page](#).

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support ["must gather"](#) page.

If you report a gateway-related problem to IBM Service and Support, include the gateway release and build information that is listed under the **About** option of the Web services gateway administrative user interface.

To help you identify and resolve gateway-related problems, use the WebSphere Application Server trace and logging trace and logging facilities. (See "Enabling trace" and "Setting up component trace (CTRACE)" in the Information center.) To enable trace for the gateway, set the application server trace string to `com.ibm.wsgw.*=all=enabled`. If you encounter a problem that you think might be related to the gateway, you can check for error messages in the WebSphere Application Server administrative console, and in the application server `stdout.log` file. You can also enable the application server debug trace to provide a detailed exception dump.

The gateway administrative user interface uses cascading style sheets to lay out its pages, and Javascript to monitor progress and to advise you as you fill in each on-screen form. Your Web browser must therefore support Javascript and cascading style sheets, and it must be configured so that Javascript and style sheets are enabled. This configuration depends on which browser you use. For example for Netscape, you select **Edit > Preferences**, click Advanced in the Category pane, then confirm that the **Enable Javascript** and **Enable style sheets** check boxes are selected.

A list of the gateway run-time system messages, with details of what each message means, is provided in Web services gateway messages.

Here is a checklist of common problems:

- **You are about to install an upgraded gateway, but you do not want to lose your existing gateway configuration.**

When you complete the installation of an upgraded gateway, any previously configured gateway is replaced with an upgraded but empty gateway. To preserve an existing gateway configuration, you need to save the configuration before you upgrade the gateway, then restore the configuration after the upgrade is installed. For detailed instructions see Preserving an existing gateway configuration.

- **You have managed to deploy your Web service in the Web services gateway but you are getting a class cast exception when you invoke the operation which takes an integer parameter.**

Check that your client is using the version of the `soap.jar` file that is supplied in the WebSphere Application Server `/AppServer/lib/app` directory. If you enable trace, you can look in the trace for the request `<SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/" xmlns:xsi="http://www.w3.org/1999/XMLSchema-instance" xmlns:xsd="http://www.w3.org/1999/XMLSchema">`

The gateway expects the 2001 version of the XML schema. Older versions of the `soap.jar` file (including 2.2) generate 1999 schema. If you have the `soap.jar` file that is supplied with WebSphere Application Server in the client class path, you can see 2001 schema in the request.

- **The persistent state of the Web services gateway has become out of sync with the channel applications.**

This mismatch can occur if you remove and reinstall the Apache SOAP channel applications. If this operation is necessary, then either verify that all corresponding channels configured with the Web services gateway are removed, or remove and reinstall the Web services gateway at the same time.

**Note:** The Web services gateway application (`wsgw.ear`) must be installed before the channel and filter applications. If the gateway application needs to be reinstalled, all channels and filters must be uninstalled first, then reinstalled after the gateway application.

- **5.1+ You get listener port time out errors when large messages are passed using the synchronous SOAP over JMS channel.**

As with any synchronous channel, time out errors can occur. To minimize the frequency of time out errors, increase the time out settings for the channel. If the problem persists, then disable trace and logging trace and logging for the gateway (by setting the application server trace string to `com.ibm.wsgw.*=all=disabled`).

- **You are getting SOAP fault messages, but cannot determine the precise problem from the fault message.**

If you receive a SOAP fault message with a faultstring that is just the value of one of the parameters of the invocation, that means the parameter value is not valid. For example if you have a service that expects an int parameter and you send it a message containing the value “1.1”, then the fault message you receive contains 1.1 as the fault string:

```
<faultcode>SOAP-ENV:Client</faultcode>
<faultstring>1.1</faultstring>
```

This message is consistent with Apache SOAP behavior, and is not correctable by the gateway.

If you receive a SOAP fault message containing an element that is not present in the WSDL for the target service, then the error message thrown can be difficult to identify. There are two possible scenarios:

- The WSDL is deployed to use **Generic Classes**. In this case the returned SOAP message contains an `IllegalArgumentException` exception. For example:

```
[Attributes={}] [faultCode=SOAP-ENV:Server]
[faultString=com.ibm.wsgw.WSGWException:
WSGW0043E: Exception while executing
 operation createEntry service ExchangeService.
Exception: org.apache.wsif.WSIFException: SOAPException:
SOAP-ENV:ClientNo mapping found for 'com.ibm.jrom.JROMValue'
using encoding style 'http://schemas.xmlsoap.org/soap/encoding/';
nested exception is:
 [SOAPException: faultCode=SOAP-ENV:Client; msg=No mapping found for
'com.ibm.jrom.JROMValue' using encoding style
'http://schemas.xmlsoap.org/soap/encoding/';
targetException=java.lang.IllegalArgumentException:
No mapping found for 'com.ibm.jrom.JROMValue' using encoding style
'http://schemas.xmlsoap.org/soap/encoding/'.]]
[faultActorURI=/wsgwsoap1/soaprprouter]
...
```

- The WSDL is deployed to use **Deployed Classes**. In this case an empty message is returned. For example:

```
[Attributes={}] [faultCode=null] [faultString=null] [faultActorURI=null]
[DetailEntries=] [FaultEntries=]
```

These messages are consistent with Apache SOAP behavior, and are not correctable by the gateway.

- **When you are specifying the security settings that are applied between the service requester (the client) and the gateway, you set Identification to Digital Signature. When you click Apply Changes, the following “AuthMethod signature is not valid” error message is displayed:**

```
WSGW0009E: Failed to deploy service. Exception: Error change service properties:
com.ibm.wsspi.wssecurity.SoaSecurityException: WSEC0105E: LoginConfig: AuthMethod Signature is not valid.
```

This problem only occurs when you set **Identification** to **Digital Signature**. The problem is caused by a mismatch between the request bindings and the response bindings. For example, you might have set **Request Sender** signing information on the request bindings instead of **Request Receiver**, or **Response Receiver** on the response bindings instead of **Response Sender**. To fix the problem, set matching request and response bindings. For instructions on setting these parameters, see

- Request receiver binding collection
- Response sender binding collection
- Request sender binding collection
- Response receiver binding collection

- **When you run secured Web services through a Web services gateway using LTPA authentication with a certificate store defined, an “Unable to build a valid CertPath” error similar to the following is displayed:**

```
[10/23/03 12:31:40:393 CDT] 78a54799 enterprise I
com.ibm.ws.webservices.engine.enterprise
TRAS0014I: The following exception was logged WebServicesFault
faultCode: {http://schemas.xmlsoap.org/ws/2003/06/secext}InvalidSecurityToken
faultString: WSEC5085E: Unable to build a valid CertPath:
java.security.cert.CertPathBuilderException:
PKIXCertPathBuilderImpl could not build a valid CertPath.;
internal cause is: java.security.cert.CertPathValidatorException:
The certificate issued by CN=Int CA2, OU=TRL, O=IBM, ST=Kanagawa, C=JP is not trusted;
internal cause is: java.security.cert.CertPathValidatorException: Certificate chaining error
```

This problem occurs when one of the defined certificate stores on the Web services gateway administrative client is missing the certificate path.

To correct this problem,

1. Add the certificate path to the certificate store configuration. For example, if you are using the sample certificate store from WebSphere Application Server, the path is:

```
X509 Certificate Path: /usr/WebSphere/AppServer/etc/ws-security/samples/intca2.cer
```

2. Run the client again.

- **When you run secured Web services through the Web services gateway, a “Failed authentication” error similar to the following is displayed:**

```
[10/3/03 21:35:48:597 CDT] 33c558 enterprise I
com.ibm.ws.webservices.engine.enterprise TRAS0014I: The following exception was
logged WebServicesFault
faultCode: {http://schemas.xmlsoap.org/ws/2003/06/secext}FailedAuthentication
faultString: WSEC5078E: Login failed: javax.security.auth.login.LoginException:
java.lang.NullPointerException
at com.ibm.wsspi.wsssecurity.auth.module.WSSecurityMappingModule._login(WSSecur
ityMappingModule.java:152)
```

The problem occurs when the Web services gateway does not enable global security and there is no LDAP user registry information to authenticate the incoming user login.

To correct this problem, enable global security on the Web services gateway application server using the same LDAP user registry that the deployment manager uses. See Enabling gateway-level authentication for more information.

**Note:** Before enabling global security on the Web services gateway, you need to uninstall the Web services gateway channels and applications, then re-install them after security is enabled.

- **When you run secured Web services through the Web services gateway, a “Failed login” error similar to the following is displayed:**

```
WSEC5078E: Login failed: com.ibm.websphere.security.auth.WSLoginFailedException:
AuthenLoginModule: Authentication failed reason = 2
```

This problem occurs when single sign-on is enabled and the same password is used on both the deployment manager and the Web services gateway application server. The login fails even though the deployment manager and the Web services gateway application server are both enabled with security, with the same LDAP user registry and with the same LTPA password. The problem occurs because the key that is generated and passed between the services is randomly generated, and is therefore different for each server even though the same password is used.

To correct this problem, export the key from one cell then import it into another.

- **You are enabling operation-level authorization, but when you install wsgwauth.ear, an error message appears in the WebSphere Application Server administrative console detailing a Java Naming and Directory Interface (JNDI) problem.**

Check that you entered, in the “EJB References” for the authorization session bean, the correct JNDI name of the imported Web service enterprise bean. Note that this home is case sensitive.

- 5.1+** You get JNDI lookup errors when you use the same names for JMS messaging queues and queue connection factories that run on application servers on different machines. You should not use the same names for messaging queues and queue connection factories that run on application servers on different machines, because the Web Services Invocation Framework (WSIF) (which the gateway uses for service invocation) always looks first for JMS destinations locally, and only uses the full JNDI reference if it cannot find the destination locally. If you deploy to the gateway a Web service that is hosted on a remote machine, and the same names are used for messaging queues and queue connection factories on the remote machine and on the machine on which the gateway is hosted, then WSIF finds and uses the local queues even if the remote JNDI destination is provided in full in the WSDL service definition.
  - You are trying to have a Web services gateway send a SOAP/HTTPS message to another Web services gateway, and you are receiving a MalformedURLException error.**

The Web services gateway can invoke Web services that include `https://` in their addresses, if the Java and WebSphere security properties are configured accordingly. To check your security property settings, see the topic Invoking Web services over HTTPS
  - You clear 'Authorization Policy - Control access to this service' from the deployment details for a Web service, and you find the service no longer works.**

A number of tasks are required to disable security. Clearing the check box for 'Authorization Policy - Control access to this service' still leaves WebSphere Application Server security in place, so basic authentication might still be required.

To disable security fully, use the WebSphere Application Server administrative console Security Center to disable Global Security.
  - You experience problems with handling Document style SOAP messages.**

If you are using the Apache SOAP channel, then the SOAP message format must be RPC style. To handle Document style SOAP messages, use the SOAP over HTTP channel (which supports both RPC style and Document style SOAP messages).
  - You experience problems with handling SOAP messages with attachments.**

To handle SOAP messages with attachments, use the SOAP over HTTP channel.
  - You experience problems with a Web service that uses complex data types. The same service works fine, when not using the gateway.**

You need to do one of two things to support Web services that use complex types in the Web services gateway:

    - Set the message part representation for the service to **Generic classes**.
    - Set the message part representation for the service to **Deployed Java classes**, and make the original classes available to the application server (either by updating the class path or by putting the JAR file somewhere like `install_root/lib/app`, where `install_root` is the root directory for your installation of IBM WebSphere Application Server). If you do not have the original classes, you can use `wsdl2java` to generate Java applications that can contain values of the complex type for the service, then compile the beans into a JAR file and make this file available to the application server.

For more information on the factors to consider when choosing between these options, see Data type representation - Choosing between Generic classes and Deployed Java classes.
- Note:**
- If your Web service has non-bean parameters (that is, it requires a custom serializer and deserializer) then it is not supported by the current release of the gateway.
  - Not all complex types that are expressible in XML schema are supported by the current release of the gateway. For more information, see Web services gateway - Supported types.
  - See also Complex data types - mapping namespaces to packages.
- You develop a filter as described in Writing a filter for the Web services gateway. When you deploy the filter to the gateway, the following error message appears: WSGW0035E: Filter context version 5 not supported.** You are trying to deploy your filter to a server other than WebSphere Application Server Enterprise Version 5 or WebSphere Business Integration Server Foundation Version

5.1. Your filter uses the gateway WorkArea to maintain context, and the gateway WorkArea is only available with IBM WebSphere Application Server Enterprise Version 5 or WebSphere Business Integration Server Foundation Version 5.1.

## Web services gateway messages

This topic contains a list of the Web services gateway run-time system messages, with details of what each message means.

WebSphere system messages are logged from a variety of sources, including application server components and applications. Messages logged by application server components and associated IBM products start with a unique message identifier that indicates the component or application that issued the message.

For more information about the message identifier format, see the topic "Message reference" in the Information Center.

**GWIN0003I: Looking for {childtype} {childname} under {parenttype} {parentname}. Values are: {0}**

**Explanation:** Gateway installation message from file setupwsgw.jac].

**User Response:**

**GWIN0004I: Looking for {childtype} {childname} under {parenttype} {parentname} and {parenttype2} {parentname2}. Values are: {0}**

**Explanation:** Gateway installation message from file setupwsgw.jac].

**User Response:**

**GWIN0005I Conflict found with existing {childtype} {childname}. Values are: {0}**

**Explanation:** Gateway installation message from file setupwsgw.jac].

**User Response:**

**GWIN0012I: Not creating requested {childtype}. Value is: {0}**

**Explanation:** Gateway installation message from file setupwsgw.jac].

**User Response:**

**GWIN0006I: Seeking {parenttype} with requested id of {parentname}. Values are: {0}**

**Explanation:** Gateway installation message from file setupwsgw.jac].

**User Response:**

**GWIN0007I: Seeking {parenttype} with requested id of {parentname} under {parenttype2} {parentname2}. Values are: {0}**

**Explanation:** Gateway installation message from file setupwsgw.jac].

**User Response:**

**GWIN0008I: Attempting to create {childtype} under {parenttype} of {parentID}. Values are: {0}**

**Explanation:** Gateway installation message from file setupwsgw.jac].

**User Response:**

**GWIN0009I: Create command that will be issued is: {0}**

**Explanation:** Gateway installation message from file setupwsgw.jac].

**User Response:**

**GWIN0010I: {childtype} {childId} was successfully created. Values are: {0}**

**Explanation:** Gateway installation message from file setupwsgw.jac].

**User Response:**

**GWIN0101I: Attempting to save new configuration.**

**Explanation:** Gateway installation message from file setupwsgw.jac].

**User Response:**

**GWIN0102I: Changes saved successfully.**

**Explanation:** Gateway installation message from file setupwsgw.jac].

**User Response:**

**GWIN0103I: Changes were not saved on this call.**  
**Explanation:** Gateway installation message from file setupwsgw.jac1.  
**User Response:**

**GWIN0014I: Looking for builtin\_rra.**  
**Explanation:** Gateway installation message from file setupwsgw.jac1.  
**User Response:**

**GWIN0015I: List for J2CResourceAdapter returned {0} members. Value is: {1}**  
**Explanation:** Gateway installation message from file setupwsgw.jac1.  
**User Response:**

**GWIN0049I: List for Applications returned {0} members. Value is: {1}**  
**Explanation:** Gateway installation message from file setupwsgw.jac1.  
**User Response:**

**GWIN0016I: Hunting J2CResourceAdapter associated with Node {nodename}. Value is: {0}**  
**Explanation:** Gateway installation message from file setupwsgw.jac1.  
**User Response:**

**GWIN0017I: Using {rraID} as builtin\_rra. Value is: {0}**  
**Explanation:** Gateway installation message from file setupwsgw.jac1.  
**User Response:**

**GWIN0018I: Using provider class of {implclass} with a classpath of {clpath}. Values are: {0}**  
**Explanation:** Gateway installation message from file setupwsgw.jac1.  
**User Response:**

**GWIN0019I: Installing to server {servername}, node {nodename} using database type of {dbtype}. Values are: {0}**  
**Explanation:** Gateway installation message from file setupwsgw.jac1. The database parameter is not used in this version of the gateway.  
**User Response:**

**GWIN0023I: Checking for installed WSGW of name {appname}. Value is: {0}**  
**Explanation:** Gateway installation message from file setupwsgw.jac1.  
**User Response:**

**GWIN0025I: ApplicationManager not running, so application will not need to be stopped.**  
**Explanation:** Gateway installation message from file setupwsgw.jac1.  
**User Response:**

**GWIN0026I: Stopping application of name {0}. Value is: {1}**  
**Explanation:** Gateway installation message from file setupwsgw.jac1.  
**User Response:**

**GWIN0027W: stopApplication command for application {0} caught exception Exc. Application might not have been running on this server. Values are: {1}**  
**Explanation:** Gateway installation message from file setupwsgw.jac1.  
**User Response:**

**GWIN0028I: Application {0} stopped successfully. Value is: {1}**  
**Explanation:** Gateway installation message from file setupwsgw.jac1.  
**User Response:**

**GWIN0029I: Removing application {0}. Value is: {1}**  
**Explanation:** Gateway installation message from file setupwsgw.jac1.  
**User Response:**

**GWIN0030I: Application {0} removed successfully. Value is: {1}**  
**Explanation:** Gateway installation message from file setupwsgw.jac1.  
**User Response:**

**GWIN0050I: Install of WSGW application {0} successful. Value is: {0}**  
Explanation: Gateway installation message from file setupwsgw.jac].  
User Response:

**GWIN0051I: Application Manager {0} found. Value is: {1}**  
Explanation: Gateway installation message from file setupwsgw.jac].  
User Response:

**GWIN0031I: Adding resource bundles to repository.**  
Explanation: Gateway installation message from file setupwsgw.jac].  
User Response:

**GWIN0035I: Url prefix found. Updating it to discoveryURL. Value is: {0}**  
Explanation: Gateway installation message from file setupwsgw.jac].  
User Response:

**GWIN0038I: ws.ext.dir processing starting.**  
Explanation: Gateway installation message from file setupwsgw.jac].  
User Response:

**GWIN0013I: JVM is: {0}**  
Explanation: Gateway installation message from file setupwsgw.jac].  
User Response:

**GWIN0040I: Out of {0} properties we located {1} matches at positions {poslist}. Values are: {2}**  
Explanation: Gateway installation message from file setupwsgw.jac].  
User Response:

**GWIN0042I: SYSPROP is: {0}**  
Explanation: Gateway installation message from file setupwsgw.jac].  
User Response:

**GWIN0043I: ws.ext.dir has been set with new sysprop. Value is: {0}**  
Explanation: Gateway installation message from file setupwsgw.jac].  
User Response:

**GWIN0107I: Changes saved successfully.**  
Explanation: Gateway installation message from file setupwsgw.jac].  
User Response:

**GWIN0044I: ws.ext.dir update skipped, required changes already present.**  
Explanation: Gateway installation message from file setupwsgw.jac].  
User Response:

**GWIN0045I: ws.ext.dir processing step complete.**  
Explanation: Gateway installation message from file setupwsgw.jac].  
User Response:

**GWIN0047I: Issuing nodeSync.**  
Explanation: Gateway installation message from file setupwsgw.jac].  
User Response:

**GWIN0048I: WSGW successfully installed.**  
Explanation: Gateway installation message from file setupwsgw.jac].  
User Response:

**GWIN0052I: WSGW successfully installed. Please restart server {0} to activate configuration changes. Value is: {1}**  
Explanation: Gateway installation message from file setupwsgw.jac].  
User Response:

**GWIN0053I: WSGWResourceBundles.jar file was not added to the repository - might already exist.**  
Explanation: Gateway installation message from file setupwsgw.jac].

**User Response:**  
**GWIN0054I: Building new props.**  
**Explanation:** Gateway installation message from file setupwsgw.jacl.

**User Response:**  
**GWIN6001E: Incorrect number of arguments passed to script.**  
**Explanation:** Gateway installation message from file setupwsgw.jacl.

**User Response:**  
**GWIN6002E: Usage: wsadmin -f setupwsgw.jacl <deployMgrPath> <serverName> <nodeName> <dbName> <dbuserid> <db2password> <db2zipLocation>**  
**Explanation:** Gateway installation message from file setupwsgw.jacl. The database parameters are not used in this version of the gateway.

**User Response:**  
**GWIN6003E: <db2userid> <db2password> <db2zipLocation> only required for db2 jdbc provider.**  
**Explanation:** Gateway installation message from file setupwsgw.jacl. Not used in this version of the gateway.

**User Response:**  
**GWIN6005E: Removal of {childtype} {childname} caught exception Exc. Values are: {0}**  
**Explanation:** Gateway installation message from file setupwsgw.jacl.

**User Response:**  
**GWIN6006E: An exception Exc occurred while creating {childtype}. Values are: {0}**  
**Explanation:** Gateway installation message from file setupwsgw.jacl.

**User Response:**  
**GWIN6008E: Unable to find requested {parenttype} of {parentname}. Values are: {0}**  
**Explanation:** Gateway installation message from file setupwsgw.jacl.

**User Response:**  
**GWIN6009E: List command for J2CResourceAdapter caught exception Exc. Value is: {0}**  
**Explanation:** Gateway installation message from file setupwsgw.jacl.

**User Response:**  
**GWIN6010E: No J2CResourceAdapter objects available.**  
**Explanation:** Gateway installation message from file setupwsgw.jacl.

**User Response:**  
**GWIN6012E: Uninstall of application {0} caught exception Exc. Values are: {1}**  
**Explanation:** Gateway installation message from file setupwsgw.jacl.

**User Response:**  
**GWIN6013E: Install of WSGW application caught exception Exc. Value is: {0}**  
**Explanation:** Gateway installation message from file setupwsgw.jacl.

**User Response:**  
**GWIN6014E: Could not get JVM.**  
**Explanation:** Gateway installation message from file setupwsgw.jacl.

**User Response:**  
**GWIN6017E: Cannot find nodeSync MBean.**  
**Explanation:** Gateway installation message from file setupwsgw.jacl.

**User Response:**  
**GWIN6018E: nodeSync failed. WSGW applications may not be fully installed.**  
**Explanation:** Gateway installation message from file setupwsgw.jacl.

**User Response:**  
**GWIN6019E: Install of WSGW application {0} caught exception Exc. Values are: {1}**  
**Explanation:** Gateway installation message from file setupwsgw.jacl.

**User Response:**

**GWIN6020E: <dbName> only required for DB2/Cloudscape.**

**Explanation:** Gateway installation message from file setupwsgw.jacl. Not used in this version of the gateway.

**User Response:**

**GWIN6021E: Use all forward slashes (/) to avoid problems with escaping back slashes (\\).**

**Explanation:** Gateway installation message from file setupwsgw.jacl.

**User Response:**

**GWIN6022E: Example: wsadmin -f setupwsgw.jacl C:/WebSphere/DeploymentManager  
bunny\_server1 bunny WSGWDB db2admin db2passwd C:/SQLLIB/java/db2java.zip**

**Explanation:** Gateway installation message from file setupwsgw.jacl. The database parameters are not used in this version of the gateway.

**User Response:**

**GWIN6101E: Error saving configuration, changes not saved due to exception Exc. Value is: {0}**

**Explanation:** Gateway installation message from file setupwsgw.jacl.

**User Response:**

**WSGW0001E: Channel name {0} from gateway configuration differs from that in JNDI: {1}**

**Explanation:** The name specified for the channel does not match the name of the channel as defined within the EAR file.

**User Response:** Ensure that the channel name is specified correctly

**WSGW0002E: Error storing endpoint address. Exception: {0}**

**Explanation:** An unexpected exception occurred when storing the endpoint address for a channel.

**User Response:** Contact IBM Support

**WSGW0003E: Error retrieving endpoint address. Exception: {0}**

**Explanation:** An unexpected exception occurred when retrieving the endpoint address for a channel.

**User Response:** Contact IBM Support

**WSGW0004E: Not used**

**Explanation:**

**User Response:**

**WSGW0005E: Error retrieving channel name. Exception: {0}**

**Explanation:** An unexpected exception occurred when retrieving the channel name from JNDI.

**User Response:** Contact IBM Support

**WSGW0006E: Error deploying service to {1}. Exception: {0}**

**Explanation:** An unexpected error occurred deploying the service to the given component.

**User Response:** This error may be caused by a previous failure. Try redeploying the service using a different gateway service name. If that fails, reinstalling the channel and gateway applications may remove the problem.

**WSGW0007E: Error getting endpoint URL from channel {0}. Exception: {1}**

**Explanation:** An unexpected error occurred generating the endpoint URL for the given channel.

**User Response:** Contact IBM Support

**WSGW0008E: Could not determine default port name for target service {0}**

**Explanation:** There are no ports in the WSDL defined for the target service that are supported by currently available WSIF providers or there is an error in the WSDL file associated with the port definition or a namespace it uses.

**User Response:** Either ensure that a WSIF provider is correctly configured for the port in the WSDL, or ensure that the WSDL contains correctly specified port information.

**WSGW0009E: Failed to deploy service. Exception: {0}**

**Explanation:** An unexpected error occurred trying to deploy the service.

- User Response:** Contact IBM Support
- WSGW0010E: The namespaceURI attribute cannot be changed when there are active services**  
**Explanation:** The namespaceURI is used to generate WSDL for gateway services. If this global setting is changed then current WSDL becomes invalid.
- User Response:** Either remove all channels or all gateway services from the gateway configuration and retry the change.
- WSGW0011E: Not used**  
**Explanation:**
- User Response:**
- WSGW0012E: Not used**  
**Explanation:**
- User Response:**
- WSGW0013E: Could not locate home {0}. Exception: {1}**  
**Explanation:** The specified home location could not be found in JNDI.
- User Response:** Ensure that the home location is specified correctly, and that it appears in JNDI.
- WSGW0014W: Could not access local home {0}. Attempting remote home {1}.**  
**Explanation:** The local home was found in JNDI but could not be used as the application server “Application classloader policy” is set to “Multiple”. The remote home will be used for this component.
- User Response:** Ensure that the application server “Application classloader policy” is set to “Single” to allow the gateway to use local interfaces. Ignore this message if you require “Application classloader policy” setting to be “Multiple”.
- WSGW0015E: Could not create instance of class {0}. Exception: {1}**  
**Explanation:** The gateway failed to create an instance of the specified Java class.
- User Response:** Ensure that the Java class has a public constructor with no parameters.
- WSGW0016E: Could not locate class {0}. Exception: {1}**  
**Explanation:** The gateway failed to locate the specified Java class.
- User Response:** Ensure that the Java class is visible to the gateway application’s classloader.
- WSGW0017E: Not used**  
**Explanation:**
- User Response:**
- WSGW0018E: Not used**  
**Explanation:**
- User Response:**
- WSGW0019E: Failed to clone definition. Exception: {1}**  
**Explanation:** An unexpected error occurred cloning a WSDL definition.
- User Response:** Contact IBM Support
- WSGW0020E: Error while loading mapped type class {0}. Exception: {1}**  
**Explanation:** An error occurred while trying to load the given Java class which represents a type in the deployed WSDL for a target service.
- User Response:** Ensure that the Java class is visible to the gateway application’s classloader.
- WSGW0021E: Expected WSDL definition to contain a <wsdl:type> element with a schema from one of the '{0}', '{1}', or '{2}' namespaces**  
**Explanation:** Schema types in WSDL definitions must be declared using one of the specified XML schema namespaces.
- User Response:** Update the WSDL definition to use the appropriate namespace.
- WSGW0022E: Unexpected Schema->Java problem when parsing WSDL file. Exception: {0}**  
**Explanation:** An unexpected exception occurred when parsing a WSDL file. This may be due to unsupported elements in the WSDL.

**User Response:** Contact IBM Support

**WSGW0023E: Unexpected Schema->JROM problem when parsing WSDL file. Exception: {0}**

**Explanation:** An unexpected exception occurred when parsing a WSDL file. This may be due to unsupported elements in the WSDL.

**User Response:** Contact IBM Support

**WSGW0024E: Channel {0} cannot be removed because it is being used by a deployed service**

**Explanation:** channels can only be removed when they are not in use by gateway services.

**User Response:** Remove the channel from gateway services to which it is deployed before removing the channel.

**WSGW0025E: Target service identity cannot be specified as null**

**Explanation:** A target service can only be selected using a non-null valid for the identity.

**User Response:** Modify the calling code to ensure that the target service identity value is never null.

**WSGW0026E: Invalid gateway service name {0}. The name must be a valid XML schema NCNAME.**

**Explanation:** The name specified for the gateway service does not conform to the required definition.

**User Response:** Correct the gateway service name so that it is a valid XML schema NCNAME.

**WSGW0027E: Port {0} does not exist for target service {1}**

**Explanation:** The requested port does not exist for the target service.

**User Response:** Ensure that a valid port is requested, or update the target service WSDL to contain a port of the requested name.

**WSGW0028E: No binding for port {0} for target service {1}**

**Explanation:** The requested port for the target service does not have a binding defined in the WSDL definition of the service.

**User Response:** Ensure that the target service WSDL has a binding for the requested port, or use a different port name.

**WSGW0029E: No portType for binding {0} for port {1} for target service {2}**

**Explanation:** The requested port for the target service does not have a portType defined in the WSDL definition of the service.

**User Response:** Ensure that the target service WSDL has a portType for the requested port, or use a different port name.

**WSGW0030E: Not used**

**Explanation:**

**User Response:**

**WSGW0031E: Channel name {0} already exists**

**Explanation:** The name specified for the channel is the same as that of a channel that is currently deployed.

**User Response:** Choose a different name for the channel, or remove the existing channel of the given name.

**WSGW0032E: Channel name {0} not found**

**Explanation:** No channel is currently deployed with the given name.

**User Response:** Use the name of a channel that is currently deployed.

**WSGW0033E: Filter {0} cannot be removed because it is being used by a deployed service**

**Explanation:** Filters can only be removed when they are not in use by gateway services.

**User Response:** Remove the filter from gateway services to which it is deployed before removing the filter.

**WSGW0034W: Invocation of filter {0} failed. Exception: {1}**

**Explanation:** An unexpected exception was thrown during processing of the given filter.

**User Response:** Contact IBM Support

**WSGW0035E: Filter context version {0} not supported**

**Explanation:** The context version that the filter requires is not supported by this version of the gateway.

**User Response:** Ensure that the filter is requesting the correct context version. It may be necessary to upgrade the gateway to support the filter.

**WSGW0036E: Target service identity information {0} not matched for gateway service {1}**

**Explanation:** A target service was requested by identity, but the identity information does not match any currently deployed target service.

**User Response:** Ensure that the identity information is correct, and that there is a target service deployed to the given gateway service with the right identity information.

**WSGW0037E: Filter name {0} already exists**

**Explanation:** The name specified for the filter is the same as that of a filter that is currently deployed.

**User Response:** Choose a different name for the filter, or remove the existing filter of the given name.

**WSGW0038E: Filter name {0} not found**

**Explanation:** No filter is currently deployed with the given name.

**User Response:** Use the name of a filter that is currently deployed.

**WSGW0039E: Error loading state from {0}. Exception {1}**

**Explanation:** An unexpected exception occurred loading the state of the gateway from the given location.

**User Response:** Ensure that the given location is visible to the gateway application.

**WSGW0040E: Failed to convert definition to string. Exception: {0}**

**Explanation:** An unexpected exception occurred converting a WSDL definition into a string in order to display it or return it to an application.

**User Response:** Contact IBM Support

**WSGW0041E: Failed to save state. Exception {0}**

**Explanation:** An unexpected exception occurred when saving the state of the gateway.

**User Response:** Contact IBM Support

**WSGW0042W: No target services available to get service definition**

**Explanation:** A request was made for the WSDL definition for the gateway service, however no target services have been defined for the gateway service, so it is not possible to generate a WSDL definition.

**User Response:** Deploy one or more target services to the gateway service.

**WSGW0043E: Exception while executing operation {0} service {1}. Exception: {2}**

**Explanation:** An unexpected exception occurred when passing a request on to a target Web service.

**User Response:** Ensure that the gateway service and target service are correctly deployed (using the correct message part representation). Ensure that the target service is available and responds correctly to direct requests (i.e. not through the gateway).

**WSGW0044E: Filter position {0} invalid**

**Explanation:** The specified position for addition or removal of the filter was not valid.

**User Response:** Ensure a valid value is specified. The value should be -1, 0 or a positive integer.

**WSGW0045E: Filter not found in list**

**Explanation:** An attempt was made to remove a filter from a gateway service specifying -1 as the index, but the filter is not in the list at all.

**User Response:** Ensure that the correct filter is specified.

**WSGW0046E: Channel {0} already defined for gateway service {1}**

**Explanation:** The given channel has already been defined for the gateway service.

**User Response:** Ensure that the correct channel name is specified.

**WSGW0047E: Channel {0} not defined for gateway service {1}**

**Explanation:** The channel cannot be removed from the gateway service as it is not currently defined for the gateway service.

**User Response:** Ensure that the correct channel name is specified.

**WSGW0048E: UDDI reference {0} already defined for gateway service {1}**

**Explanation:** The given UDDI reference has already been defined for the gateway service.

**User Response:** Ensure that the correct UDDI reference name is specified.

**WSGW0049E: UDDI reference {0} not defined for gateway service {1}**

**Explanation:** The UDDI reference cannot be removed from the gateway service as it is not currently defined for the gateway service.

**User Response:** Ensure that the correct UDDI reference name is specified.

**WSGW0050E: Target service with location {0} already defined for gateway service {1}**

**Explanation:** The given target service location has already been defined for the gateway service.

**User Response:** Ensure that the correct target service location is specified.

**WSGW0051E: Target service with location {0} not defined for gateway service {1}**

**Explanation:** The target service location cannot be removed from the gateway service as it is not currently defined for the gateway service.

**User Response:** Ensure that the correct target service location is specified.

**WSGW0052E: Target service with location {0} was not found for gateway service {1}**

**Explanation:** The target service WSDL definition could not be obtained from the given location.

**User Response:** Ensure that the correct target service location is specified.

**WSGW0053E: gateway service {0} cannot be removed as active entities and force not specified**

**Explanation:** A gateway service with one or more target services, channels, filters or UDDI references cannot be removed.

**User Response:** Remove the target services, channels, filters and UDDI references from the gateway service.

**WSGW0054E: An exported definition for gateway service {0} is not available as there are no defined channels for the service**

**Explanation:** A request was made for the WSDL definition for the gateway service, however no channels have been defined for the gateway service, so it is not possible to generate a WSDL definition.

**User Response:** Deploy one or more channels to the gateway service.

**WSGW0055E: Not used**

**Explanation:**

**User Response:**

**WSGW0056E: No default target service available for {0}**

**Explanation:** The default target service location cannot be obtained for the gateway service as no target services are defined.

**User Response:** Ensure that one or more target services are defined for the gateway service.

**WSGW0057E: No receiving channel name in context**

**Explanation:** A request has reached the gateway that does not contain the receiving channel name in the context.

**User Response:** Contact the supplier of the channel application.

**WSGW0058E: Channel {0} not defined for gateway service {1}**

**Explanation:** A request has reached the gateway for the given service through a channel which is not defined for that service. The request is rejected.

**User Response:** If the channel should be valid for the service, add the channel, otherwise check that the client of the request is making a valid request. This exception may be thrown when a client is making a malicious attack.

**WSGW0059E: gateway service {0} does not exist**

**Explanation:** A request was made for a gateway service that does not exist.

**User Response:** Ensure that the correct gateway service name is specified.

**WSGW0060E: gateway service {0} already exists**

**Explanation:** An attempt was made to create a new gateway service using a name that is used by an existing gateway service.

**User Response:** Use a different name for the gateway service.

**WSGW0061E: Could not find Service in UDDI registry {0} with parameters {1}, {2}, {3}**

**Explanation:** The given parameters for UDDI lookup did not yield a match.

**User Response:** Ensure that the parameters are correct. Also ensure that the UDDI reference parameters are correct and correspond to those used to publish the service to UDDI.

**WSGW0062E: Target service WSDL contains no <service> elements**

**Explanation:** The target service WSDL could be loaded but does not contain a <service> element. This is necessary to be able to invoke the target service.

**User Response:** Ensure that the target service WSDL contains one or more <service> element.

**WSGW0063E: Target service WSDL contains more than one service, and either target service name or namespace not specified**

**Explanation:** When adding a target service to a gateway service, you must specify both the service name and namespace values if there is more than one <service> element in the target service WSDL.

**User Response:** Specify the target service name and namespace as well as the location.

**WSGW0064E: Target service name {0} does not match service name in WSDL: {1}**

**Explanation:** A target service name was specified that is not the same as any target service name in the WSDL at the given location.

**User Response:** Ensure that a valid target service name is specified.

**WSGW0065E: Target service namespace {0} does not match service namespace in WSDL: {1}**

**Explanation:** A target service namespace was specified that is not the same as any target service namespace in the WSDL at the given location.

**User Response:** Ensure that a valid target service namespace is specified.

**WSGW0066E: Target service name {0} or namespace {1} not found in WSDL definition**

**Explanation:** A target service name and namespace were both specified, but do not match any target service name and namespace combination in the WSDL at the given location.

**User Response:** Ensure that a valid target service name and namespace combination is specified.

**WSGW0067E: UDDI reference {0} cannot be removed because it is being used by a deployed service**

**Explanation:** UDDI references can only be removed when they are not in use by gateway services.

**User Response:** Remove the UDDI reference from gateway services to which it is deployed before removing the UDDI reference.

**WSGW0068E: UDDI reference {0} already exists**

**Explanation:** The name specified for the UDDI reference is the same as that of a UDDI reference that is currently deployed.

**User Response:** Choose a different name for the UDDI reference, or remove the existing UDDI reference of the given name.

**WSGW0069E: UDDI reference {0} not found**

**Explanation:** No UDDI reference is currently deployed with the given name.

**User Response:** Use the name of a UDDI reference that is currently deployed.

**WSGW0070E: Invalid target service location type {0}**

**Explanation:** The location type for the target service is not a valid value.

- User Response:** Ensure that a correct value is specified for the target service location type.
- WSGW0071E: Failed to load URL definition from {0}**  
**Explanation:** The URL location specified was incorrect, or the WSDL it refers to cannot be loaded.
- User Response:** Ensure that the URL location is correct, and refers to a valid WSDL document.
- WSGW0072E: Failed to load UDDI definition from {0}**  
**Explanation:** The UDDI location specified was incorrect, or the WSDL it refers to cannot be loaded.
- User Response:** Ensure that the UDDI location is correct, and refers to a valid WSDL document.
- WSGW0073W: Not used**  
**Explanation:**
- User Response:**
- WSGW0074W: Invocation of filter {0} failed. Exception: {1}**  
**Explanation:** An unexpected exception was thrown during processing of the named filter.
- User Response:** Investigate the reason for the exception being thrown. Ensure that the filter application is available.
- WSGW0075E: Failed to set gateway end point address. Exception {0}**  
**Explanation:** An unexpected exception occurred when automatically setting the gateway's end point address.
- User Response:** Contact IBM Support
- WSGW0076E: Unable to access the gateway configuration bean. Exception {0}**  
**Explanation:** An unexpected exception occurred looking up the gateway's configuration bean in JNDI.
- User Response:** Restart the application server.
- WSGW0077E: Failed to remove gateway configuration session. Exception {0}**  
**Explanation:** An unexpected exception occurred removing the session bean while access the gateway's configuration bean.
- User Response:** Contact IBM Support
- WSGW0078E: Unable to access the gateway EndPoint bean. Exception {0}**  
**Explanation:** An unexpected exception occurred looking up the gateway's endpoint bean in JNDI.
- User Response:** Restart the application server.
- WSGW0079E: Failed to remove endpoint session. Exception {0}**  
**Explanation:** An unexpected exception occurred removing the session bean while access the gateway's endpoint bean.
- User Response:** Contact IBM Support
- WSGW0080E: Performance monitoring error. Exception {0}**  
**Explanation:** An unexpected exception occurred when recording performance monitoring information.
- User Response:** Contact IBM Support
- WSGW0081E: Unexpected error in method {0}. Exception {1}**  
**Explanation:** An unexpected exception occurred in the given method.
- User Response:** Contact IBM Support
- WSGW0082E: Unable to determine WAS security setting**  
**Explanation:** The WAS security setting could not be determined. It will be assumed that security is enabled.
- User Response:** No action required.
- WSGW0083W: Failed to authorize request for operation {0} on service {1}. Exception {2}**  
**Explanation:** Authorization of the given request failed. The request has been rejected.
- User Response:** Ensure that the required authorization bean has been generated for the given service, and that the correct authorization policy is defined.

**WSGW0084W: Invocation of filter {0} version {1} failed. Exception {2}**

**Explanation:** An exception was thrown during processing of the given filter. Processing of the request continues.

**User Response:** Investigate the reason for the exception being thrown by the filter. Refer to the documentation for the filter on how to resolve the problem.

**WSGW0085E: Failed to publish service {0} to UDDI registry {1}. Exception: {2}**

**Explanation:** An unexpected exception occurred when publishing the given service to a UDDI registry.

**User Response:** Ensure that the properties of the gateway service and UDDI reference are specified correctly.

**WSGW0086E: Failed to unpublish service {0} from UDDI registry {1}. Exception: {2}**

**Explanation:** An unexpected exception occurred when unpublishing the given service from a UDDI registry.

**User Response:** Ensure that the properties of the gateway service and UDDI reference are specified correctly.

**WSGW0087I: Published service {0} to UDDI registry {1}**

**Explanation:** The service was successfully published to the UDDI registry.

**User Response:** None

**WSGW0088I: Unpublished service {0} from UDDI registry {1}**

**Explanation:** The service was successfully unpublished from the UDDI registry.

**User Response:** None

**WSGW0089I: No MessageWarehouse registered. Requests will not be logged**

**Explanation:** A MessageWarehouse implementation was not found at the expected location in JNDI, so none is being used.

**User Response:** If a MessageWarehouse has been implemented, ensure that it is bound to JNDI at the correct location.

**WSGW0090I: No ExceptionHandler registered. Exceptions will not be handled**

**Explanation:** An ExceptionHandler implementation was not found at the expected location in JNDI, so none is being used.

**User Response:** If an ExceptionHandler has been implemented, ensure that it is bound to JNDI at the correct location.

**WSGW0091I: Usage: java -jar GenAuth -DWAS\_HOME=<was.install.directory> <HostName> <ServiceName>**

where <was.install.directory> is the location of the WebSphere installation directory and <HostName> is the url pointed to by the installation of the gateway and <ServiceName> is the name of the deployed gateway service. (Please note the ServiceName is case sensitive).

For example

```
-jar GenAuth.jar -DWAS_HOME=c:\\websphere\\AppServer http://host.machine.name.com/wsgw ServiceName
```

Successful execution will generate a file named <ServiceName>.ear

**Explanation:** Usage statement. This message is used by the WSGWAuthGen command-line utility.

**User Response:** No action required.

**WSGW0092I: Retrieving Service :**

**Explanation:** Progress message indicating that the service definition is being retrieved. This message is used by the WSGWAuthGen command line utility.

**User Response:** No action required.

**WSGW0093I: Retrieving Port Type :**

**Explanation:** Progress message indicating that the port type information is being retrieved. This message is used by the WSGWAuthGen command line utility.

**User Response:** No action required.

**WSGW0094I: Retrieving Methods :**

**Explanation:** Progress message indicating that method information is being retrieved. This message is used by the WSGWAuthGen command line utility.

**User Response:** No action required.

**WSGW0095I: Making Directory :**

**Explanation:** Progress message indicating that a directory is being created. This message is used by the WSGWAuthGen command-line utility.

**User Response:** No action required.

**WSGW0096I: Using Directory :**

**Explanation:** Progress message indicating that a directory is being used. This message is used by the WSGWAuthGen command-line utility.

**User Response:** No action required.

**WSGW0097I: About to compile....**

**Explanation:** Progress message indicating that a compilation is about to start. This message is used by the WSGWAuthGen command line utility.

**User Response:** No action required.

**WSGW0098I: Command Status :**

**Explanation:** General command status message. This message is used by the WSGWAuthGen command-line utility.

**User Response:** No action required.

**WSGW0099I: About to create jar....**

**Explanation:** Progress message indicating that a JAR file is about to be created. This message is used by the WSGWAuthGen command line utility.

**User Response:** No action required.

**WSGW0100I: About to create ear....**

**Explanation:** Progress message indicating that an EAR file is about to be created. This message is used by the WSGWAuthGen command line utility.

**User Response:** No action required.

**WSGW0101E: Error retrieving port from service {1}**

**Explanation:** An error occurred retrieving the port from the service in the WSDL. This message is used by the WSGWAuthGen command line utility.

**User Response:** Ensure that the service name is specified correctly and is deployed to the gateway with at least one target service and one channel.

**WSGW0102E: Error retrieving service {0}**

**Explanation:** An error occurred retrieving the service. This message is used by the WSGWAuthGen command-line utility.

**User Response:** Ensure that the service name is specified correctly and is deployed to the gateway with at least one target service and one channel.

**WSGW0103E: Exception while retrieving service definition from URL:**

**{0}/ServiceDefinition?name={1}. Exception: {2}**

**Explanation:** An unexpected exception occurred retrieving WSDL from the given location. This message is used by the WSGWAuthGen command-line utility.

**User Response:** Ensure that the service name is specified correctly and is deployed to the gateway with at least one target service and one channel.

**WSGW0104E: Error retrieving methods from service {0}**

**Explanation:** An unexpected exception occurred retrieving the methods that correspond to operations on the service.

**User Response:** Contact IBM Support

**WSGW0105E: Error retrieving WAS\_HOME environment variable**

**Explanation:** The value of the WAS\_HOME environment variable could not be retrieved.

**User Response:** Ensure that the WAS\_HOME variable is set correctly in the environment under which the command is being executed.

**WSGW0106E: Error compiling files**

**Explanation:** An unexpected error occurred compiling the generated Java files.

**User Response:** Contact IBM Support

**WSGW0107E: Error executing JAR command**

**Explanation:** An unexpected error occurred generating a JAR file.

**User Response:** Contact IBM Support

**WSGW0110E: A client attempted to load imported URL {0} for gateway service {1}. This URL is not imported by the definition for that service.**

**Explanation:** An attempt was made to use the gateway's import mapping servlet to load information from a URL that does not correspond to one that is referenced by the WSDL definition for that service.

**User Response:** Ensure that the client is making a valid request. This may be a malicious attempt to obtain information that the client does not have access to.

**WSGW0111W: Unsupported elements within the WSDL definition for target service {0} were ignored. The functionality of this service may be compromised.**

**Explanation:** In order to be able to use the given WSDL definition within the gateway, certain elements of the definition were ignored.

**User Response:** Refer to the service provider's documentation to determine whether this will affect the use of the service.

**WSGW0112E: Exception while sending response to queue {0}. Exception {1}, linked exception {2}**

**Explanation:** An unexpected exception occurred during execution of the JMS channel.

**User Response:** Ensure that the JMS channel and its prerequisites are correctly configured. Examine the linked exception for information on how to resolve the problem.

**WSGW0113E: Exception while creating Object Message to send response. Exception {1}, linked exception {2}**

**Explanation:** An unexpected exception occurred during execution of the JMS channel.

**User Response:** Ensure that the JMS channel and its prerequisites are correctly configured. Examine the linked exception for information on how to resolve the problem.

**WSGW0114E: Exception while creating Queue Sender to send response. Exception {1}, linked exception {2}**

**Explanation:** An unexpected exception occurred during execution of the JMS channel.

**User Response:** Ensure that the JMS channel and its prerequisites are correctly configured. Examine the linked exception for information on how to resolve the problem.

**WSGW0115E: Exception while creating Reply To Queue to send response. Exception {1}, linked exception {2}**

**Explanation:** An unexpected exception occurred during execution of the JMS channel.

**User Response:** Ensure that the JMS channel and its prerequisites are correctly configured. Examine the linked exception for information on how to resolve the problem.

**WSGW0116E: Exception while creating Queue Session to send response. Exception {1}, linked exception {2}**

**Explanation:** An unexpected exception occurred during execution of the JMS channel.

**User Response:** Ensure that the JMS channel and its prerequisites are correctly configured.  
Examine the linked exception for information on how to resolve the problem.

**WSGW0117E: Exception while creating Queue Connection Factory to send response. Exception {1}, linked exception {2}**

**Explanation:** An unexpected exception occurred during execution of the JMS channel.

**User Response:** Ensure that the JMS channel and its prerequisites are correctly configured.  
Examine the linked exception for information on how to resolve the problem.

**WSGW0118E: End point address keyword {0} is not valid for the JMS channel**

**Explanation:** The keyword specified in the end point address for the JMS channel is not valid.

**User Response:** Consult the documentation for a list of valid keywords for the JMS channel end point address.

**WSGW0119E: End point address for the JMS channel must be keyword=value pairs separated by the '&' character**

**Explanation:** The end point address specified does not have the correct syntax.

**User Response:** Consult the documentation for a specification of the syntax of the JMS channel end point address.

**WSGW0120E: Not used in this version of the gateway**

**Explanation:**

**User Response:**

**WSGW0121E: Not used in this version of the gateway**

**Explanation:**

**User Response:**

**WSGW0122E: Not used in this version of the gateway**

**Explanation:**

**User Response:**

**WSGW0123E: Not used in this version of the gateway**

**Explanation:**

**User Response:**

**WSGW0124E: Failed to find Business in UDDI Register**

**Explanation:** Used for SRPUDDIPublisher.

**User Response:**

**WSGW0125E: Not used**

**Explanation:**

**User Response:**

**WSGW0126E: Not used**

**Explanation:**

**User Response:**

**WSGW0127E: Not used**

**Explanation:**

**User Response:**

**WSGW0128E: Not used in this version of the gateway**

**Explanation:**

**User Response:**

**WSGW0129E: Not used in this version of the gateway**

**Explanation:**

**User Response:**

**WSGW0130E: Not used in this version of the gateway**

**Explanation:**

**User Response:**

**WSGW0131E: Not used in this version of the gateway**  
**Explanation:**  
**User Response:**

**WSGW0132E: Not used in this version of the gateway**  
**Explanation:**  
**User Response:**

**WSGW0133E: Not used in this version of the gateway**  
**Explanation:**  
**User Response:**

**WSGW0134E: Not used in this version of the gateway**  
**Explanation:**  
**User Response:**

**WSGW0135E: Not used in this version of the gateway**  
**Explanation:**  
**User Response:**

**WSGW0136E: Not used in this version of the gateway**  
**Explanation:**  
**User Response:**

**WSGW0137E: Not used in this version of the gateway**  
**Explanation:**  
**User Response:**

**WSGW0138E: Not used in this version of the gateway**  
**Explanation:**  
**User Response:**

**WSGW0139E: Not used in this version of the gateway**  
**Explanation:**  
**User Response:**

**WSGW0140E: Not used in this version of the gateway**  
**Explanation:**  
**User Response:**

**WSGW0141E: Not used in this version of the gateway**  
**Explanation:**  
**User Response:**

**WSGW0142E: Not used in this version of the gateway**  
**Explanation:**  
**User Response:**

**WSGW0143E: Not used in this version of the gateway**  
**Explanation:**  
**User Response:**

**WSGW0144E: Not used in this version of the gateway**  
**Explanation:**  
**User Response:**

**WSGW0145E: Not used in this version of the gateway**  
**Explanation:**  
**User Response:**

**WSGW0146E: Not used in this version of the gateway**  
**Explanation:**  
**User Response:**

**WSGW0147E: Not used in this version of the gateway**

**Explanation:**

**User Response:**

**WSGW0148E: A problem occurred whilst processing an attachment**

**Explanation:**

**User Response:**

**WSGW0149E: Failed to import the configuration. Exception: {0}**

**Explanation:** An unexpected error occurred when trying to import the configuration.

**User Response:** Contact IBM Support

**WSGW0150W: Security config for gateway service {0} has errors. Service will not be available.**

**Exception: {1}**

**Explanation:** The security configuration for the gateway service has errors which prevent the service from being available.

**User Response:** Review the security settings for the gateway service.

**WSGW0151W: Security config for target service {0} has errors. No security will be applied to the outgoing message. Exception: {1}**

**Explanation:** The security configuration for the target service has errors. No security will be applied to the outgoing message.

**User Response:** Review the security settings for the target service.

**WSGW0152E: A problem occurred whilst processing an attachment. Exception: {0}**

**Explanation:**

**User Response:**

**WSGW0153E: Handler name {0} already exists**

**Explanation:** The name specified for the handler is the same as that of a handler that is currently deployed.

**User Response:** Choose a different name for the handler, or remove the existing handler of the given name.

**WSGW0154E: Handler name {0} not found**

**Explanation:** No handler is currently deployed with the given name.

**User Response:** Use the name of a handler that is currently deployed.

**WSGW0155E: Error managing inbound handlers list at position {0} for service {2} and channel {1}**

**Explanation:**

**User Response:**

**WSGW0156E: Error managing outbound handlers list at position {0} for service {2} and target port {1}**

**Explanation:**

**User Response:**

**WSGW0157E: Target port {0} invalid or handlers list for the port does not exist**

**Explanation:**

**User Response:**

**WSGW0158E: Error removing handler {0} from outbound chain**

**Explanation:**

**User Response:**

**WSGW0159E: Channel name {0} invalid or handlers list for channel does not exist**

**Explanation:**

**User Response:**

**WSGW0160E: Attempt to remove handler {0} without "force" flag**

**Explanation:**

**User Response:**

**WSGW0161E: Unable to load handler implementation: {0}**

**Explanation:** The class specified could not be found on the classpath.

**User Response:** Make sure the class is available to the gateway application.

**WSGWJ001: An error occurred using the Web Services gateway.**

**Explanation:** This message is used by JSPs.

**User Response:**

**WSGWJ002: The following error occurred while processing the operation**

**Explanation:** This message is used by JSPs.

**User Response:**

**WSGWJ003: The reason this error occurred (the original exception) is as follows**

**Explanation:** This message is used by JSPs.

**User Response:**

**WSGWJ004: The stack trace for the error is as follows**

**Explanation:** This message is used by JSPs.

**User Response:**

**WSGWJ005: The stack trace for the original exception is as follows**

**Explanation:** This message is used by JSPs.

**User Response:**

---

## Chapter 13. Class loading

Class loaders affect the packaging of applications and the run-time behavior of packaged applications deployed on application servers.

1. Read about class loaders. The article "“Class loading: Resources for learning” on page 928” points to additional sources.
2. If necessary, migrate class-loader Module Visibility Mode settings for Version 4.0.x applications to Version 5.0 application or WAR class-loader policies.
3. If an application module uses a resource, create a resource provider that specifies the directory name of the resource drivers. Do not specify the resource JAR file names. All JAR files in the specified directory will be added into the class path of the WebSphere Application Server extensions class loader.

4. Configure class loaders of an application server for the run-time environment.

- a. Click **Servers > Application Servers > *server\_name*** and, on the settings page for an application server, set the application class-loader policy and application class-loader mode.

The application class-loader policy controls the isolation of applications running in the system. When set to SINGLE, applications are not isolated; a single application class loader is used to contain all EJB modules, dependency JAR files, and shared libraries in the system. When set to MULTIPLE, applications are isolated from each other; each application receives its own class loader to load that application’s EJB modules, dependency JAR files, and shared libraries.

The application class-loader mode specifies the class-loader mode when the application class-loader policy is SINGLE. PARENT\_FIRST causes the class loader to first delegate the loading of classes to its parent class loader before attempting to load the class from its local class path. PARENT\_LAST causes the class loader to first attempt to load classes from its local class path before delegating the class loading to its parent. This allows an application class loader to override and provide its own version of a class that exists in the parent class loader.

- b. On the settings page for an application server, click **Classloader**. On the Classloader page, click **New**.
  - c. On the settings page for a class loader, specify the class-loader mode. PARENT\_FIRST causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local classpath. PARENT\_LAST causes the class loader to attempt to load classes from its local class path before delegating the class loading to its parent. Then, click **OK**.
  - d. On the settings page for a class loader, click **Libraries**. From the Library Ref page, click **Add**. On the settings page for a library reference, specify variables for the library reference as needed and click **OK**. Repeat the previous step until you define a library reference instance for each library file that your application needs. To define a library reference, you must first define one or more shared libraries. (See “Managing shared libraries” in the Information Center.)
5. When configuring an installed enterprise application for deployment in the run-time environment, set the class-loader mode and the WAR class-loader policy.
  6. When configuring an installed Web module for deployment in the run-time environment, set the class-loader mode.

---

### Class loaders

Class loaders are part of the Java virtual machine (JVM) code and are responsible for finding and loading class files. Class loaders affect the packaging of applications and the run-time behavior of packaged applications deployed on application servers.

The run-time environment of WebSphere Application Server uses the following class loaders to find and load new classes for an application in the following order:

1. The **bootstrap, extensions, and CLASSPATH class loaders** created by the JVM.

The bootstrap class loader uses the boot classpath (typically classes in jre/lib) to find and load classes. The extensions class loader uses the system property `java.ext.dirs` (typically `jre/lib/ext`) to find and load classes. The CLASSPATH class loader uses the CLASSPATH environment variable to find and load classes.

The CLASSPATH class loader contains the J2EE APIs of the WebSphere Application Server product (inside `j2ee.jar`). Because the J2EE APIs are in this class loader, you can add libraries that depend on J2EE APIs to the classpath system property to extend a server's classpath. However, a preferred method of extending a server's classpath is to add a shared library.

## 2. A **WebSphere-specific extensions class loader**.

The WebSphere extensions class loader loads the WebSphere run-time and J2EE classes that are required at run time. The extensions class loader uses a `ws.ext.dirs` system property to determine the path used to load classes. Each directory in the `ws.ext.dirs` classpath and every JAR file or ZIP file in these directories is added to the classpath used by this class loader.

The WebSphere extensions class loader also loads resource provider classes into a server if an application module installed on the server refers to a resource that is associated with the provider and if the provider specifies the directory name of the resource drivers.

## 3. One or more **application module class loaders** that load elements of enterprise applications running in the server.

The application elements can be Web modules, EJB modules, resource adapters, and dependency JAR files. Application class loaders follow J2EE class-loading rules to load classes and JAR files from an enterprise application. The WebSphere run time enables you to associate a shared library classpath with an application.

Each class loader is a child of the class loader above it. That is, the application module class loaders are children of the WebSphere-specific extensions class loader, which is a child of the CLASSPATH Java class loader. Whenever a class needs to be loaded, the class loader usually delegates the request to its parent class loader. If none of the parent class loaders can find the class, the original class loader attempts to load the class. Requests can only go to a parent class loader; they cannot go to a child class loader. If the WebSphere class loader is requested to find a class in a J2EE module, it cannot go to the application module class loader to find that class and a `ClassNotFoundException` occurs. Once a class is loaded by a class loader, any new classes that it tries to load reuse the same class loader or go up the precedence list until the class is found.

## **Class-loader isolation policies**

The number and function of the application module class loaders depends on the class-loader policies specified in the server configuration. Class loaders provide multiple options for isolating applications and modules to enable different application packaging schemes to run on an application server.

Two class-loader policies control the isolation of applications and modules:

### **Application class-loader policy**

Application class loaders consist of EJB modules, dependency JAR files, resource adapters, and shared libraries. Depending on the application class-loader policy, an application class loader can be shared by multiple applications (SINGLE) or unique for each application (MULTIPLE). The application class-loader policy controls the isolation of applications running in the system. When set to SINGLE, applications are not isolated. When set to MULTIPLE, applications are isolated from each other.

### **WAR class-loader policy**

By default, Web module class loaders load the contents of the `WEB-INF/classes` and `WEB-INF/lib` directories. The application class loader is the parent of the Web module class loader. You can change the default behavior by changing the application's WAR class-loader policy.

The WAR class-loader policy controls the isolation of Web modules. If this policy is set to APPLICATION, then the Web module contents also are loaded by the application class loader (in

addition to the EJB files, RAR files, dependency JAR files, and shared libraries). If the policy is set to MODULE, then each web module receives its own class loader whose parent is the application class loader.

**Note:** WebSphere server class loaders never load application client modules.

For each application server in the system, you can set the application class-loader policy to SINGLE or MULTIPLE. When the application class-loader policy is set to SINGLE, then a single application class loader loads all EJB modules, dependency JAR files, and shared libraries in the system. When the application class-loader policy is set to MULTIPLE, then each application receives its own class loader used for loading that application's EJB modules, dependency JAR files, and shared libraries.

This application class loader can load each application's Web modules if that WAR module's class-loader policy is also set to APPLICATION. If the WAR module's class-loader policy is set to APPLICATION, then the application's loader loads the WAR module's classes. If the WAR class-loader policy is set to MODULE, then each WAR module receives its own class loader.

The following example shows that when the application class-loader policy is set to SINGLE, a single application class loader loads all EJB modules, dependency JAR files, and shared libraries of all applications on the server. The single application class loader can also load Web modules if an application has its WAR class-loader policy set to APPLICATION. Applications having a WAR class-loader policy set to MODULE use a separate class loader for Web modules.

Application class-loader policy: SINGLE

```
Application 1
Module: EJB1.jar
Module: WAR1.war
 MANIFEST Class-Path: Dependency1.jar
 WAR Classloader Policy = MODULE
Application 2
Module: EJB2.jar
 MANIFEST Class-Path: Dependency2.jar
Module: WAR2.war
 WAR Classloader Policy = APPLICATION
```

The following example shows that when the application class-loader policy of an application server is set to MULTIPLE, each application on the server has its own class loader. An application class loader also loads its Web modules if the application's WAR class-loader policy is set to APPLICATION. If the policy is set to MODULE, then a Web module uses its own class loader.

Application class-loader policy: MULTIPLE

```

Application 1
Module: EJB1.jar
Module: WAR1.war
MANIFEST Class-Path: Dependency1.jar
WAR Classloader Policy = MODULE
Application 2
Module: EJB2.jar
MANIFEST Class-Path: Dependency2.jar
Module: WAR2.war
WAR Classloader Policy = APPLICATION

```

## Class-loader modes

There are two possible values for a class-loader mode:

### PARENT\_FIRST

The PARENT\_FIRST class-loader mode causes the class loader to first delegate the loading of classes to its parent class loader before attempting to load the class from its local classpath. This is the default for class-loader policy and for standard JVM class loaders.

### PARENT\_LAST

The PARENT\_LAST class-loader mode causes the class loader to first attempt to load classes from its local classpath before delegating the class loading to its parent. This policy allows an application class loader to override and provide its own version of a class that exists in the parent class loader.

The following settings determine a class loader's mode:

- If the application class-loader policy of an application server is SINGLE, the application class-loader policy of an application server defines the mode for an application class loader.
- If the application class-loader policy of an application server is MULTIPLE, the class-loader mode of an application defines the mode for an application class loader.

- If the WAR class-loader policy of an application is MODULE, the WAR class-loader policy of a Web module defines the mode for a WAR class loader.

---

## Class loader collection

Use this page to manage class-loader instances on an application server. A class loader determines whether an application class loader or a parent class loader finds and loads Java class files for an application.

To view this administrative console page, click **Servers > Application Servers > *server\_name* > Classloader**.

### Classloader ID

States a string unique to the server identifying the class-loader instance. The product assigns the identifier.

### Classloader Mode

Specifies the class-loader mode when the application class-loader policy is SINGLE. PARENT\_FIRST causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path. PARENT\_LAST causes the class loader to attempt to load classes from its local class path before delegating the class loading to its parent; this allows an application class loader to override and provide its own version of a class that exists in the parent class loader.

## Class loader settings

Use this page to configure a class loader for applications that reside on an application server.

To view this administrative console page, click **Servers > Application Servers > *server\_name* > Classloader > *class\_loader\_ID***.

### Classloader ID

States a string unique to the server identifying the class-loader instance. The product assigns the identifier.

<b>Data type</b>	String
------------------	--------

### Classloader Mode

Specifies the class-loader mode when the application class-loader policy is SINGLE. PARENT\_FIRST causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path. PARENT\_LAST causes the class loader to attempt to load classes from its local class path before delegating the class loading to its parent; this allows an application class loader to override and provide its own version of a class that exists in the parent class loader.

<b>Data type</b>	String
<b>Default</b>	PARENT_FIRST

---

## Migrating the class-loader Module Visibility Mode setting

WebSphere Application Server Version 4.0.x had a server-wide configuration setting called **Module Visibility Mode**. For Version 5.0, you use application or WAR class-loader policies instead of module visibility modes. The Version 5.0 policies provide additional flexibility because you can configure applications running in a server for an application class-loader policy of SINGLE or MULTIPLE and for a WAR class-loader policy of APPLICATION or MODULE.

To migrate module visibility modes in your Version 4.0.x applications to their equivalents in Version 5.0, change the settings for your Version 4.0.x applications and modules to the Version 5.0 values shown in the

table below.

Version 4.0.x module visibility mode	Version 5.0 application class-loader policy	Version 5.0 WAR class-loader policy
Server	SINGLE	APPLICATION
Compatibility	SINGLE	MODULE
Application	MULTIPLE	APPLICATION
Module*	MULTIPLE	MODULE
J2EE	MULTIPLE	MODULE

\*There is no exact equivalent for the Version 4.0.x Module mode because it isolated EJB modules within an application.

---

## Class loading: Resources for learning

Use the following links to find relevant supplemental information about class loaders. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.

## Chapter 14. Using EJB query

The EJB query language is used to specify a query over container-managed entity beans. The language is similar to SQL. An EJB query is independent of the bean's mapping to a persistent store.

An EJB query can be used in three situations:

- To define a finder method of an EJB entity bean.
- To define a select method of an EJB entity bean.
- To dynamically specify a query using the `executeQuery()` dynamic API.

Finder and select queries are specified in the bean's deployment descriptor using the `<ejb-ql>` tag. Queries specified in the deployment descriptor are compiled into SQL during deployment. Dynamic queries require the interface provided by WebSphere Application Server Enterprise.

WebSphere's EJB query language is compliant with the EJB QL defined in Sun's EJB 2.0 specification and has additional capabilities as listed in the topic [Comparison of EJB 2.0 specification and WebSphere Query Language](#).

In your WebSphere application, you can define an EJB query in the following ways:

- **Assembly Toolkit.** When defining an EJB 2.0 entity bean in an EJB deployment descriptor editor, on the **Beans** page click **Add** under **Queries** and, in the Add Finder Descriptor wizard, define a `find` or `ejbSelect` method. See the online [Assembly Toolkit information](#) for documentation on wizard options.
- **WebSphere Studio Application Developer.** When defining an entity bean, specify the `<ejb-ql>` tag for the finder or select method.
- **Dynamic query service.** Add the `executeQuery()` method to your application. The dynamic query API is provided as an Enterprise Extension to WebSphere Application Server.

Before using EJB query, familiarize yourself with query language concepts, starting with the topic, [EJB Query Language](#).

See the topic [Example: EJB queries](#).

---

### EJB query language

An EJB query is a string that contains the following elements:

- a `SELECT` clause that specifies the EJBs or values to return;
- a `FROM` clause that names the bean collections;
- an optional `WHERE` clause that contains search predicates over the collections;
- an optional `GROUP BY` and `HAVING` clause (see [Aggregation functions](#));
- an optional `ORDER BY` clause that specifies the ordering of the result collection.

The `SELECT` clause is optional in order to maintain compatibility with WebSphere Application Server Version 4.

Collections of entity beans are identified in EJB queries through the use of their abstract schema name in the query `FROM` clause.

The elements of EJB query language are discussed in more detail in the following related topics.

## Example: EJB queries

Here is an example EJB schema, followed by a set of example queries:

Table 9. DeptBean schema

Entity bean name (EJB name)	DeptEJB (not used in query)
Abstract schema name	DeptBean
Implementation class	com.acme.hr.deptBean (not used in query)
Persistent attributes (cmp fields)	<ul style="list-style-type: none"><li>deptno - Integer (key)</li><li>name - String</li><li>budget - BigDecimal</li></ul>
Relationships	<ul style="list-style-type: none"><li>emps - 1:Many with EmpEJB</li><li>mgr - Many:1 with EmpEJB</li></ul>

Table 10. EmpBean schema

Entity bean name (EJB name)	EmpEJB (not used in query)
Abstract schema name	EmpBean
Implementation class	com.acme.hr.empBean (not used in query)
Persistent attributes (cmp fields)	<ul style="list-style-type: none"><li>empid - Integer (key)</li><li>name - String</li><li>salary - BigDecimal</li><li>bonus - BigDecimal</li><li>hireDate - java.sql.Date</li><li>birthDate - java.util.Calendar</li><li>address - com.acme.hr.Address</li></ul>
Relationships	<ul style="list-style-type: none"><li>dept - Many:1 with DeptEJB</li><li>manages - 1:Many with DeptEJB</li></ul>

Address is a serializable object used as cmp field in EmpBean. The definition of address is as follows:

```
public class com.acme.hr.Address extends Object implements Serializable {
public String street;
public String state;
public String city;
public Integer zip;
public double distance (String start_location) { ... } ;
public String format () { ... } ;
}
```

The following query returns all departments:

```
SELECT OBJECT(d) FROM DeptBean d
```

The following query returns departments whose name begins with the letters "Web". Sort the result by name:

```
SELECT OBJECT(d) FROM DeptBean d WHERE d.name LIKE 'Web%' ORDER BY d.name
```

The keywords SELECT and FROM are shown in uppercase in the examples but are case insensitive. If a name used in a query is a reserved word, the name must be enclosed in double quotes to be used in the query. There is a list of reserved words later in this document. Identifiers enclosed in double quotes are case sensitive. This example shows how to use a cmp field that is a reserved word:

```
SELECT OBJECT(d) FROM DeptBean d WHERE d."select" > 5
```

The following query returns all employees who are managed by Bob. This example shows how to navigate relationships using a path expression:

```
SELECT OBJECT (e) FROM EmpBean e WHERE e.dept.mgr.name='Bob'
```

A query can contain a parameter which refers to the corresponding value of the finder or select method. Query parameters are numbered starting with 1:

```
SELECT OBJECT (e) FROM EmpBean e WHERE e.dept.mgr.name= ?1
```

This query shows navigation of a multivalued relationship and returns all departments that have an employee that earns at least 50000 but not more than 90000:

```
SELECT OBJECT(d) FROM DeptBean d, IN (d.emps) AS e
WHERE e.salary BETWEEN 50000 and 90000
```

There is a join operation implied in this query between each department object and its related collection of employees. If a department has no employees, the department does not appear in the result. If a department has more than one employee that earns more than 50000, that department appears multiple times in the result.

The following query eliminates the duplicate departments:

```
SELECT DISTINCT OBJECT(d) from DeptBean d, IN (d.emps) AS e WHERE e.salary > 50000
```

Find employees whose bonus is more than 40% of their salary:

```
SELECT OBJECT(e) FROM EmpBean e where e.bonus > 0.40 * e.salary
```

Find departments where the sum of salary and bonus of employees in the department exceeds the department budget:

```
SELECT OBJECT(d) FROM DeptBean d where d.budget <
(SELECT SUM(e.salary+e.bonus) FROM IN(d.emps) AS e)
```

A query can contain DB2 style date-time arithmetic expressions if you use java.sql.\* datatypes as CMP fields and your datastore is DB2. Find all employees who have worked at least 20 years as of January 1st, 2000:

```
SELECT OBJECT(e) FROM EmpBean e where year('2000-01-01' - e.hireDate) >= 20
```

If the datastore is not DB2 or if you prefer to use java.util.Calendar as the CMP field, then you can use the java millisecond value in queries. The following query finds all employees born before Jan 1, 1990:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e.birthDate < 631180800232
```

Find departments with no employees:

```
SELECT OBJECT(d) from DeptBean d where d.emps IS EMPTY
```

Find all employees whose earn more than Bob:

```
SELECT OBJECT(e) FROM EmpBean e, EmpBean b
WHERE b.name = 'Bob' AND e.salary + e.bonus > b.salary + b.bonus
```

Find the employee with the largest bonus:

```
SELECT OBJECT(e) from EmpBean e WHERE e.bonus =
(SELECT MAX(e1.bonus) from EmpBean e1)
```

The above queries all return EJB objects. A finder method query must always return an EJB Object for the home. A select method query can in addition return CMP fields or other EJB Objects not belonging to the home.

The following would be valid select method queries for EmpBean. Return the manager for each department:

```
SELECT d.mgr FROM DeptBean d
```

Return department 42 manager's name:

```
SELECT d.mgr.name FROM DeptBean d WHERE d.deptno = 42
```

Return the names of employees in department 42:

```
SELECT e.name FROM EmpBean e WHERE e.dept.deptno=42
```

Another way to write the same query is:

```
SELECT e.name from DeptBean d, IN (d.emps) AS e WHERE d.deptno=42
```

Finder and select queries allow only a single CMP field or EJBObject in the SELECT clause.

The dynamic query api allows multiple expressions in the SELECT clause. The following query would be a valid dynamic query, but not a valid select or finder query:

```
SELECT e.name, e.salary+e.bonus as total_pay , object(e), e.dept.mgr
FROM EmpBean e
ORDER BY 2
```

The following dynamic query returns the number of employees in each department:

```
SELECT e.dept.deptno as department_number , count(*) as employee_count
FROM EmpBean e
GROUP BY by e.dept.deptno
ORDER BY 1
```

The dynamic query api allows queries that contain bean or value object methods:

```
SELECT object(e), e.address.format()
FROM EmpBean e EmpBean e
```

## FROM clause

The FROM clause specifies the collections of objects to which the query is to be applied. Each collection is identified either by an abstract schema name and an identification variable, called a range variable, or by a collection member declaration that identifies a multivalued relationship and an identification variable.

Conceptually, the semantics of the query is to first form a temporary collection of tuples R. Tuples are composed of elements from the collections identified in the FROM clause. Each tuple contains one element from each of the collections in the FROM clause. All possible combinations are formed subject to the constraints imposed by the collection member declarations. If any schema name identifies a collection for which there are no records in the persistent store, then the temporary collection R will be empty.

### Example: FROM clause

DeptBean contains records 10, 20 and 30 in the persistent store. EmpBean contains records 1, 2 and 3 that are related to department 10 and records 4, 5 that are related to department 20. Department 30 has no related employees.

```
FROM DeptBean d, EmpBean e
```

This forms a temporary collection R that contains 15 tuples.

```
FROM DeptBean d, DeptBean d1
```

This forms a temporary collection R that contains 9 tuples.

```
FROM DeptBean d, IN (d.emps) AS e
```

This forms a temporary collection R that contains 5 tuples. Department 30 because it contains no employees will not be in R. Department 10 will be contained in R three times and department 20 will be contained in R twice.

After forming the temporary collection the search conditions of the WHERE clause will be applied to R and this will yield a new temporary collection R1. The ORDER BY and SELECT clauses are applied to R1 to yield the final result set.

An identification variable is a variable declared in the FROM clause using the operator IN or the optional AS.

```
FROM DeptBean AS d, IN (d.emps) AS e
```

is equivalent to:

```
FROM DeptBean d, IN (d.emps) e
```

An identification variable that is declared to be an abstract schema name is called a range variable. In the query above "d" is a range variable. An identification variable that is declared to be a multivalued path expression is called a collection member declaration. "d" and "e" in the example above are collection member declarations.

Note that the following path expression is illegal as a collection member declaration because it is not multivalued:

```
e.dept.mgr
```

## Inheritance in EJB query

If an EJB inheritance hierarchy has been defined for an abstract schema, using the abstract schema name in a query statement implies the collection of objects for that abstract schema as well as all subtypes.

### Example: Inheritance

Suppose that bean ManagerBean is defined as a subtype of EmpBean and ExecutiveBean is a subtype of ManagerBean in an EJB inheritance hierarchy. The following query returns employees as well as managers and executives:

```
SELECT OBJECT(e) FROM EmpBean e
```

## Path expressions

An identification variable followed by the navigation operator ( . ) and a cmp or relationship name is a path expression.

A path expression that leads to a cmr field can be further navigated if the cmr field is single-valued. If the path expression leads to a multi-valued relationship, then the path expression is terminal and cannot be further navigated. If the path expression leads to a cmp field whose type is a value object, it is possible to navigate to attributes of the value object.

### Example: Value object

Assume that address is a cmp field for EmpBean, which is a value object.

```
SELECT object(e) FROM EmpBean e
WHERE e.address.distance('San Jose') < 10 and e.address.zip = 95037
```

It is best to use the composer pattern to map value object attributes to relational columns if you intend to search on value attributes. If you store value objects in serialized format, then each value object must be retrieved from the database and deserialized. Value object methods can only be done in dynamic queries.

A path expression can also navigate to a bean method. The method must be defined on either the remote or local bean interface. Methods can only be used in dynamic queries. You cannot mix both remote and local methods in a single query statement.

If the query contains remote methods, the dynamic query must be executed using the query remote interface. Using the query remote interface causes the query service to activate beans and create instances of the remote bean interface

Likewise, a query statement with local bean methods must be executed with the query local interface. This causes the query service to activate beans and local interface instances.

Do not use get methods to access cmp and cmr fields of a bean.

If a method has overloaded definitions, the overloaded methods must have different number of parameters.

Methods must have non-void return types and method arguments and return types must be either primitive types byte, short, int, long, float, double, boolean, char or wrapper types from the following list:

Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Character, java.util.Calendar, java.sql.Date, java.sql.Time, java.sql.Timestamp, java.util.Date

If any input argument to a method is NULL, it is assumed the method returns a NULL value and the method is not invoked.

A collection valued path expression can be used in the FROM clause as a collection member declaration, and with the IS EMPTY, MEMBER OF, and EXISTS predicates in the WHERE clause.

FROM EmpBean e WHERE e.dept.mgr.name='Bob'	OK
FROM EmpBean e WHERE e.dept.emps.name='BOB'	INVALID -- cannot navigate through emps because it is multivalued
FROM EmpBean e, IN (e.dept.emps) e1 WHERE e1.name='BOB'	OK
FROM EmpBean e WHERE e.dept.emps IS EMPTY	OK

## WHERE clause

The WHERE clause contains search conditions composed of the following:

- literal values
- input parameters
- expressions
- basic predicates
- quantified predicates
- BETWEEN predicate
- IN predicate
- LIKE predicate
- NULL predicate
- EMPTY collection predicate
- MEMBER OF predicate
- EXISTS predicate
- IS OF TYPE predicate

If the search condition evaluates to TRUE, the tuple is added to the result set.

## Literals

A string literal is enclosed in single quotes. A single quote that occurs within a string literal is represented by two single quotes; For example: 'Tom's'. A string literal cannot exceed the maximum length that is supported by the underlying persistent datastore.

A numeric literal can be any of the following:

- an exact value such as 57, -957, +66
- any value supported by Java long
- a decimal literal such as 57.5, -47.02
- an approximate numeric value such as 7E3, -57.4E-2

A decimal or approximate numeric value must be in the range supported by the underlying persistent datastore.

A boolean literal can be the keyword TRUE or FALSE and is case insensitive.

## Input parameters

Input parameters are designated by the question mark followed by a number; For example: ?2

Input parameters are numbered starting at 1 and correspond to the arguments of the finder or select method; therefore, a query must not contain an input parameter that exceeds the number of input arguments.

An input parameter can be a primitive type of byte, short, int, long, float, double, boolean, char or wrapper types of Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Char, java.util.Calendar, java.util.Date, java.sql.Date, java.sql.Time, java.sql.Timestamp or an EJBObject.

An input parameter must not have a NULL value. To search for the occurrence of a NULL value the NULL predicate should be used.

## Expressions

Conditional expressions can consist of comparison operators and logical operators (AND, OR, NOT).

Arithmetic expressions can be used in comparison expressions and can be composed of arithmetic operations and functions, path expressions that evaluate to a numeric value and numeric literals and numeric input parameters.

String expressions can be used in comparison expressions and can be composed of string functions, path expressions that evaluate to a string value and string literals and string input parameters. A cmp field of type char is handled as if it were a string of length 1.

Boolean expressions can be used with = and <> comparison and can be composed of path expressions that evaluate to a boolean value and TRUE and FALSE keywords and boolean input parameters.

Reference expressions can be used with = and <> comparison and can be composed of path expressions that evaluate to a cmr field, an identification variable and an input parameter whose type is an EJB reference

Four different expression types are supported for working with date-time types. For portability the java.util.Calendar type should be used. DB2 style date, time and timestamp expressions are supported if the datastore is DB2 and the CMP field is of type java.util.Date, java.sql.Date, java.sql.Time or java.sql.Timestamp.

A Calendar type can be compared to another Calendar type, an exact numeric literal or input parameter of type long whose value is the standard Java long millisecond value.

The following query finds all employees born before Jan 1, 1990:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e.birthDate < 631180800232
```

Date expressions can be used in comparison expressions and can be composed of operators + - , date duration expressions and date functions, path expressions that evaluate to a date value, string representation of a date and date input parameters.

Time expressions can be used in comparison expressions and can be composed of operators + - , time duration expressions and time functions, path expressions that evaluate to a time value, string representation of time and time input parameters.

Timestamp expressions can be used in comparison expressions and can be composed of operators + - , timestamp duration expressions and timestamp functions, path expressions that evaluate to a timestamp value, string representation of a timestamp and timestamp input parameters.

Standard bracketing ( ) for ordering expression evaluation is supported.

The operators and their precedence order from highest to lowest are:

- Navigation operator ( . )
- Arithmetic operators in precedence order:
  - + - unary
  - \* / multiply, divide
  - + - add, subtract
- Comparison operators: =, >, <, >=, <=, <>(not equal)
- Logical operator NOT
- Logical operator AND
- Logical operator OR

In some datastores, a zero length string value ( " ) is treated as a null value and affects the results of queries. Some datastores perform division between two integer values using integer arithmetic rules and other datastores use non integer rules. This also can affect the results of queries. For portability, avoid the use of zero length string values and division of integer values in an EJB query.

**Null value semantics:** The following describe the semantics of NULL values:

- Comparison or arithmetic operations with an unknown (NULL) value yield an unknown value
- Path expressions that contain NULL evaluate to NULL
- The IS NULL and IS NOT NULL operators can be applied to path expressions and return TRUE or FALSE. Boolean operators AND, OR and NOT use three valued logic.

AND	True	False	Unknown
True	True	False	Unknown
False	False	False	False
Unknown	Unknown	False	Unknown

OR	True	False	Unknown
True	True	True	True
False	True	False	Unknown
Unknown	True	Unknown	Unknown

	NOT
True	False
False	True
Unknown	Unknown

### Example: Null value semantics

```
select object(e) from EmpBean where e.salary > 10 and e.dept.budget > 100
```

If salary is NULL the evaluation of `e.salary > 10` returns unknown and the employee object is not returned. If the cmr field dept or budget is NULL evaluation of `e.dept.budget > 100` returns unknown and the employee object is not returned.

```
select object(e) from EmpBean where e.dept.budget is null
```

If dept or budget is NULL evaluation of `e.dept.budget is null` returns TRUE and the employee object is returned.

```
select object(e) from EmpBean e , in (e.dept.emps) e1 where e1.salary > 10
```

If dept is NULL, then the multivalued path expression `e.dept.emps` results in an empty collection (not a collection that contains a NULL value). An employee with a null dept value will not be returned.

```
select object(e) from EmpBean e where e.dept.emps is empty
```

If dept is NULL the evaluation of the predicate in unknown and the employee object is not returned.

```
select object(e) from EmpBean e , EmpBean e1 where e member of e1.dept.emps
```

If dept is NULL evaluation of the member of predicate returns unknown and the employee is not returned.

**Date time arithmetic and comparisons:** DATE, TIME and TIMESTAMP values may be compared with another value of the same type. Comparisons are chronological. Date time values can also be incremented, decremented, and subtracted.

If the datastore is DB2, then DB2 string representation of DATE, TIME and TIMESTAMP types can also be used. A string representation of a date or time can use ISO, USA, EUR or JIS format. A string representation of a timestamp uses ISO format.

Format	Date format	Date examples	Time format	Time examples
ISO	yyyy-mm-dd	1987-02-24 1987-2-24	hh.mm.ss	13.50.00 13.50
USA	mm/dd/yyyy	2/24/1987	hh:mm AM or PM	1:50 pm 02:10 AM
EUR	dd.mm.yyyy	24.02.1987 24.2.1987	hh.mm.ss	13.50.00 13.55
JIS	yyyy-mm-dd	1987-02-24	hh:mm:ss	13:50 13:50:05

### Example 1: Date time arithmetic comparisons

```
e.hiredate > '1990-02-24'
```

The timestamp of February 24th, 1990 1:50 pm can be represented as follows:

```
'1990-02-24-13.50.00.000000' or
'1990-02-24-13.50.00'
```

If the datastore is DB2, DB2 decimal durations can be used in expressions and comparisons. A date duration is a decimal(8,0) number that represents the difference between two dates in the format YYYYMMDD. A time duration is a decimal(6,0) number that represents the difference between two time values as HHMMSS. A timestamp duration is a decimal(20,6) number representing the differences between two timestamp values as YYYYMMDDHHMMSS.ZZZZZZ (ZZZZZZ is the number of microseconds and is to the right of the decimal point) .

Two date values (or time values or timestamp values) can be subtracted to yield a duration. If the second operand is greater than the first the duration is a negative decimal number. A duration can be added or subtracted from a datetime value to yield a new datetime value.

## Example 2: Date time arithmetic comparisons

`DATE('3/15/2000') - '12/31/1999'` results in a decimal number 215 which is a duration of 0 years, 2 months and 15 days.

Durations are really decimal numbers and can be used in arithmetic expressions and comparisons.

`( DATE('3/15/2000') - '12/31/1999' ) + 14 > 215` evaluates to TRUE.

`DATE('12/31/1999') + DECIMAL(215,8,0)` results in a date value 3/15/2000.

`TIME('11:02:26') - '00:32:56'` results in a decimal number 102930 which is a time duration of 10 hours, 29 minutes and 30 seconds.

`TIME('00:32:56') + DECIMAL(102930,6,0)` results in a time value of 11:02:26.

`TIME('00:00:59') + DECIMAL(240000,6,0)` results in a time value of 00:00:59.

`e.hiredate + DECIMAL(500,8,0) > '2000-10-01'` means compare the hiredate plus 5 months to the date 10/01/2000.

## Basic predicates

Basic predicates can be of two forms

`expression-1 comparison-operator expression-2`

`expression-3 comparison-operator ( subselect )`

The subselect must not return more than one value and the subselect can not return a type of an EJB reference. Boolean types and reference types only support = and <> comparisons.

### Example: Basic predicates

```
d.name='Java Development'
e.salary > 20000
e.salary > (select avg(e.salary) from EmpBean e)
```

## Quantified predicates

A quantified predicate compares a value with a set of values produced by a subselect.

`expression comparison-operator SOME | ANY | ALL ( subselect )`

The expression must not evaluate to a reference type.

When SOME or ANY is specified the result of the predicate is as follows:

- TRUE if the comparison is true for at least one value returned by the subselect.
- FALSE if the subselect is empty or if the comparison is false for every value returned by the subselect.
- UNKNOWN if the comparison is not true for all of the values returned by the subselect and at least one of the comparisons is unknown because of a null value.

When ALL is specified the result of the predicate is as follows:

- TRUE if the subselect returns empty or if the comparison is true to every value returned by the subselect.
- FALSE if the comparison is false for at least one value returned by the subselect.
- UNKNOWN if the comparison is not false for all values returned by the subselect and at least one comparison is unknown because of a null value.

## BETWEEN predicate

The BETWEEN predicate determines whether a given value lies between two other given values.

`expression [NOT] BETWEEN expression-2 AND expression-3`

**Example: BETWEEN predicate**

```
e.salary BETWEEN 50000 AND 60000
```

is equivalent to:

```
e.salary >= 50000 AND e.salary <= 60000
e.name NOT BETWEEN 'A' AND 'B'
```

is equivalent to:

```
e.name < 'A' OR e.name > 'B'
```

**IN predicate**

The IN predicate compares a value to a set of values and can have one of two forms:

```
expression [NOT] IN (subselect)
expression [NOT] IN (value1, value2,)
```

ValueN can either be a literal value or an input parameter. The expression can not evaluate to a reference type.

**Example: IN predicate**

```
e.salary IN (10000, 15000)
```

is equivalent to

```
(e.salary = 10000 OR e.salary = 15000)
e.salary IN (select e1.salary from EmpBean e1 where e1.dept.deptno = 10)
```

is equivalent to

```
e.salary = ANY (select e1.salary from EmpBean e1 where e1.dept.deptno = 10)
e.salary NOT IN (select e1.salary from EmpBean e1 where e1.dept.deptno = 10)
```

is equivalent to

```
e.salary <> ALL (select e1.salary from EmpBean e1 where e1.dept.deptno = 10)
```

**LIKE predicate**

The LIKE predicate searches a string value for a certain pattern.

```
string-expression [NOT] LIKE pattern [ESCAPE escape-character]
```

The pattern value is a string literal or parameter marker of type string in which the underscore ( `_` ) stands for any single character and percent ( `%` ) stands for any sequence of characters ( including empty sequence ). Any other character stands for itself. The escape character can be used to search for character `_` and `%`. The escape character can be specified as a string literal or an input parameter.

If the string-expression is null, then the result is unknown.

If both string-expression and pattern are empty, then the result is true.

**Example: LIKE predicate**

- `'' LIKE ''` is true
- `'' LIKE '%'` is true
- `e.name LIKE '12%3'` is true for '123' '12993' and false for '1234'
- `e.name LIKE 's_me'` is true for 'some' and 'same', false for 'soome'
- `e.name LIKE '/_foo'` escape '/' is true for '/\_foo', false for 'afoo'
- `e.name LIKE '//_foo'` escape '/' is true for '/afoo' and for '/bfoo'
- `e.name LIKE '///_foo'` escape '/' is true for '/\_foo' but false for '/afoo'

## NULL predicate

The NULL predicate tests for null values.

```
single-valued-path-expression IS [NOT] NULL
```

### Example: NULL predicate

```
e.name IS NULL
e.dept.name IS NOT NULL
e.dept IS NOT NULL
```

## EMPTY collection predicate

To test if a multivalued relationship is empty, use the following syntax:

```
collection-valued-path-expression IS [NOT] EMPTY
```

### Example: Empty collection predicate

To find all departments with no employees:

```
SELECT OBJECT(d) FROM DeptBean d WHERE d.emps IS EMPTY
```

## MEMBER OF predicate

This expression tests whether the object reference specified by the single valued path expression or input parameter is a member of the designated collection. If the collection valued path expression designates an empty collection the value of the MEMBER OF expression is FALSE.

```
{ single-valued-path-expression | input_parameter } [NOT] MEMBER [OF] collection-valued-path-expression
```

### Example: MEMBER OF predicate

Find employees that are not members of a given department number:

```
SELECT OBJECT(e) FROM EmpBean e , DeptBean d
WHERE e NOT MEMBER OF d.emps AND d.deptno = ?1
```

Find employees whose manager is a member of a given department number:

```
SELECT OBJECT(e) FROM EmpBean e, DeptBean d
WHERE e.dept.mgr MEMBER OF d.emps and d.deptno=?1
```

## EXISTS predicate

The exists predicate tests for the presence or absence of a condition specified by a subselect.

```
EXISTS (subselect)
EXISTS collection-valued-path-expression
```

The result of EXISTS is true if the subselect returns at least one value or the path expression evaluates to a nonempty collection, otherwise the result is false.

To negate an EXISTS predicate, precede it with the logical operator NOT.

### Example: EXISTS predicate

Return departments that have at least one employee earning more than 1000000:

```
SELECT OBJECT(d) FROM DeptBean d
WHERE EXISTS (SELECT 1 FROM IN (d.emps) e WHERE e.salary > 1000000)
```

Return departments that have no employees:

```
SELECT OBJECT(d) FROM DeptBean d
WHERE NOT EXISTS (SELECT 1 FROM IN (d.emps) e)
```

The above query can also be written as follows:

```
SELECT OBJECT(d) FROM DeptBean d WHERE NOT EXISTS d.emps
```

## IS OF TYPE predicate

The IS OF TYPE predicate is used to test the type of an EJB reference. It is similar in function to the Java instance of operator. IS OF TYPE is used when several abstract beans have been grouped into an EJB inheritance hierarchy. The type names specified in the predicate are the bean abstract names. The ONLY option can be used to specify that the reference must be exactly this type and not a subtype.

```
identification-variable IS OF TYPE ([ONLY] type-1, [ONLY] type-2,)
```

### Example: IS OF TYPE predicate

Suppose that bean ManagerBean is defined as a subtype of EmpBean and ExecutiveBean is a subtype of ManagerBean in an EJB inheritance hierarchy.

The following query returns employees as well as managers and executives:

```
SELECT OBJECT(e) FROM EmpBean e
```

If you are interested in objects which are employees and not managers and not executives:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e IS OF TYPE(ONLY EmpBean)
```

If you are interested in object which are managers or executives:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e IS OF TYPE(ManagerBean)
```

The above query is equivalent to the following query:

```
SELECT OBJECT(e) FROM ManagerBean e
```

If you are interested in managers only and not executives:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e IS OF TYPE(ONLY ManagerBean)
```

or:

```
SELECT OBJECT(e) FROM ManagerBean e
WHERE e IS OF TYPE (ONLY ManagerBean)
```

## Scalar functions

EJB query contains scalar built-in functions for doing type conversions, string manipulation, and for manipulating date-time values. The list of scalar functions is documented in the topic EJB query: Scalar functions.

### Example: Scalar functions

Find employees hired in 1999:

```
SELECT OBJECT(e) FROM EmpBean e where YEAR(e.hireDate) = 1999
```

The only scalar functions that are guaranteed to be portable across backend datastore vendors are the following:

- ABS
- SQRT
- CONCAT
- LENGTH
- LOCATE
- SUBSTRING

The other scalar functions should be used only when DB2 is the backend datastore.

## EJB query: Scalar functions

EJB query contains scalar built-in functions, as listed below, for doing type conversions, string manipulation, and for manipulating date-time values.

### Numeric functions

ABS ( < any numeric datatype > ) -> < any numeric datatype >  
SQRT ( < any numeric datatype > ) -> Double

### Type conversion functions

CHAR ( < any numeric datatype > ) -> string  
CHAR ( < string > ) -> string  
CHAR ( < any datetime datatype > [, Keyword k ] ) -> string

Datetime datatype is converted to its string representation in a format specified by the keyword k. The valid keywords values are ISO, USA, EUR or JIS. If k is not specified the default is ISO.

BIGINT ( < any numeric datatype > ) -> Long  
BIGINT ( < string > ) -> Long

The following function converts the argument to an integer n by truncation and returns the date that is n-1 days after January 1, 0001:

DATE ( < date string > ) -> Date  
DATE ( < any numeric datatype> ) -> Date

The following function returns date portion of a timestamp:

DATE( timestamp ) -> Date  
DATE ( < timestamp-string > ) -> Date

The following function converts number to decimal with optional precision p and scale s.

DECIMAL ( < any numeric datatype > [, p [, s ] ] ) -> Decimal

The following function converts string to decimal with optional precision p and scale s.

DECIMAL ( < string > [, p [, s ] ] ) -> Decimal  
DOUBLE ( < any numeric datatype > ) -> Double  
DOUBLE ( < string > ) -> Double  
FLOAT ( < any numeric datatype > ) -> Double  
FLOAT ( < string > ) -> Double

Float is a synonym for DOUBLE.

INTEGER ( < any numeric datatype > ) -> Integer  
INTEGER ( < string > ) -> Integer  
REAL ( < any numeric datatype > ) -> Float  
SMALLINT ( < any numeric datatype > ) -> Short  
SMALLINT ( < string > ) -> Short  
TIME ( < time > ) -> Time  
TIME ( < time-string > ) -> Time  
TIME ( < timestamp > ) -> Time  
TIME ( < timestamp-string > ) -> Time  
TIMESTAMP ( < timestamp > ) -> Timestamp  
TIMESTAMP ( < timestamp-string > ) -> Timestamp

### String functions

CONCAT ( <string>, <string> ) -> String

The following function returns a character string representing absolute value of the argument not including its sign or decimal point. For example, digits( -42.35) is "4235".

DIGITS ( Decimal d ) -> String

The following function returns the length of the argument in bytes. If the argument is a numeric or datetime type, it returns the length of internal representation.

LENGTH ( < string > ) -> Integer

The following function returns a copy of the argument string where all upper case characters have been converted to lower case.

LCASE ( < string > ) -> String

The following function returns the starting position of the first occurrence of argument 1 inside argument 2 with optional start position. If not found, it returns 0.

LOCATE ( String s1 , String s2 [, Integer start ] ) -> Integer

The following function returns a substring of s beginning at character m and containing n characters. If n is omitted, the substring contains the remainder of string s. The result string is padded with blanks if needed to make a string of length n.

SUBSTRING ( String s , Integer m [ , Integer n ] ) -> String

The following function returns a copy of the argument string where all lower case characters have been converted to upper case.

UCASE ( < string > ) -> String

### **Date - time functions**

The following function returns the day portion of its argument. For a duration, the return value can be -99 to 99.

DAY ( Date ) -> Integer  
DAY ( < date-string > ) -> Integer  
DAY ( < date-duration > ) -> Integer  
DAY ( Timestamp ) -> Integer  
DAY ( < timestamp-string > ) -> Integer  
DAY ( < timestamp-duration > ) -> Integer

The following function returns one more than number of days from January 1, 0001 to its argument.

DAYS ( Date ) -> Integer  
DAYS ( < Date-string > ) -> Integer  
DAYS ( Timestamp ) -> Integer  
DAYS ( < timestamp-string > ) -> Integer

The following function returns the hour part of its argument. For a duration, the return value can be -99 to 99.

HOUR ( Time ) -> Integer  
HOUR ( < time-string > ) -> Integer  
HOUR ( < time-duration > ) -> Integer  
HOUR ( Timestamp ) -> Integer  
HOUR ( < timestamp-string > ) -> Integer  
HOUR ( < timestamp-duration > ) -> Integer

The following function returns the microsecond part of its argument.

MICROSECOND ( Timestamp ) -> Integer  
MICROSECOND ( < timestamp-string > ) -> Integer  
MICROSECOND ( < timestamp-duration > ) -> Integer

The following function returns the minute part of its argument. For a duration, the return value can be -99 to 99.

```

MINUTE (Time) -> Integer
MINUTE (< time-string >) -> Integer
MINUTE (< time-duration >) -> Integer
MINUTE (Timestamp) -> Integer
MINUTE (< timestamp-string >) -> Integer
MINUTE (< timestamp-duration >) -> Integer

```

The following function returns the month portion of its argument. For a duration, the return value can be -99 to 99.

```

MONTH (Date) -> Integer
MONTH (< date-string >) -> Integer
MONTH (< date-duration >) -> Integer
MONTH (Timestamp) -> Integer
MONTH (< timestamp-string >) -> Integer
MONTH (< timestamp-duration >) -> Integer

```

The following function returns the second part of its argument. For a duration, the return value can be -99 to 99.

```

SECOND (Time) -> Integer
SECOND (< time-string >) -> Integer
SECOND (< time-duration >) -> Integer
SECOND (Timestamp) -> Integer
SECOND (< timestamp-string >) -> Integer
SECOND (< timestamp-duration >) -> Integer

```

The following function returns the year portion of its argument. For a duration, the return value can be -9999 to 9999.

```

YEAR (Date) -> Integer
YEAR (< date-string >) -> Integer
YEAR (< date-duration >) -> Integer
YEAR (Timestamp) -> Integer
YEAR (< timestamp-string >) -> Integer
YEAR (< timestamp-duration >) -> Integer

```

## Aggregation functions

Queries that return aggregate values can only be used with the dynamic query interface available in WebSphere Business Integration Server. However, aggregation functions can be used in non-dynamic queries if the aggregation function is used in a subselect or HAVING clause.

Aggregation functions operate on a set of values to return a single scalar value. The following is an example of an aggregation:

```
SELECT SUM (e.salary + e.bonus) FROM EmpBean e WHERE e.dept.deptno =20
```

This computes the total salary and bonus for department 20.

The aggregation functions are avg, count, max, min and sum. The syntax of an aggregation function is as follows:

```
aggregation-function ([ALL | DISTINCT] expression)
```

or:

```
COUNT(*)
```

The DISTINCT option eliminates duplicate values before applying the function. ALL is the default and does not eliminate duplicates. Null values are ignored in computing the aggregate function except for COUNT(\*) which returns a count of all elements in the set.

MAX and MIN can apply to any numeric, string or datetime datatype and returns the same datatype. SUM and AVG take a numeric type as input. SUM and AVG return numeric type. The actual numeric type returned by SUM and AVG depends on the underlying datastore. COUNT can take any datatype and returns an integer.

If you are using an Informix datastore, the argument to COUNT must be an asterisk or a single valued path expression. The argument to SUM, AVG, MIN, or MAX used with DISTINCT must be a single valued path expression.

The set of values that is used for the aggregate function is determined by the collection that results from the FROM and WHERE clause of the subquery. This set can be divided into groups and the aggregation function applied to each group. This is done by using a GROUP BY clause in the subquery. The GROUP BY clause defines grouping members which is a list of path expressions. Each path expression specifies a field that is a primitive type of byte, short, int, long, float, double, boolean, char, or a wrapper type of Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Character, java.util.Calendar, java.util.Date, java.sql.Date, java.sql.Time or java.sql.Timestamp.

Finder or select queries can not return aggregation function values. In other words, aggregation functions can not appear in the top level SELECT of a finder or select query but can be used in subqueries.

### Example: Aggregation functions

```
SELECT e.dept.deptno, AVG (e.salary) FROM EmpBean e GROUP BY e.dept.deptno
```

The above query computes the average salary for each department.

In dividing a set into groups, a NULL value is considered equal to another NULL value.

Just as the WHERE clause filters tuples from the FROM clause, the groups can be filtered using a HAVING clause that tests group properties involving aggregate functions or grouping members:

```
SELECT e.dept.deptno, AVG (e.salary) FROM EmpBean e
GROUP BY e.dept.deptno
HAVING COUNT(*) > 3 AND e.dept.deptno > 5
```

This query returns average salary for departments that have more than 3 employees and the department number is greater than 5.

It is possible to have a HAVING clause without a GROUP BY clause in which case the entire set is treated as a single group to which the HAVING clause is applied.

## SELECT clause

For finder and select queries, the syntax of the SELECT clause is as follows:

```
SELECT [ALL | DISTINCT]
{ single-valued-path-expression | OBJECT (identification-variable) }
```

The SELECT clause consists of either a single identification variable that is defined in the FROM clause or a single valued path expression that evaluates to a object reference or CMP value. The keyword DISTINCT can be used to eliminate duplicate references.

For a query that defines a finder method the query must return an object type consistent with the home for which the finder method associated with the query. In other words, a finder method for a department home can not return employee objects.

For dynamic queries the syntax is as follows:

```
SELECT { ALL | DISTINCT } [selection ,]* selection
selection ::= { expression [[AS] id] | scalar-subselect }
```

A scalar-subselect is a subselect that returns a single value.

### Example: SELECT clause

Find all employees that earn more than John:

```
SELECT OBJECT(e) FROM EmpBean ej, EmpBean e
WHERE ej.name = 'John' and e.salary > ej.salary
```

Find all departments that have one or more employees who earn less than 20000:

```
SELECT DISTINCT e.dept FROM EmpBean e where e.salary < 20000
```

A select method query can have a path expression that evaluates to an arbitrary value:

```
SELECT e.dept.name FROM EmpBean e where e.salary < 2000
```

The above query returns a collection of name values for those departments having employees earning less than 20000.

### Example: Valid dynamic queries

The following are examples of dynamic queries:

```
SELECT e.name, e.salary+e.bonus as total_pay from EmpBean e
SELECT SUM(e.salary+e.bonus) from EmpBean e where e.dept.deptno = ?1
```

## ORDER BY clause

The ORDER BY clause specifies an ordering of the objects in the result collection:

```
ORDER BY [order_element ,]* order_element
order_element ::= { path-expression | integer } [ASC | DESC]
```

The path expression must specify a single valued field that is a primitive type of byte, short, int, long, float, double, char or a wrapper type of Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Character, java.util.Calendar, java.util.Date, java.sql.Date, java.sql.Time, java.sql.Timestamp.

ASC specifies ascending order and is the default. DESC specifies descending order.

Integer refers to a selection expression in the SELECT clause.

### Example: ORDER BY clause

Return department objects in decreasing deptno order:

```
SELECT OBJECT(d) FROM DeptBean d ORDER BY d.deptno DESC
```

Return employee objects sorted by department number and name:

```
SELECT OBJECT(e) FROM EmpBean e ORDER BY e.dept.deptno ASC, e.name DESC
```

The following is a valid dynamic query:

```
SELECT OBJECT(e), e.salary+e.bonus as total_pay FROM EmpBean e ORDER BY 2 DESC
```

## Subqueries

A subquery can be used in quantified predicates, EXISTS predicate or IN predicate. A subquery should only specify a single element in the SELECT clause. When a path expression appears in a subquery, the identification variable of the path expression must be defined either in the subquery, in one of the containing subqueries, or in the outer query. A scalar subquery is a subquery that returns one value. A scalar subquery can be used in a basic predicate and in the SELECT clause of a dynamic query.

### Example: Subqueries

```
SELECT OBJECT(e) FROM EmpBean e
WHERE e.salary > (SELECT AVG(e1.salary) FROM EmpBean e1)
```

The above query returns employees who earn more than average salary of all employees.

```
SELECT OBJECT(e) FROM EmpBean e WHERE e.salary >
(SELECT AVG(e1.salary) FROM IN (e.dept.emps) e1)
```

The above query returns employees who earn more than average salary of their department.

```
SELECT OBJECT(e) FROM EmpBean e WHERE e.salary =
(SELECT MAX(e1.salary) FROM IN (e.dept.emps) e1)
```

The above query returns employees who earn the most in their department.

```
SELECT OBJECT(e) FROM EmpBean e
WHERE e.salary > (SELECT AVG(e.salary) FROM EmpBean e1
WHERE YEAR(e1.hireDate) = YEAR(e.hireDate))
```

The above query returns employees who earn more than the average of employees hired in same year.

## EJB query restrictions

An EJB query is compiled into an SQL query and executed against the underlying datastore based on schema mapping of the abstract bean to the datastore schema. The semantics of comparison and arithmetic operations are that of the underlying datastore. In the case of SQL, note that two strings are equal if the shorter string padded with blanks equals the longer string. For example, 'A' is equal to 'A '. This differs from the equality of strings in the Java language. Arithmetic overflow operations are an error in SQL.

A cmp field can not be used in comparison operations or predicates (except for LIKE) if that cmp field is mapped to a long varchar or large objects (LOB) column or any other column type for which the database server does not support predicates or comparison operations.

A cmp field of any type can be used in a SELECT clause. Fields that can be used in predicates, grouping, or ordering operations must be of the types listed below:

- Primitive types : byte, short, int, long, float, double, boolean, char
- Object types: Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Char, java.util.Calendar , java.util.Date
- JDBC types: java.sql.Date, java.sql.Time, java.sql.Timestamp

The field must be mapped to a table column that is compatible in type either by using a "top-down" default mapping generated by the WebSphere deploy tool, or using a "meet-in-the-middle" mapping between compatible types.

In order to search on attributes of a cmp field that is a user-defined value object, you should use a "meet-in-the-middle" mapping and use a composer to map each attribute to a compatible column. The default "top-down" mapping stores the object as a serialized object in a column of type blob, which does not allow searching.

If a cmp field is mapped to a column using a "meet-in-the-middle" mapping with a converter, that field can only be used with the NULL predicate or with basic predicates of the following form:

```
path-expression <comparison> literal_value
path-expression <comparison> input_parameter
```

In this situation, the converter method `toData()` is called to convert the right-hand side of the predicate to an SQL value.

Example of allowable predicate on a cmp field with user defined converter:

```
e.name = 'Chris'
e.name > ?1
e.name IS NULL
```

Examples of unallowable predicates:

```
substring(e.name, 1, 3) = 'ABC'
e.salary > d.budget
```

A converter should preserve equality, collating sequence and null values when doing a conversion. Otherwise cmp fields created by the converter should not be used in WHERE, GROUP, HAVING or ORDER clauses of a query.

## EJB Query: Reserved words

The following words are reserved in WebSphere EJB query:

all, as, distinct, empty, false, from, group, having, in, is, like, select, true, union, where

Avoid using identifiers that start with underscore (for example, `_integer`) as these are also reserved.

## EJB query: BNF syntax

```
EJB QL ::= [select_clause] from_clause [where_clause]
 [group_by_clause] [having_clause] [order_by_clause]
from_clause ::= FROM identification_variable_declaration

## Comparison of EJB 2.0 specification and WebSphere query language

Item	EJB 2.0 specification	WebSphere Query	WebSphere Enterprise (Dynamic) Query
Bean methods	no	no	yes
Calendar comparisons	yes	yes	yes
Delimited identifiers	no	yes	yes
Dependent Value attributes	no	yes	yes
Dependent Value methods	no	no	yes
Dynamic Query APIs	no	no	yes
EXISTS predicate	no	yes	yes
Inheritance	no	yes	yes
Multiple element select clauses	no	no	yes
Order by	no	yes	yes
Scalar functions	yes *	yes	yes
Select clause	required	optional	optional
SQL Date/time expressions	no	yes	yes
String comparisons	= and <> only	= <> > <	= <> > <
Subqueries, aggregations, group by, and having clauses	no	yes	yes

\* EJB 2.0 defines the following scalar functions: abs, sqrt, concat, length, locate and substring. WebSphere query and dynamic query support additional scalar functions as listed in the topic, EJB query: Scalar functions.

---

## Using the dynamic query service

Consider using the dynamic query service (available with Integration Server) when any of the following are true:

- You do not know the query search criteria until application runtime.
- You need to return multiple cmp or cmr fields from a query (deployment queries allow only a single element to be specified in the SELECT clause). For more information, see the Example: EJB queries article.
- You want to perform aggregation in the query (deployment queries do not allow use of aggregation function SUM, AVG, COUNT, MAX, MIN in the top level SELECT of a query).
- You want to use value object methods or bean methods in the query statement. For more information, see Path expressions.

- You want to interactively test an EJB query during development but do not want to repeatedly deploy your application each time you update a finder or select query.

If you have a query that has a high frequency of execution you should define it as a finder or select method and consider using SQLJ as a deployment option for best performance. The dynamic query service always uses JDBC and must parse and process the EJB query at runtime.

If you need security control over which queries a user can execute, you need to define the queries as finder or select methods and use EJB method authorization. The dynamic query service does not have fine grain security control at this time. You can control who is permitted access to the remote query bean and the local query bean, but once authorized a user can execute any valid query and return any data in the server.

The dynamic query API is a stateless session bean. Using the dynamic query API is similar to using any other J2EE EJB application bean.

The default JNDI name for the query bean is as follows, but your system administrator can change this name:

```
com/ibm/websphere/ejbquery/Query
```

The system administrator might need to install the query.ear application into the application server. The WebSphere product install does this only for the default server.

**Note:** The query.ear file is located in the <WAS\_HOME>/installableApps directory where <WAS\_HOME> is the location of the WebSphere Application Server.

The query bean has both a remote and a local interface to support both remote and local clients.

- remote interface = com.ibm.websphere.ejbquery.Query
- remote home interface = com.ibm.websphere.ejbquery.QueryHome
- local interface = com.ibm.websphere.ejbquery.QueryLocal
- local home interface = com.ibm.websphere.ejbquery.QueryLocalHome

To use the local interface or bean methods on the remote interface of the query bean, you must configure your server to use the following:

```
Application Classloader Policy = SINGLE
```

Using a value of MULTI may result in your application being unable to find the local interface for the query bean home.

The following Jar files comprise the query service:

Jar	Location	Usage
query.jar	server - AppServer/lib	query parser
qjcup.jar	server - AppServer/lib	auxillary classes for parser
querybean.jar	server - installedApps	query session bean
querymd.jar	server - AppServer/lib	auxillary classes for parser
queryws.jar	server - AppServer/lib	adapter classes for runtime
qryclient.jar	client	client stubs and classes

1. To execute a query, have your client do a JNDI lookup for the QueryHome and create an instance of the query bean. The query bean contains the executeQuery() method, which takes as parameters the query statement in the form of a string, and input parameters in the form of an array of java.lang.Object values. Remote clients also pass as arguments the size of the result set to return.

The results of the query are returned for remote clients as:

```
com.ibm.websphere.ejbquery.QueryIterator
```

or for local clients as:

```
com.ibm.websphere.ejbquery.QueryLocalIterator
```

If you want to return remote EJB references from the query, or if the query statement contains remote methods, you must use the query remote interface.

If you want to return local EJB references from the query, or if the query statement contains local methods, you must use the query local interface.

Calling the next() method on the iterator returns an instance of com.ibm.websphere.ejbquery.IQueryTuple, which contains the actual data values or object references. The iterator also contains the following methods:

```
getFieldName(int i)
getFieldsCount();
```

2. Compile and run your client program with the file **qryclient.jar** in the classpath.

For more details, see the following articles:

- Javadoc for package com.ibm.websphere.ejbquery.
- Class IQueryTuple
- Class QueryIterator

The WebSphere Sample Gallery contains a complete working example of the dynamic query service.

**Security Considerations.** WebSphere does not have security access control for CMP and CMR fields. You must therefore secure the query bean methods executeQuery(), prepareQuery(), and executePlan(), and the create() method on the query home; otherwise, any user is able to perform a dynamic query and retrieve data from your application.

## Example: Dynamic query remote client

The following is an example of the Dynamic query remote client with added explanation.

```
import com.ibm.websphere.ejbquery.QueryHome;
import com.ibm.websphere.ejbquery.Query;
import com.ibm.websphere.ejbquery.QueryIterator;
import com.ibm.websphere.ejbquery.IQueryTuple;
import com.ibm.websphere.ejbquery.QueryException;

try {
String query =
"select e.name as name , object(e) as emp from EmpBean e where e.salary < 50000";

InitialContext ic = new InitialContext();

Object obj = ic.lookup("com/ibm/websphere/ejbquery/Query");

QueryHome qh =
(QueryHome) javax.rmi.PortableRemoteObject.narrow(obj, QueryHome.class);
Query qb = qh.create();

You must specify a maximum size of the query result set. In this example 99 is used.
QueryIterator it = qb.executeQuery(query, null, null ,0, 99);
```

The iterator contains a collection of IQueryTuple objects. Each tuple contains one value of name and one value of object(e) from the query. To display the contents of the query result, use the following code:

```

while (it.hasNext()) {
IQueryTuple tuple = (IQueryTuple) it.next();
System.out.print(it.getFieldName(1));
String s = (String) tuple.getObject(1);
System.out.println(s);

System.out.println(it.getFieldName(2));
Emp e = (Emp) javax.rmi.PortableRemoteObject.narrow(tuple.getObject(2), Emp.class);
System.out.println(e.getPrimaryKey().toString());
}

```

The output from the program might look something like the following:

```

name Bob
emp 1001
name Dave
emp 298003
...

```

Finally, catch and process any exceptions. An exception might occur because of a syntax error in the query statement or a run-time processing error. The following is an example that catches and processes these exceptions:

```

} catch (QueryException qe) {
 System.out.println("Query Exception "+ qe.getMessage());
}

```

## Example: Dynamic query from local client

Establish a transaction context prior to calling `executeQuery` so that a call to `begin()` and `commit()` is needed. The `QueryLocalIterator` becomes invalid at end of a transaction. Therefore, you must use the iterator in the same transaction scope as the `executeQuery` call.

```

import com.ibm.websphere.ejbquery.QueryLocalHome;
import com.ibm.websphere.ejbquery.QueryLocal;
import com.ibm.websphere.ejbquery.QueryLocalIterator;
import com.ibm.websphere.ejbquery.IQueryTuple;
import com.ibm.websphere.ejbquery.QueryException;

String query =
"select e.name, object(e) from EmpBean e where e.salary < 50000 ";

InitialContext ic = new InitialContext();
QueryLocalHome qh = (LocalQueryHome) ic.lookup("java:comp/env/ejb/query");
QueryLocal qb = qh.create();
userTransaction.begin();
QueryLocalIterator it = qb.executeQuery(query, null, null);
while (it.hasNext()) {
IQueryTuple tuple = (IQueryTuple) it.next();
System.out.print(it.getFieldName(1));
String s = (String) tuple.getObject(1);
System.out.println(s);

System.out.println(it.getFieldName(2));
EmpLocal e = (EmpLocal) tuple.getObject(2);
System.out.println(e.getPrimaryKey().toString());
}
userTransaction.commit();

```

## Dynamic query service performance considerations

You can use the dynamic query service to build and execute queries against entity beans constructed dynamically at runtime, rather than defining them at deployment time. By using dynamic query you gain

the flexibility of queries defined at runtime and utilize the power of EJB-Query Language (QL). Apart from supporting all of the capabilities of an EJB-QL query, dynamic query adds additional functionality not available to standard static query. Two examples are the ability to select multiple data fields directly from the bean itself (static queries currently only allow one) and executing business methods directly in the query.

When used as a direct replacement for an equivalent static query, dynamic query is slower than the static variation. This slowdown is due to the need for parsing and building a plan for the query, in addition to executing it. In the static variation, these costs are paid at deploy time. In WebSphere Application Server Enterprise 5.0, expect to see 60% degradation in performance between executing a predefined static query and the equivalent dynamic query. Through optimizations implemented in WebSphere Application Server Enterprise 5.01, a cache for recently used query plans and other performance improvements, this degradation is reduced to about 25%.

You can effectively create more efficient and less resource intensive applications with dynamic query. For example, two data fields are required from the results of a query. Because a standard EJB-QL query can only select one data field, it is necessary to select the entire EJB object and extract the needed data from the returned results through data access methods, possibly traversing Container Managed Relationships (CMR) boundaries in the process. However, when using dynamic query, you can get both pieces of data directly from the query without additional CMR traversal or accessor methods. This principle is the key to evaluating whether or not dynamic query can be used for performance gain. You should review the amount of data that must be retrieved, in addition to the amount of business logic needed to retrieve it, for example, CMR traversal or accessor methods.

Using parameters in the query rather than literal values is another performance consideration. Under most circumstances, it is better to define conditional values as parameters in the query and then pass those parameters through the appropriate mechanisms. By using this method, you have a greater chance of matching a cached query plan and you eliminate the need to parse and build the plan from scratch. For example, "SELECT Object(o) FROM schemaname AS o WHERE o.fieldname LIKE foo", is more appropriately expressed as "SELECT Object(o) FROM schemaname AS o WHERE o.fieldname LIKE ?1" with the value *foo* passed as a parameter to the executeQuery method. The result is that any subsequent execution of a dynamic query structure that is the same, except for different string literal conditions, are registered as a plan cache hit affecting observed performance.

The dynamic query service is inherently handicapped from a performance viewpoint because of the necessary work of parsing the supplied queries dynamically and building the subsequent query plans. Despite this, the added functionality gained through the use of dynamic query, specifically the ability to select multiple data fields in a single query even across CMRs, creates opportunities to utilize dynamic query for the sake of performance improvement. The additional benefits of dynamic query in WebSphere Application Server Enterprise 5.01, like the use of parameters within the query, further improves the performance through caching and reusing a more general set of plans.

---

## Chapter 15. Using the internationalization service

The internationalization service adds APIs and tooling that enable J2EE applications to manage the distribution of internationalization information, or *internationalization context*, necessary to perform localizations within server-side application components. This topic summarizes the steps involved in using the internationalization service.

1. If you have an application that uses the WebSphere Version 4.0 internationalization service, migrate your application as needed.
2. Use the internationalization context API within application components to obtain or manage internationalization context. Servlet and enterprise bean business methods can use internationalization context to perform locale- and time zone-sensitive localizations. EJB client applications, and server components configured to manage internationalization context must use the internationalization context API to set the context elements scoped to their invocations.

You use the internationalization context API within Web service-enabled J2EE client programs and stateless session beans in the same manner as you would in conventional J2EE components, with one exception: Internationalization context propagated over Web services requests contains a time zone ID, whereas conventional RMI/IIOP requests propagate complete time zone information, including the raw offset, DST information, and so on.

3. Assemble internationalized applications.

Internationalization type specifies the internationalization policy applicable to a servlet or an enterprise bean and, in particular, indicates whether the application component or its hosting J2EE container will manage internationalization context. Container internationalization attributes can be specified for container-managed servlet and enterprise bean business methods. These attributes tailor a policy by indicating which context the container will scope to an invocation. Configuring internationalization policies declaratively prescribes, by means of the application's deployment descriptor, the distribution and management of context throughout an application.

**5.1+** While you edit the deployment descriptor for assembly, you can also set the internationalization type and configure any container internationalization attributes for the servlets and enterprise beans in your application.

You configure internationalization type and container internationalization attributes for Web service-enabled stateless session beans in the same manner as you do for conventional beans.

4. Manage the internationalization service. Use the administrative console to enable the service on all application servers.

By default, the service is enabled within J2EE client environments but is disabled on application servers. You must enable the service on all application servers hosting your application's servlets and enterprise beans in order to use internationalization context.

This also applies to J2EE Web service client environments and Web service-enabled enterprise beans.

5. Troubleshoot the internationalization service as needed. Use the administrative console to enable the trace service to log internationalization service messages when debugging your applications.

---

### Internationalization

An application that can present information to users according to regional cultural conventions is said to be *internationalized*. The application can be configured to interact with users from different localities in culturally appropriate ways. In an internationalized application, a user in one region sees error messages, output, and interface elements in the requested language. Date and time formats, as well as currencies, are presented appropriately for users in the specified region. A user in another region sees output in the conventional language or format for that region.

Historically, the creation of internationalized applications has been restricted to large corporations writing complex systems. Internationalization techniques have traditionally been expensive and difficult to implement, so they have been applied only to major development efforts. However, given the rise in

distributed computing and in the use of the World Wide Web, application developers have been pressured to internationalize a much wider variety of applications. This requires making internationalization techniques much more accessible to application developers.

In an application that is not internationalized, the interface that the user sees is unalterably written into the application code. On the other hand, localizing the displayed strings adds a layer of abstraction into the design of the application. Instead of simply printing an error message, an internationalized application represents the error message with some language-neutral information; in the simplest case, each error condition corresponds to a key. To print a usable error message, then, the application looks up the key in the configured message catalog. Each message catalog is a list of keys with associated strings. Different message catalogs provide strings for the different languages supported. The application looks up the key in the appropriate catalog, retrieves the corresponding error message in the requested language, and prints this string for the user.

Localization of text can be used for far more than translating error messages. For example, by using keys to represent each element in a graphical user interface (GUI) and by providing the appropriate message catalogs, the GUI itself (buttons, menus, and so on) can support multiple languages. Extending support to additional languages requires that you provide message catalogs for those languages; in many cases, the application itself needs no further modification.

Internationalization of an application is driven by two variables, the time zone and the locale. The time zone indicates how to compute the local time as an offset from a standard time like Greenwich Mean Time. The locale is a collection of information about language, currency, and the conventions for presenting information like dates. In a localized application, the locale also indicates the message catalog from which an application is to retrieve message strings. A time zone can cover many locales, and a single locale can span time zones. With both time zone and locale, the date, time, currency, and language for users in a specific region can be determined.

**5.1 +** WebSphere Business Integration Server Foundation provides an Internationalization Service, which manages the distribution of locale and time-zone information, or *internationalization context*, within Java applications.

---

## Internationalization service: Overview

In a distributed client-server environment, application processes can run on different machines, configured to different locales, corresponding to different cultural conventions; they can also be located across geographical boundaries. For an understanding of how these differences impact application development, review the topic Internationalization challenges in distributed applications.

The J2EE platform provides support for application components executing on computers with differing endian architecture and code sets, but does not provide dedicated support for application components that run on computers having different locales or time zones.

The conventional method for solving locale and time zone mismatch across remote application components is to pass one or more extra parameters on all business methods needed to convey the client-side locale or time zone to the server. Although simple, this technique has the following limitations when used in EJB applications:

- It is intrusive because it requires that one or more parameters be added to all bean methods in the call chain to locale-sensitive or time zone-sensitive methods.
- It is inherently error-prone.
- It is impracticable within applications that do not afford modification, such as legacy applications.

## The internationalization service solution

The WebSphere internationalization service addresses the challenges posed by locale and time zone mismatch without incurring the limitations of conventional techniques. It does this by systematically managing the distribution of internationalization contexts across the various components of EJB applications, including client applications, enterprise beans, and servlets.

The service works by associating an internationalization context with every thread of execution within an application. When a client-side component invokes a business method, the internationalization service interposes by obtaining the internationalization context associated with the current thread of the client-side process and attaching that context to the outgoing request. On the server-side, the internationalization service again interposes by detaching the context from the incoming request and associating it with the thread of the server-side process on which the business method will execute, effectively scoping the context to the business method. The service propagates internationalization context on subsequent business method invocations in the same manner and thus distributes the context of the originating request over the entire chain of business method invocations.

This basic operation of scoping and propagation is defined precisely by internationalization context management policies. Internationalization policies specify whether an application component or its hosting J2EE container are to manage internationalization context. For container-managed components, the policy indicates which internationalization context the container will scope to invocations on that component. Server components configured to manage internationalization context, as well as EJB clients, must use the internationalization context API to manage the internationalization context elements scoped to their invocations.

Every application component has a default policy, which can be overridden and tailored for servlets and enterprise beans at assembly time.

At execution time, application components can use the internationalization context API to get any element of the internationalization contexts scoped to an invocation. To programmatically access context elements, application components first resolve an internationalization context API reference, then invoke the appropriate API method to access the various context elements, such as the caller locale or the invocation time zone. These elements can be used in calls to Java 2 SDK internationalization API methods; for example, to perform localizations such as formatting messages, configuring dates, or comparing strings.

## Internationalization challenges in distributed applications

With the advent of Internet-based business computational models, such as eCommerce, applications increasingly comprise clients and servers that operate in different locales and geographical regions. These differences introduce challenges to the task of designing a sound client-server infrastructure. Specifically, clients and servers can:

- Execute on computers having different endian architectures or code sets.
- Be located in different locales.
- Be located in different time zones.

The following sections describe these three challenges in more detail.

### Computers with differing endian architectures or code sets

Clients and servers can reside in computers having different endian architectures: a client could reside in a little-endian CPU, while the server code runs in a big-endian one. As a more complex instance, a client might want to invoke a business method on a server running in a code set different from that of the client.

A client-server infrastructure must define precise endian and code set tracking and conversion rules. Both CORBA and J2EE have addressed the problems of endian and code set mismatches. The language-neutral CORBA formalism uses byte order indicator in all marshalled data streams to indicate the

byte order of the originating machine; in case of an endian mismatch, the receiving side can perform byte swapping for endian correction. The code set mismatch is addressed by CORBA using a comprehensive framework for code set conversion.

J2EE has nearly eliminated these problems in a unique way by relying on its Java Virtual Machine (JVM), which encodes all string data in UCS-2 format and externalizes everything in big-endian format. The JVM employs a set of platform-specific programs for interfacing with the native platform. These programs perform any necessary code set conversions between UCS-2 and the native code set of a platform.

### **Computers located in different locales**

Client and server processes can execute in geographical locations having different locales. For example, a Spanish client might invoke a business method upon an object residing on an American server. Some business methods can be locale-sensitive in nature; for example, given a business method that returns a sorted list of strings, the Spanish client expects that list to be sorted according to the Spanish collating sequence, not in the server's English collating sequence. Since data retrieval and sorting procedures run on the server, the locale of the client must be available in order to perform a legitimate sort.

A similar consideration applies in instances where the server has to return strings containing date, time, currency, exception messages, and so on, formatted according to the client's cultural expectations. Neither the CORBA nor the J2EE specifications have architecturally addressed the locale mismatch problem and other options involving extra parameters are not practical or have limitations. For example, requiring an extra parameter could require interface changes, which is a serious concern for deployed applications.

### **Computers located in different time zones**

Client and server processes can execute in geographical locations having different time zones. To date, all internationalization literature and resources have concentrated mainly on code set and locale-related issues. They have generally ignored the time zone issue, even though business methods can be sensitive to time zone as well as to locale.

For example, suppose that a vendor makes the claim that "orders received before 2:00 PM will be processed by 5:00 PM the same day". The times given, of course, are in the time zone of the server that is processing the order. It is important to know the client's time zone in order to give customers in other time zones the correct times for same-day processing.

Other time zone-sensitive operations include time stamping messages logged to a server, and accessing file or database resources. The concept of Daylight Savings Time (DST) further complicates the time zone issue. Neither the CORBA nor the J2EE specifications address time zone issues adequately, and conventional methods of solving this problem are limited.

---

## **Migrating internationalized applications**

Applications that used the internationalization service in WebSphere Application Server Version 4 can use the service in Version 5 with no modification. The packaging and structure of the internationalization context API remain identical across releases. Most importantly, the semantics of the API remain as well.

In Version 4, the internationalization service did not provide internationalization deployment descriptor policy information to direct how the service manages internationalization context across the various application components. Rather, the service employed the implicit client-side internationalization (CSI) and server-side internationalization (SSI) policies, which dictated how the service managed context according to the type of J2EE container hosting a component. For details, refer to the combined information center for WebSphere Application Server Version 4. Briefly, all server components in Version 4 were SSI, and all EJB client applications were CSI.

In Version 5, the internationalization type setting of all server components is configured to Container by default. The internationalization service assigns the default container internationalization attribute, RunAsCaller, to any container-managed (CMI) servlet or enterprise bean invocation lacking a container internationalization attribute. Hence, invocations of server components lacking internationalization policy information in the deployment descriptor run under the policy, [CMI, RunAsCaller], which is semantically equivalent to the SSI internationalization policy of Version 4; EJB client applications run under the logical policy [AMI, RunAsServer], which is equivalent to the CSI policy of Version 4.

When migrating a Version 4 application to Version 5, it is unnecessary to configure the internationalization deployment descriptor information during application assembly because all component invocations execute under semantically equivalent internationalization context management policies.

---

## Assembling internationalized applications

**5.1+** Use the Assembly Toolkit to configure internationalization in the deployment descriptors for servlets and enterprise beans.

### 1. Set the **internationalization type**.

All servlets and enterprise beans have an internationalization type setting that specifies whether internationalization context is managed by the application component or by its hosting J2EE container during invocations of their respective life cycle and business methods. Internationalization type can be configured for all server application components except entity beans, which are container-managed only.

By default, all server components employ container-managed internationalization (CMI). The default setting should suffice in most cases; when it does not, modify the internationalization type setting by completing the steps described in one of the following topics:

- “Setting the internationalization type for servlets”
- “Setting internationalization type for enterprise beans” on page 961

### 2. Set the **container internationalization attribute**.

You can associate CMI servlets, and business methods of CMI enterprise beans, with a container internationalization attribute that specifies which of three internationalization contexts - **Caller**, **Server**, or **Specified** - the container is to scope to an invocation. When running as specified, the container internationalization attribute also specifies the custom internationalization context elements.

Named container internationalization attributes can be associated with sets of servlets or with sets of EJB business methods. Initially, CMI servlets and business methods implicitly run as caller and do not associate with a container internationalization attribute. When the implicit behavior or an associated attribute setting is unsuitable, configure an attribute by completing the steps described in one of the following topics:

- “Configuring container internationalization for servlets” on page 960
- “Configuring container internationalization for enterprise beans” on page 961

## Setting the internationalization type for servlets

This task sets the internationalization type for a servlet within a Web module.

### **5.1+**

Make sure that you have enabled server target support for J2EE projects and that you set the target server as **Integration Server v5.1**.

1. **5.1+** Start the Assembly Toolkit.
2. **5.1+** If necessary, import your application.
  - a. From the menu bar, click **File > Import**.

- b. Select **EAR file** from the list.
  - c. In the Enterprise Application Import panel, enter the path for your EAR file.
  - d. Click **Finish**.
3. **5.1+** In the J2EE perspective, select the Web module for which you want to set the internationalization type.
4. **5.1+** In the Deployment Descriptor Editor, select the Extended Services tab.
5. **5.1+** From the **Servlets and JSPs** list of the Extended Services panel, select the servlet for which you want to set the internationalization type.
6. **5.1+** Under **Internationalization**, select a value from the **Internationalization type** list. Valid values are **Application managed** or **Container managed**. If you select **Container managed**, you can then set container-managed internationalization attributes for methods within the servlet. For more information, see "Configuring container internationalization for servlets."
7. **5.1+** From the menu bar, click **File > Save**.

The internationalization type setting is assigned to the servlet.

## Configuring container internationalization for servlets

This task configures container internationalization for a servlet within a Web module.

### 5.1+

Make sure that you have enabled server target support for J2EE projects and that you set the target server as **Integration Server v5.1**.

This procedure relates one or more servlets to a container internationalization attribute.

1. **5.1+** Start the Assembly Toolkit.
2. **5.1+** If necessary, import your application.
  - a. From the menu bar, click **File > Import**.
  - b. Select **EAR file** from the list.
  - c. In the Enterprise Application Import panel, enter the path for your EAR file.
  - d. Click **Finish**.
3. **5.1+** In the J2EE perspective, select the Web module for which you want to set the internationalization type.
4. **5.1+** In the Deployment Descriptor Editor, select the Extended Services tab.
5. **5.1+** From the **Servlets and JSPs** list of the Extended Services panel, select the servlet for which you want to configure container-managed internationalization (CMI) attributes. As a group, CMI attributes form an *internationalization policy*.
6. **5.1+** Under **Internationalization**, select **Container managed** from the **Internationalization type** list.
7. **5.1+** Set the **Run As** field by selecting **Caller**, **Server**, or **Specified**.
8. **5.1+** If the servlet is to be run as **Specified**, select an internationalization policy from the **Specified** list or define a new policy.
  - a. To define an internationalization policy, click **New**. The New Specified Initialization wizard opens.
  - b. In the **Description** field, give the policy a name.

- c. Set a time zone ID and add a time zone description as needed. If you do not find the appropriate time zone in the ID list, click **Customize** to define one relative to Greenwich Mean Time (GMT).
- d. If needed, create a locale for the policy. To create a locale, click **Add**; select a language and (optional) geographic region; specify a variant as needed. Add a locale description and click **OK** to finish. The new locale is added to the **Locales** list.
- e. Select a locale from the **Locales** list and click **Finish**.

Selected servlets are now configured to run under the associated internationalization settings.

## Setting internationalization type for enterprise beans

This task sets the internationalization type for an enterprise bean within an EJB module.

### 5.1+

Make sure that you have enabled server target support for J2EE projects and that you set the target server as **Integration Server v5.1**.

Container-managed internationalization (CMI) is the default type; entity beans cannot be set to application-managed internationalization (AMI).

Use this also for a stateless session bean enabled for Web services.

1. **5.1+** Start the Assembly Toolkit.
2. **5.1+** If necessary, import your application.
  - a. From the menu bar, click **File > Import**.
  - b. Select **EAR file** from the list.
  - c. In the Enterprise Application Import panel, enter the path for your EAR file.
  - d. Click **Finish**.
3. **5.1+** In the J2EE perspective, select the EJB module for which you want to set the internationalization type.
4. **5.1+** Edit the deployment descriptor for the module. With the EJB module selected, right click and then select **Open with > Deployment Descriptor Editor**. The Deployment Descriptor Editor opens.
5. **5.1+** In the Deployment Descriptor Editor, select the Internationalization tab. Any enterprise beans already configured for AMI appear in the **Internationalization type** list.
6. **5.1+** To set the internationalization type to AMI, click **Add** below the **Internationalization type** list. The Internationalization Type wizard opens. Only message-driven or session beans can be selected.
7. **5.1+** Select the beans you want to set and click **Finish** to exit the wizard.
8. **5.1+** From the menu bar, click **File > Save**.

The internationalization type is assigned to the bean.

## Configuring container internationalization for enterprise beans

This task configures container internationalization for enterprise bean business methods.

### 5.1+

Make sure that you have enabled server target support for J2EE projects and that you set the target server as **Integration Server v5.1**.

This procedure relates one or more business methods to one or more container-managed internationalization (CMI) attributes.

Use this also for stateless session beans that are enabled for Web services.

1. **5.1 +** Start the Assembly Toolkit.
2. **5.1 +** If necessary, import your application.
  - a. From the menu bar, click **File > Import**.
  - b. Select **EAR file** from the list.
  - c. In the Enterprise Application Import panel, enter the path for your EAR file.
  - d. Click **Finish**.
3. **5.1 +** In the J2EE perspective, select the EJB module for which you want to set the internationalization type.
4. **5.1 +** Edit the deployment descriptor for the module. With the EJB module selected, right click and then select **Open with > Deployment Descriptor Editor**. The Deployment Descriptor Editor opens.
5. **5.1 +** In the Deployment Descriptor Editor, select the Internationalization tab. Any methods already configured appear in the **Internationalization attributes** list.
6. **5.1 +** To configure a CMI business method, click **Add** below the **Internationalization attributes** list. The Internationalization Attributes wizard opens.
7. **5.1 +** Set the **Run As** field by selecting **Caller**, **Server**, or **Specified**. Add a meaningful description. As a group, the CMI attribute settings comprise an internationalization policy. The description appears as the policy name shown in the **Internationalization attributes** list when you are finished. If you do not provide a description, the policy name appears as `null`.

If the bean is to be run as **Specified**, complete the following steps to specify the context elements that the container will scope to bean method invocations.

  - a. Set a time zone ID and add a time zone description as needed. If you do not find the appropriate time zone in the ID list, click **Custom** to define one relative to Greenwich Mean Time (GMT).
  - b. Set a locale. Select a language and (optional) geographic region; specify a variant as needed. Add a locale description as needed and click **OK** to finish.
8. **5.1 +** Click **Next**.
9. **5.1 +** Select the beans for which you want to configure method-level internationalization attributes and click **Next**.
10. **5.1 +** Select the methods that you want to configure and click **Next**. A check box appears next to each method name that you select.
  - Clicking **Apply to All** places a check box next to the displayed bean name.
  - Clicking **Select Beans** enables you to select more beans with CMI.
11. **5.1 +** Click **Finish** to exit the wizard.
12. **5.1 +** From the menu bar, click **File > Save**.

The bean methods are now configured to run under the associated internationalization settings.

---

## Using the internationalization context API

Enterprise JavaBeans (EJB) client applications, servlets, and enterprise beans can programmatically obtain and manage internationalization context using the internationalization context API.

The `java.util` and `com.ibm.websphere.i18n.context` packages contain all classes necessary to use the internationalization service within an EJB application. Classes specific to the internationalization service reside in the file `WAS_HOME/lib/i18nctx.jar`. Before compiling application components that import internationalization service classes, add the `i18nctx.jar` file to your `CLASSPATH`.

1. Gain access to the internationalization context API.
2. Access caller locales and time zone.
3. Access invocation locales and time zone.

Each EJB application component uses the internationalization context API differently. Three code examples are provided that illustrate how to use the API within each application type. Differences in API usage, as well as other coding tips, are noted in comments that precede the relevant statement blocks.

For Web services client applications and stateless session beans, you use the API to obtain and manage internationalization context in the same manner as for EJB clients and enterprise beans, respectively.

## Gaining access to the internationalization context API

This topic describes how to access the internationalization service by resolving a reference to the internationalization context API.

### Tip:

Resolve internationalization context API references once over the lifecycle of an application component, within the initialization method of that component (for example, within the `init()` method of servlets, or within the `SetXxxContext()` method of enterprise beans).

For Web service client programs, perform the following task to resolve a reference to the internationalization context API during initialization. For stateless session beans enabled for Web services, resolve the reference in the `setSessionContext()` method.

1. Resolve a reference to the `UserInternationalization` interface by performing a lookup on the JNDI name `java:comp/websphere/UserInternationalization`. For example:

```
//-----
// Internationalization context imports.
//-----
import com.ibm.websphere.i18n.context.*;
import javax.naming.*;
...

public class MyApplication {
 ...

 //-----
 // Resolve a reference to the UserInternationalization interface.
 //-----
 InitialContext initCtx = null;
 UserInternationalization userI18n = null;
 final String UserI18nUrl = "java:comp/websphere/UserInternationalization";
 try {
 initCtx = new InitialContext();
 userI18n = (UserInternationalization)initCtx.lookup(UserI18nUrl);
 }
```

```

 }
 catch (NamingException ne) {
 // UserInternationalization URL is unavailable.
 }
}

```

If the `UserInternationalization` object is unavailable due to an anomaly or a restriction, the JNDI lookup invocation throws a `javax.naming.NameNotFoundException` that contains the `java.lang.IllegalStateException`.

2. Use the `UserInternationalization` reference to create references to the `CallerInternationalization` or `InvocationInternationalization` objects, which provide access to elements of the Caller or Invocation internationalization contexts, respectively. The `CallerInternationalization` reference can be bound to the `Internationalization` interface, only; the `InvocationInternationalization` reference can be bound to either the `Internationalization` or the `InvocationInternationalization` interfaces, depending on whether the application requires read-only or read-write access to invocation context. For example:

```

...
//-----
// Resolve references to the Internationalization and
// InvocationInternationalization interfaces.
//-----
Internationalization callerI18n = null;
InvocationInternationalization invocationI18n = null;
try {
 callerI18n = userI18n.getCallerInternationalization();
 invocationI18n = userI18n.getInvocationInternationalization();
}
catch (IllegalStateException ise) {
 // An Internationalization interface(s) is unavailable.
}

```

## Accessing caller locales and time zone

An application component must first resolve a reference to the `CallerInternationalization` object and then bind it to the `Internationalization` interface.

Every remote invocation of an application component has an associated caller internationalization context associated with the thread running that invocation. Caller context is propagated by the internationalization service and middleware to the target of a request, such as an EJB business method or servlet service method. Perform the following task to access elements of the Caller internationalization context.

This task also applies to Web service client programs and stateless session beans enabled for Web services.

1. Obtain the desired caller context elements.

```

java.util.Locale [] myLocales = null;
try {
 myLocales = callerI18n.getLocales();
}
catch (IllegalStateException ise) {
 // The Caller context is unavailable;
 // is the service started and enabled?
}
...

```

The `Internationalization` interface contains the following methods to get caller internationalization context elements:

- **Locale [] getLocales()** Returns the list of caller locales associated with the current thread.
- **Locale getLocale()** Returns the first in the list of caller locales associated with the current thread.
- **TimeZone getTimeZone()** Returns the caller `SimpleTimeZone` associated with the current thread.

The `Internationalization` interface allows read-only access to internationalization context within application components. Methods of the `Internationalization` interface are available to all EJB application components and are used in the same manner for each, but the method semantics vary

according to the component's type. For instance, when obtaining caller locale within an EJB client application, the interface returns the default locale of the host JVM; in contrast, when obtaining caller context within a servlet service method (for example, `doPost()` or `doGet()` methods), the interface returns the first locale (accept-language) propagated within the corresponding HTML request. See Internationalization context for a discussion of how the service propagates internationalization context throughout an application.

2. Use the caller context elements to localize computations under a locale or time zone of the calling process.

```
DateFormat df = DateFormat.getDateInstance(myLocale);
String localizedDate = df.getDateInstance().format(aDateInstance);
...
```

## Accessing invocation locales and time zone

An application component must first resolve a reference to the `InvocationInternationalization` object and then bind it to the `InvocationInternationalization` interface of the internationalization context API.

Every remote invocation of a servlet service or EJB business method has an invocation internationalization context associated with the thread running that invocation. Invocation context is the internationalization context under which servlet and business method implementations execute; it is propagated on subsequent invocations by the internationalization service and middleware. Perform the following task to access elements of the invocation internationalization context.

This task also applies to Web services clients and stateless session beans enabled for Web services.

1. Obtain the desired invocation context elements.

```
java.util.Locale myLocale;
try {
 myLocale = invocationI18n.getLocale();
}
catch (IllegalStateException ise) {
 // The invocation context is unavailable;
 // is the service started and enabled?
}
...
```

The `InvocationInternationalization` interface contains the following methods to both get and set invocation internationalization context elements:

- **Locale [] getLocales()**. Returns the list of invocation locales associated with the current thread.
- **Locale getLocale()**. Returns the first in the list of invocation locales associated with the current thread.
- **TimeZone getTimeZone()**. Returns the invocation `SimpleTimeZone` associated with the current thread.
- **setLocales(Locale [])**. Sets the list of invocation locales associated with the current thread to the supplied list.
- **setLocale(Locale)**. Sets the list of invocation locales associated with the current thread to a list containing the supplied locale.
- **setTimeZone(TimeZone)**. Sets the invocation time zone associated with the current thread to the supplied `SimpleTimeZone`.
- **setTimeZone(String)**. Sets invocation time zone associated with the current thread to a `SimpleTimeZone` having the supplied ID.

The `InvocationInternationalization` interface allows read and write access to invocation internationalization context within application components. However, according to internationalization context management policies, only components configured to manage internationalization context (AMI components) have write access to invocation internationalization context elements. Calls to set invocation context elements within CMI application components result in a `java.lang.IllegalStateException`. Any differences in how application components can use `InvocationInternationalization` methods are explained in Internationalization context.

2. Use the invocation context elements to localize a computation under a locale or time zone of the invoking process.

```
DateFormat df = DateFormat.getDateInstance(myLocale);
String localizedDate = df.getDateInstance().format(aDateInstance);
...
```

In the following code example, locale (en,GB) and simple time zone (GMT) transparently propagate on the call to the myBusinessMethod() method. Server-side application components, such as myEjb, can use the InvocationInternationalization interface to obtain these context elements.

```
...
//-----
// Set the invocation context under which the business method or
// servlet will execute and propagate on subsequent remote business
// method invocations.
//-----
try {
 invocationI18n.setLocale(new Locale("en", "GB"));
 invocationI18n.setTimeZone(SimpleTimeZone.getTimeZone("GMT"));
}
catch (IllegalStateException ise) {
 // Is the component CMI; is the service started and enabled?
}
myEjb.myBusinessMethod();
```

Within CMI application components, the Internationalization and InvocationInternationalization interfaces are semantically equivalent, and either of these interfaces can be used to obtain the context associated with the thread on which that component is running. For instance, both interfaces can be used to obtain the list of locales propagated to the servlet doPost() service method.

## Example: Internationalization context in an EJB client program

The following code example illustrates how to use the internationalization context API within a contained EJB client program.

This example also applies to Web service client programs.

```
//-----
// Basic Example: J2EE EJB client.
//-----
package examples.basic;

//-----
// INTERNATIONALIZATION SERVICE: Imports.
//-----
import com.ibm.websphere.il8n.context.UserInternationalization;
import com.ibm.websphere.il8n.context.Internationalization;
import com.ibm.websphere.il8n.context.InvocationInternationalization;

import javax.naming.InitialContext;
import javax.naming.Context;
import javax.naming.NamingException;
import java.util.Locale;
import java.util.SimpleTimeZone;

public class EjbClient {

 public static void main(String args[]) {

 //-----
 // INTERNATIONALIZATION SERVICE: API references.
 //-----
 UserInternationalization userI18n = null;
 Internationalization callerI18n = null;
 InvocationInternationalization invocationI18n = null;
```

```

//-----
// INTERNATIONALIZATION SERVICE: JNDI name.
//-----
final String UserI18NUrl =
 "java:comp/websphere/UserInternationalization";

//-----
// INTERNATIONALIZATION SERVICE: Resolve the API.
//-----
try {
 Context initialContext = new InitialContext();
 userI18n = (UserInternationalization)initialContext.lookup(
 UserI18NUrl);
 callerI18n = userI18n.getCallerInternationalization();
 invI18n = userI18n.getInvocationInternationalization ();
} catch (NamingException ne) {
 log("Error: Cannot resolve UserInternationalization: Exception: " + ne);
} catch (IllegalStateException ise) {
 log("Error: UserInternationalization is not available: " + ise);
}
...

//-----
// INTERNATIONALIZATION SERVICE: Set invocation context.
//
// Under Application-managed Internationalization (AMI), contained EJB
// client programs may set invocation context elements. The following
// statements associate the supplied invocation locale and time zone
// with the current thread. Subsequent remote bean method calls will
// propagate these context elements.
//-----
try {
 invocationI18n.setLocale(new Locale("fr", "FR", ""));
 invocationI18n.setTimeZone("ECT");
} catch (IllegalStateException ise) {
 log("An anomaly occurred accessing Invocation context: " + ise);
}
...

//-----
// INTERNATIONALIZATION SERVICE: Get locale and time zone.
//
// Under AMI, contained EJB client programs can get caller and
// invocation context elements associated with the current thread.
// The next four statements return the invocation locale and time zone
// associated above, and the caller locale and time zone associated
// internally by the service. Getting a caller context element within
// a contained client results in the default element of the JVM.
//-----
Locale invocationLocale = null;
SimpleTimeZone invocationTimeZone = null;
Locale callerLocale = null;
SimpleTimeZone callerTimeZone = null;
try {
 invocationLocale = invocationI18n.getLocale();
 invocationTimeZone =
 (SimpleTimeZone)invocationI18n.getTimeZone();
 callerLocale = callerI18n.getLocale();
 callerTimeZone = (SimpleTimeZone)callerI18n.getTimeZone();
} catch (IllegalStateException ise) {
 log("An anomaly occurred accessing I18n context: " + ise);
}

...
} // main

```

```

...
void log(String s) {
 System.out.println ((s == null) ? "null" : s);
}
} // EjbClient

```

## Example: Internationalization context in an EJB servlet

The following code example illustrates how to use the internationalization context API within a servlet. Note the `init()` and `doPost()` methods.

```

...
//-----
// INTERNATIONALIZATION SERVICE: Imports.
//-----
import com.ibm.websphere.i18n.context.UserInternationalization;
import com.ibm.websphere.i18n.context.Internationalization;
import com.ibm.websphere.i18n.context.InvocationInternationalization;

import javax.naming.InitialContext;
import javax.naming.Context;
import javax.naming.NamingException;
import java.util.Locale;

public class J2eeServlet extends HttpServlet {

 ...
 //-----
 // INTERNATIONALIZATION SERVICE: API references.
 //-----
 protected UserInternationalization userI18n = null;
 protected Internationalization i18n = null;
 protected InvocationInternationalization invI18n = null;

 //-----
 // INTERNATIONALIZATION SERVICE: JNDI name.
 //-----
 public static final String UserI18NUrl =
 "java:comp/websphere/UserInternationalization";

 protected Locale callerLocale = null;
 protected Locale invocationLocale = null;

 /**
 * Initialize this servlet.
 * Resolve references to the JNDI initial context and the
 * internationalization context API.
 */
 public void init() throws ServletException {

 //-----
 // INTERNATIONALIZATION SERVICE: Resolve API.
 //
 // Under Container-managed Internationalization (CMI), servlets have
 // read-only access to invocation context elements. Attempts to set these
 // elements result in an IllegalStateException.
 //
 // Suggestion: cache all internationalization context API references
 // once, during initialization, and use them throughout the servlet
 // lifecycle.
 //-----
 try {
 Context initialContext = new InitialContext();
 userI18n = (UserInternationalization)initialContext.lookup(UserI18NUrl);
 callerI18n = userI18n.getCallerInternationalization();
 invI18n = userI18n.getInvocationInternationalization();
 } catch (NamingException ne) {

```

```

 throw new ServletException("Cannot resolve UserInternationalization" + ne);
 } catch (IllegalStateException ise) {
 throw new ServletException ("Error: UserInternationalization is not
 available: " + ise);
 }
 ...
} // init

/**
 * Process incoming HTTP GET requests.
 * @param request Object that encapsulates the request to the servlet
 * @param response Object that encapsulates the response from the
 * Servlet.
 */
public void doGet(
 HttpServletRequest request,
 HttpServletResponse response)
 throws ServletException, IOException {
 doPost(request, response);
} // doGet

/**
 * Process incoming HTTP POST requests
 * @param request Object that encapsulates the request to
 * the Servlet.
 * @param response Object that encapsulates the response from
 * the Servlet.
 */
public void doPost(
 HttpServletRequest request,
 HttpServletResponse response)
 throws ServletException, IOException {

 ...
 //-----
 // INTERNATIONALIZATION SERVICE: Get caller context.
 //
 // The Internationalization service extracts the accept-languages
 // propagated in the HTTP request and associates them with the
 // current thread as a list of locales within the caller context.
 // These locales are accessible within HTTP Servlet service methods
 // using the caller internationalization object.
 //
 // If the incoming HTTP request does not contain accept languages,
 // the service associates the server's default locale. The service
 // always associates the GMT time zone.
 //
 //-----
 try {
 callerLocale = callerI18n.getLocale(); // caller locale
 // the following code enables you to get invocation locale,
 // which depends on the Internationalization policies.
 invocationLocale = invI18n.getLocale(); // invocation locale
 } catch (IllegalStateException ise) {
 log("An anomaly occurred accessing Invocation context: " + ise);
 }
 // NOTE: Browsers may propagate accept-languages that contain a
 // language code, but lack a country code, like "fr" to indicate
 // "French as spoken in France." The following code supplies a
 // default country code in such cases.
 if (callerLocale.getCountry().equals(""))
 callerLocale = AccInfoJBean.getCompleteLocale(callerLocale);

 // Use iLocale in JDK locale-sensitive operations, etc.
 ...
} // doPost

```

```

...
void log(String s) {
 System.out.println ((s == null) ? "null" : s);
}
} // CLASS J2eeServlet

```

## Example: Internationalization context in a session bean

The following code example illustrates how to perform a localized operation using the internationalization service within a session bean.

This example also applies to Web service-enabled session beans.

```

...
//-----
// INTERNATIONALIZATION SERVICE: Imports.
//-----
import com.ibm.websphere.i18n.context.UserInternationalization;
import com.ibm.websphere.i18n.context.Internationalization;
import com.ibm.websphere.i18n.context.InvocationInternationalization;

import javax.naming.InitialContext;
import javax.naming.Context;
import javax.naming.NamingException;
import java.util.Locale;

/**
 * This is a stateless Session Bean Class
 */
public class J2EESessionBean implements SessionBean {

 //-----
 // INTERNATIONALIZATION SERVICE: API references.
 //-----
 protected UserInternationalization userI18n = null;
 protected InvocationInternationalization invI18n = null;

 //-----
 // INTERNATIONALIZATION SERVICE: JNDI name.
 //-----
 public static final String UserI18NUrl =
 "java:comp/websphere/UserInternationalization";
 ...

 /**
 * Obtain the appropriate internationalization interface
 * reference in this method.
 * @param ctx javax.ejb.SessionContext
 */
 public void setSessionContext(javax.ejb.SessionContext ctx) {

 //-----
 // INTERNATIONALIZATION SERVICE: Resolve the API.
 //-----
 try {
 Context initialContext = new InitialContext();
 userI18n = (UserInternationalization)initialContext.lookup(
 UserI18NUrl);
 invI18n = userI18n.getInvocationInternationalization();
 } catch (NamingException ne) {
 log("Error: Cannot resolve UserInternationalization: Exception: " + ne);
 } catch (IllegalStateException ise) {
 log("Error: UserInternationalization is not available: " + ise);
 }
 } // setSessionContext

```

```

/**
 * Set up resource bundle using I18n Service
 */
public void setResourceBundle()
{
 Locale invLocale = null;

 //-----
 // INTERNATIONALIZATION SERVICE: Get invocation context.
 //-----
 try {
 invLocale = invI18n.getLocale();
 } catch (IllegalStateException ise) {
 log ("An anomaly occurred while accessing Invocation context: " + ise);
 }
 try {
 Resources.setResourceBundle(invLocale);
 // Class Resources provides support for retrieving messages from
 // the resource bundle(s). See Currency Exchange sample source code.
 } catch (Exception e) {
 log("Error: Exception occurred while setting resource bundle: " + e);
 }
} // setResourceBundle

/**
 * Pass message keys to get the localized texts
 * @return java.lang.String []
 * @param key java.lang.String []
 */
public String[] getMsgs(String[] key) {
 setResourceBundle();
 return Resources.getMsgs(key);
}

...
void log(String s) {
 System.out.println(((s == null) ? ";null" : s));
}
} // CLASS J2EESessionBean

```

## Internationalization context API: Programming reference

Application components programmatically manage internationalization context through the `UserInternationalization`, `Internationalization`, and `InvocationInternationalization` interfaces in the `com.ibm.websphere.i18n.context` package. The following code example introduces the internationalization context API:

```

public interface UserInternationalization {
 public Internationalization getCallerInternationalization();
 public InvocationInternationalization
 getInvocationInternationalization();
}

public interface Internationalization {
 public java.util.Locale[] getLocales();
 public java.util.Locale getLocale();
 public java.util.TimeZone getTimeZone();
}

public interface InvocationInternationalization
 extends Internationalization {
 public void setLocales(java.util.Locale[] locales);
 public void setLocale(java.util.Locale jmLocale);
 public void setTimeZone(java.util.TimeZone timeZone);
 public void setTimeZone(String timeZoneId);
}

```

## UserInternationalization interface

The UserInternationalization interface provides factory methods for obtaining references to the CallerInternationalization and InvocationInternationalization context objects. Use these references to access elements of the caller and invocation contexts correlated to the current thread.

Methods of the UserInternationalization interface:

### Internationalization **getCallerInternationalization()**

Returns a reference implementing the Internationalization interface that allows access to elements of the caller internationalization context correlated to the current thread. If the service is disabled, this method throws an `IllegalStateException`.

### InvocationInternationalization **getInvocationInternationalization()**

Returns a reference implementing the InvocationInternationalization interface. If the service is disabled, this method throws an `IllegalStateException`.

## Internationalization interface

The Internationalization interface declares methods affording read-only access to internationalization context. Given a caller or invocation internationalization context object created with the UserInternationalization interface, bind the object to the Internationalization interface in order to get elements of that context type. Observe that caller internationalization context can be accessed only through this interface.

Methods of the Internationalization interface:

### **Locale[] getLocales()**

Returns the chain of locales within the internationalization context (object) bound to the interface, provided the chain is not null; otherwise this method returns a chain of length(1) containing the default locale of the JVM.

### **Locale getLocale()**

Returns the first in the chain of locales within the internationalization context (object) bound to the interface, provided the chain is not null; otherwise this method returns the default locale of the JVM.

### **TimeZone getTimeZone()**

Returns the caller time zone (that is, the `SimpleTimeZone`) associated with the current thread, provided the time zone is non-null; otherwise this method returns the process time zone.

## InvocationInternationalization interface

The InvocationInternationalization interface declares methods affording read and write access to InvocationInternationalization context. Given an invocation internationalization context object created with the UserInternationalization interface, bind the object to the InvocationInternationalization interface in order to get and set elements of the invocation context.

**Note:** According to the container-managed internationalization (CMI) policy, all set methods, `setXxx()`, throw an `IllegalStateException` when called within a CMI servlet or enterprise bean.

Methods of the InvocationInternationalization interface:

### **void setLocales(java.util.Locale[] locales)**

Sets the chain of locales to the supplied chain, *locales*, within the invocation internationalization context. The supplied chain can be null or have length( $\geq 0$ ). When the supplied chain is null or has length(0), the service sets the chain of invocation locales to an array of length(1) containing the default locale of the JVM. Null entries can exist within the supplied locale list, for which the service substitutes the default locale of the JVM on remote invocations.

### **void setLocale(java.util.Locale locale)**

Sets the chain of locales within the invocation internationalization context to an array of length(1)

containing the supplied locale, *locale*. The supplied locale can be null, in which case the service instead sets the chain to an array of length(1) containing the default locale of the JVM.

**void setTimeZone(java.util.TimeZone timeZone)**

Sets the time zone within the invocation internationalization context to the supplied time zone, *time zone*. If the supplied time zone is not an exact instance of `java.util.SimpleTimeZone` or is null, the service instead sets the invocation time zone to the default time zone of the JVM.

**void setTimeZone(String timeZoneId)**

Sets the time zone within the invocation internationalization context to the `java.util.SimpleTimeZone` having the supplied ID, *timeZoneId*. If the supplied time zone ID is null or invalid (that is, it does not appear in the list of IDs returned by the `java.util.TimeZone.getAvailableIds()` method) the service sets the invocation time zone to the simple time zone having an ID of GMT, an offset of 00:00, and otherwise invalid fields.

## Internationalization context

An *internationalization context* is a distributable collection of internationalization information containing an ordered list, or chain, of locales and a single time zone, where the locales and time zone are instances of Java SDK types, `java.util.Locale` and `java.util.TimeZone`. A locale chain is ordered according to the user's preference.

The internationalization service manages and makes available two varieties of internationalization context: the *caller context*, which represents the caller's localization environment, and the *invocation context*, which represents the localization environment under which a business method runs. Server application components use elements of the caller and invocation internationalization contexts to appropriately tailor locale-sensitive and time zone-sensitive computations.

**Note:** The internationalization service does not support time zone types other than Java SDK type `java.util.SimpleTimeZone`. Unsupported time zone types silently map to the default time zone of the JVM when supplied to internationalization context API methods. For a complete description of the `java.util.Locale`, `java.util.TimeZone`, and `java.util.SimpleTimeZone` types, refer the Java SDK API documentation.

### Caller context

Caller internationalization context contains the locale chain and time zone received on incoming EJB business method and servlet service method invocations; it is the internationalization context propagated from the calling process. Use caller context elements within server application components to localize computations to the calling component. Caller context is read-only and can be accessed by all application components by using the **Internationalization** interface of the internationalization context API.

Caller context is computed in the following manner: On an EJB business method or servlet service method invocation, the internationalization service extracts the internationalization context from the incoming request and scopes this context to the method as the caller context. For any missing or null context element, the service inserts the corresponding default element of the JVM (for example, `java.util.Locale.getDefault()` or `java.util.TimeZone.getDefault()`.)

The service performs a similar insertion whenever missing or null Caller context elements are encountered on invocations of stateless session beans that are enabled for Web services.

Formally, caller context is the invocation context of the calling business method or application component.

### Invocation context

Invocation internationalization context contains the locale chain and time zone under which EJB business methods and servlet service methods execute. It is managed by either the hosting container or the application component, depending on the applicable internationalization policy. On outgoing business

method requests, it is the context that propagates to the target process. Use invocation context elements to localize computations under the specified settings of the current application component.

Invocation context is computed in the following manner: On an incoming business method or servlet service method invocation, the internationalization service queries the associated context management policy. If the policy is container-managed internationalization (CMI), the container scopes the context designated by the policy to the invocation; otherwise the policy is application-managed internationalization (AMI), and the container scopes a vacuous context to the invocation that can be altered by the method implementation.

Application components can access invocation context elements through both the **Internationalization** and **InvocationInternationalization** interfaces of the internationalization context API. Invocation context elements can be set (overwritten) under the application-managed internationalization policy only.

On an outgoing business method request, the service obtains the currently scoped invocation context and attaches it to the request. This outgoing exported context becomes the caller context of the target invocation. When supplying invocation context elements, either for export on outgoing requests or through the API, the internationalization service always provides the most recent element set using the API; also, the service supplies the corresponding default element of the JVM for any null invocation context element.

Because the internationalization context that is propagated over Web services (SOAP) requests contains a time zone ID rather than the entire state of a `java.lang.SimpleTimeZone` object, time zone information might be lost when a Web service-enabled client program or session bean becomes involved in remote business computation.

### **Internationalization context: Propagation and scope**

The scope of internationalization context is implicit. Every EJB client application, servlet service method, and EJB business method invocation has two internationalization contexts under which it executes. For each application component invocation, the container enters the caller context and the invocation context, as indicated by the pertinent internationalization policy, into scope before the container delegates to the actual implementation. When the implementation returns, the service removes these contexts from scope. The internationalization service supplies no programmatic mechanism for components to explicitly manage the scope of internationalization context.

The service scopes internationalization context differently with respect to application component type:

- EJB client programs (contained)
- Servlets
- Enterprise beans
- Web service client programs (contained)
- Stateless session beans that are enabled for Web services

Internationalization context observes by-value semantics over remote method requests, meaning that changes to internationalization context elements scoped to an invocation do not affect the corresponding elements of the internationalization context scoped to the remote calling process. Also, modifications to context elements obtained using the internationalization context API do not affect the corresponding elements scoped to the invocation.

### **EJB client programs (contained)**

Before it invokes the `main()` method of a client program, the J2EE client container introduces into scope invocation and caller internationalization contexts containing null elements. These contexts remain in scope throughout the life of program. EJB client programs are the base in a chain of remote business method invocations and, technically, do not have a logical caller context. Accessing a caller context element yields the corresponding default element of the client JVM. On outgoing EJB business method requests, the internationalization service propagates the invocation context to the target process. Any

unset (null) invocation context elements are replaced with the default of the JVM when exported by the internationalization context API or by outgoing requests.

**Tip:**

To propagate values other than the JVM defaults to remote business methods, EJB client programs, as well as AMI servlets or enterprise beans, must set (override) elements of the invocation context. To learn how to set invocation context elements, see the topic *Accessing invocation locales and time zone*.

**Servlets**

On every servlet service method (`doGet()`, `doPost()`) invocation, the J2EE web container introduces caller and invocation internationalization contexts into scope before delegating to the service method implementation. The caller context contains the accept-languages propagated in the HTTP servlet request, typically from a Web browser. The invocation context contains whichever context is indicated by the container internationalization attribute of the internationalization policy associated with the servlet. Any unset (null) invocation context elements are replaced with the default of the server JVM when exported by the internationalization context API or by outgoing requests. The caller and invocation contexts remain effective until immediately after the implementation returns, at which time the container removes them from scope.

**Enterprise beans**

On every EJB business method invocation, the J2EE EJB container introduces caller and invocation internationalization contexts into scope before delegating to the business method implementation. The caller context contains the internationalization context elements imported from the incoming IIOP request; if the incoming request lacks a particular internationalization context element, the container scopes a null element. The invocation context contains whichever context is indicated by the container internationalization attribute of the internationalization policy associated with the business method. On outgoing EJB business method requests, the service propagates the invocation context to the target process. Any unset (null) invocation context elements are replaced with the default of the server JVM when exported by the internationalization context API or by outgoing requests. The caller and invocation contexts remain effective until immediately after the implementation returns, at which time the container removes them from scope.

Consider a simple WebSphere EJB application having a Java client that invokes remote bean method, `myBeanMethod()`. On the client side, the application could use the Internationalization Service API to set invocation context elements. When the client calls `myBeanMethod()`, the service exports the client's invocation context to the outgoing request. On the server side, the service detaches the imported context from the incoming request and scopes it to the method as its caller context; it also scopes the invocation context to the method as indicated by the associated internationalization context management policy. The EJB container then calls the `myBeanMethod()`, which can use the internationalization context API to access elements of either the caller or invocation contexts. When `myBeanMethod()` returns, the EJB container removes these contexts from scope.

**Web service client programs (contained)**

Before it calls the `main()` method of a Web service client program, the J2EE client container introduces into scope both invocation and caller internationalization contexts that contain null elements. These contexts remain in scope throughout the duration of program execution. Web service client programs are the base in a chain of remote business method invocations and, technically, do not have a logical caller context. Accessing a Caller context element yields the corresponding default element of the client virtual machine.

On outgoing Web service requests, the internationalization service transparently creates a Simple Object Access Protocol (SOAP) header block that contains the invocation context associated with the current thread; the SOAP representation of invocation context is propagated through the request to the target process. Any unset (that is, null) invocation context elements are replaced with the default element of the JVM when exported by the internationalization context API or by outgoing requests. Also, because the header contains only a time zone ID, the additional state of the invocation context's time zone object (`java.lang.SimpleTimeZone`) might be lost, because it does not get propagated through the request.

**Tip:**

To propagate values other than the JVM defaults to remote business methods, Web service client programs, as well as AMI servlets or enterprise beans, must set (override) elements of the invocation context. For more information, see "Accessing invocation locales and time zone."

**Stateless session beans that are enabled for Web services**

On every method invocation of a Web service-enabled bean, the EJB container introduces caller and invocation internationalization contexts into scope before delegating control to the business method implementation. The caller context contains the internationalization context elements imported from the SOAP header block of the incoming request. If the incoming request lacks a particular internationalization context element, the container introduces a null element into scope. The invocation context contains whichever context is indicated by the container internationalization attribute of the internationalization policy that is associated with the business method.

On outgoing EJB business method requests, the service propagates the invocation context to the target process. Any unset (that is, null) invocation context elements are replaced with the default element of the server JVM when exported by the internationalization context API or by outgoing requests. The caller and invocation contexts remain effective until immediately after control returns from the business method implementation, at which time the container removes them from scope.

On outgoing Web service requests, the internationalization service transparently creates a SOAP header block that contains the invocation context associated with the current thread. The SOAP representation of the invocation context is propagated through the request to the target process. Any unset (that is, null) invocation context elements are replaced with the default element of the JVM when exported by the internationalization context API or by outgoing requests.

**Thread association considerations**

The Web and EJB containers scope internationalization contexts to a method by associating it with the thread that executes the method's implementation. Similarly, methods of the internationalization context API either associate context with, or obtain context associated with, the thread on which these methods execute. In cases where new threads are spawned within an application component (for instance, a user-generated thread inside the `service()` method of a servlet, or a system-generated event handling thread in an AWT client) the internationalization contexts associated with the parent thread does not automatically transfer to the newly-spawned thread. In such instances, the service exports the default locale and time zone of the JVM on any remote business method request and on any API calls executed on the new thread. If the default context is inappropriate, the desired invocation context elements must be explicitly associated to the new thread using the `setXxx()` methods of the **InvocationInternationalization** interface. Currently, internationalization context management policies allow invocation context to be set within EJB client programs, as well as within servlets, session beans, and message-driven beans employing application-managed internationalization.

**Example: Internationalization context in a SOAP header:** The following code example illustrates how internationalization context is represented within the Simple Object Access Protocol (SOAP) header of a Web service request.

```

<InternationalizationContext>
 <Locales>
 <Locale>
 <LanguageCode>ja</LanguageCode>
 <CountryCode>JP</CountryCode>
 <VariantCode>Nihonbushi</VariantCode>
 </Locale>
 <Locale>
 <LanguageCode>fr</LanguageCode>
 <CountryCode>FR</CountryCode>
 </Locale>
 <Locale>
 <LanguageCode>en</LanguageCode>
 <CountryCode>US</CountryCode>
 </Locale>
 </Locales>
 <TimeZoneID>JST</TimeZoneID>
</InternationalizationContext>

```

## Internationalization context: Management policies

Internationalization policies declaratively prescribe how J2EE application components or their hosting containers (the service) will manage internationalization context on component invocations. There are two internationalization context management policies applicable to all component types:

- Application-managed internationalization (AMI)
- Container-managed internationalization (CMI)

These policies are represented in two parts:

- Internationalization type
- Container internationalization attribute

The service defines a default, or implicit, internationalization policy for every application component type. At development time, assemblers can override the default policy for server component types by explicitly configuring their internationalization type, and optional container internationalization attributes. Policies configured during assembly are preserved in the application's deployment descriptor.

All components have an internationalization type that indicates whether it is AMI or CMI; that is, whether a component is to deploy under the application-managed or the container-managed internationalization policy. Application assemblers can set the internationalization type for servlets, session beans, and message-driven beans. Entity beans are implicitly CMI and EJB clients are implicitly AMI; neither can be configured otherwise.

For CMI servlets and enterprise beans, optional container internationalization attributes can be specified to indicate which invocation internationalization context the container is to scope to service or business methods. A CMI service or business method invocation can run under the context of the caller's process, under the default context of the server's JVM, or under a custom context specified in the attribute. Assemblers can specify one container internationalization attribute per disjoint set of CMI servlets within a Web module, or one Attribute per disjoint set of business methods of CMI beans within an EJB module. In other words, a container internationalization attribute can be associated with more than one method, but a method cannot be associated with more than one attribute.

When a WebSphere application server launches an application, the internationalization service collects policy information from the deployment descriptor, then uses this information to construct and associate an internationalization policy to every component invocation. A policy is denoted as:

```
[<Internationalization Type>,<Container Internationalization Attribute>]
```

There are several cases where the deployment descriptor appears to lack policy information, for example: EJB client applications have no configurable internationalization policy settings; AMI components do not have container internationalization attributes; and you are not required to specify container internationalization attributes for CMI components. When the service cannot obtain the explicit

internationalization type and container attribute settings from a well-formed deployment descriptor, it implicitly inserts the appropriate setting into the policy.

The service observes the following conventions when applying policies to invocations:

- Servlets (service) and EJB business methods lacking all internationalization policy information in the deployment descriptor implicitly execute under policy [CMI,RunAsCaller].
- CMI servlets and business methods lacking a container internationalization attribute in the deployment descriptor implicitly execute under policy [CMI,RunAsCaller].
- AMI servlets and business methods always lack container internationalization attributes in the deployment descriptor, but implicitly execute under the logical policy [AMI,RunAsServer].
- EJB clients always lack internationalization policy information in the deployment descriptor. By definition, EJB clients are implicitly AMI and run under the invocation context of the JVM; they execute under the logical policy [AMI,RunAsServer].

For conditions other than these, such as a malformed deployment descriptor, refer to the topic Internationalization service errors.

Internationalization policies for EJB clients and HTTP clients cannot be configured; HTTP clients do, however, run under the language priority settings of the hosting Web browser. These settings are configurable under the options dialog of most Web browsers; refer to your Web browser's documentation for details.

### ***Internationalization type:***

Every server application component has an *internationalization type* setting that indicates whether the invocation internationalization context is to be managed by the component or by the hosting J2EE container.

Server application components can be deployed to use one of two types of internationalization context management:

- Application-managed internationalization (AMI)
- Container-managed internationalization (CMI)

A server component may be deployed as AMI or CMI, but not both; CMI is the default. The setting applies to the entire component on every invocation. Entity beans use CMI and cannot be configured otherwise. EJB client applications do not have an internationalization type setting; they implicitly use AMI.

### **Application-managed internationalization (AMI)**

Under the AMI deployment policy, component developers assume complete control over the invocation internationalization context. AMI components can use the internationalization context API to programmatically set invocation context elements.

AMI components are expected to manage invocation context. Invocations of AMI components implicitly run under the default locale and time zone of the hosting JVM. Invocation context elements not set using the API default to the corresponding elements of the JVM when accessed through the API or when exported on business methods. To export context elements other than the JVM defaults, AMI servlets, AMI enterprise beans, and EJB client applications must set (overwrite) invocation elements using the internationalization context API. Moreover, the container logically suspends caller context imported on AMI servlet lifecycle method and AMI EJB business method invocations. To continue propagating the context of the calling process, AMI servlets and enterprise beans must use the API to transfer caller context elements to the invocation context.

Specify AMI for server components that have internationalization context management requirements not supported by container-managed internationalization (CMI).

## Container-managed internationalization (CMI)

CMI is the preferred internationalization context management policy for server application components; it is also the default policy. Under CMI, the internationalization service collaborates with the Web and EJB containers to set the invocation internationalization context for servlets and enterprise beans. The service sets invocation context according to the container internationalization attribute of the policy associated with a servlet (service method) or an EJB business method.

A CMI policy contains a container internationalization attribute that indicates which internationalization context the container is to scope to an invocation. For details, see topic Container internationalization attributes. By default, invocations of CMI components run under the caller's internationalization context; or rather, they adhere to the implicit policy `[CMI,RunasCaller]` whenever the servlet or business is not associated with an attribute in the deployment descriptor. For complete details, see the topic Internationalization context: Management policies.

Methods within CMI components can obtain elements of the invocation context using the internationalization context API, but cannot set them. Any attempt to set invocation context elements within CMI components results in a `java.lang.IllegalStateException`.

Specify container-managed internationalization for server application components requiring standard internationalization context management, then specify the container internationalization attributes for CMI servlets and for business methods of CMI enterprise beans that should not run under the caller's internationalization context.

### **Container internationalization attributes:**

The internationalization policy of every CMI servlet and EJB business method has a *container internationalization attribute* that specifies which internationalization context the container is to scope to its invocation.

The container internationalization attribute has three main fields:

- Run as
- Locales
- Time zone ID

As a convenience, you can create named container internationalization attributes and associate them to the following:

- Subsets of CMI servlets within a Web module
- Subsets of business methods of CMI enterprise beans within an Enterprise JavaBeans (EJB) module
- Subsets of business methods of Web service-enabled session beans. In the following descriptions, the term *supported enterprise bean* refers to both CMI enterprise beans and Web service-enabled session beans.

### **Run-as field**

The **Run-as** field specifies one of three types of invocation context that a container can scope to a method. For servlet service and EJB business methods, the container constructs the invocation internationalization context according to the **Run as** field setting and associates this context to the current thread before delegating to the method's implementation.

By default, invocations of servlet service methods and EJB business methods implicitly run as caller (`RunAsCaller`) unless the **Run as** field of a policy's attribute specifies otherwise. EJB client applications and AMI server components always run as server (`RunAsServer`).

Invocation context types specifiable with the **Run as** field are:

**Caller** The container invokes the method under the internationalization context of the calling process. For

any missing context element, the container supplies the corresponding default context element of the JVM. Select `run as caller` when you want the invocation to execute under the invocation context of the calling process.

#### **Server**

The container invokes the method under the default locale and time zone of the JVM. Select `run as server` when you want the invocation to execute under the invocation context of the JVM.

#### **Specified**

The container invokes the method under the internationalization context specified in the attribute. Select `run as specified` when you want the invocation to execute under the custom invocation context specified in the policy, then provide the custom context elements by completing the `Locales` and `Time zone ID` fields.

**Note:** JMS messages do not contain internationalization context. Although container-managed message-driven beans can be configured to run as caller, the container associates the default elements of the server process when invoking the `onMessage()` method of any message-driven bean configured as `[CMI, RunAsCaller]`.

You can also configure the **Run as** field for Web service business methods.

#### **Locales field**

The **Locales** field specifies an ordered list of locales that the container scopes to an invocation. A locale represents a specific geographical, cultural, or political region and contains three fields:

- **Language code.** Ideally, language code is one of the lower-case, two-character codes defined by ISO-639; however, language code is not restricted to ISO codes and is not a required field. A valid locale must specify a language code if it does not specify a country code.
- **Country code.** Ideally, country code is one of the upper-case, two-character codes defined by ISO-3166; however, country code is not restricted to ISO codes and is not a required field. A valid locale must specify a country code if it does not specify a language code.
- **Variant.** Variant is a vendor-specific code. Variant is not a required field and serves only to supplement the language and country code fields according to application- or platform-specific requirements.

A valid locale must specify at least a language code or a country code; the variant is always optional. The first locale of the list is returned when accessing invocation context using the internationalization context API method `getLocale()`.

#### **Time zone ID field**

The **Time zone ID** field specifies a shorthand identifier for a time zone that the container scopes to an invocation.

You can also configure the **Time zone ID** field for Web service business methods.

A time zone represents a temporal offset and computes daylight savings information. A valid ID indicates any time zone supported by the SDK type, `java.util.TimeZone`. Specifically, a valid ID is any of the IDs appearing in the list of time zone IDs returned by method `java.util.TimeZone.getAvailableIds()`, or a custom ID having the form `GMT[+|-]hh[[:]mm]`; for example, `America/Los_Angeles`, `GMT-08:00` are valid time zone IDs.

---

## **Managing the internationalization service**

To use internationalization context in an Enterprise JavaBeans (EJB) application, the internationalization service must be enabled in the run-time environments for all server-side components (servlets and enterprise beans) as well as all client-side components (EJB client applications).

During installation of this product, if you installed the **Additional services** option but do not require the internationalization service, disable the service on all J2EE clients and application servers. Disabling the service eliminates any possible performance degradation incurred by the implicit distribution of internationalization resources.

**Note:** The internationalization service cannot be enabled for HTTP clients because support for internationalization in that case is provided by the browser, not by the application server.

1. As needed, enable or disable the internationalization service for servlets and enterprise beans. The service is disabled by default within WebSphere enterprise application servers. You enable the service by using either the administrative console or the wsadmin tool.

This step applies also to Web service-enabled session beans.

2. As needed, enable or disable the internationalization service for EJB clients within the hosting WebSphere J2EE client environments. The service is enabled by default within the WebSphere J2EE client container.

This step applies also to Web service clients.

## Enabling the internationalization service for servlets and enterprise beans

Any servlet or enterprise bean can use internationalization context if the internationalization service is enabled within the hosting WebSphere application server instance.

This task applies also to Web service-enabled enterprise beans.

1. Start the administrative console.
2. Select **Servers > Application Servers > server\_name > Internationalization Service**.
3. Enable the internationalization service.
  - a. If not already selected, select the **Startup** checkbox.
  - b. Click **OK**.

When the **Startup** setting is selected, the application server automatically initializes, starts, and enables the internationalization service whenever the server starts. If you change this setting, be sure to restart the application server in order for the new setting to take effect.

To disable the service, clear the **Startup** checkbox. In this case, the internationalization service is initialized but is neither started nor enabled when the application server starts.

### Administration through scripting

Alternatively, the internationalization service can be enabled from the command line by using the wsadmin tool. To do this, start the wsadmin tool and enter the following commands:

```
set x [$AdminConfig list I18NService]
$AdminConfig modify $x { { enable true } }
$AdminConfig save
exit
```

If you enable or disable the internationalization service, be sure to stop and then restart the application server in order for the new setting to take effect.

### Internationalization service settings

Use this page to enable or disable the internationalization service.

The internationalization service manages the implicit propagation and scoping of locale and time zone information, called *internationalization context*, within enterprise applications. When the service is enabled,

server-side application components can use the internationalization context API to programmatically manage locale and time zone information, or to use this information with the J2SE Internationalization API to perform server-side localizations.

To view this administrative console page, click **Servers > Application Servers > *server\_name* > Internationalization Service** .

### **Startup:**

Specifies whether the server will attempt to start the internationalization service.

<b>Default</b>	Selected
<b>Range</b>	Valid values are Selected or Cleared

More information about valid values follows:

#### **Selected**

When the application server starts, it attempts to start the internationalization service automatically.

#### **Cleared**

The server does not try to start the internationalization service. If internationalization is to be used in applications that run on this server, the system administrator must select this property then restart the server.

## **Enabling the internationalization service for EJB clients**

By default, the internationalization service is enabled for use within Enterprise JavaBeans (EJB) client applications whenever the **i18nctx.jar** file is in the CLASSPATH setting constructed by the launchClient tool.

The internationalization service is also enabled for Web service-enabled clients.

When invoking a Java client application, the launchClient tool sets the CLASSPATH to include the i18nctx.jar file and then activates the WebSphere J2EE client (container), which initializes, starts, and enables the service before delegating to the specified application.

To disable the service for all application server instances in your installation, remove the i18nctx.jar file from the *install\_root/lib* directory. This prevents the file from inadvertently being included in the CLASSPATH setting constructed by the launchClient tool.

To selectively disable the service, include the argument `-CCDI18NService.enable=false` or `-CCDI18NService.enable=no` when invoking the launchClient tool.

---

## **Troubleshooting the internationalization service**

To have your application server emit trace statements for the internationalization service, specify the appropriate trace string to the server's diagnostic trace service.

1. Start the administrative console.
2. Select **Servers > application servers > *server\_name* > Diagnostic Trace Service**.
3. Select the **Enable Trace** checkbox.
4. In the **Trace Specification** field, type the following as a continuous string (no spaces and no line breaks):

```
com.ibm.ws.i18n.context.*=all=enabled:
com.ibm.websphere.i18n.context.*=all=enabled
```
5. Click **OK**.

6. Click **Save** on the taskbar.
7. Click **Save** in the **Save to Master Repository** panel.

These settings enable the internationalization service trace when you start or restart the corresponding application server.

## Internationalization service errors

The following conditions can occur while your internationalized application is running. These conditions might cause the internationalization service not to start, to throw instances of `IllegalStateException`, or to exercise default behaviors:

- The service is disabled
- The service is not started
- Invalid context element
- Missing context element
- Invalid policy
- Missing policy

If you encounter unexpected or exceptional behavior, the problem is likely related to one of these conditions. You need to examine the trace log to investigate these conditions, which requires that you configure the diagnostic trace service to generate messages about internationalization service function. To do this, see the topic [Troubleshooting the internationalization service](#).

### The service is disabled

The internationalization service does not initialize and start when the service's startup setting is cleared. The service generates a message indicating whether it is enabled or disabled. Applications cannot access the internationalization API when the service is disabled. If an application attempts a JNDI lookup to obtain the `UserInternationalization` reference, the lookup fails with a `NamingException` indicating the reference could not be found. In addition, the service does not scope (propagate) internationalization context on incoming (outgoing) business method invocations.

### The service is not started

The internationalization service is operational whenever it is in the `STARTED` state. For example, if an application attempts to access internationalization context and the service is not started, the API throws an `IllegalStateException`. In addition, the service does not provide runtime support for servlets and enterprise beans.

As an application server progresses through its lifecycle, it initializes, starts, stops, and terminates (destroys) the internationalization service. If an anomaly occurs during initialization, the service does not start. Once the service has been started, its state can change to `BLOCKED` in the event that a serious error occurs. The service generates a message for every state change.

If a trace message indicates that the service is not `STARTED`, examine previous messages to determine the problem. For instance, the internationalization service does not start if the activity service is unavailable and a message is displayed to that effect during initialization of the internationalization service.

During startup, the following messages indicate potential configuration or run-time problems:

#### **No ORB support**

The service could not obtain an instance of the ORB. This is a fatal error. Examine the logs for information.

#### **No TCM support**

The service could not obtain an instance of its thread context manager. This is a fatal error. Examine the logs for information.

**No IOP (Activity service) support**

The service could not register with the Activity service. This is a fatal error. The internationalization service cannot propagate or receive context on IOP requests without Activity service support. Review the logs for error conditions related to the Activity service.

**No AsynchBeans support**

The service could not register into the AsynchBeans environment. This warning indicates that the AsynchBeans environment cannot support internationalization context. If the application server should have AsynchBeans support, verify that the `asynchbeans.jar` and `asynchbeansimpl.jar` files exist in the classpath and review the trace log for any AsynchBeans error conditions.

**No EJB container support**

The service could not register with the EJB container. This is a warning that the internationalization service cannot support enterprise beans. Without EJB container support, internationalization contexts do not scope properly to EJB business methods. Review the trace log for any EJB container-related error conditions.

**No Web container support**

The service could not register with the Web container. This is a warning that the internationalization service cannot support servlets and Java Server Pages (JSPs). Without Web container support, internationalization contexts do not scope properly to servlet service methods. Review the trace log for any Web container-related error conditions.

**No Meta-data support**

The service could not register with the meta-data service. This is a warning that the internationalization service cannot process the internationalization policies within application deployment descriptors. Without meta-data support, the service associates the default internationalization context management policy, [CMI, RunAsCaller], to every servlet lifecycle method and enterprise bean business method invocation. Review the trace log for any meta-data service-related error conditions.

**No JNDI (Name service) support**

The service could not bind the `UserInternationalization` object into the namespace. This is a fatal error. Application components are unable to access internationalization context API references, and are therefore unable to access internationalization context elements. Review the trace log for any Naming (JNDI) service-related error conditions.

**No API support**

The service could not obtain an instance of an internationalization context API object. This is a fatal error. Application components are unable to access internationalization context API references, and are therefore unable to access internationalization context elements.

**Invalid context element**

The service detected an invalid internationalization context element. For example, the internationalization service does not support `TimeZone` instances of a type other than `java.util.SimpleTimeZone`. If the service encounters an invalid element, it logs a message and substitutes the corresponding default element of the JVM.

**Missing context element**

The service detected a missing internationalization context element. Incoming requests, for example from application servers not supporting the internationalization service will lack internationalization context. When the service attempts to access a caller internationalization context element, which does not exist in this case, it logs a message and substitutes the corresponding default element of the JVM.

Whenever possible, the internationalization service should be enabled within all clients and hosting application servers comprising a WebSphere enterprise application. For more information see the topic [Managing the internationalization service](#).

## Invalid policy

The internationalization service detected a malformed internationalization policy in the application deployment descriptor. At execution, the service replaces the malformed attribute with the appropriate default. For instance, if the internationalization type for an entity bean is set to **Application** during the execution of a servlet or EJB business method invocation, the service logs the inconsistency and enforces the **Container** setting instead.

Also, AMI application components do have an implicit container internationalization attribute. By default they run as server. The service silently enforces the implicit policy, [AMI, RunAsServer], and logs messages to this effect.

Invalid container internationalization attributes are likely to occur when specifying the Locales and Time zone ID fields. When encountering invalid Locales and Time zone ID within attributes, the service replaces each with the corresponding default element of the JVM. Be sure to follow the guidelines provided in the topic Assembling internationalized applications.

## Missing policy

The service detected a missing internationalization policy. At execution, the service replaces the missing policy with the appropriate default. For instance, if the internationalization type is missing for a servlet or enterprise bean, the service sets the attribute to Container.

Container internationalization attributes are not mandatory for CMI application components. In the event that a CMI servlet or EJB business method lacks a container internationalization attribute, the service silently enforces the implicit policy [CMI, RunAsCaller].

When an application lacks internationalization policies in its deployment descriptor, or meta-data support is unavailable, the service logs a message and applies the policy [CMI, RunAsCaller] on every servlet service method and EJB business method invocation.

For more information, see the following topics:

- Assembling internationalized applications
- Container internationalization attributes
- Internationalization type
- Migrating internationalized applications

## Internationalization service exceptions

The internationalization service employs one exception: `java.lang.IllegalStateException`. This exception indicates one of the following things:

- An application component attempted an operation not supported by the service's programming model. `IllegalStateException` is thrown whenever a server application component whose internationalization type is set to container-managed Internationalization (CMI) attempts to set invocation context. This is a violation of the CMI policy, under which servlets and enterprise beans cannot modify their invocation internationalization context.
- An anomaly occurred that disabled the service.

For instance, if the internationalization service does not properly initialize, the JNDI lookup on the `UserInternationalization` URL throws a `javax.naming.NameNotFoundException` containing an instance of `IllegalStateException`. Refer to the trace log to determine the reason for failure and, if necessary, contact your IBM support representative.

---

## Internationalization: Resources for learning

Use the following links to find relevant supplemental information about internationalization. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to this product but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

## Chapter 16. Application profiling

Application profiling enables you to configure multiple access intent policies on the same entity bean. Application profiling reflects the fact that different invocations against the same entity can require different kinds of support from the server run-time environment. For more information, see Application Profiling: Overview.

1. Assembling applications for application profiles. This topic describes how to configure tasks, create application profiles, and configure tasks on profiles.
2. Managing application profiles. This topic describes how to add and remove tasks from application profiles using the administrative console.
3. Using the TaskNameManager API. This topic describes how to programmatically set the current task name, but you should use this technique sparingly. Wherever possible, use the declarative method instead, which results in more portable function.

---

### Application profiling: Overview

Application profiling enables you to identify particular units of work to the WebSphere Application Server run time environment. The run time can tailor its support to the exact requirements of that unit of work. Access intent is currently the only run time component that makes use of the application profiling functionality. For example, you can configure one transaction to load an entity bean with strong update locks and configure another transaction to load the same entity bean without locks.

Application profiling introduces two new concepts in order to achieve this function: *tasks* and *profiles*.

**Tasks** A task is a named unit of work within a distributed application. *Unit of work* in this case means a unique path within the application that may or may not correspond to a transaction or activity session. The name of the path is typically assigned declaratively to the method of an enterprise bean, to a J2EE client or servlet. This point of configuration marks the head of a graph or subgraph identified by the name of the task; the task name flows from the head of the graph downstream on all subsequent IOP requests, identifying each subsequent invocation along the graph as belonging to the developer-configured task.

#### Profiles

A profile is simply a mapping of a task to a set of access intent policies that are configured on entity beans. When an invocation on a bean (whether by a finder method, a CMR getter, or a dynamic query) requires data to be retrieved from the back end system, the current task associated with the request is used to determine the exact requirement of the transaction. The same bean loads and behaves differently in the context of the task-to-profile mapping. Each profile provides the developer an opportunity to reconfigure the application's access intent. If a request is operating in the absence of a task, the run time environment uses either a method-level access intent (if any) or a bean-level default access intent.

### Application profiles

An application profile is the set of access intent policies that should be selectively applied for a particular unit of work (a transaction or *ActivitySession*).

Application profiling enables applications to run under different sets of policies depending on the active task under which the application is operating.

Consider an application that centralizes the student records for a school district. These records are frequently accessed by the school district's central office in order to generate reports. The report generation process would be optimized if it held no locks with the back end system, and if the records could be read into memory with as few back end operations as possible. Occasionally, however, the records are updated by the students' instructors. Without the ability to distinguish between transactions, the developer is forced to assume a worst-case scenario and, wishing to use pessimistic concurrency, lock the records for all transactions.

Using the application profiling service, the developer can configure in as many ways as necessary the access intent under which the students' records are loaded. Under one profile, the records can be configured with an exclusive pessimistic update intent, not only locking-out competing transactions but ensuring that the student is not removed from the system before the transaction completes. Under another profile, the records can be configured with an optimistic intent as part of an object graph that is read from the back end system in a single database operation. The task represented by the pessimistic profile receives the strong-locking semantics required for certain transactions, while the task represented by the optimistic profile receives the performance benefits appropriate for other transactions.

## Application profiling performance considerations

Application profiling enables assembly configuration techniques that improve your application runtime, performance and scalability. You can configure tasks that identify incoming requests, identify access intents determining concurrency and other data access characteristics, and profiles that map the tasks to the access intents. The capability to configure the application server can improve performance, efficiency and scalability, while reducing development and maintenance costs. The application profiling service has no tuning parameters, other than a checkbox for disabling the service if the service is not necessary. However, the overhead for the application profile service is small and should not be disabled, or unpredictable results can occur.

Access intents enable you to specify data access characteristics. The WebSphere run-time environment uses these hints to optimize the access to the data, by setting the appropriate isolation level and concurrency. Various access intent hints can be grouped together in an access intent policy.

In WebSphere Application Server, access intent policies are configured on methods; when an invocation of a method drives the activation of a bean, the access intent configured on that method controls the data access characteristics, such as concurrency. In WebSphere Business Integration Server Foundation, application profiling enables you to configure multiple access intent policies on the entity bean. WebSphere Business Integration Server Foundation chooses the appropriate access intent for the entity bean, using the task associated with the current unit of work (UOW). Some callers can load a bean with the intent to read data, while others can load the bean for update. The capability to configure the application server can improve performance, efficiency, and scalability, while reducing development and maintenance costs.

Access intents enable the EJB container to be configured providing optimal performance based on the specific type of enterprise bean used. Various access intent hints can be specified declaratively at deployment time to indicate to WebSphere resources, such as the container and persistence manager, to provide the appropriate access intent services for every EJB request.

The application profiling service improves overall entity bean performance and throughput by fine tuning the runtime behavior. The application profiling service enables EJB optimizations to be customized for multiple user access patterns without resorting to "worst case" choices, such as pessimistic update on a bean accessed with the `findByPrimaryKey` method, regardless of whether the client needs it for read or for an update.

Application profiling provides the capability to define the following hierarchy: **Container Tasks** > **Application Profiles** > **Access Intent Policies** > **Access Intent Overrides**. Container tasks identify UOW and are associated with a method or a set of methods. When a method associated with the task is invoked, the task name is propagated with the request. For example, a UOW refers to a unique path within the application that can correspond to a transaction or activity session. The name of the task is assigned declaratively to a J2EE client or servlet, or to the method of an enterprise bean. The task name identifies the starting point of a call graph or subgraph; the task name flows from the starting point of the graph downstream on all subsequent IOP requests, identifying each subsequent invocation along the graph as belonging to the configured task. As a best practice, wherever a UOW starts, for example, a transaction or an `ActivitySession`, assign a task to that starting point and make sure the task remains associated with that UOW. It is best to configure the application server so that no more than one transaction is associated with more than one task.

The application profile service associates the propagated tasks with access intent policies. When a bean is loaded and data is retrieved, the characteristics used for the retrieval of the data are dictated by the application profile. The application profile configures the access intent policy and the overrides that should be used to access data for a specific task.

Access intent policies determine how beans are loaded for specific tasks and how data is accessed during the transaction. The access intent policy is a named group of access intent hints. The hints can be used, depending on the characteristics of the database and resource manager. Various access intent hints applied to the data access operation govern data integrity. The general rule is, the more data integrity, the more overhead. More overhead causes lower throughput and the opportunity for simultaneous data access from multiple clients.

If specified, access intent overrides provide further configuration for the access intent policy.

## Best practices

Application profiling is effective in a variety of different scenarios. The following are example situations where application profiling is useful

- **The same bean is loaded with different data access patterns**

The same bean or set of beans can be reused across applications, but each of those applications has differing requirements for the bean or for beans within the invocation graph. One application can require that beans be loaded for update, while another application requires beans be loaded for read only. Application profiling enables deploy time configuration for beans to distinguish between EJB loading requirements.

- **Different clients have different data access requirements**

The same bean or set of beans can be used for different types of client requests. When those clients have different requirements for the bean, or for beans within the invocation graph, application profiling can be used to tailor the bean loading characteristics to the requirements of the client. One client can require beans be loaded for update, while another client requires beans be loaded for read only. Application profiling enables deploy time configuration for beans to distinguish between EJB loading requirements.

## Monitoring tools

You can use the Tivoli Performance Viewer, database and logs as monitoring tools.

You can use the Tivoli Performance Viewer to monitor various metrics associated with beans in an application profiling configuration. The following sections describe at a high level the Tivoli Performance Viewer metrics that reflect changes when access intents and application profiling are used:

- **Collection scope**

The enterprise beans group contains EJB life cycle information, either a cumulative value for a group of beans, or for specific beans. You can monitor this information to determine the difference between using the `ActivitySession` scope versus the transaction scope. For the transaction scope, depending on how the container transactions are defined, `activates` and `passivates` can be associated with method invocations. The application could use the `ActivitySession` scope to reduce the frequency of `activates` and `passivates`. For more information, see "Using the `ActivitySession` service."

- **Collection increment**

The enterprise beans group contains EJB life cycle information, either a cumulative value for a group of beans, or for specific beans. You can monitor `Num Activates` to watch the number of enterprise beans activated for a particular `findByPrimaryKey` operation. For example, if the collection increment is set to 10, rather than the default 25, the `Num Activates` value shows 25 for the initial `findByPrimaryKey`, before any result set iterator runs. If the number of `activates` rarely exceeds the collection increment, consider reducing the collection increment setting.

- **Resource manager prefetch increment**

The resource manager prefetch increment is a hint acted upon by the database engine to depend upon the database. The Tivoli Performance Viewer does not have a metric available to show the effect of the resource manager prefetch increment setting.

- **Read ahead hint**

The enterprise beans group contains EJB life cycle information, either a cumulative value for a group of beans, or for specific beans. You can monitor *Num Activates* to watch the number of enterprise beans activated for a particular request. If a read ahead association is not in use, the *Num Activates* value shows a lower initial number. If a read ahead association is in use, the *Num Activates* value represents the number of activates for the entire call graph.

**Database tools** are helpful in monitoring the different bean loading characteristics that introduce contention and concurrency issues. These issues can be solved by application profiling, or can be made worse by the misapplication of access intent policies.

Database tools are useful for monitoring locking and contention characteristics, such as locks, deadlocks and connections open. For example, for locks the DB2 Snapshot Monitor can show statistics for lock waits, lock time-outs and lock escalations. If excessive lock waits and time-outs are occurring, application profiling can define specific client tasks that require a more string level of locking, and other client tasks that do not require locking. Or, a different access intent policy with less restrictive locking could be applied. After applying this configuration change, the snapshot monitor shows less locking behavior. Refer to information about the database you are using on how to monitor for locking and contention.

The **application server logs** can be monitored for information about rollbacks, deadlocks, and other data access or transaction characteristics that can degrade performance or cause the application to fail.

---

## Application profiling tasks

Tasks are named units of work. They are the mechanism by which the run time environment determines which access intent policies to apply when an entity bean's data is loaded from the back end system.

Application profiles enable developers to configure an entity bean with multiple access intent policies; if there are  $n$  instances of profiles in a given application, each bean can be configured with as many as  $n$  access intent policies.

A task is a unit of work that is given a name by a developer. A task is assigned to any thread executing within a J2EE component, then propagated implicitly across all IOP requests. The WebSphere Application Server run time environment queries the task at the invocation of any entity bean, and establishes the appropriate access intent policy with which an entity instance is associated. A task typically corresponds to the execution of a concrete and high-level job within the application.

If an entity bean is loaded in a unit of work that is not associated with a task, or is associated with a task that is unassociated with an application profile, the default bean-level access intent or the method-level access intent configuration is applied. If a unit of work is associated with a task that is configured with an application profile, the bean-level access intent configuration within the appropriate application profile is applied.

For example, consider a school district application that calls through a session bean in order to interact with student records. One method on the session bean allows administrators to modify the students' records; another method supports student requests to view their own records. Without application profiling, the two tasks would operate anonymously and the run time environment would be unable to distinguish work operating on behalf of one task or the other. To optimize the application, a developer can configure one of the methods on the session bean with the task "updateRecords" and the other method on the session bean with the task "readRecords". When registered with an application profile that has the student bean configured with the appropriate locking access intent, the "updateRecords" task is assured that it is not unnecessarily blocking transactions that need to only read the records.

Tasks can be configured to be managed by the container or to be programmatically established by the application. Container managed tasks can be configured on servlets, Java Server Pages (JSPs), application clients, and the methods of Enterprise Java Beans (EJBs). Application managed tasks are configured on all J2EE components.

---

## Assembling applications for application profiling

Application profiling enables multiple access intent policies to be configured on the same entity bean, each specified for a particular unit of work. You can use the one of the default policies or create your own, as described in the topic, *Creating a custom access intent policy*.

1. Configuring tasks. Declaratively configure tasks as described in the following topics:
  - Configuring container-managed tasks for Enterprise Java Beans.
  - Configuring container-managed tasks for web components.
  - Configuring container-managed tasks for application clients.

On rare occasions, you might find it necessary to configure tasks *programmatically*. Application profiling supports this requirement with a simple interface that enables both overriding of the current task associated with the thread of execution, and resetting of the current task to the original task. See *Using the TaskNameManager interface*.

2. Creating an application profile.

## Automatic configuration of application profiling

Application profiling requires accurate knowledge of an application's transactional configuration and the interaction of the application with its persistent state during the course of each transaction.

The WebSphere Integration Server assembly tooling includes a static analysis engine that can assist you in configuring application profiling. The tool examines the compiled classes and the deployment descriptor of a Java 2 Enterprise Edition (J2EE) application to determine the entry point of transactions, calculate the set of entities enlisted in each transaction, and determine whether the entities are read or updated during the course of each identified transaction.

You can execute the analysis in either *closed world* or *open world* mode. A closed-world analysis assumes that all possible clients of the application are included in the analysis and that the resulting analysis is complete and correct. The results of a closed-world analysis report the set of all transactions that can be invoked by a web, JMS, or application client. The results exclude many potential transactions that never execute at run time.

An open-world analysis assumes that not all clients are available for analysis or that the analysis cannot return complete or accurate results. An open-world analysis returns the complete set of possible transactions.

The results of an analysis persist as an application profiling configuration. The tool establishes container managed tasks for servlets, Java Server Pages (JSPs), application clients, and Message Driven Beans (MDBs). Application profiles for the tasks are constructed with the appropriate access intent for the entities enlisted in the transaction represented by the task. However, in practice, there are many situations where the tool returns at best incomplete results. Not all applications are amenable to static analysis. Some factory and command patterns make it impossible to determine the call graphs. The tool does not support the analysis of *ActivitySessions*.

You should examine the results of the analysis very carefully. In many cases you must manually modify them to meet the requirements of the application. However, the tool can be an effective starting place for most applications and may offer a complete and quick configuration of application profiles for some applications.

## Automatically configuring application profiles and tasks

You can automatically configure application profiling for an application through static analysis.

1. Start the Assembly Toolkit.
2. Optional: Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. Optional: Open the J2EE Hierarchy view. Click **Window > Show View > J2EE Hierarchy**. Other helpful views include the Project Navigator view (**Window > Show View > Other > J2EE > Project Navigator**) and the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

**Note:** Ensure that you have Enabled Server Target support for J2EE projects and that you set the target server as *Integration Server v5.1* or *WebSphere Application Server EE v5.0*.

For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

- a. Select **File > Import > EAR file > Next**
  - b. Select the EAR file.
  - c. In the *Target server* field, select *Integration Server v5.1* or *WebSphere Application Server EE v5.0*
  - d. Select **Finish**
5. Be sure that the application and its modules successfully compile. To include Java Server Pages (JSPs) in the analysis, you must precompile the JSPs. Also, be sure that you have configured all transactional attributes before analyzing.
  6. In the J2EE Hierarchy view of the J2EE perspective, right-click the **Enterprise Application** to configure, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the application project is displayed in the property pane.
  7. In the property pane, select the **Extended Services** tab.
  8. Beneath the *Application Profiles* table, select **Auto...**
  9. Select the projects to be analyzed and configured. Select **Next**.
  10. To limit the returned results of the analysis, choose *closed world analysis*. Closed world analysis generates application profiles only if a client entry point in a message driven bean (MDB), servlet, JSP, or application client is resolved that begins a transaction and enlists entities. If closed world is not selected, the analysis returns the set of application profiles for all possible transactions represented by the application.

**Note:** At this point you can also choose the **Clean** attribute. If you set this attribute, the existing configuration of selected modules is removed and the new configuration is applied fresh. If you do not select this option, the new configuration is merged into the existing configuration.

11. Choose the concurrency for the default configuration of the access intent for generated application profiles.
12. Select **Analyze > Next**.
13. Examine the results of the analysis. Each top-level entry in the table represents a transaction identified by the analysis. The nested entries represent the callers of the transaction, the entities enlisted by the transaction, and the attributes read or modified during the course of the transaction.
14. Select **Finish** to automatically configure the container-managed tasks and application profiles represented by the analysis.

## Applying profile-scoped access intent policies to entity beans

Configure entities with access intent for an application profile

1. Start the Assembly Toolkit.

2. Optional: Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. Optional: Open the J2EE Hierarchy view. Click **Window > Show View > J2EE Hierarchy**. Other helpful views include the Project Navigator view (**Window > Show View > Other > J2EE > Project Navigator**) and the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

**Note:** Ensure that you have Enabled Server Target support for J2EE projects and that you set the target server as *Integration Server v5.1* or *WebSphere Application Server EE v5.0*.

For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

- a. Select **File > Import > EAR file > Next**
  - b. Select the EAR file.
  - c. In the *Target server* field, select *Integration Server v5.1* or *WebSphere Application Server EE v5.0*
  - d. Select **Finish**
5. In the J2EE Hierarchy view of the J2EE perspective, right-click the **EJB module** for the application profile instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.
  6. Select the **Extended Access** tab.
  7. Select the **application profile** for which you want to specify the access intent.
  8. Beneath the **Access Intent for Entities 2.x (Profile Level)** panel, select **Add...**
  9. Select the **entities** to configure and click **Next...**
  10. Select the **access intent policy** to apply. Select **Read Ahead Hint** if a read ahead hint is desired.
  11. Select **Next**.
  12. Optional: Specify the **collection scope**

#### **Transaction**

This is the default. Collections of entities cannot be used beyond the scope of the transaction in which you create the collection.

#### **ActivitySession**

Collections of entities cannot be used beyond the scope of the *ActivitySession* in which you create the collection. The collection can be used in a new transaction if that transaction is nested under the original *ActivitySession*, although you might have to reload the object by querying the underlying data store.

13. Optional: Specify the **collection increment**. Specify a valid integer to define the chunks that populate a remote collection. This value only applies to *remote* collections and is ignored by local collections. The default for access types that result in U locks is 1. Otherwise, the default is 25.
14. Optional:
15. Specify the **resource manager prefetch increment**. Specify a valid integer to set as the fetch size on the JDBC statement when you execute queries for a bean type. The default is 0.
16. Select **Next**.
17. If you selected *read ahead*, choose the **preload path**.
18. Select **Finish** to apply.
19. Select **OK**.

## **Creating a custom access intent policy**

Define a custom access intent policy which can be configured for 2.0 entity beans.

1. Start the Assembly Toolkit.

2. Optional: Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. Optional: Open the J2EE Hierarchy view. Click **Window > Show View > J2EE Hierarchy**. Other helpful views include the Project Navigator view (**Window > Show View > Other > J2EE > Project Navigator**) and the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

**Note:** Ensure that you have Enabled Server Target support for J2EE projects and that you set the target server as *Integration Server v5.1* or *WebSphere Application Server EE v5.0*.

For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

- a. Select **File > Import > EAR file > Next**
  - b. Select the EAR file.
  - c. In the *Target server* field, select *Integration Server v5.1* or *WebSphere Application Server EE v5.0*
  - d. Select **Finish**
5. In the J2EE Hierarchy view of the J2EE perspective, right-click the **EJB module**, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the Enterprise Java Bean (EJB) project is displayed in the property pane.
  6. In the property pane, select the **Extended Access** tab.
  7. Beneath the **Defined Access Intent Policies** panel, select **Add**.
  8. Specify a **unique name** by which the policy is referenced when applied to entity beans.
  9. Optional: Specify a **description** of the policy.
  10. Specify an **access type**.
  11. Specify the **collection scope**.

#### **Transaction**

This is the default. Collections of entities cannot be used beyond the scope of the transaction in which the collection is created.

#### **ActivitySession**

Collections of entities cannot be used beyond the scope of the *ActivitySession* in which the collection is created. The collection can be used in a new transaction if that transaction is nested under the original *ActivitySession*, although you might need to reload the object by querying the underlying data store.

12. Specify the **collection increment**. Specify a valid integer to define the chunks that populate a remote collection. This value only applies to *remote* collections and is ignored by local collections. The default value for access types that result in U locks is 1. Otherwise, the default is 25.
13. Specify the **resource manager prefetch increment**. Specify a valid integer to set as the fetch size on the JDBC statement when executing queries for a bean type. The default value is 0.
- 14.

Applying access intent policies to entity beans.

## **Creating an application profile**

An application profile contains a set of access intent policies applied to an application's entity beans. The access intent policies are only applied for requests that are associated with tasks configured on the application profile.

1. Start the Assembly Toolkit.
2. Optional: Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.

3. Optional: Open the J2EE Hierarchy view. Click **Window > Show View > J2EE Hierarchy**. Other helpful views include the Project Navigator view (**Window > Show View > Other > J2EE > Project Navigator**) and the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

**Note:** Ensure that you have Enabled Server Target support for J2EE projects and that you set the target server as *Integration Server v5.1* or *WebSphere Application Server EE v5.0*.

For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

- a. Select **File > Import > EAR file > Next**
  - b. Select the EAR file.
  - c. In the *Target server* field, select *Integration Server v5.1* or *WebSphere Application Server EE v5.0*
  - d. Select **Finish**
5. In the J2EE Hierarchy view of the J2EE perspective, right-click the **EJB module**, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the Enterprise Java Bean (EJB) project is displayed in the property pane.
  6. In the property pane, select the **Extended Access** tab.
  7. Beneath the **Application Profiles** table, select **Add...**
  8. Select or type the **name** of the task for which this profile applies. You cannot map the task to any other profile within the module. The task name should have been configured already as a task on a web component (container managed task, application managed task), an application client (container managed task, application managed task), or the method of an EJB (container managed task, application managed task).
  9. Optional: Specify a **description** of the task.
  10. Select **Next**.
  11. Select the entities that are enlisted in the unit of work represented by the application profile. You can add additional entities as a separate task after the profile has been created.
  12. Select **Finish**.

Configuring access intent for application profiles.

## Configuring container managed tasks for application clients

Configure an application client's container-managed task to associate requests from the client with an application profile.

1. Start the Assembly Toolkit.
2. Optional: Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. Optional: Open the J2EE Hierarchy view. Click **Window > Show View > J2EE Hierarchy**. Other helpful views include the Project Navigator view (**Window > Show View > Other > J2EE > Project Navigator**) and the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

**Note:** Ensure that you have Enabled Server Target support for J2EE projects and that you set the target server as *Integration Server v5.1* or *WebSphere Application Server EE v5.0*.

For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

- a. Select **File > Import > EAR file > Next**
- b. Select the EAR file.
- c. In the *Target server* field, select *Integration Server v5.1* or *WebSphere Application Server EE v5.0*

- d. Select **Finish**
5. In the J2EE Hierarchy view of the J2EE perspective, right-click the **Application Client module**, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the application client project is displayed in the property pane.
6. Select the **Extended Services** tab.
7. Enter the **name** and **description** of the task in the **Container-Managed Task** section. The task name is mapped to application profiles and used by the run time to determine the appropriate access intent to use for enlisted entities. Task names do not have to be unique within an application. However, task names should be shared consciously and conservatively. At run time, all tasks with the same name are treated the same way, regardless of where you configured the task.  
The description is provided for your convenience, it is not used by the run time environment.
8. Select **OK**.

## Configuring container managed tasks for web components

Configure a web component's container managed task to associate requests from a servlet or Java Server Page (JSP) with an application profile.

1. Start the Assembly Toolkit.
2. Optional: Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. Optional: Open the J2EE Hierarchy view. Click **Window > Show View > J2EE Hierarchy**. Other helpful views include the Project Navigator view (**Window > Show View > Other > J2EE > Project Navigator**) and the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

**Note:** Ensure that you have Enabled Server Target support for J2EE projects and that you set the target server as *Integration Server v5.1* or *WebSphere Application Server EE v5.0*.

For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

- a. Select **File > Import > EAR file > Next**
- b. Select the EAR file.
- c. In the *Target server* field, select *Integration Server v5.1* or *WebSphere Application Server EE v5.0*
- d. Select **Finish**
5. In the J2EE Hierarchy view of the J2EE perspective, right-click the **WEB module** for the web component instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the web project is displayed in the property pane.
6. Select the **Extended Services** tab.
7. Select the servlet or JSP that you want to change.
8. Enter the **name** and **description** of the task in the **Container-Managed Task** section. The task name is mapped to application profiles and used by the run time to determine the appropriate access intent to use for enlisted entities. Task names do not have to be unique within an application. However, task names should be shared consciously and conservatively. At run time, all tasks with the same name are treated the same way, regardless of where you configured the task.  
The description is provided for your convenience, it is not used by the run time environment.
9. Select **OK**.

## Configuring container managed tasks for Enterprise Java Beans

Configure an Enterprise Java Bean's (EJB) container managed tasks to associate requests from the bean with application profiles.

1. Start the Assembly Toolkit.
2. Optional: Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. Optional: Open the J2EE Hierarchy view. Click **Window > Show View > J2EE Hierarchy**. Other helpful views include the Project Navigator view (**Window > Show View > Other > J2EE > Project Navigator**) and the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

**Note:** Ensure that you have Enabled Server Target support for J2EE projects and that you set the target server as *Integration Server v5.1* or *WebSphere Application Server EE v5.0*.

For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

- a. Select **File > Import > EAR file > Next**
  - b. Select the EAR file.
  - c. In the *Target server* field, select *Integration Server v5.1* or *WebSphere Application Server EE v5.0*
  - d. Select **Finish**
5. In the J2EE Hierarchy view of the J2EE perspective, right-click the **EJB module** for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.
  6. Select the **Extended Access** tab.
  7. Beneath the **Container-Managed Tasks** table, select **Add...**
  8. Select the **bean** for which you want to configure the task.
  9. Select **Next**.
  10. Select the **method** for which you want to configure the task.
  11. Select **Next**.
  12. Enter the **name** and **description** of the task. The task name is mapped to application profiles and used by the run time to determine the appropriate access intent to use for enlisted entities. Task names do not have to be unique within an application. However, task names should be shared consciously and conservatively. At run time, all tasks with the same name are treated the same way, regardless of where you configured the task.  
The description is provided for your convenience, it is not used by the run time environment.
  13. Select **OK**.

## Configuring application managed tasks for application clients

Configure application managed tasks for an application client to associate requests from the client with application profiles.

1. Start the Assembly Toolkit.
2. Optional: Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. Optional: Open the J2EE Hierarchy view. Click **Window > Show View > J2EE Hierarchy**. Other helpful views include the Project Navigator view (**Window > Show View > Other > J2EE > Project Navigator**) and the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

**Note:** Ensure that you have Enabled Server Target support for J2EE projects and that you set the target server as *Integration Server v5.1* or *WebSphere Application Server EE v5.0*.

For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

- a. Select **File > Import > EAR file > Next**

- b. Select the EAR file.
  - c. In the *Target server* field, select *Integration Server v5.1* or *WebSphere Application Server EE v5.0*
  - d. Select **Finish**
5. In the J2EE Hierarchy view of the J2EE perspective, right-click the **Client module**, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the application client project is displayed in the property pane.
  6. In the property pane, select the **Extended Services** tab.
  7. Beneath the **Application-Managed Tasks** panel, select **Add...**
  8. Specify the name of the **task reference**. The task reference name is used programmatically by the application client. The task reference is the logical representation of the task that is used by the run time environment.
  9. Enter the **name** and **description** of the task. The task name is mapped to application profiles and used by the run time to determine the appropriate access intent to use for enlisted entities. Task names do not have to be unique within an application. However, task names should be shared consciously and conservatively. At run time, all tasks with the same name are treated the same way, regardless of where you configured the task.  
The description is provided for your convenience, it is not used by the run time environment.
  10. Select **OK**.

## Configuring application-managed tasks for web components

Configure web components' application managed tasks to associate requests from a servlet or Java Server Page (JSP) with application profiles.

1. Start the Assembly Toolkit.
2. Optional: Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. Optional: Open the J2EE Hierarchy view. Click **Window > Show View > J2EE Hierarchy**. Other helpful views include the Project Navigator view (**Window > Show View > Other > J2EE > Project Navigator**) and the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

**Note:** Ensure that you have Enabled Server Target support for J2EE projects and that you set the target server as *Integration Server v5.1* or *WebSphere Application Server EE v5.0*.

For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

- a. Select **File > Import > EAR file > Next**
  - b. Select the EAR file.
  - c. In the *Target server* field, select *Integration Server v5.1* or *WebSphere Application Server EE v5.0*
  - d. Select **Finish**
5. In the J2EE Hierarchy view of the J2EE perspective, right-click the **Web module** for the web component instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the web project is displayed in the property pane.
  6. In the property pane, select the **Extended Services** tab.
  7. Select the servlet or JSP that you want to change.
  8. Beneath the **Application-Managed Tasks** table, select **Add...**
  9. Specify the name of the **task reference**. The task reference name is used programmatically by the servlet or JSP. The task reference is the logical representation of the task that is used by the run time environment.
  10. Enter the **name** and **description** of the task. The task name is mapped to application profiles and used by the run time to determine the appropriate access intent to use for enlisted entities. Task

names do not have to be unique within an application. However, task names should be shared consciously and conservatively. At run time, all tasks with the same name are treated the same way, regardless of where you configured the task.

The description is provided for your convenience, it is not used by the run time environment.

11. Select **OK**.

## Configuring application managed tasks for Enterprise Java Beans

Configure an Enterprise Java Bean's (EJB) application managed tasks to associate requests from the bean with application profiles.

1. Start the Assembly Toolkit.
2. Optional: Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. Optional: Open the J2EE Hierarchy view. Click **Window > Show View > J2EE Hierarchy**. Other helpful views include the Project Navigator view (**Window > Show View > Other > J2EE > Project Navigator**) and the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

**Note:** Ensure that you have Enabled Server Target support for J2EE projects and that you set the target server as *Integration Server v5.1* or *WebSphere Application Server EE v5.0*.

For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

- a. Select **File > Import > EAR file > Next**
  - b. Select the EAR file.
  - c. In the *Target server* field, select *Integration Server v5.1* or *WebSphere Application Server EE v5.0*
  - d. Select **Finish**
5. In the J2EE Hierarchy view of the J2EE perspective, right-click the **EJB module** for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.
  6. Select the **Extended Access** tab.
  7. Beneath the **Application-Managed Tasks** table, select **Add...**
  8. Select the bean for which you want to configure the task.
  9. Type the **name** of the task reference. The task reference name is used programmatically by the bean. The task reference is the logical representation of the task used by the run time environment.
  10. Enter the **name** and **description** of the task. The task name is mapped to application profiles and used by the run time to determine the appropriate access intent to use for enlisted entities. Task names do not have to be unique within an application. However, task names should be shared consciously and conservatively. At run time, all tasks with the same name are treated the same way, regardless of where you configured the task.

The description is provided for your convenience, it is not used by the run time environment.

11. Select **OK**.

## Specifying target servers for J2EE projects

The J2EE tooling of the Assembly Toolkit and the WebSphere Studio Application Developer Integration Edition enables you to target a specific server during your application development. For example, if you want to take advantage of the features of JDK 1.4.1, which is used as the run time environment for WebSphere Application Server Version 5.1, your applications require different class path entries than those that were used previously. With this server targeting feature, you can now easily update your class path

entries appropriately for running on WebSphere Application Server V5.1 using the JDK 1.4 run time environment. But more than just supporting JDK 1.4.1, targeting a server is an easy way to specify the JAR files available at run time for a specific server.

When a target server is specified for a project, a *.server* file is added to the project resources indicating the target server.

After you enable the server targeting feature in the preferences, the J2EE project creation and import wizards include an additional option where you can specify a target server for the project. The list of target servers that you can choose from is filtered based on the J2EE level of the application as well as the J2EE module type. For example, for an EJB project, only servers that support Enterprise Java Beans are displayed.

For more information about target servers, refer to the WebSphere Studio Application Developer Integration Edition documentation under the following topics:

- Specifying target servers for J2EE projects
- Modifying the target server for J2EE projects
- Synchronizing the target servers for J2EE projects

To enable the server targeting support:

1. Select **Window > Preferences** . The **Preferences** window opens.
2. On the **J2EE** page of the preferences, select the **Enable** radio button in the **Server Targeting Support** section.
3. Select **OK**.

## Modifying the target server for J2EE projects

If you enabled the server targeting feature in the J2EE preferences, you can switch the specified target server for existing EAR projects or EAR module projects. When a target server is specified for a project, a *.server* file is added to the project resources indicating the target server.

For more information about target servers, refer to the WebSphere Studio Application Developer Integration Edition documentation under the following topics:

- Specifying target servers for J2EE projects
  - Modifying the target server for J2EE projects
  - Synchronizing the target servers for J2EE projects
1. In the J2EE Hierarchy view of the J2EE perspective, right-click the enterprise application or module project, and select Target Server > Modify from the pop-up menu. The Modify Target Server dialog box opens.
  2. In the Target Server field, select the server that you want to target. If your project needs to be supported by earlier versions of this product, select the No target server specified option.
  3. Select the Update EAR modules and utility projects to the selected target server to synchronize the target server between the EAR and all modules. This ensures that the enterprise application project and all module and utility projects, as well as Web application library projects, all have the same target server.
- Click OK.

---

## Managing application profiles

Manage your application profiles using the administrative console. From the console, you can add tasks to, and remove tasks from, application profiles.

1. Start the administrative console.

2. Select **Applications > Applications > *application\_name* > Application Profile > *profile\_name* > Tasks**.
3. On the Tasks collection page, you can add new tasks to the profile, delete tasks, edit current task settings, and so on.  
Note that no task can, within the scope of an application, be configured on more than one application profile. In such a situation, your application cannot be restarted until you correct the configuration.
4. Save your configuration.
5. Restart the application in order for your changes to take effect.

## Using the TaskNameManager interface

You can declaratively configure container managed tasks for J2EE web components, application clients, and Enterprise Java Beans (EJBs). On rare occasions, you might find it necessary to *programmatically* set the current task name. Application profiling supports this requirement with a simple interface that enables both overriding of the current task associated with the thread of execution, and resetting of the current task with the original task.

Application profiling does not support queries of the task that is in operation at run time. Instead, applications interact with logical task names that are declaratively configured as application managed tasks. Logical references enable the actual task name to be changed without having to recompile applications.

Wherever possible, avoid setting tasks programmatically. The declarative method results in more portable function that can be easily adjusted without requiring redevelopment and recompilation.

1. Configure application-managed tasks. Application profiling requires that a task name reference be declared for any task that is to be set programmatically. Task name references introduce a level of indirection so that the actual task set at run time can be adjusted by reassembly without requiring recoding or recompilation. Any attempt to set a task name that is undeclared as a task reference results in the raising of an exception.

Configure application-managed tasks as described in the following topics:

- Configuring application managed tasks for web components.
- Configuring application managed tasks for application clients.
- Configuring application managed tasks for EJBs.

2. Perform a JNDI lookup on the TaskNameManager interface:

```
InitialContext ic = new InitialContext();
TaskNameManager tnManager = ic.lookup
("java:comp/websphere/AppProfile/TaskNameManager");
```

The *TaskNameManager* interface is not bound into the namespace if the application profiling service is disabled.

3. Set the task name:

```
try {
tnManager.setTaskName("updateAccount");
}
catch (IllegalTaskNameException e) {
// task name reference not configured. Handle error.
}
// . . .
rnManager.resetTaskName();
```

Resetting the task name undoes the effects of any *setTaskName()* method operations and reestablishes whatever task name was current when the component began execution. If the *setTaskName()* method has not been called, the *resetTaskName()* method has no effect.

## TaskNameManager interface

The TaskNameManager interface is available to all J2EE components using the following JNDI lookup:

```
java:comp/websphere/AppProfile/TaskNameManager
```

```
package com.ibm.websphere.appprofile;
```

```
/**
 * The TaskNameManager is the programmatic interface
 * to the application profiling function. Using this interface,
 * programmers can set the current task name on the
 * thread of execution. The task name must have been
 * configured in the deployment descriptors as a task
 * reference associated with a task. The set task
 * name's scope is the duration of the method
 * invocation in the EJB and Web components and for
 * the duration of the client process, or until the
 * resetTaskName() method is invoked.
 */
public interface TaskNameManager {

/**
 * Set the thread's current task name to the specified
 * parameter. The task name must have been configured as
 * a task reference with a corresponding task or the
 * IllegalArgumentException exception is thrown.
 */
public void setTaskName(String taskName) throws IllegalArgumentException;

/**
 * Sets the thread's task name to the value that was set
 * at, or imported into, the beginning of the method
 * invocation (for EJB and Web components) or process
 * (for J2EE clients).
 */
public void resetTaskName();

}
```

## Application profiling exceptions

The following exceptions are thrown in response to various illegal actions related to application profiling:

### **com.ibm.ws.exception.RuntimeWarning**

This exception is thrown when the application is started, if the application is configured incorrectly.

The startup is consequently terminated. Some examples of misconfiguration include:

- A task configured on two different application profiles.
- A method configured with two different task run-as policies .

### **com.ibm.websphere.appprofile.IllegalTaskNameException**

This exception is raised if an application attempts to programmatically set a task when that task has not been configured as a task name reference.

## Application profiling service settings

Use this page to enable or disable the application profiling service.

Applications that are configured to use the application profiling service will not start successfully unless the application profiling service is enabled.

To view this administrative console page, click **Servers > Application Servers > server\_name > Application Profiling Service**.

### **Startup**

Specifies whether the server will attempt to start the application profiling service.

**Default  
Range**

Selected  
**Selected**

When the application server starts, it attempts to start the application profiling service automatically.

**Cleared**

This option is unavailable. The application profiling service cannot be disabled.

## Application profile collection

Use this page to manage application profiles.

An application profile is a set of policies that are to be applied during the execution of an enterprise bean and a set of tasks that are associated with that profile. Mapping tasks to application profiles will control which access intent policies are applied at run time for the units of work that correspond to a particular task.

To view this administrative console page, click **Applications > Applications > *application\_name* > Application Profile**.

### Name

The name of the application profile.

The name must be unique; multiple profiles cannot share the same name.

**Data type** String

### Description

A description of the application profile.

**Data type** String

## Application profile settings

Use this page to modify application profile settings.

To view this administrative console page, click **Applications > Applications > *application\_name* > Application Profile > *application\_profile\_name***.

### **Name:**

The name of the application profile.

The name must be unique; multiple profiles cannot share the same name.

**Data type** String

### **Description:**

A description of the application profile.

**Data type** String

### **Task collection:**

Use this page to manage tasks.

Requests associated with any of the configured tasks operate under the access-intent policies that are configured with the profile. A task can be configured on only *one* application profile.

To view this administrative console page, click **Applications > Applications > application\_name > Application Profile > application\_profile\_name > Tasks**.

*Name:*

The name of the task.

The task name must be unique among the set of application profiles.

**Data type** String

*Description:*

A description of the task.

**Data type** String

*Task settings:*

Use this page to modify task settings.

To view this administrative console page, click **Applications > Applications > application\_name > Application Profile > application\_profile\_name > Tasks > task\_name**.

*Name:*

The name of the task.

The task name must be unique among the set of application profiles.

**Data type** String

*Description:*

A description of the task.

**Data type** String

---

## Chapter 17. Using Business Rule Beans

This topic provides a brief overview of the steps involved in externalizing Business Rule Beans. To gain an understanding of business rules and Business Rule Beans (BRBeans), review the topic Overview of Business Rule Beans. The following sections provide an overview of externalizing business rules using Business Rule Beans:

1. Developing BRBeans
2. Assembling applications for use with BRBeans
3. Managing rules

To help you get started quickly, a sample BRBeans application is provided. Samples are installed by default during a typical WebSphere installation or you can select to install specific samples during a custom installation.

The BRBeans sample is an online movie store application. The application's EAR file is installed and the application is configured to use the Cloudscape database (Cloudscape is provided with WebSphere Application Server). A number of rules are created that you can view using the Rule Management Application (RMA). To do this, change to the `<install_root>/bin` directory and type one of the following commands:

- On a Microsoft Windows platform:

```
rulemgmt ..\samples\lib\BRBeans\movieSampleProperties
```
- On a Unix platform:

```
rulemgmt.sh ../samples/lib/BRBeans/movieSampleProperties
```

By running the sample, you can see how these rules are used. The source code for the sample also is provided in the `<install_root>/samples/src/BRBeans/Movie` directory. To see the use of trigger points, search the code for places where the `trigger()` method is used.

---

### Advantages of externalizing business rules

Business Rule Beans (BRBeans) provide a framework in which business applications can externalize business rules. You can externalize rules by extending your application analysis and design processes to identify the points of variability (or "trigger points") in application behavior. When the application is implemented, the business logic required at the points of variability is externalized into a business rule. This allows certain aspects of the behavior to be changed without actually changing the application code.

Here are some advantages of externalizing business rules:

#### **Explicit documentation of business practice decisions**

Separating business rule values from the application code makes the code easier for others to view and understand while isolating information that relates to business practice decisions.

#### **Clearer understanding of application behavior**

Externalization makes it possible to inspect the application to see which business rules are being applied, when they are applied, and under what circumstances.

#### **Reuse of rules across business processes**

Separating rules from the business logic of the application makes it easy to reuse a business practice decision in a consistent fashion.

#### **Increased consistency of business practices**

Because externalized rules promote reuse and facilitate clear understanding of business practice decisions, they provide a basis for improving business practice consistency across applications.

#### **Decreased maintenance and testing costs**

Externalized rules have a clearly defined scope and are not tightly coupled to the application code. This makes them easy to modify, quick to test, and decreases costs and improves cycle time.

### **Improved manageability of business practice decisions**

Externalization, change history, and inspectability all promote clear ownership and consequently a better definition of who can change rules and under what circumstances.

### **Increased confidence in predicting the business impact of proposed changes**

Because rules are available for inspection, have well-defined scope, and are not tightly coupled to application business logic, they make it easy to understand the likely impact of changes and to predict whether contemplated modifications or additions will have unwanted ripple effects.

### **Ability to identify and correct conflicting business rules in different parts of the business**

Externalized rules make it easy to check that rules being used in two different parts of an application or even two different applications dealing with different parts of the business, are consistent.

---

## **Overview of Business Rule Beans**

Business Rule Beans are used to create and modify rules that keep pace with complex business practices. This enables your application's core behavior and user interface objects to remain intact and untouched, even as business practices change.

The Business Rule Beans (BRBeans) framework enables you to organize rules in folders. Folders provide a structure similar to the file system on your computer's hard drive. For example:

- Rules can be placed in folders based on any criteria you want.
- A rule folder can contain any number of rules and other rule folders.

In the BRBeans framework, each business rule is represented by an entity bean that persistently stores information related to that rule. Each business rule is assigned an appropriate rule name and stored in an appropriate rule folder (See Rule folders for more information).

When naming rules and folders, adhere to the Java package naming convention. That is, name rules and folders based on the domain name of the organization for which the rules are developed. For example, ACME's `isSeniorCitizen` rule's fully qualified rule name ("full rule name"), might be `com/acme/ageRules/isSeniorCitizen`. In this example, the `com/acme` path is used by all of the rules developed by ACME and the `ageRules` folder is used to separate "age" rules from rules of other kinds. The root folder has no name; therefore, fully qualified path names never start with a forward slash (`/`).

A fully qualified rule name consists of the following:

- The full path of the folder followed by a forward slash (`/`)
- The name of the rule

This fully qualified rule name is used by a trigger point to identify the rule to trigger. Trigger points are small pieces of code that interface with the Business Rule Beans trigger point framework to run business rules during application execution. See [Placing a trigger point](#) for more information.

By default, trigger points can only trigger rules that are currently in effect based on the current date and time when the trigger point is called. A business rule has a start date and an end date (see [Rule attributes](#) for more information) that together define the interval during which the rule is in effect (see [Rule states](#) for more information). This behavior can be overridden by specifying a date on the trigger point. This date is referred to as the "As Of Date". If no start date is specified, the rule is not valid and cannot be found by trigger points. Conversely, if no end date is specified, the rule never expires. Dates and times with a precision of one second can be assigned using the "Rule Management Application".

When there is more than one rule with the same fully qualified name, all of the rules with that name that are currently in effect are triggered and the results are combined using the combining strategy specified on the trigger point. See the `CombiningStrategy` method for more information.

## Externalized business rules

A business rule is a statement that defines or constrains some aspect of a business by asserting control over some behavior of that business.

A business rule officiates over frequently changing business practices and can come from within the company or be mandated from outside, typically by regulatory agencies. Typical uses for business rules include the following:

- Determining the current interest rate for a home loan
- Calculating a discount for a product
- Calculating the tax to apply to a given product
- Determining whether a given person is a senior citizen

The objects used to implement a business rule contain methods and attributes used by the Business Rule Beans (BRBeans) run-time environment, its administrative component, or both. An externalized business rule is implemented as a pair of objects:

- Rule
- RuleImplementor

The **Rule** is an entity enterprise bean that stores all of the persistent data for the business rule. This is the object that the trigger point framework code actually deals with directly. When a trigger point is invoked, the internal framework code performs a query to find the Rule object or objects representing the business rules to be triggered. Once the Rules are found, the framework code determines where the Rule is invoked, either local to the trigger point or remotely on the application server. Then, it invokes the `fire` method on either the Rule enterprise bean itself (for remote triggering) or on a local copy of the enterprise bean (for local triggering) to perform the function of the business rule.

The class name of the business rule's **RuleImplementor** is stored persistently in the Rule. The RuleImplementor is a transient object (not managed by the application server) that the Rule instantiates and then uses to do the actual work. When the `fire()` method is called on the Rule object, the Rule object combines its persistent set of values with the parameters it received on invocation. This creates the parameter list for the RuleImplementor prior to invoking `fire()` on the RuleImplementor with this parameter list. The actual execution of the RuleImplementor algorithm can take place either remotely (within the application server where the BRBeans enterprise beans are installed) or locally (within the Java virtual machine (JVM) where the trigger point was called).

## Types of business rules

Business rules can be divided into the following types:

- Base rules
- Classifier rules

**Base rules** are the most common type of rule and are triggered by the `TriggerPoint.trigger` method.

You can divide Base rules into the following categories:

### Derivation rules

These rules use an algorithm to return a value. These rules return any type of value that makes sense in the business context in which they are used. For example, a derivation rule can calculate a discount or compute the total price of an order.

### Constraint rules

These rules confirm that an operation has met all of its obligations and that a particular constraint or edit has been met. For instance, a constraint rule can check that a value entered by an external user is within legal bounds. Business Rule Beans (BRBeans) provide a special return type, `com.ibm.websphere.brb.ConstraintReturn`, which can be returned by a constraint-type rule. A `ConstraintReturn` object contains a boolean value so that if it is false, it can contain information that can be used to produce an external message explaining what constraint was not met.

## Invariant rules

These rules ensure that multiple changes made by an operation are properly related to one another.

## Script rules

These rules implement "micro-workflow" or electronic performance support. They are small, variable pieces of a business process that provide assistance to end-users to get the most from the application.

On the surface, **classifier rules** are much like base rules. However, classifier rules can be used to determine the ways in which variables are classified by a business. Classifier rules are triggered by the `TriggerPoint.triggerClassifier` method.

A classifier rule is used to compute a classification for a particular business situation. The classification returned is required to be of type `string`. For instance, bank customers may be classified into gold, silver, and bronze categories based on their spending history or the amount of money they have in their account. For more information on this type of rule, refer to Situational trigger point.

## Rule folders

Rule folders are similar to the directories that divide a computer's hard drive in that they split a large number of files into conceptual units. The rule folder adds its path to the fully qualified rule name. Like the directories on a hard drive, a rule folder can contain any number of rules or rule folders.

Although you can name the folders whatever you deem appropriate, it is recommended that you follow the Java package naming convention. That is, base the names on the domain name of the organization where the rules are developed. So, the fully qualified rule name or full rule name of ACME's `isSeniorCitizen` might be `com/acme/ageRules/isSeniorCitizen`. In this example, the `com/acme` path is used by all of the rules developed by ACME and the `ageRules` folder is used to separate "age" rules from rules of other kinds.

**Note:** The root folder has no name, which means that fully qualified path names never start with a '/'.

When using the Rule Management APIs, a rule folder contains instances of `IRules`, which also are referred to as "rules". To begin working with rules, get the root rule folder by using the `getRootFolder` method on `RuleMgmtHelper` class. From the root rule folder you can add, delete, and retrieve folders and rules using methods on this interface.

## Rule attributes

### Rule name

A name for the rule that is appropriate to its business context.

### Rule folder

The folder that contains the rule.

### Start date

This is the date and time at which the rule goes into effect. Prior to this time, it will not be found by trigger points. Together with the end date, the start date defines a period of time during which the rule is effective. A rule that does not have a start date specified is not a valid rule and will not be found by trigger points.

### End date

This is the date and time at which the rule is no longer effective. After this date and time the rule is no longer in effect and will not be found by trigger points. Together with the start date, the end date defines a period of time during which the rule is effective. A rule that does not have an end date specified is valid and will never expire.

**Ready** This indicates whether the rule is ready to be used. Rules that are not marked as ready will not be found by trigger points. This is intended to be an easy way to keep a rule from being used until it is completely defined or to temporarily turn a rule off without having to change the basic rule data such as start and end dates.

**Java Rule Implementor name**

This is the fully package-qualified name of a Java class that implements the BRBeans RuleImplementor interface. The `fire` method of the class performs the function of the rule. Business Rule Beans (BRBeans) provide several predefined rule implementors or you can write your own. See Rule Implementors or Customized rule implementors for more information.

**Initialization parameters**

This is an array of parameters that are passed to the rule implementor to initialize it. Each element in the array can be any object. This also can be referred to as the rule data, which is the external data that may change over time. The initialization parameters defined for a rule are passed directly to the `init` method of the rule implementor when it is instantiated. See "Rule Implementors" for more information on how rule implementors can use initialization parameters.

**Firing parameters**

Normally, firing parameters are simply the parameters passed on the trigger point when a rule is triggered. However, it is allowed to override these parameters by specifying parameters on the rule itself. This is where these overriding parameters are specified.

**Firing location**

This specifies where the rule implementor for this rule is instantiated and run. The following values are allowed:

**Local** This option instantiates the rule implementor and runs it local to the trigger point (in the same JVM as the trigger point call). This is run on the client machine if the trigger point call is done there or on the server if the server part of an application makes a trigger point call. Use this option for the best performance since, once a rule is cached on the client, the entire triggering process can be performed locally without going to the server at all. The main disadvantage of this option is that the class files for the rule implementors need to be available on every client that can trigger rules.

**Remote**

This will instantiate the rule implementor and run it on the application server where the Business Rule Beans enterprise beans are installed. When using this option at least one remote method call always is required to trigger a rule since the trigger takes place on the server. The advantage is that the rule implementor class files only need to be available on the server.

**Anywhere**

This option tries to instantiate and run the rule implementor locally, and, if the class cannot be found, it tries to trigger it remotely.

**Classification**

For classified rules, this is the classification to which the rule applies. This is used when you use a situational trigger. Once a classification is computed for the situational trigger point, rules that apply to that classification are found and triggered. For more information, see Situational trigger point.

**Classifier**

This indicates whether this rule computes a classification. Classification is used for a situational trigger. A classifier rule is used to perform the first step of a situational trigger which computes a classification that is used to find rules to deal with the situation. For more information, see "Situational trigger point".

**Dependent rules**

In many cases, a rule triggers other rules to complete the overall task. These other rules are referred to as dependent rules and can be specified using the dependent rules attribute. For more information, see Dependent rules.

**Business intent**

This is a text description of the intent of this rule from the view point of the business analyst. You can store any text string here.

**Description**

This is a text description of the rule at the programmer's level. You can store any text string here.

### Original requirement

This is a text description of the initial business analyst requirement of this rule. You can use this description to keep track of why this rule was originally created (for example, to keep auditing records). You can store any text string here.

### User-defined data

You can store a user-defined text string here. The format and use of this data is completely determined by the user.

### Primary key

Every rule has a primary key to uniquely identify it in the database where the enterprise beans are stored. Normally, a unique primary key is generated automatically when you create a new rule. However, you can use the rule management APIs to specify your own primary key, if desired. See Rule management APIs for more information.

### Precedence

This is the relative priority of this rule. The default finding strategy uses this value to order the rules found in the database, from lowest to highest, when more than one rule is found for a particular trigger point. Rules are sorted numerically by precedence with the numerically lowest precedence first and the numerically highest precedence last.

## Rule states

Rules can be in any one of the following states at any particular time:

### scheduled

The rule is scheduled to become effective (its start date is in the future) and will not be found by current trigger points.

### in effect

The rule is currently in effect and can be found by trigger points.

### expired

The rule is no longer in effect (the end date is in the past) and will not be found by trigger points.

### invalid

The rule is not correctly defined and will not be found by trigger points.

Typically, only those rules that are "in effect" are found by the Business Rule Beans (BRBeans) run-time environment. This behavior can be overridden by setting an `asOfDate` on the `TriggerPoint` object, which then will execute "as if" the current date is the given date. For more information, see "As Of Date".

When a Rule is first created, it is marked as "ready for use" and is found when firing Rules. If the Rule is not complete and you do not want it to be found by BRBeans, then use either of the following to mark the Rule:

- Use the `setReady(false)` method in the Rule Management APIs
- Use the Rule Management Application to mark the rule as not ready

## Rule results

In general, a rule can return any type of result that makes sense for the business purpose of the rule. The return type on the `fire()` method is `java.lang.Object` so any Java object can be returned, including arrays. You cannot return a Java primitive since the results must be an object. However, you can return the object form of the primitives. For example, you can return a `java.lang.Integer` instead of an `int`. If the rule is fired remotely, the returned value must implement `java.io.Serializable`.

## Dependent rules

When a business rule triggers other business rules as part of its implementation, the rules that are triggered are called **dependent rules** of the first rule. An example is the `RuleAND` rule implementor supplied with Business Rule Beans (BRBeans). It uses two or more dependent rules, each of which is assumed to return a true or false value. When a rule with `RuleAND` as its implementor is triggered, it triggers each of its dependent rules and a logical AND operation is performed on all of the returned results. The result of this AND operation is returned as the result of the top-level rule.

Dependent rules are specified in the attributes of the top-level rule where the fully qualified name of each dependent rule is listed. When the top-level rule is triggered, an array of dependent rule names is passed to the rule implementor's `init()` method. They are stored here until they are triggered by the `fire()` method.

**Note:** The BRBeans framework does not ensure that the dependent rules specified in the enterprise beans are actually triggered. Triggering the dependent rules and interpreting their results is entirely up to the rule implementor of the top-level rule.

Dependent rules can be nested within other dependent rules. In other words, a dependent rule of some particular rule can have its own dependent rules which, in turn, can have their own dependent rule and so on. The BRBeans framework does not place any restriction on the number of levels that dependent rules can be nested. The only practical restriction is the complexity of the rule set that is built up when dependent rules are nested many levels deep.

## BRBeans run-time environment

The Business Rule Beans (BRBeans) run-time environment is used to find and trigger rules.

The BRBeans run-time environment is made up of two parts:

- Code that runs on the **client** ("client" here meaning wherever the trigger point is located). This consists of code that does the following:
  - Finds the specified rules
  - Decides where the rules should be triggered
  - Calls the `fire` method on all rules
  - Combines the results from the rules
- Code that runs on the **server**. This consists of enterprise beans used to represent rules and rule folders. These enterprise beans do the following:
  - Provides for business rule persistence
  - Provides query functions that the client part of the run time can use to find rules to be triggered

## BRBeans run-time behavior

Business Rule Beans (BRBeans) run-time behavior can best be described by giving a simple example of a trigger point selecting, executing, and then responding to the results of a business rule.

The first step in triggering a rule is for the trigger point framework to perform a query on the rule server to determine which rules to trigger. The main item used for the query is the fully qualified rule name. Other items used in the query include the start and end date, whether this is a classifier, the classification of the rule, and whether the rule is marked "ready". This query returns zero or more rules. If there is at least one rule, the trigger point assembles the data that is sent as parameters to each rule. The trigger point then loops through the list of rules invoking the `fire()` method on each and passing the parameters. The results are combined depending on the combining strategy used.

When the trigger point framework invokes `fire` on a rule, it instantiates the `RuleImplementor` and uses it to do the actual work (to execute the rule algorithm or test). Once it has arrived at a result, the `RuleImplementor` returns that result. For constraint rules (ones that arrive at a boolean true or false answer) the returned value is, by convention, a `ConstraintReturn`. A `ConstraintReturn` is a data structure that indicates whether the constraint was satisfied. If not, the `ConstraintReturn` indicates what went wrong. For derivation rules (ones that calculate a single, generally non-boolean value), the return value can be any type. In the simplest case, the return value from each `RuleImplementor` is returned back to the trigger point where it is analyzed to determine what action to take.

The following is an overview of what happens when the `maxTruckDriverHours` rule is triggered:

A rule exists named `maxTruckDriverHours`. The purpose of this rule is to check that the number of hours entered by a user for a particular truck driver does not exceed the maximum allowed value. This rule contains an initialization parameter list consisting of a single value of 8. This rule is bound to a

RuleImplementor class called MaxRuleImpl. MaxRuleImpl tests the parameter it is passed against the initialization list value and returns a ConstraintReturn. The ConstraintReturn is set to true if the passed parameter is less than or equal to the initialization value. Otherwise, a ConstraintReturn is set to false and some information is added that describes which values were compared and why the test failed.

When this rule is triggered, the following details the trigger point process:

1. During the execution of the application, the application reaches a point where it needs to verify that the number of truck driver hours that was entered is valid. The application code invokes a simple trigger point passing the name of the rule to be triggered and a parameter list containing the entered hours for the driver.
2. The trigger point framework performs a query on the rule server to find the rule with the specified name. It receives back a sequence of rule objects. In this case, this sequence contains one rule, maxTruckDriverHours.
3. The framework determines whether this rule is to be triggered on a local or remote machine. If local, the framework gets a local copy of the rule object and calls the fire method on the copy. If remote, the framework calls the fire method on the enterprise bean reference. The parameter list containing the weight is passed to the fire method.
4. The maxTruckDriverHours rule (either the copy or the enterprise bean itself) creates an instance of the rule implementor class, maxRuleImpl, if it does not already have one. When a new rule implementor instance is created, the rule calls its init method passing any initialization parameters defined for the rule. In this case, the initialization parameter list contains the single value 8. If the rule already has a rule implementor instance, it uses that one and does not call the init method.
5. The maxTruckDriverHours rule calls the fire method on the rule implementor instance. The firing parameters passed to the trigger point are passed to the rule implementor and are possibly modified by any firing parameters defined in the rule itself. In this case, the firing parameters are passed directly from the trigger point.
6. The maxRuleImpl returns a ConstraintReturn object to the rule that indicates the result of its comparison. This ConstraintReturn is returned to the trigger point framework and ultimately to the application.
7. The application checks the value in the ConstraintReturn and takes the appropriate action.

## BRBeans run-time exception handling

Business Rule Beans (BRBeans) defines one general exception class for exceptions that might be exposed to the user. All other BRBeans exceptions inherit from this class. The name of this class is `com.ibm.websphere.brb.BusinessRuleBeansException`. A `BusinessRuleBeansException` is generally thrown when an unexpected error occurs within BRBeans. A `BusinessRuleBeansException` might have information in it about the original exception that caused the error. Doing a `printStackTrace` on the `BusinessRuleBeansException` prints out this information and the stack trace for the `BusinessRuleBeansException` itself. Also, there are methods to access the original exception programmatically, if desired.

BRBeans also defines a **ConstraintViolationException**, which extends `BusinessRuleBeansException`. A `ConstraintViolationException` is thrown if the `ThrowViolationCombiningStrategy` is specified on the `TriggerPoint` and the rule returns a false value (either a `ConstraintReturn` or a boolean).

Finally, BRBeans defines two exceptions, **NoRuleFoundException** and **MultipleRulesFoundException**, that are thrown by some of the predefined filtering strategies if an unexpected number of rules is found on a trigger point call. These two exceptions both extend `UnexpectedRulesFoundException` which, in turn, extends `BusinessRuleBeansException`.

## Rule implementors

A rule implementor, in terms of Business Rule Beans, is an algorithm written in Java that implements the `BRBeans RuleImplementor` interface.

A Business Rule Beans (BRBeans) Rule is a persistent object that exists on the BRBeans Rule server. One of the rule's persistent attributes, in addition to `startDate`, `endDate`, `initParams`, and so on, is `javaRuleImplementorName`, which is the name of its rule implementor.

BRBeans supplies a number of predefined rule implementor classes that can be used in user-defined BRBeans rules (see the BRBeans Javadoc) to implement the BRBeans `RuleImplementor` Interface. The Java source code for these rule implementors is supplied as BRBeans sample code in the `com.ibm.websphere.brb.implementor` package. This sample code, packaged in a JAR file, appears in the CLASSPATH of the BRBeans Rule Server (for "remote" firing) or is co-located in the CLASSPATH of the application or applications using it (for "local" firing). Typically, the `RuleImplementor` is in the application EAR file.

Using standard Java development tools, you can externalize BRBeans by attaching them to either enterprise beans or ordinary Java objects. Programming a new rule implementation in Java is typically a simple process. If you write your own rule implementor, you must create a new Java class that implements the `com.ibm.websphere.brb.RuleImplementor` interface. This class must implement the following methods:

**Default constructor**

The class must have a default, no-argument constructor so that it can be instantiated when a rule using it is triggered.

**init** The `init` method comes from the `RuleImplementor` interface and is called when the rule implementor is first. Its purpose is to perform an initialization needed by the rule implementor instance before it is actually fired. The following parameters are passed to the `init` method:

**The initialization parameters defined for the rule being triggered**

These can be any parameters needed to properly initialize the rule implementor instance. Often the initialization parameters consist of constants required by the algorithm. For example, when using a rule implementor that checks whether a number is greater than a threshold value, the threshold value normally is passed as an initialization parameter. This parameter is null if there are no initialization parameters for the rule.

**An array of names of dependent rules for the rule being triggered**

Normally, the rule implementor stores these names to be used when the `fire` method is called. These dependent rules are intended to be triggered as part of the algorithm performed by the rule implementor. See *Dependent Rules* for more information. This parameter is null if there are no dependent rules defined for the rule.

**The user-defined data for the rule being triggered**

This data is completely defined by the user of the Business Rule Beans (BRBeans). BRBeans does not interpret this data in any way. This parameter is null if there is no user-defined data defined for the rule.

**A reference to the actual rule being triggered**

This can be used to extract attribute values from the rule, if needed.

**fire** The `fire` method comes from the `RuleImplementor` interface. This method is called to perform the algorithm of the rule implementor. Any desired algorithm can be performed here. Normally, a value is returned by the `fire` method that is ultimately returned as the result of triggering the rule. The following parameters are passed to the `fire` method:

**The TriggerPoint object that is being used to trigger the rule**

This parameter is needed if the rule has dependent rules that the `fire` method needs to trigger.

**The target object for this particular trigger call**

This parameter can be any object that is thought of as the target of the rule. However, the parameter can be null.

**A reference to the actual rule being triggered**

This parameter can be used to extract attribute values from the rule, if needed.

**The firing parameters for this particular trigger call**

Normally, these parameters are the firing parameters passed by the code that invoke the trigger point. However, these can be overridden by specifying firing parameters on the rule itself. Wherever they ultimately come from, these are the parameters that the rule implementor needs at run time to perform its function. Normally, these are run-time

variables that are to be processed by the rule implementor. For example, when using a rule implementor that checks whether a number is greater than a threshold value, the number to be checked normally is passed as a firing parameter. This parameter is null if no firing parameters are passed by the caller and none are defined on the rule itself.

### **getDescription**

`getDescription` comes from the `RuleImplementor` interface. The purpose of this method is to return a text string that describes the function of the rule implementor. This information might be displayed on a user interface to help select what implementor to use. This method, however, is currently not used by the BRBeans framework. Users can incorporate this information if they create their own rule implementor. For additional information, see the BRBeans Javadoc for the `RuleImplementor` interface.

## **Trigger point framework**

A trigger point is the location in a method of an object where externalized business rules are invoked.

The proper placement of trigger points can add substantially to the flexibility and speed with which a business application adapts to new business practices.

Wherever a trigger point is placed in user-written code, the Business Rule Beans (BRBeans) trigger point framework needs to do the following:

1. Assemble the parameter list to send to the rules
2. Find the potential rules that apply
3. Filter out any rules which do not apply (optional)
4. Fire the rules in the filtered rule set
5. Combine the results of the rule firings in some meaningful way

The application code that contains the trigger point needs to perform the following functions:

1. Establish a value for the target object. Usually the target object is the object in which the trigger point is encountered. The target object is one of the parameters passed to the `fire` method of the `RuleImplementor`. However, this is an optional parameter. If the rule implementor does require a target object, null can be passed instead.
2. Build the array of objects containing the run-time parameters needed to satisfy the trigger point's business purpose. This array is normally passed as one of the parameters of the `fire` method of the `RuleImplementor`. If firing parameters are specified on the rule itself, then those firing parameters are passed instead of the ones passed by the caller.
3. Invoke the `trigger()`, `triggerClassifier()`, or `triggerSituational()` method of the `TriggerPoint` class.
4. Catch and handle any exceptions that might occur as a result of firing the rules. Otherwise, take action based upon the rule firing results.

The two simple trigger methods, `trigger` and `triggerClassifier`, perform their function in four steps:

1. Find the rules
2. Filter out those rules which are not desired
3. Fire the remaining rules
4. Combine the results and return to the caller

The complex trigger method, `triggerSituational` does this sequence of steps twice. In the first phase, the method performs the four steps once to find a rule that returns a classification. This classification is fed into the second phase. The second phase triggers rules that have the name specified in the `triggerSituational` method and have a classification equal to the value returned by the first phase.

How each of these steps is performed can be modified through various methods on the `TriggerPoint` object. The implementation of each step is defined by a **strategy** object. For more information on strategies, see *Administering strategy objects to control triggers*.

## Trigger points

Examples of how to code a trigger point call are provided in the following topics:

- Simple trigger point
- Classifier trigger point
- Situational trigger point

### Simple trigger point

A simple trigger point is used to trigger a rule or rules specified by name. This type of trigger point is used by invoking the trigger method on an instance of the `TriggerPoint` class. All rules with the specified name are triggered and the results are combined using the `CombiningStrategy` specified on the `TriggerPoint` object. This type of trigger point only finds rules that are not marked as classifiers.

The following shows an example of using a simple trigger point to trigger a rule named `isSeniorCitizen` (in the `com/acme/ageRules` folder), which determines whether a person is classified as a senior citizen based on the passed in age:

```
...
// create an instance of TriggerPoint for triggering the rule and specify that the
// ReturnFirstCombiningStrategy is to be used to return only the first result if
// multiple rules are found.
TriggerPoint tp = new TriggerPoint();
tp.setCombiningStrategy(CombiningStrategy.RETURN_FIRST, TriggerPoint.ALL_RULES);

// define parameter list that's passed to the rule
Object [] plist = new Object[1];

// define age of person to be tested
Integer age = new Integer(64);

// define name of rule to be fired
String ruleName = "com/acme/ageRules/isSeniorCitizen";

// define result of rule firing
Object result = null;

// initialize parameter list
plist[0] = age;

try {

 // fire "com/acme/ageRules/isSeniorCitizen" rule passing parameter list containing age.
 // Note: in this case the target object is not used and could be null.
 result = tp.trigger(this, plist, ruleName);

 // put result into usable format. A single result is returned since we specified to use
 // the ReturnFirstCombiningStrategy. By default an array of results would be returned.
 boolean seniorCitizen = ((Boolean)result).booleanValue();

 // make use of result
 if(seniorCitizen) {
 ...
 }
}
catch(BusinessRuleBeansException e) {

 // handle exception
 ...
}
}
```

## Classifier trigger point

A classifier trigger point is identical to a simple trigger point except that it only finds rules marked as classifiers. Classifiers are rules that determine what sort of business situation is present. These rules then return a classification string that indicates the result.

Usually these rules are used as part of a situational trigger point, but they also can be triggered on their own. This type of trigger point is used by invoking the `triggerClassifier` method on an instance of the `TriggerPoint` class.

The following shows an example of using a classifier trigger point to trigger a rule named `determineCustomerLevel` (in folder `com/acme/customerClassifiers`). This rule classifies customers into levels (gold, silver, and bronze) based on their spending history.

```
...
// create an instance of TriggerPoint for triggering the rule and specify that the
// ReturnFirstCombiningStrategy is to be used to return only the first result if
// multiple rules are found.
TriggerPoint tp = new TriggerPoint();
tp.setCombiningStrategy(CombiningStrategy.RETURN_FIRST, TriggerPoint.ALL_RULES);

// define parameter list that's passed to the rule
Object [] plist = new Object[1];

// information about the customer to be checked is stored in this object
Customer cust = ...;

// define name of rule to be fired
String ruleName = "com/acme/customerClassifiers/determineCustomerLevel";

// define result of rule firing
Object result = null;

// initialize parameter list
plist[0] = cust;

try {

 // fire "com/acme/customerClassifiers/determineCustomerLevel" rule passing parameter
 // list containing the customer to be checked.
 // Note: in this case the target object is not used and could be null.
 result = tp.triggerClassifier(this, plist, ruleName);

 // put result into usable format. A single result is returned since we specified to use
 // the ReturnFirstCombiningStrategy. By default an array of results would be returned.
 String customerLevel = (String) result;

 // make use of result
 if(customerLevel.equals("Gold")) {
 ...
 } else if (customerLevel.equals("Silver")) {
 ...
 } else if (customerLevel.equals("Bronze")) {
 ...
 } else {
 ...
 }
}
catch(BusinessRuleBeansException e) {

 // handle exception
 ...
}
}
```

## Situational trigger point

A situational trigger point is used when the rule or rules to be triggered depend on the business situation.

This example evaluates a customer's past purchasing history to place them into one of three levels: Gold, Silver, or Bronze. Their classification determines how much of a discount they receive.

To use a situational trigger point to handle this case, it is first necessary to define four rules:

- one **classifier** rule to determine under which of the three levels to classify the customer
- three **classified** rules to determine the actual discount to offer

All of the classified rules have the same name and are marked as applying to one of the three customer levels by specifying the level in its classification attribute. For example, the rule to determine the discount for a Gold level customer will contain the string "Gold" in its classification attribute.

The situational trigger point takes two rule names as input: the name of the classifier rule and the name of the classified rule. The situational trigger point then proceeds in two phases:

1. Find the specified classifier rule and trigger it to generate a classification string.
2. Find the rules that have the name specified for the classified rule and have a classification attribute equal to the classification string returned by the first phase.

These rules then are triggered to produce the final result, in this case the discount to offer.

The following shows an example of a situational trigger point used to handle the case described previously:

```
...
// create an instance of TriggerPoint for triggering the rule and specify that the
// ReturnFirstCombiningStrategy is to be used to return only the first result if
// multiple rules are found.
TriggerPoint tp = new TriggerPoint();
tp.setCombiningStrategy(CombiningStrategy.RETURN_FIRST, TriggerPoint.ALL_RULES);

// define parameter list that's passed to the classifier rule
Object [] classifierPlist = new Object[1];

// define parameter list that's passed to the classified rule
Object [] classifiedPlist = new Object[1];

// information about the customer to be checked is stored in this object
Customer cust = ...;

// define name of classifier rule to be fired
String classifierRuleName = "com/acme/customerClassifiers/determineCustomerLevel";

// define name of classified rule to be fired
String classifiedRuleName = "com/acme/discountRules/determinedDiscount";

// define result of rule firing
Object result = null;

// initialize parameter lists
classifierPlist[0] = cust;
classifiedPlist[0] = cust;

try {
 // fire the rules to get the discount to offer
 // Note: in this case the target object is not used and could be null.
 result = tp.triggerSituational(this, classifiedPlist, classifierPlist, classifiedRuleName, classifierRuleName);

 // put result into usable format. A single result is returned since we specified to use
 // the ReturnFirstCombiningStrategy. By default an array of results would be returned.
 Float discountToOffer = (Float) result;
}
```

```

// make use of result
...
}
catch(BusinessRuleBeansException e) {

// handle exception
...
}

```

## As Of Date

An "As Of Date" can cause rules to be triggered as if the given date is the current date. This is especially useful when you want to test a rule, see what effect a future change in rules or regulations may have on the overall framework, or see what past or future rates, discounts, or both might be.

Normally, a rule only can be triggered if it is "in effect" (see "Rule States") as of the current date and time.

To set an "As Of Date", call the `setAsOfDate()` method on the `TriggerPoint` object and pass the date that you want to be used. To use the current date again, call `unsetAsOfDate` or `setAsOfDate` and pass null for the date.

## Predefined strategy objects

The following is a list of predefined strategy objects that are provided in Business Rule Beans:

### FindingStrategy

Accesses the data store and returns those rules that meet the search criteria specified

### FilteringStrategy

Takes the list of rules that were found by the `FindingStrategy` and filters out the rules that should not be fired

### FiringStrategy

Takes the rules that were found by the `FindingStrategy`, (possibly modified by the `FilteringStrategy`), fires them each in order, and returns an array containing the results of each rule

### CombiningStrategy

Takes the results of the rules that are fired by the `FiringStrategy` and combines them to form a reasonable result to the `TriggerPoint` caller.

## FindingStrategy method

The job of the `FindingStrategy` is to access the data store and return those rules that meet the search criteria specified. There are two `FindingStrategy` classes provided by Business Rule Beans (BRBeans):

- `DefaultClassifierFindingStrategy`
- `DefaultNonClassifierFindingStrategy`

Both of these strategies perform a case-sensitive search for Rules that are marked "ready" and match the given search criteria. Results are ordered by precedence from highest to lowest (the first rule in the array has the numerically smallest precedence, the next rule has the next smallest precedence, and so on). If no rules are found, then an empty array is returned. The former strategy returns classifier rules (`classifier=true`) only and the latter returns non-classifier rules (`classifier=false`) only.

These default strategies are used automatically by the `TriggerPoint`. There is no need to call `setFindingStrategy` to use these strategies. Instances of these two default finding strategies are stored in static constants defined on the `FindingStrategy` interface.

## FilteringStrategy method

The job of the `FilteringStrategy` is to take the list of rules that were found by the `FindingStrategy` and filter out the rules that should not be fired. There are three sets of filtering strategies used in

`TriggerPoint`:

- strategy for **zero** rules found
- strategy for **one** rule found

- strategy for **multiple** rules found

A different strategy can be used for each of these scenarios, along with different strategies for classifier and non-classifier rules. The zero rules strategy is invoked if no rules are found by the finding strategy, the one rule strategy is invoked if exactly one rule is found and the multiple rules strategy is invoked if more than one rule is found.

Business Rule Beans (BRBeans) provides the following filtering strategies that can be used:

**Accept Any**

BRBeans utilizes all of the rules found (this is the default).

**Accept One**

BRBeans expects one rule only.

**Accept First**

BRBeans utilizes the first rule found.

**Accept Last**

BRBeans utilizes the last rule found.

Instances of these filtering strategies are stored in static constants defined in the `FilteringStrategy` interface. You can use these for setting the strategies on a `TriggerPoint`.

As an example, here is one common way to use filtering strategies. You want to ensure that exactly one rule is found on a `TriggerPoint` call. Thus, set all three strategies (zero rules, one rule, and multiple rules) for this `TriggerPoint` to `FilteringStrategy.ACCEPT_ONE`. This strategy throws an exception if the number of rules is not exactly one. The following sequence of method calls accomplishes this for `TriggerPoint tp`:

```
tp.setNoRulesFilteringStrategy(FilteringStrategy.ACCEPT_ONE, TriggerPoint.ALL_RULES);
tp.setOneRuleFilteringStrategy(FilteringStrategy.ACCEPT_ONE, TriggerPoint.ALL_RULES);
tp.setMultipleRulesFilteringStrategy(FilteringStrategy.ACCEPT_ONE, TriggerPoint.ALL_RULES);
```

## FiringStrategy method

The `FiringStrategy` takes the rules that were found by the `FindingStrategy`, (possibly modified by the `FilteringStrategy`), fires them each in order, and returns an array containing the results of each rule.

A single default `FiringStrategy` is provided by Business Rule Beans (BRBeans) as all of the rules are fired in the same way. This implementation takes each rule in order and performs the following steps:

1. Determines what firing parameters to pass to the rule. If there are no firing parameters specified for this rule, the implementation uses the firing parameters passed on the `TriggerPoint` call. Otherwise, it uses the firing parameters specified in the rule in place of the parameters passed on the `TriggerPoint` call.
2. Calls the `fire` method on the rule and passes the firing parameters from the first step.

Unexpected exceptions result in a `BusinessRuleBeansException` being thrown that contains the original exception.

## CombiningStrategy method

The job of the `CombiningStrategy` is to take the results of the rules that are fired by the `FiringStrategy` and combine them to form a reasonable result to the `TriggerPoint` caller. Business Rule Beans (BRBeans) provides several combining strategies to be used in applications:

**Return All**

Returns the results from all of the rules fired in an array (this is the default)

**Return First**

Returns only the result from the first rule fired

**Return Last**

Returns only the result from the last rule fired

**Return AND**

Returns the logical AND of the results from all the rules fired. This strategy requires that all of the

results returned by the fired rules are either `ConstraintReturn` objects or `java.lang.Boolean` objects. An exception is thrown if this is not the case.

#### **Return OR**

Returns the logical OR of the results from all of the rules fired. This strategy requires that all of the results returned by the fired rules are either `ConstraintReturn` objects or `java.lang.Boolean` objects. An exception is thrown if this is not the case.

#### **Throw Violation**

Throws a `ConstraintViolationException` containing all of the failed `ConstraintReturn` objects if any `ConstraintReturns` contain `false`. Otherwise, it returns a `true` `ConstraintReturn`.

Instances of these combining strategies are stored in static constants defined in the `CombiningStrategy` interface. You can use these for setting the strategies on a `TriggerPoint`. For example, the following method call sets the `CombiningStrategy` on `TriggerPoint` `tp` to be the `Return_First` strategy:

```
tp.setCombiningStrategy(CombiningStrategy.RETURN_FIRST, TriggerPoint.ALL_RULES);
```

## **Customized strategy objects**

The process of triggering a rule or set of rules is controlled by a set of strategy objects. The following four strategies are used each time a rule is triggered:

#### **FindingStrategy**

The `FindingStrategy` accesses the persistent data store to find the set of rules matching the search criteria passed to the trigger call. The search criteria are based on the rule ID information passed on the trigger call. The set of rules found is passed to the `FilteringStrategy`.

#### **FilteringStrategy**

The `FilteringStrategy` can change the set of rules that were found by the `FindingStrategy`. The set of rules returned is the set that are fired by the `FiringStrategy`.

#### **FiringStrategy**

The `FiringStrategy` fires the rules found by the `FindingStrategy`, which may be modified by the `FilteringStrategy`. It gathers the results of the individual rules and passes them to the `CombiningStrategy`.

#### **CombiningStrategy**

The `CombiningStrategy` takes the results from firing the rules and combines them to produce the final result of the trigger.

Each `TriggerPoint` object has its own set of strategies that can be changed independent of any other `TriggerPoint` object. There is a set of default strategies that are used by the `TriggerPoint` if none are explicitly set.

For each of the four strategies, you can set different strategies for **classifier** rules and for **non-classifier** rules. The strategies set for classifier rules are used when the Business Rule Beans (BRBeans) framework is triggering a classifier rule. The strategies for non-classifier rules are used in all other cases.

It is also possible to set three different sets of filtering strategies:

- one to be used if no rules are found
- one to be used if exactly one rule is found
- one to be used if more than one rule is found

This capability can be used to set up filtering strategies that throw exceptions if the expected number of rules is not found.

Strategy classes must implement one of the strategy interfaces provided by BRBeans in the `com.ibm.websphere.brb` package:

- `FindingStrategy`
- `FilteringStrategy`
- `FiringStrategy`
- `CombiningStrategy`

Users can write their own strategy implementations to perform special functions not performed by the predefined implementations. Write these strategy implementations with care since part of the functionality of the BRBeans framework is replaced when you write a custom strategy. One simple example of writing a custom strategy is creating a new firing strategy that logs every rule that is fired.

The basic requirement for a strategy implementation is that it implements the appropriate strategy interface.

For the **filtering** and **combining** strategies, create a class that implements either `FilteringStrategy` or `CombiningStrategy` and either the `filterRules()` method (for `FilteringStrategy`) or the `combineResults()` method (for `CombiningStrategy`) to perform the required functions. At run time, create an instance of the new class and pass it to the `TriggerPoint` object using the appropriate set method so that the new strategy is used when rules are triggered using that `TriggerPoint`.

The **finding** and **firing** strategies are more complicated to customize since they provide more function than the simple filtering and combining strategies. Default finding and firing strategy implementations are provided that define a general outline of the steps necessary to perform the function. It is suggested that you subclass these when you customize your own strategies and then override the desired methods on the default implementation to provide the new behavior.

The BRBeans Javadoc provides more information about the `FindingStrategy`, `FilteringStrategy`, `FiringStrategy`, and the `CombiningStrategy` interfaces.

## Customized rule implementors

To write your own rule implementor, create a new Java class that implements the `com.ibm.websphere.brb.RuleImplementor` interface. This class must implement the following methods:

### Default constructor

The class must have a default, no-argument constructor so that it can be instantiated when a rule using it is triggered.

**init** The `init` method comes from the `RuleImplementor` interface and is called when the rule implementor is first created. Its purpose is to perform an initialization needed by the rule implementor instance before it is actually fired. The following parameters are passed to the `init` method:

#### The initialization parameters defined for the rule being triggered

These can be any parameters needed to properly initialize the rule implementor instance. Often the initialization parameters consist of constants required by the algorithm. For example, when using a rule implementor that checks whether a number is greater than a threshold value, the threshold value normally is passed as an initialization parameter. This parameter is null if there are no initialization parameters for the rule.

#### An array of names of dependent rules for the rule being triggered

Normally, the rule implementor stores these names to be used when the `fire` method is called. These dependent rules are intended to be triggered as part of the algorithm performed by the rule implementor. See `Dependent Rules` for more information. This parameter is null if there are no dependent rules defined for the rule.

#### The user-defined data for the rule being triggered

This data is completely defined by the user of the Business Rule Beans (BRBeans). BRBeans does not interpret this data in any way. This parameter is null if there is no user-defined data defined for the rule.

#### A reference to the actual rule being triggered

This can be used to extract attribute values from the rule, if needed.

**fire** The `fire` method comes from the `RuleImplementor` interface. This method is called to perform the algorithm of the rule implementor. Any desired algorithm can be performed here. Normally, a value is returned by the `fire` method that is ultimately returned as the result of triggering the rule. The following parameters are passed to the `fire` method:

**The TriggerPoint object that is being used to trigger the rule**

This parameter is needed if the rule has dependent rules that the fire method needs to trigger.

**The target object for this particular trigger call**

This parameter can be any object that is thought of as the target of the rule. However, the parameter can be null.

**A reference to the actual rule being triggered**

This parameter can be used to extract attribute values from the rule, if needed.

**The firing parameters for this particular trigger call**

Normally, these parameters are the firing parameters passed by the code invoking the trigger point. However, these can be overridden by specifying firing parameters on the rule itself. Wherever they ultimately come from, these are the parameters that the rule implementor needs at run time to perform its function. Normally, these will be run-time variables that are to be processed by the rule implementor. For example, when using a rule implementor that checks whether a number is greater than a threshold value, the number to be checked normally is passed as a firing parameter. This parameter is null if no firing parameters are passed by the caller and none are defined on the rule itself.

**getDescription**

getDescription comes from the RuleImplementor interface. The purpose of this method is to return a text string that describes the function of the rule implementor. This information might be displayed on a user interface to help a user select what implementor to use. This method, however, is currently not used by the BRBeans framework. For additional information, see the RuleImplementor interface in the BRBeans Javadoc.

## Rule management command

The Rule management command assists the user in performing high-level administration of rules and rule folders.

This includes the capability to create, modify, delete, import, or export rules or rule folders. This command can be used initially by the programmer to define rules interactively and then used by the domain analyst for rule management tasks. You can use the following files:

- On Microsoft Windows platforms, rulemgmt.bat
- On Unix platforms, rulemgmt.sh

rulemgmt properties-file [host-address port-number]

**Parameters****<properties-file>**

The fully qualified name of a file containing the JNDI names of the rule EJBs for the rule set that is to be accessed.

The following must be specified in the file:

```
RuleJndi=<JNDI name of the Rule EJB>
RuleFolderJndi=<JNDI name of the RuleFolder EJB>
RuleHelperJndi=<JNDI name of the RuleHelper EJB>
```

See <WAS\_HOME>/bin/brbeansDefaultProperties for an example.

**Arguments****host-address**

This is the host name of the name server. The default is the local host.

**port-number**

This is the port number of the name server. The default is 2809.

## Rule importer command

The rule importer command imports rules into a database from one or more XML documents.

The rule importer command can be invoked using the Rule Management Application (RMA). The user interface in RMA provides some assistance in specifying the parameters required by the importer. Alternatively, the rule importer can be invoked from the command line using the following scripts:

- For Microsoft Windows platforms, `ruleimporter.bat`
- For UNIX platforms, `ruleimporter.sh`

```
ruleimporter <properties-file> <import-files> [options]
```

### Parameters

#### <properties-file>

The fully qualified name of a file containing the JNDI names of the Business Rule Beans (BRBeans) enterprise beans for the rule set that is to be accessed. Refer to BRBeans Properties file for a definition of the contents of this file. This parameter is required.

#### <import-files>

One or more fully qualified names of the files containing XML rule definitions to be imported. These files must contain XML in the format defined in `<WAS_HOME>\bin\brb.dtd` file. This parameter is required.

### Options

#### -[v]erbose

Shows verbose output while importing. This shows the rule definition of every rule that is imported.

-[t]est Parses the input files only and does not create rules on the application server. This will ensure that there are no errors in the syntax of the rule definitions provided in the XML document. Combined with the **-verbose** option, it also can be used to see exactly what rules will be imported.

#### -[u]pdate

Update the existing rule with values from the input file when a rule in an input file has the same primary key as an existing rule. If this option is not specified, then any rule with the same primary key as an existing rule causes an error and that rule is not imported.

#### -[c]ommitteach

Performs a commit after each rule is created rather than creating all of the rules in a single transaction. If this option is not specified, then all rules are created in a single transaction. This means that if any rule causes an error, the entire transaction is rolled back and none of the rules are imported. If **-commiteach** is specified and a rule causes an error, only that rule is not imported. Other rules are still imported.

#### -[h]ost <host-name>

Specifies the name of the host for the name server. The default is the local host.

#### -[p]ort <port-number>

Specifies the port number for the name server. The default is 2809.

## Rule exporter command

The rule exporter command exports rules from a database into an XML document.

The rules that are exported are determined by an XML document, which is provided to the command. The rule exporter function can be invoked using the Rule Management Application (RMA). The user interface in RMA provides some assistance in specifying the parameters required by the exporter. Alternatively, the rule exporter can be invoked from the command line using the following scripts:

- For Microsoft Windows platforms, `ruleexporter.bat`
- For UNIX platforms, `ruleexporter.sh`

```
ruleexporter <properties-file> <export-list-files> [options]
```

### Parameters

#### <properties-file>

The fully qualified name of a file containing the JNDI names of the BRBeans enterprise beans for the rule set that is to be accessed. Refer to BRBeans Properties file for a definition of the contents of this file. This parameter is required.

### <export-list-files>

One or more fully qualified names of files containing a list of rules, folders, or both to be exported. These files must contain XML in the format defined in the <WAS\_HOME>\AppServer\bin\brb-export-list.dtd file. This parameter is required.

### Options

#### -[v]erbose

Shows verbose output while exporting.

#### -[o]utput <file-name>

Specifies the name of the output file where the XML rule definitions are stored. This is a required parameter.

#### -[h]ost <host-name>

Specifies the name of the host for the name server. The default is the local host.

#### -[p]ort <port-number>

Specifies the port number for the name server. The default is 2809.

## BRBeans properties file

Applications that use the Business Rule Beans (BRBeans) enterprise beans (this includes applications that trigger rules or use the rule management APIs) must specify the JNDI names for these enterprise beans so that the application can find them at run time. If the application is running in a J2EE client container, in a servlet, or on the application server itself (for example, as part of another enterprise bean), then these names probably have been specified by the person who configured the application. If the application is not running in a container, the names must be specified some other way. The BRBeans properties file provides a way to do this.

At run time, the BRBeans code looks for a special Java property that identifies the name of the properties file. This Java property can be specified on the command line as `-DbrbPropertiesFile=<file_name>`. The file specified is expected to contain the JNDI names used to find the BRBeans enterprise beans. The BRBeans framework uses these names when it needs to locate the enterprise beans.

When an application attempts to reference BRBeans enterprise beans, the code first looks for the `brbPropertiesFile` Java property. If this property is specified, the names listed in that file are used to find the enterprise beans and to override any EJB references that were specified in the container (if the application is running in a container). If the property is not specified, then BRBeans attempts to use the EJB references specified in the container.

The host name and port number used to access the name server also can be set in this file. If these are not specified, the BRBeans framework uses the name server used by the container in which the application is running. If the application is not running in a container, then localhost is used for the host name and 2809 is used for the port number.

The properties file must be in the following format (entries can be specified in any order):

```
host=<host-name-for-name-server>
port=<port-number-for-name-server>
RuleJndi=<JNDI-name-for-Rule-EJB>
RuleFolderJndi=<JNDI-name-for-RuleFolder-EJB>
RuleHelperJndi=<JNDI-name-for-RuleHelper-EJB>
```

### Location

A default properties file is shipped as `<WAS_HOME>\AppServer\bin\brbeansDefaultProperties`.

There are a set of JAR files that conform to the BRBeans<database-type>.jar naming convention (depending on the type of database that you want to use). If the JAR files are used without changing the JNDI names, then you also can use the default properties file.

## Usage note

The file name still must be specified even if you want to use the default file. There is no file that is used automatically if the `brbPropertiesFile` property is not set.

The tools shipped with BRBeans (the Rule Management Application, the rule importer, and the rule exporter) all run outside of any container. Hence, the JNDI names need to be specified when these tools are run. The scripts for these tools all require that you pass a properties file name as a command line parameter. This name then is specified as the value for the `brbPropertiesFile` property when the tool is run.

## Database considerations for BRBeans

The following relational databases are supported by Business Rule Beans (BRBeans):

- IBM DB2
- IBM Cloudscape
- Microsoft SQL Server
- Oracle
- Sybase
- Informix

This documentation does not provide you with specific instructions on how to use any of these databases. For help with specific commands, consult the documentation that accompanied your database software. The following are general considerations for relational databases that are supported by BRBeans:

### Large character data

There are several attributes in the BRBeans Rule enterprise beans that might contain large amounts of data. This includes fields such as: `businessIntent`, `dependentRules`, `description`, `firingParameters`, `initParameters`, `originalReq`, and `userDefinedData`. The value for these attributes is stored in a character type column within a database table. Whenever possible, the values are stored in large character fields like `LONG VARCHAR` (for DB2) and `TEXT` (for Sybase).

There are several cases where the use of large character fields is problematic, mostly in terms of a lack of query support. Refer to each of the supported database sections for details on the column type used for storing the values in these attributes.

### Isolation level

All of the enterprise beans accessed in a transaction must specify the same isolation level. If your application contains enterprise beans that are used in the same transaction as the rules, you must do one of the following:

- Change the BRBeans enterprise beans (`Rule`, `RuleFolder`, and `RuleHelper`) to the same isolation level as your beans.
- Change your beans to the same isolation level as the BRBeans enterprise beans.
- Place the BRBeans enterprise beans in a different database than your enterprise beans and configure the application to run using the two-phase commit protocol. This causes the beans to run in different transactions; thereby removing the restriction that they need to have the same isolation level.

## Oracle considerations

### Large character data

The preferred Oracle data type for storing large character objects is `CLOB`. However, Oracle does not allow a `CLOB` to be queried. Because of this, a data type of `VARCHAR2` is used by Business Rule Beans (BRBeans). A specific length must be specified when specifying `VARCHAR2`. The maximum length for a `VARCHAR2` is 4000 bytes.

To determine the default size of VARCHAR2, look in the table.ddl file that was generated when you deployed the code. If the default size is not acceptable for your application, you can do one of the following:

#### **Increase the size of the columns**

Keep in mind that maximum size for a VARCHAR2 in Oracle is 4000. Increase the column size either by changing the value in the **create table statement** or by changing the schema mapping and deploying the BRBeans JAR file.

#### **Change the schema mapping to specify CLOB**

Do this for any of the attributes that you do not wish to query and then deploy the BRBeans JAR file.

#### **Isolation level**

The default isolation level is REPEATABLE\_READ. Oracle does not support this isolation level. Therefore, the IBM WebSphere runtime environment converts this to the next highest isolation level, which in this case is SERIALIZED. Be aware that this isolation level tends to be overly restrictive as it prevents two clients from reading data at the same time. The BRBeansOracle.jar file specifies an isolation level of READ\_COMMITTED.

### **Sybase considerations**

#### **Allowing null values**

By default, Sybase does not allow null values in string columns (like VARCHAR, TEXT, and so on). You can change this default value for a database using "isql" by issuing the following command:

```
sp_dboption databasename, "allow nulls by default", true
```

In this example "databasename" is your database name.

#### **Large character data**

The large character data fields are stored in a column of type TEXT. Sybase allows TEXT fields to be queried only using the SQL "LIKE" operator. Queries against the columns that perform the SQL "IS NULL" or "IS NOT NULL" operations are not allowed by Sybase. The alternative is to specify a column type of VARCHAR. However, the maximum allowed size for a VARCHAR in Sybase is 255 characters. This is not considered a large enough value for storing firingParameters, initParameters, descriptions, and so on.

If performing "IS NULL" and "IS NOT NULL" type queries is important and the 255 character limitation is acceptable, change these column types to VARCHAR. To accomplish this, alter the schema mapping for the Rule bean and then deploy the BRBeans JAR file.

The query APIs (in the com.ibm.websphere.brb.query package) allow for "IS NULL" and "IS NOT NULL" type queries to be performed on several of these fields. In addition, the Rule Management Application allows the firing parameters to be queried in this manner. These queries fail on Sybase with the default column type of TEXT.

### **Informix considerations**

#### **Large character data**

The preferred Informix data type for storing large character data is CLOB. However, Informix does not allow a CLOB to be queried. Because of this, a data type of LVARCHAR is used by BRBeans. The maximum length for an Informix LVARCHAR is 2,000 characters. If 2,000 characters is not acceptable and your application does not need to query these data types, you can change the schema mapping to specify CLOB. Then, deploy the BRBeans JAR file.

#### **Custom properties for the data source**

When configuring the data source for your application, you must specify the following properties:

- `ifxIFXHOST`=Name of the physical machine on which the Informix instance is installed
- `serverName`=Informix instance name
- `portNumber`=Port number for which the Informix instance is configured
- `informixLockModeWait`=500

A setting of 500 causes a connection to wait for up to 500 seconds for a lock. If you have a busy system, this wait can appear to be a system hang. This setting has the same effect as running SET LOCK MODE TO WAIT 500 on the connection.

**Note:** The previous configuration values are subject to change. Consult your Informix documentation for updates.

## Rule Management Application

The Rule Management Application (RMA) is a tool that assists the user in performing high-level administration of rules and rule folders.

This includes the capability to create, modify, delete, import, or export rules or rule folders. The RMA tool can be used initially by the programmer to define rules interactively, and then by the domain analyst for rule management tasks. The main window for the RMA is the Rules Browser.

The column on the left side of the Rule Browser window shows a nested hierarchy of all of the existing rule folders. Click one of these folders to display the rules it contains. The names of these rules appear in the right column.

Navigate as you would in a typical file-management browser.

1. Click the "+" icon to expand by one level and click the "-" icon to collapse it.
2. Click a rule or folder name to highlight it, right-click the rule or folder name to launch a list of actions, or select an option from the main menu.

RMA is designed to be a general purpose tool for interactive management of rules. Alternatively, you can write your own user interface that is tailored more specifically to the domain in which you work. For instance, a domain-specific user interface can provide more help to the user in the task of managing rules than a general purpose tool such as RMA. If you plan to write your own user interface, refer to the `RuleImplementor` of the BRBeans Javadoc for assistance.

## Rule management APIs

Business Rule Beans (BRBeans) provide a set of APIs to perform rule management tasks programmatically. These tasks include creating, deleting, and updating rules and folders. These APIs are provided to simplify the interaction with the BRBeans enterprise beans. Use these APIs to perform rule management tasks instead of coding directly in the EJB interfaces.

The rule management APIs consist of the classes in the `com.ibm.websphere.brb.mgmt` package. You might use the following main classes:

### IRule

This is the interface used to access the object representing a business rule in BRBeans. It provides methods to read and update attributes of the rule, to delete the rule, and to make a copy of the rule. The methods to create rules are in the `IRuleFolder` interface since you must always create a rule and specify a particular folder in which it will reside. In the rule management APIs, any time you get a rule, you have the option to receive a reference to the enterprise bean itself or to receive a local copy of the data contained in the enterprise beans. Regardless of which option you choose, the `IRule` interface can be used to access the returned object. If a local copy is requested, it is possible to cast the returned object to an `IRuleCopy`. `IRuleCopy` extends `IRule` and adds a couple additional methods to those defined by `IRule`. See the **IRuleCopy** section for more details.

## **IRuleCopy**

This is the interface used to access a local copy of the enterprise bean that represents a business rule. An object implementing this interface is returned from rule management API methods if you ask for a local copy of the rule. The main reason for requesting a local copy is performance. Calling a method on a local copy is much faster than calling the method on the actual enterprise bean. If you need to access several different rule attributes, this may make a big difference. Similarly, when updating a rule, all updates can be sent to the enterprise bean in one method call instead of many. The individual set methods are called on the copy and then the `updatePersistentRule()` method is called to actually send the updates to the enterprise bean.

## **IRuleFolder**

This is the interface used to access the object representing a rule folder. It provides methods to create, delete, and find rules and subfolders. It also provides methods to move and rename the folder, and to get the parent folder. The `IRuleFolder` representing the root folder is generally what you start with when performing rule management tasks. Once you have the root folder you can navigate up and down the folder hierarchy and access rules contained within the folders.

## **RuleMgmtHelper**

This is a helper class intended to contain methods that are of general use for performing rule management tasks. Currently, the only methods available are used to get the `IRuleFolder` representing the root folder. The root folder is normally the starting point for performing rule management tasks.

## **IParameter**

This is the interface used to represent an initialization or firing parameter stored in a Rule EJB. Every parameter has a user description and a value that are accessible from this interface. The following classes are provided to implement the `IParameter` interface:

### **ConstantParameter**

This is the most common type of parameter. It represents a single constant value that is to be passed as an initialization or firing parameter.

### **MethodCallParameter**

This class represents a parameter whose value is determined by calling a method on the target object. The method to call must be a public method and must take zero parameters. This is only used for firing parameters.

### **TriggerPointParameter**

This class represents a parameter that is retrieved from one of the trigger point firing parameters. This is mainly used for reordering the firing parameters passed on the trigger point. This is only used for firing parameters.

For more details on the rule management interfaces, including a number of coding examples, refer to the `com.ibm.websphere.brb.mgmt` package in the BRBeans Javadoc.

## **BRBeans performance enhancements**

Externalizing business logic using Business Rule Beans (BRBeans) has many benefits, but does not come completely without a cost. Since every business rule is represented by an enterprise bean, then, in general, every rule trigger is performed in three parts:

1. a query is performed to find the enterprise beans that represent the rules to be triggered.
2. a remote method call is performed on the EJB instance to trigger the rule.
3. a remote method call is made to determine whether to fire the rule locally or remotely.

The first two steps both require server processing so processing can become rather slow.

This section documents the following ways to improve performance:

- Performance enhancements through caching
- Performance enhancements using indexes
- Performance enhancements by changing the firing location

## Performance enhancements through caching

The Business Rule Beans (BRBeans) framework incorporates a cache on the client side; that is, wherever the `trigger()` method on the `TriggerPoint` object is called. This cache is scoped to the Java virtual machine (JVM) in which the client is running so that any trigger calls performed in a particular JVM use the same cache and two triggers performed in different JVMs use two different caches. The BRBeans cache caches the results of all of the queries performed to find a set of rules to be triggered. The next time a trigger is performed in that JVM with the same rules specified, the rules are found in the cache and the query does not require server processing.

Once the rules are found in the cache they are triggered, either locally or remotely, depending on how they were defined. If a rule found in the cache is specified to be triggered locally, then the entire trigger process for that rule is performed on the client without calling the server. Even if the rule is specified to be triggered remotely, finding the rule in the cache eliminates one call to the server since the query is not performed on the server.

The BRBeans cache can improve performance greatly, however it has one disadvantage: changes made to rules are not recognized immediately.

When a change is made to a rule on the server, there is no way to inform all of the potential clients that something has changed and that they may need to refresh their caches. Thus, the client cache must check periodically to see if anything in the persistent rule data has changed. This is implemented by associating a polling frequency with the cache. This polling frequency specifies an interval of time that the cache waits before checking to see if anything has changed. The next time a trigger is performed after a polling interval has passed, the cache checks to see if any changes have been made to the persistent rule data stored on the server. If no changes have been made, then the cache is not refreshed. If any changes have been made, the entire cache is cleared so that the changes are picked up. Thus, changes to the rules are only picked up by the cache after a polling interval has passed.

The default polling frequency is 10 minutes. The user can change this value by changing the single initialization parameter specified for the special rule named `com/ibm/websphere/brb/BRB CacheRule`. The value for this initialization parameter is in the following format: `hh:mm:ss`

hh stands for hours, mm stands for minutes, and ss stands for seconds.

Thus the default of 10 minutes is specified by a value of `00:10:00`. To specify a polling frequency of, for example, 1 hour, 30 minutes, specify `01:30:00`

When this value is changed, it does not take effect until the previous polling interval has passed. Thus, if the previous polling interval is set to 24 hours and the polling frequency is changed to 1 hour, the new frequency does not take effect until the previous 24 hour polling interval passes. The only other ways to get the new frequency to take effect are to either restart the client (since this causes the cache to be re-initialized from scratch) or have the client code call the `refreshCache()` method on the `TriggerPoint` object. If there is more than one client JVM performing triggers, this must be done for each client since each JVM has its own cache.

**Note:** There is only one `BRB CacheRule` and this rule applies to all clients. There is no way to set different polling frequencies for different clients.

Caching can be disabled for a particular `TriggerPoint` object using the `disableCaching()` method. After the `disableCaching()` method is called any triggers performed using that `TriggerPoint` object can not use the cache. Triggers performed using other `TriggerPoint` objects are not affected.

## Performance enhancements using indexes

Creating an index over the database table that is used to store rules is an important way to improve the performance of rule queries. It is recommended that an index be created over the rulename column of the table containing the rules. This greatly improves the performance of rule-triggered queries that are looking for a rule or rules with a specific name. The index saves the query from searching every row in the table. Refer to the documentation for your database for instructions on how to create an index.

## Performance enhancements by changing the firing location

The Business Rule Beans (BRBeans) framework allows you to specify where to fire a particular rule. This determines where the rule implementor is instantiated and invoked. The following lists the possible values for the firing location:

**Local** Fires the Java rule implementor in the same JVM in which the trigger was performed.

### Remote

Fires the Java rule implementor on the server where the rules exist.

### Anywhere

Tries to fire the Java rule implementor locally. If the Java rule implementor cannot be found, then it fires the the implementor remotely. This is the default value.

For simple rule implementors that do not perform any server-intensive work, specifying **Local** usually results in the best performance. This is true both without and with caching. A complete comparison of local firing versus remote firing must consider four cases: local and remote firing without caching and local and remote firing with caching. A description of these four cases follow:

### Remote call without caching

Without caching, the work done to fire a rule remotely involves the following:

1. Finding the rule.
2. Determining whether the rule is to be fired locally or remotely.
3. Calling fire on the remote rule.

Each of these three operations requires a remote call to the server.

### Local call without caching

Without caching the work done to fire a rule locally involves the following:

1. Finding the rule.
2. Determining whether the rule is to be fired locally or remotely.
3. Calling fire on a local copy of the rule.

This requires only two remote calls. Firing locally results in a savings of one remote method call.

### Local call with caching

With caching, local firing results in even more dramatic improvements. The work done to fire a rule remotely involves the following:

1. Finding the rule. This involves a search of the local cache and does not involve calling the database.
2. Calling fire on the remote copy of the rule found in the server's cache.

This requires only one remote method call.

### Remote call with caching

The work done to fire a rule locally with caching involves the following:

1. Finding the rule. This involves a search of the local cache and does not involve calling the database.
2. Calling fire on the local copy of the rule found in the cache.

This does not involve any remote method calls. The entire rule firing process takes place locally without remote method calls. To get the full benefit of the BRBeans cache, use local firing. However, remotely fired rules still benefit from the cache due to the elimination of the query on the server and the elimination of the remote call to determine whether the rule is being fired locally or remotely.

There may be some cases where a rule implementor must perform some work that requires significant interaction with the server. In these cases, it may be beneficial to have rules using this rule implementor defined to be fired remotely. This might make the server interaction performed by the implementor more efficient.

**Note:** In addition to performance, maintenance also must be considered in relation to specifying a firing location. The rule implementor classes for rules that are defined to be fired locally must be present on any client system that tries to fire those rules. Otherwise, the implementor cannot be instantiated when the rule is fired. This can result in maintenance problems when the rule implementors are changed since they must be updated on many different systems.

---

## Developing BRBeans

Although the development tasks in this article are shown in sequential order, the exact sequence is left to your discretion. In particular, you might choose to create the business rules before or after the trigger point is placed. Also, you can write the rule implementor before or after creating the actual business rules. However, if you do not have the rule implementor at the time that the business rule is created, then you cannot complete the rule implementor field or the initialization parameters in the rule. However, you can leave the business rule marked as not ready until you can complete that information. For this reason, we have chosen to list the task of writing the rule implementor first. Complete the following tasks to develop Business Rule Beans:

1. Determining where to place the trigger point Determine where there are points of variability and where business logic must be externalized as part of application analysis and design process.
2. Placing a trigger point in the application code Add code to the application to invoke the trigger point framework, to find business rules, and to fire the rules.
3. Administering strategy objects to control triggers Control the process of triggering the rules using a set of strategy objects.
4. Implementing the business rules Use a rule implementor, written in Java, to implement the BRBeans `RuleImplementor` interface. Also, create business rules invoked by the rule implementor.

It is possible to develop your own customized strategy objects and rule implementors. See Customized strategy objects and Customized rule implementors for more information.

## Determining where to place a trigger point

To determine where to place your trigger points, you can use either the case analysis or the Object Interaction Diagrams (OIDs) method. The following are examples of methods that you can use to determine where to place a trigger point:

### Use case analysis

Trigger points can be found during analysis by inspecting the use cases or user interaction scenarios that are typically developed as statements of requirement as input to the analysis process. A fragment of a use case is shown below:

*The vehicle is entered into the system or chosen. The customer service representative attempts to locate the named driver in the system. If the driver is not found, she or he is added to the system and then picked.*

*Otherwise the found driver is simply picked. If the vehicle is an auto, anyone between the ages of 16 and 75 can be picked as a driver. If the vehicle is a truck, only drivers 16 to 70 years old can be picked. And if the vehicle is a motorcycle, drivers 14 to 65 can be picked.*

*After the driver has been picked, a rate quote can be performed...*

To identify potential trigger locations in use case analyses such as this one, look for **keywords** such as:

- "if X is in a special category Y" (For example, "if the vehicle is a truck")
- "except when"
- "unless"
- "depends on"

## Object Interaction Diagrams (OIDs)

OIDs that are based on use cases can yield a number of observable patterns that can be used to identify trigger points fairly easy. The following are some of the rules to look for and where the trigger point might be placed:

- Validation of edits on create methods.
- Validation of edits on set methods.
- Referential integrity of edits on methods that set references.
- Cardinality checks at a consistency point (a point in time where all of the data is expected to be self consistent).
- Required fields checks at a consistency point.
- Cross field edits at a consistency point.
- Constraints or derivations that have a high potential for reuse (especially if the algorithm is complex) at any appropriate point.
- Constraints or derivations that a business desires to be consistent across applications (at any appropriate point).
- Constraints or derivations where the business wants to decouple the maintenance cycle for a rule from the maintenance cycle for the code (at any appropriate point).

By using either method, you will be able to identify where to locate trigger points to use Business Rule Beans (BRBeans) effectively.

Once the trigger points have been identified, place the trigger point or points. See [Placing a trigger point](#) for more information.

## Placing a trigger point in the application code

Before placing a trigger point, review the following topics:

- Trigger point framework
- Determining where to place a trigger point

The `TriggerPoint` class is the primary interface of the Business Rule Beans (BRBeans) Trigger Point framework. The class is used to transfer control to the Trigger Point framework to find and fire the rules specified in the application's trigger point.

1. Create an instance of the `com.ibm.websphere.brb.TriggerPoint` class. All rule triggers must be performed against an instance of this class. Also, set any desired strategies on the `TriggerPoint` instance.
2. Gather together the parameters to be passed on the trigger.

For the simple `trigger()` and `triggerClassifier()` methods this includes the following:

### **An optional target object**

This can be used to specify an object that is to be the target of the rule's algorithm. Whether this is needed depends completely on the design of the rule implementor being used.

### The firing parameters for this rule trigger

This is an array of run-time parameters needed by the rule to satisfy its business purpose. The exact set of required firing parameters is determined by the rule implementor that is used by the rule.

**Note:** Any firing parameters defined on the rule itself will override whatever is passed here.

### Information identifying the rule or rules to be triggered

Normally this is either a single String containing the name of the rule to be triggered or an array of Strings each element of which is the name of a rule to be triggered. However if a custom finding strategy is being used, this could be whatever information it needs in order to find the correct rules.

The `triggerSituational` method differs in that it takes two sets of firing parameters and two sets of rule identification information: one set for the classifier rules and one for the classified rules.

3. Invoke the `trigger()`, `triggerClassifier()`, or `triggerSituational()` method of the `TriggerPoint` instance. This will actually trigger the rule or rules.
4. Process the results of the triggered rule or rules.

Examples of how to code a trigger point call are provided in the following topics:

- Simple trigger point
- Classifier trigger point
- Situational trigger point

For a detailed description of the trigger point programming interfaces refer to the `Trigger Point` class in the BRBeans Javadoc.

## Administering strategy objects to control triggers

Strategy objects are used to alter `TriggerPoint` functions. The two simple trigger methods, `trigger()` and `triggerClassifier()`, perform their function in the following sequence:

1. Find the rules.
2. Filter out those rules which are not desired.
3. Fire the remaining rules.
4. Combine the results and return to the caller.

The complex trigger method `triggerSituational()` does this sequence of steps twice; the first sequence finds the classification to feed into the second sequence.

Default strategy objects already are defined for each of the four `TriggerPoint` steps and they are used if none are specified explicitly. For each of these steps, there are at least two strategy objects used, one for triggering classifier rules, and one for triggering non-classifier rules. For the filtering step, there are actually three pairs of strategies that are used, based on the number of rules which the finding strategy returns (zero, one, or multiple).

While the sheer number of strategies that are available can be intimidating (twelve different strategy classes can be set), very few will need updating. Most users will modify the filtering strategies or the combining strategies only.

A number of predefined strategy objects are provided and can be used for the majority of cases. Although the following strategies are described separately, they have a definite dependency on each other. For example, the `FilteringStrategy` filters rules from the `FindingStrategy`; the `FiringStrategy` uses the results of the `FindingStrategy` to operate; and the `CombiningStrategy` depends on the results of the `FiringStrategy`.

### FindingStrategy

The `FindingStrategy` accesses the data store and returns those rules that meet the search criteria specified. See the `FindingStrategy` method for more information.

### **FilteringStrategy**

The FilteringStrategy takes the list of rules that were found by the FindingStrategy and filters out the rules that should not be fired. See the FilteringStrategy method for more information.

### **FiringStrategy**

The FiringStrategy takes the rules that were found by the FindingStrategy, (possibly modified by the FilteringStrategy), fires them each in order, and returns an array containing the results of each rule. See the FiringStrategy method for more information.

### **CombiningStrategy**

The CombiningStrategy takes the results of the rules that are fired by the FiringStrategy and combines them to form a reasonable result to the TriggerPoint caller. See the CombiningStrategy method for more information.

The Java classes for these strategy objects are defined in the `com.ibm.websphere.brb.strategy` package. Static constants also are defined in the interfaces for the various strategies. This allows easy access to instances of the strategy classes to set them on the TriggerPoint.

Also, it is possible to write your own strategy class if the supplied ones do not perform the function you need. See Customized strategy objects for more details.

## **Implementing business rules**

After determining where to place a trigger point, placing the trigger point, and defining your strategy objects, you must provide a method to implement the business rules and then create the rules. In addition, you might choose to organize your rules by creating rule folders.

**Note:** Although the development tasks in this article are shown in sequential order, the exact sequence is left to your discretion. In particular, you might choose to write the rule implementor before or after creating the actual business rules.

The business rule encapsulates and externalizes the business logic for the rule and any data that parameterizes the rule. Complete the following process to implement business rules:

1. Provide an implementation, called a rule implementor, for each business rule that you create. The rule implementor provides the actual business logic for the rule, implemented in Java. The rule implementor's `fire()` method is called when the business rule is triggered to actually perform the processing for the rule. Several generic rule implementors are shipped with BRBeans, which might be useful in some situations. However, if these rule implementors do not meet your needs, you can write your own rule implementor. Refer to the section on writing your own rule implementor for details.

2. Use the Rule Management Application (RMA) to create the business rule

- a. In the **Rule Browser** window, select the folder where you want the new rule to be created.
- b. From the main menu, click **File > New > Rule**.

In the **New Rule** properties window, use the following tabs to define the rule:

#### **General**

Use this tab to enter general information about the rule.

#### **Implementation**

Use this tab to define the manner in which the rule is implemented.

#### **Description**

Use this tab to define the purpose and intent of the rule.

#### **Dependent Rules**

Use this tab to specify the rules that the newly created rule will depend upon.

**Other** Use this tab to establish precedence, and enter information that is relevant to you, but does not fit into any other category.

- c. To complete the creation of the rule, click **OK**. If there are any mandatory fields still undefined, either go back and give them a value, or make the rule unavailable for use (see **Status** in the **General** tab for more information on this).

3. Create a rule folder using the Rule Management Application to contain the new business rule
  - a. In the **Rule Browser** window, select the folder where you want the new folder to be nested.
  - b. From the main menu, click **File > New > Folder**. A new folder appears in the folder hierarchy in edit mode. Enter a folder name and hit the **Enter** key.

---

## Assembling applications for use with BRBeans

When you are ready to ship your application, include a Business Rule Beans (BRBeans) JAR file in your EAR file. There are several of these JAR files in the <WAS\_HOME>/BRBeans directory; one for each supported database. Each name reflects the database type that it uses (for example, BRBeansDB2.jar). These JAR files contain three enterprise beans with the following JNDI names:

- brbeans/application/Rule
- brbeans/application/RuleFolder
- brbeans/application/RuleHelper

In your EAR files, complete the following steps:

1. Change the JNDI names of the BRBeans enterprise beans to make them unique for your application. For example, if your application is called MyApp, you could change the first one to brbeans/MyApp/Rule or com/MyCompany/MyApp/Rule.
2. Define EJB references to these three enterprise beans in any module where a trigger...() method exists in one or more of its classes. You can do this using the WebSphere Studio Application Developer tool or the Application Assembly tool. The Name field should contain the following and correspond to the enterprise beans listed above:
  - ejb/com/ibm/ws/brb/Rule
  - ejb/com/ibm/ws/brb/RuleFolder
  - ejb/com/ibm/ws/brb/RuleHelper

**Note:** The JNDI name on the **Bindings** tab should be the same as the JNDI names that you gave earlier to the enterprise beans.

Since the BRBeans enterprise beans refer to each other, there are also EJB references defined within the BRBeans JAR file itself. Each of the three BRBeans enterprise beans has two EJB references defined. These six references also need to be updated with the JNDI names you assigned earlier.

3. If you are not using the BRBeansCloudscape.jar file, skip this step. In the BRBeansCloudscape.jar file each entity enterprise bean has a resource reference defined for the data source it will use. You must update the JNDI binding for this reference to specify the JNDI name of the actual data source you want to use for the BRBeans entity enterprise bean. The shipped BRBeansCloudscape.jar file contains a dummy JNDI name for each binding. There are two resource references that need to be updated: one for the Rule enterprise bean and one for the RuleFolder enterprise bean. You can use the WebSphere Studio Application Developer tool or the Assembly Toolkit to perform this update.

After you have an EAR file that includes your application code and the BRBeans enterprise beans, complete the following steps to install and run the application:

1. Deploy the EAR file to generate run-time code for the BRBeans enterprise beans and any other enterprise beans that you may have in your application. Deployment can be accomplished either as a separate step (using the ejbdeploy command) or as part of the process of installing the EAR file onto an application server. Refer to the base WebSphere documentation for more information about deploying an EAR file.
2. The deployment process generates a file named Table.ddl. Table.ddl contains database commands to create the database tables needed by the BRBeans entity enterprise beans. You must use your database software to create a database and then use the commands in the Table.ddl file to create tables in this database. Refer to your database software documentation for more information on the commands needed to set up a database and the database tables.

3. Create a JDBC provider and a data source to access the database created in the previous step. For all of the databases except IBM Cloudscape, the BRBeans enterprise beans are configured to require a Version 4 data source. For Cloudscape, you can use a normal data source.

**Note:** The JNDI name you specify for the data source also must be specified when you install the EAR file on the application server so that the server knows which data source to use. Refer to the base WebSphere documentation for more information on these topics.

4. Install the EAR file on an application server. To install the EAR file, either use command line tools or the WebSphere Administrative Console.

**Note:** The EAR file can be deployed either as a separate step or as part of the installation process on the server.

Refer to the base WebSphere documentation for more information on installing an EAR file on an application server.

5. Start the application using the WebSphere Administrative Console.

You now have an application installed and running using BRBeans.

---

## Managing rules

In Business Rule Beans (BRBeans), rule management involves making changes to the set of business rules used by applications. This can include any of the following activities:

- Implementing the business rules: Creating rules and rule folders
- Copying and moving rule or rule folders
- Working with Quick Copy
- Finding a rule
- Deleting rules
- Deleting rule folders
- Changing the properties of a rule
- Importing a rule
- Exporting a rule
- Renaming rules
- Renaming rule folders
- Formatting columns
- Changing the date and time format

There are two different interfaces that can be used for rule management:

### **Rule Management Application**

An external user interface that allows users to manage rules interactively. It provides a general purpose interface for managing rules where no assumptions are made about the content or implementation of the rules. For information on how to use the Rule Management Application, see [Starting the Rule Management Application](#).

### **Rule management APIs**

A programmatic interface that can be used by programmers to manage rules or to customize an external user interface. For more information on Rule management APIs, see the [com.ibm.websphere.brb.mgmt](#) package.

Rules can be managed in any way that makes sense for your application, but the BRBeans framework was designed with the following administrative paradigm in mind:

1. Understand the desired change in business behavior.
2. Inspect the application documentation (in particular information that indicates where trigger points are located) to understand where the changes need to be made in the system.
3. Inspect the corresponding set of existing business rules using the Rule Management Application (or your own custom management application, if you have one) to understand which rules need to change.

4. Use the Rule Management Application, on a test system, to create one or more new rules that implement the required new behavior. Give these rules the correct name so that they are triggered by the appropriate trigger point. Also, make sure that these new rules are currently in effect.
5. Withdraw (by setting the end date of the rule), on the test system, all of the rules that are to be superseded.
6. Test the application to ensure that it behaves as expected.
7. Export the new rules using the Rule Exporter on the test system. Schedule the rules to become effective at the correct point in time.
8. Export the rules to be superseded using the Rule Exporter on the test system. Set them to expire when the new rules come into effect.
9. Import the new rules using the Rule Importer on the production system. This creates the new rules and schedules them to become effective at the date you specified when you exported them.
10. Import the rules to be superseded using the Rule Importer on the production system. This puts the new end date into the existing rules on the production system and sets them to expire on the specified date.

For more information on the overall topic of Externalizing business rules, see Using Business Rule Beans

## Starting the Rule Management Application

Review the overview topic Managing rules

To administer BRBeans, use the Rule Management Application (RMA). To launch the RMA, complete the following steps:

1. Open a command window and change to the following directory: `<WAS_HOME>/bin`
2. For Microsoft Windows platforms, enter `rulemgmt.bat <properties-file>`. For UNIX platforms, enter `rulemgmt.sh <properties-file>` where `<properties-file>` is a fully qualified name of a file containing port, host, and JNDI names used for the Business Rule Beans (BRBeans) enterprise beans. If you are using localhost port 2809 and you are using the default JNDI names for the BRBeans enterprise beans, you can specify the following in the default properties file:  
`<WAS_HOME>/bin/brbeansDefaultProperties`. For a full definition of the contents of this file, see the BRBeans properties file.

## Copying or moving rules or rule folders

Copy or move rules or rule folders either by cutting and pasting, or dragging and dropping.

To copy or move rules or rule folders, proceed as follows:

### Cutting and pasting

Use the menu commands (**Edit > Copy**, **Edit > Cut** and **Edit > Paste**) or keyboard commands (**CTRL-C**, **CTRL-V**, and **CTRL-X**).

### Dragging and dropping

Highlight the rule or rule folder you want to copy. Then press and hold the right mouse button, drag the cursor to the target location, and release. Select **Copy** or **Move** from the list.

**Note:** A rule also can be copied so that the copy replaces the existing rule at a specified date. This is referred to as a Quick Copy.

See Managing rules for other tasks related to the management of your rules.

## Working with Quick Copy

Use **Quick Copy** to make a copy of a rule that will replace the existing one on a specified date.

For example, suppose that we have an "isSeniorCitizen" rule. Currently a person is considered a senior citizen if they are 62 years of age or older. Starting on January 1, 2002, we are going to change this to 65. Use Quick Copy to specify the new date, and change the age from 62 to 65. The current rule will be set to expire on the same date that the new rule will take effect with the new senior citizen age defined as 65.

To use **Quick Copy** from the Rule Browser or Search Results window, proceed as follows:

1. Select the rules you want to **Quick Copy**.
2. From the main menu, click **Edit > Quick Copy**.
3. In the Quick Copy window, specify in the following fields how the copy will differ from the original:
  - Start Date For New Rule**  
Enter the date that the new rule will replace the existing rule. Use the date and time format that is shown.
  - Change parameter values for new rule**  
Enter the new parameter values.
4. Click **OK** to finish.

See Managing rules for other tasks related to the management of your rules.

## Finding a rule

To search for a specific rule using the Rule Management Application **Find** function, proceed as follows:

1. To search through all rules in all folders:
  - a. From the main menu of the Rule Browser, click **Edit > Find**.
  - b. Use the tabs in the Find Rules window to determine your search criteria.
2. To search a specific folder:
  - a. Right-click the folder and select **Find** from the list.
  - b. Use the tabs in the Find Rules window to determine your search criteria.

The results of your search are displayed in a Search Results window.

See Managing rules for other tasks related to the management of your rules.

## Deleting rules

To delete rules from the Rule Browser or Search Results window, proceed as follows:

1. Select the rules you want to delete.
2. From the main menu, click **File > Delete**.
3. Click **Delete** and then confirm the delete request.

**Note:** You cannot delete `com/ibm/websphere/brb/BRB CacheRule` as this rule is needed by the Business Rule Beans run-time environment.

See Managing rules for other tasks related to the management of your rules.

## Deleting rule folders

To delete rule folders from the Rule Browser window, proceed as follows:

1. Select the folder you want to delete.
2. From the main menu, click **File > Delete**.
3. Click **Delete** and then confirm the delete request.

**Note:** You cannot delete the root folder or any of the folders in the path `com/ibm/websphere/brb`.

See Managing rules for other tasks related to the management of your rules.

## Changing the properties of a rule

To change the properties of a rule, perform the following steps in either the Rule Browser or Search Result window:

1. Highlight the rule you wish to edit.
2. From the main menu, click **File > Properties**.

In the Rule Properties properties window, use the following tabs to edit the rule's definition:

### **General**

Use this tab to edit general information about the rule.

### **Implementation**

Use this tab to edit the manner in which the rule is implemented.

### **Description**

Use this tab to edit the purpose and intent of the rule.

### **Dependent Rules**

Use this tab to edit the list of rules that the newly created rule will depend upon.

**Other** Use this tab to establish precedence, and enter information that is relevant to you, but does not fit into any other category.

3. To complete the editing of the rule, click **OK**. If there are any mandatory fields still undefined, either go back and give them a value, or make the rule unavailable for use (see **Status** in the **General** tab for more information on this).

See Managing rules for other tasks related to the management of your rules.

## Importing a rule

To import rules from an XML format, use the Rule Browser window and proceed as follows:

1. In the main menu, click **File > Import**.
2. In the Import Rules window, specify the file you want to import.
3. Click **OK**. Rules and rule folders are created as specified within the XML.

See Managing rules for other tasks related to the management of your rules.

## Exporting a rule

To export rules, use the Rule Browser or Search Results window and proceed as follows:

1. In the main menu click **File > Export**.
2. In the **Export Rules Wizard**, proceed as follows:
  - a. In the Specify Rules to Export window, select the rule or rules that you want to export and click **Next**.
  - b. In the Change Effective Dates On Exported Rules window, alter the start and end dates of the rule (if desired) and click **Next**.
  - c. In the Select File For Rule Export window, choose a name and location for the exported rule.
3. Click **Export** to finish.

See Managing rules for other tasks related to the management of your rules.

## Renaming rules

To rename rules, use the Rule Browser or Search Results window and proceed as follows:

1. Highlight the rule you want to rename.
2. From the main menu, click **File > Rename**.
3. Type a new name and press the **Enter** key. To cancel the name change while it is still in progress, press the **Esc** key.

See Managing rules for other tasks related to the management of your rules.

## Renaming rule folders

To rename rule folders, use the Rule Browser or Search Results window and proceed as follows:

1. Place the folder name in edit mode by performing one of the following tasks:
  - a. Right-click the folder and select **Rename** from the list.
  - b. Highlight the folder and click **File >Rename** in the main menu.
  - c. Click the folder name twice with a slight pause between each click.
2. Type a new name and press the **Enter** key. To cancel the name change while it is still in progress, press the **Esc** key.

**Note:** You cannot change the name of the root folder.

See Managing rules for other tasks related to the management of your rules.

## Specifying columns

To choose which columns you want shown in your Rule Browser window, perform the following steps in either the Rule Browser or Search Results window:

1. From the main menu, click **View > Specify Columns**.
2. In the Specify Column window, proceed as follows:

### To add a new column

Select one or more entries in the **Available columns** list and click the **Add** button. The selected entries are added to the end of the Columns displayed list.

### To remove a column

Select one or more entries in the Columns displayed list and click the **Remove** button. The selected entries are added to the end of the Available columns list.

### To reorder columns

Select one or more entries in the Columns displayed list. To move the entries towards the top of the list, click the Up arrow. To move them towards the bottom, click the Down arrow.

See Managing rules for other tasks related to the management of your rules.

## Changing the date and time format

To change the date and time format, use either the **Rule Browser** or **Search Results** window and proceed as follows:

1. In the main menu, click **View > Specify Date/Time Format**.
2. In the **Specify Date/Time Format** window, choose one of the following radio button options:

### Use default format for this locale

Use this option to adjust the date and time format to match the default setting of your current locale.

### Select a predefined format for the date and time

Use this option to choose from one of several existing date and time formats.

### Specify a custom format for the date and time

Use this option to determine your own format for your date and time display.

3. When the example in the lower left of the window meets your needs, click **OK** to finish.

See Managing rules for other tasks related to the management of your rules.

---

## Rule Browser

The Rule Browser is the main window of the Rule Management Application (RMA), which is the tool used to administer business rules for Business Rules Beans. The RMA is a simple graphic user interface that assists the user in the high-level administration of rules and rule folders. The column on the left side of the Rule Browser window shows a nested hierarchy of all of the existing rule folders. Open one of these rule folders to display the rules. The names of these folders appear in the right column.

To navigate through the information, perform the following actions:

- Click the **+** icon to expand the folder by one level; click the **-** icon to collapse it.
- Click a file name to highlight it, right-click it to launch a list of actions, or select an option from the main menu.

## File menu

This article describes the options available in the File menu window.

### New

Use the **New** option to create one of the following objects:

#### Folder

The **Folder** selection creates a new folder within the folder currently selected in the browser. To create a new folder, complete the following steps:

1. Select the folder, in the Rule Browser window in which to nest the new folder.
2. Click **File > New > Folder** from the main menu. A new folder appears in the folder hierarchy in edit mode.
3. Enter a folder name and press **Enter**.

**Rule** The **Rule** selection creates a new rule within the folder that is currently selected in the browser. To create a new rule, complete the following steps:

1. Select the folder, in the Rule Browser window, where you want to create the new rule.
2. Click **File > New > Rule** from the main menu.
3. Use the following options, in the New Rule Properties window, to define the rule. For more information on each of these tabs, see the associated help file.

#### General

Use the **General** tab to enter general information about the rule. For more information, click the **New Rule properties window: General tab** link under Related reference.

#### Implementation

Use the **Implementation** tab to define the manner in which the rule is implemented. For more information, click the **New Rule properties window: Implementation tab** link under Related reference.

#### Description

Use the **Description** tab to define the purpose and intent of the rule. For more information, click the **New Rule properties window: Description tab** link under Related reference.

#### Dependent Rules

Use the **Dependent Rules** tab to specify the rules that the newly created rule will depend upon. For more information, click the **New Rule properties window: Dependent Rules tab** link under Related reference.

**Other** Use the **Other** tab to establish precedence and enter information that is relevant to

you, but does not fit into any other category. For more information, click the **New Rule properties window: Other tab** link under Related reference.

**Note:** When you change the properties of a rule and there are undefined mandatory fields, either give them a value or make the rule unavailable for use. See "status" on the General tab for more information.

4. Click **OK** to complete the creation of the rule.

### Rule Browser Window

This selection opens a new Rule Browser window on your desktop and shows the content of the currently selected folder.

## Import

Use the **Import** option to import rules that are defined in a file and written in XML. The rules are imported into folders as specified within the XML.

### Importing rules

You can use the Rule Browser window to import from an XML format. To import rules, complete the following steps:

1. Click **File > Import** in the main menu.
2. Specify the file, in the Import Rules window, that you want to import.
3. Click **OK**. The rules are imported as specified within the XML.

For more information, see the **Import Rules window** link under Related reference.

## Export

Use the Export option to export a file in an XML format.

### Exporting rules

You can export rules from the Rule Browser or Search Results windows. To export rules, complete the following steps:

1. Click **File > Export**, in the main menu.
2. Proceed as follows using the Export Rules Wizard:
  - In the Select Rules to Export window, select the rule or rules that you want to export and click **Next**.
  - In the Change Effective Dates On Exported Rules window, alter the start and end dates of the rule, if desired, and click **Next**.
  - In the Select File For Rule Export window, choose a name and location for the exported rule.
3. Click **Export** to finish.

For more information on this Export Rules Wizard, see the **Select Rules to Export window** link under Related reference.

## Delete

Use the **Delete** option to delete the selected rule or rule folder. If a rule folder is selected, all of the rules and subfolders the folder contains also are deleted.

### Deleting rules

You can delete rules from the Rule Browser or Search Results windows. To delete rules, complete the following steps:

1. Select the rules that you want to delete using the Rule Browser window.
2. Click **File > Delete** from the main menu.
3. Click **Delete** and then confirm the delete request.

**Note:** You cannot delete `com/ibm/websphere/brb/BRB CacheRule` as this rule is needed by the Business Rule Beans run-time environment.

### Deleting a folder

To delete a folder, complete the following steps:

1. Select the folder you want to delete using the Rule Browser window.
2. Click **File > Delete** in the main menu.
3. Click **Delete** and then confirm the delete request.

**Note:** You cannot delete the root folder.

### Rename

Use the **Rename** option to rename the selected rule or rule folder.

### Renaming a rule

You can rename rules from the Rule Browser or Search Results windows. To rename a folder, complete the following steps:

1. Highlight the rule you want to rename.
2. Click **File >Rename** from the main menu.
3. Type a new name and press **Enter**. To cancel the name change while it is still in progress, press **Esc**.

### Renaming a folder

1. Place the folder name in edit mode by doing any of the following:
  - Right-click the folder and select **Rename** from the list.
  - Highlight the folder and click **File >Rename** in the main menu.
  - Click the folder name twice with a slight pause between each click.
2. Type a new name and press **Enter**. To cancel the name change while it is still in progress, press **Esc**.

**Note:** You cannot rename the root folder.

## Properties

Use the **Properties** option to modify the properties of the selected rule or rule folder and then click **OK**.

Use the following tabs, in the **Rule Properties** window, to define the rule. For more information on each of these tabs, see the associated help file.

### General

Use the **General** tab to enter general information about the rule. For more information, click the **Rule properties window: General tab** link under Related reference.

### Implementation

Use the **Implementation** tab to define the manner in which the rule is implemented. For more information, click the **Rule properties window: Implementation tab** link under Related reference.

### Description

Use the **Description** tab to define the purpose and intent of the rule. For more information, click the **Rule properties window: Description tab** link under Related reference.

### Dependent Rules

Use the **Dependent Rules** tab to specify the rules that the newly created rule will depend upon. For more information, click the **Rule properties window: Dependent Rules tab** link under Related reference.

**Other** Use the **Other** tab to establish precedence and enter information that is relevant to you, but does not fit into any other category. For more information, click the **Rule properties window: Other tab** link under Related reference.

**Note:** When you change the properties of a rule and there are undefined mandatory fields, either give the fields a value or make the rule unavailable for use. See "status" on the **Rule properties window: General tab** for more information.

## Validate

Use the **Validate** option to verify the correctness of the selected rules or folder. A report is generated and displayed in system browser window. Use the browser functionality to view, save, and print the results. The following items are validated:

### Start and End dates

Specifies a valid start date. The end date must be empty (never expires) or be later than the start date.

### Java rule implementor name

Specifies a valid and existing Java rule implementor name. The specified class must implement the RuleImplementor interface.

### Dependent rules

Verifies the existence of each specified dependent rule.

When this option is selected, the Validate Rules window displays. You must specify a Java class path to validate rule implementor classes.

## Close

Use the **Close** option to terminate the application and close the window.

## New Rule properties window: General tab

Use the **New Rule properties window: General tab** to enter general information about the rule. The following fields and options are available on this tab:

### Name and location

#### Folder name

(Required) Use the **Folder name** field to identify the folder in which to create the rule. To browse the existing folders, click the **ellipses** button to the right of the text field.

**Name** (Required) Use the **Name** field to give the rule a name. The name cannot include the forward slash '/' and must contain at least one non-blank character. The name cannot exceed the maximum length of the rule name column in the database table.

### Period when rule is in effect

#### Start date

(Required) Use the **Start date** field to specify the date and time that the rule will go into effect. If you do not specify the time, a value of midnight is used.

#### End date

Use the **End date** field to determine the date when this rule expires. If you do not specify a value, the rule never expires.

## Classification

Use this section to specify your rule's classification status. Choose one of the following options:

- Rule is not classified and does not perform a classification (default)
- Rule performs a classification
- Rule is classified with the following classification

## Status

### Rule is available for use

Select **Rule is available for use** when the rule is available for use by the Business Rule Beans run-time environment. This feature is useful when you have not finished creating the rule, but need to save your changes.

## New Rule properties window: Implementation tab

Use the **New Rule properties window: Implementation** tab to define the manner in which the rule is implemented.

**Note:** The rule contains the data, but it does not perform the implementation. Rather, the Java rule implementor implements the rule.

For example, suppose you want to create a rule that determines whether a given person is a senior citizen, 62 years old or older. To implement this rule, give the "com.ibm.websphere.brb.implementor.RuleGreaterThanEqual" Java rule implementor the value 62 and specify it as an initialization parameter. When the application fires the rule, the person's age is passed to the Java rule implementor as a firing parameter and 62 is passed as an initialization parameter. The person's age is compared against the initialization parameter of 62 and a value of true or false is returned from the Java rule implementor to the application. To change the age at which a person is considered a senior citizen, change the value of the initialization parameter.

The following fields and options are available on this tab:

**Java rule implementor:** (Required) Use the **Java rule implementor** field to specify a class to implement this rule. The initialization and firing parameters that are required are determined by looking at the documentation for the specified Java rule implementor.

**Firing location:** Use the **Firing location** field to determine where the rule is fired. You can fire the Java rule implementor on the server where the rules exist or fire it locally on the client machine. The client can be a servlet running on the server. Specify one of the following values for the firing location:

**Local** Use the **Local** option to fire the Java rule implementor local to the application that fired the rule.

### **Remote**

Use the **Remote** option to fire the Java rule implementor on the server where the rules exist.

### **Anywhere (default)**

Use the **Anywhere** option to attempt to fire the Java rule implementor locally first. If the Java rule implementor cannot be found, then it is fired remotely.

To choose the value of the firing location, you must take both performance and maintenance into consideration. Most rules perform better if they are run on the same Java virtual machine (JVM) as the application (locally). However, there might be cases where a Java rule implementor performs server-intensive tasks, in which case the rules might run better when they run on the server. To run locally, you must have all of the Java rule implementors installed locally. They must be accessible by the application that fires the rules.

**Initialization parameters:** The initialization parameters contain constant values passed to the rule implementor when it is initialized. Typically, the initialization parameters contain values that might change as your business practices evolve, such as the age at which a person is considered a senior citizen or the current interest rate for a loan.

To add a new initialization parameter to the list, click **Add** and fill in the fields in the Add Initialization Parameter window.

To edit an existing initialization parameter, highlight it, click **Change**, and fill in the fields in the Change Initialization Parameter window.

To delete an initialization parameter, highlight it and click **Delete**.

To change the order of the initialization parameters, highlight one and click the up or down arrows to move it to a new location.

**Firing parameters:** The firing parameters contain values passed from the trigger point in the application to the Java rule implementor at run time. You can alter the parameters coming from the application before passing them to the Java rule implementor. Typically, these parameters are left unaltered.

For example, when implementing the "isSeniorCitizen" rule that determines whether a person is a senior citizen, you might want to pass a person from the application to the rule as the target object. However, the "isSeniorCitizen" rule uses the RuleGreaterThanEqual Java rule implementor, which requires that you pass an integer value. You can alter the firing parameters to specify that the method "getAge" is called on the person object and pass that result to the Java rule implementor.

You must choose one of the following options:

**Pass firing parameters from trigger point unchanged**

The parameters specified in the trigger point of the application are passed to the Java rule implementor without being altered. This is the default value.

**Specify firing parameters**

The values specified in the table are passed to the Java rule implementor.

To add a new firing parameter to the list, click **Add** and fill in the fields in the Add Firing Parameter window.

To edit an existing firing parameter, highlight the firing parameter, click **Change**, and fill in the fields in the Change Firing Parameter window.

To delete a parameter, highlight the firing parameter and click **Delete**.

To change the order of the firing parameters, highlight one and click the up or down arrows to move it to a new location.

**Add Initialization Parameter window:** Use the Add Initialization Parameter window to add initialization parameters to a rule. The initialization parameters contain constant values passed to the Java rule implementor when it is initialized. Typically, the initialization parameters contain values that will change as your business practices evolve. These values might be the age at which a person is considered a senior citizen or the current interest rate for a loan.

To add an initialization parameter, proceed as follows:

1. Fill in the fields as needed.
2. Click **Add**. The initialization parameter is added and the window remains open to specify additional parameters.
3. When you are finished specifying initialization parameters, click **Close**.

The following fields and options are available in this window:

*Description:* Use the **Description** field to specify a description of the initialization parameter. This field can contain any information necessary to describe the purpose of the initialization parameter.

*Type:* Use the **Type** field to specify the type of data that is contained within this initialization parameter. The data itself is stored in the **Value** field (see the following field description). For example, if this initialization parameter specifies the age at which a person is considered a senior citizen, then the Type likely is an "Integer". If the initialization parameter specifies a company name, such as "IBM", then the Type is a "String".

The following values are available:

- String
- Character
- Byte
- Short

- Integer
- Long
- Float
- Double
- Boolean
- java.math.BigDecimal
- java.math.BigInteger
- Null Value

*Value:* Use the **Value** field to add a value for the parameter. For example, if the initialization parameter is intended to specify the age at which a person is considered a senior citizen, then this field might be set to 62.

**Change Initialization Parameter window:** Use the Change Initialization Parameter window to edit an existing initialization parameter.

The initialization parameters contain constant values passed to the Java rule implementor when it is initialized. Typically, the initialization parameters contain values that change as your business practices evolve. These values might be the age at which a person is considered a senior citizen or the current interest rate for a loan.

To edit an existing initialization parameter, modify the fields and click **OK**.

The following fields are available in this window:

*Description:* Use the **Description** field to specify a description of the initialization parameter. This field can contain any information necessary to describe the purpose of the initialization parameter.

*Type:* Use the **Type** field to specify the type of data that is contained within this initialization parameter. The data itself is stored in the **Value** field (see the following field description). For example, if this initialization parameter specifies the age at which a person is considered a senior citizen, then the Type likely is an "Integer". If the initialization parameter specifies a company name, such as "IBM", then the Type is a "String".

The following values are available:

- String
- Character
- Byte
- Short
- Integer
- Long
- Float
- Double
- Boolean
- java.math.BigDecimal
- java.math.BigInteger
- Null Value

*Value:* Use the **Value** field to add a value for the parameter. For example, if the initialization parameter is intended to specify the age at which a person is considered a senior citizen, then this field might be set to 62.

### **New Rule properties window: Description tab**

Use the **New Rule properties window: Description** tab to define the purpose and intent of the rule. All of the fields in this panel are optional and none of them are used by the Business Rule Beans run time. The following fields are available on this tab:

**Business Intent:** Use the **Business Intent** field to describe the business intent of this rule.

**Description:** Use the **Description** field to define a general description of the rule and its purpose.

**Original requirement:** Use the **Original requirement** field to compose a description of the original requirement that created this rule.

### **New Rule properties window: Dependent Rules tab**

Use the **New Rule properties window: Dependent Rules** tab to specify the rules that the newly created rule will depend upon.

To add names to the **Dependent rule names** field, proceed as follows:

1. Locate the dependent rule. You can do this in one of two ways:

#### **Browse for a rule**

If you are familiar with the location of the dependent rule, then click **Browse**. Navigate to the rule's location and highlight it.

#### **Find a rule**

If you are unfamiliar with the location of the rule, then click **Find**. This launches a Find Rules window in which you can specify options and then initiate a search. When you have located the rule, highlight it.

2. Click **Add**.

To change the name of a rule in the **Dependent rule names** field, highlight one or more rules and click **Edit**. Specify the new name for the rule and click **OK**.

To change the folder name of a rule in the **Dependent rule names** field, highlight one or more rules and click **Change Folder**. Fill-in the fields in the Change Folder window. All selected rules are updated with the newly specified values.

To delete a rule from the **Dependent rule names** field, highlight the rule and click **Delete**.

To change the order of the rules in the **Dependent rule names** field, highlight a rule and click the up or down arrows to move it to a new location.

### **New Rule properties window: Other tab**

Use the **New Rule properties window: Other tab** to establish precedence and enter information that is relevant to you, but does not fit into any other category. The following fields are available on this tab:

**Precedence:** Use the **Precedence** field to specify the relative priority when firing the rule. This value is used to order the rules from lowest to highest.

**User defined data:** Use the **User defined data** field to enter any additional text that you want to store. The Business Rule Beans run time does not use this field.

### **Import Rules window**

Use the Import Rules window to select and import a rule expressed in an XML format. The following fields and options are available in this window:

**File Name:** Use the **File Name** field to specify the name of a file that contains the rules that you want to import. To search for a file, click the **ellipses** icon to the right of the text entry field.

**Show output from rule importer:** Select **Show output from rule importer** to display detailed information about the rules that you want to import.

**Show rules to be created but do not create them:** Select **Show rules to be created but do not create them** to validate the XML prior to committing to the rule's creation. The rule XML runs through the importer but is not created.

**Update existing rules with the same primary key:** Select **Update existing rules with the same primary key** to update the rules with the same primary key. If this check box is clear, the rule is not imported if one is found with this same primary key. An error message is shown and the transaction in which this rule was created is not committed. The primary key is an optional tag within the XML and there is a possibility that a rule already exists on the system with this same primary key.

**Transaction Option:** The following is a list of transaction options:

**One transaction per rule**

Use the **One transaction per rule** option to start a transaction for each rule. If one rule fails to import, it does not prevent other rules in the specified file from being imported.

**One transaction for all rules**

Use the **One transaction for all rules** option to stop all of the rules from being imported if any rule fails to import successfully. Use this feature to ensure that all of your rules are in a consistent state. Typically, it is undesirable to have only a portion of the rules imported successfully since rules might have dependencies on other rules.

## Select Rules To Export window

This is the first of three windows in the Export Rules Wizard. Use the Select Rules To Export window to select the rules to export. After entering the appropriate information in the following fields, click **Next**.

**Note:** If you specify a folder, the tool exports the entire contents of the folder including its subfolders.

The following options are available in this window:

**Add:** Use the **Add** option to open a window in which you can type the fully qualified name of a rule or a rule folder. If there are multiple rules with the specified name, they are all exported.

**Find:** Use the **Find** option to open a Find Rules window in which you can specify your search criteria. If there are multiple rules with the same name, only the selected rules are exported.

**Browse button:** Use the **Browse** button to open a window and browse for rules to add to the list. If there are multiple rules with the same name, only the selected rules are exported.

**Remove button:** Use the **Remove** button to remove the selected rules from the list.

**Show output from rule exporter:** Select **Show output from rule exporter** to open a window that contains details about the export operation of the select rules. This window is shown when the export operation begins.

**Change Effective Dates On Exported Rules window:** This is the second of three windows in the Export Rules Wizard. Use the Change Effective Dates on Exported Rules window to alter the rule's start and end times. This procedure is useful when the application and the rules are tested on a development system prior to being deployed on a production system. You can change the dates of the rules and test on the development system using the current date, even if you plan to use the rules on the production system at a future date. The rules on the development system are not changed; only the exported version of the rules are changed. After determining whether to select the check boxes in the following descriptions, click **Next**.

The following fields and options are available in this window:

**Change start date and time on exported rules:** Select **Change start date and time on exported rules** to alter the start date of the rules to export. You must specify a valid date and time using the format shown. For example, the format might be "m/d/yy h:mm a" resulting in 10/23/01 1:45 PM.

**Change end date and time on exported rules:** Select **Change end date and time on exported rules** to alter the end date of the rules to export. You must specify a valid date and time using the format shown. For example, the format might be "m/d/yy h:mm a" resulting in 10/23/01 1:45 PM.

**Select File For Rule Export window:** This is the third of three windows in the Export Rules Wizard. Use the Select File For Rule Export window to choose a name and location for the exported rule.

1. Browse to an existing directory or create a new one.
2. Type the name of the file. Typically, the file will end with an ".xml" extension.
3. Click **Export**.

### Rule properties window: General tab

Use the **Rule properties window: General** tab to enter general information about the rule. The following fields and options are available in this window:

#### Name and location

##### Folder name

(Required) Use the **Folder name** field to identify the folder in which to create the rule. To browse the existing folders, click the **ellipses** button to the right of the text field.

**Name** (Required) Use the **Name** field to give the rule a name. The name cannot include the forward slash '/' and must contain at least one non-blank character. The name cannot exceed the maximum length of the rule name column in the database table.

#### Period when rule is in effect

##### Start date

(Required) Use the **Start date** field to specify the date and time that the rule goes into effect. If you do not specify the time, a value of midnight is used.

##### End date

Use the **End date** field to determine the date when this rule expires. If you do not specify a value, the rule never expires.

#### Classification

Use the **Classification** section to specify your rule's classification status. Choose one of the following options:

- Rule is not classified and does not perform a classification (default)
- Rule performs a classification
- Rule is classified with the following classification

#### Status

##### Rule is available for use

Select **Rule is available for use** when the rule is available for use by the Business Rule Beans run-time environment. This feature is useful when you have not finished creating the rule, but you want to save your changes.

### Rule properties window: Implementation tab

Use the **Rule properties window: Implementation** tab to define the manner in which the rule is implemented.

**Note:** The rule contains the data and it does not perform the implementation. Rather, the Java rule implementor implements the rule

For example, suppose you want to create a rule that determines whether a given person is a senior (62 years old or older). To implement this rule, give the "com.ibm.websphere.brb.implementor.RuleGreaterThanEqual" Java rule implementor the value 62 and specify it as an initialization parameter. When the application fires the rule, the person's age is passed to the Java rule implementor as a firing parameter and 62 is passed as an initialization parameter. The person's age is compared against the initialization parameter of 62 and a value of true or false is returned from the Java rule implementor to the application. To change the age at which a person is considered a senior citizen, change the value of the initialization parameter.

The following fields and options are available on this tab:

**Java rule implementor:** (Required) Use the **Java rule implementor** field to specify a class to implement this rule. The initialization and firing parameters that are required are determined by looking at the documentation for the specified Java rule implementor.

**Firing location:** Use the **Firing location** field to determine where the rule is fired. You can fire the Java rule implementor on the server where the rules exist or fire it locally on the client machine. The client can be a servlet running on the server. Specify one of the following values for the firing location:

**Local** Use the **Local** option to fire the Java rule implementor local to the application that fired the rule.

**Remote**

Use the **Remote** option to fire the Java rule implementor on the server where the rules exist.

**Anywhere (default)**

Use the **Anywhere** option to attempt to fire the Java rule implementor locally first. If the Java rule implementor cannot be found, then it is fired remotely.

To choose the value of the firing location, you must take both performance and maintenance into consideration. Most rules perform better if they are run on the same Java virtual machine (JVM) as the application (locally). However, there might be cases where a Java rule implementor performs server-intensive tasks, in which case the rules might run better when they run on the server. To run locally, you must have all of the Java rule implementors installed locally. They must be accessible by the application that fires the rules.

**Initialization parameters:** The initialization parameters contain constant values passed to the rule implementor when it is initialized. Typically, the initialization parameters contain values that might change as your business practices evolve, such as the age at which a person is considered a senior citizen or the current interest rate for a loan.

To add a new initialization parameter to the list, click **Add** and fill in the fields in the Add Initialization Parameter window.

To edit an existing initialization parameter, highlight it, click **Change**, and fill in the fields in the Change Initialization Parameter window.

To delete an initialization parameter, highlight it and click **Delete**.

To change the order of the initialization parameters, highlight one and click the up or down arrows to move it to a new location.

**Firing parameters:** The firing parameters contain values passed from the trigger point in the application to the Java rule implementor at run time. You can alter the parameters coming from the application before passing them to the Java rule implementor. Typically these parameters are left unaltered.

For example, when implementing the "isSeniorCitizen" rule that determines whether a person is a senior citizen, you might want to pass a person from the application to the rule as the target object. However, the "isSeniorCitizen" rule uses the RuleGreaterThanEqual Java rule implementor, which requires that you pass an integer value. You can alter the firing parameters to specify that the method "getAge" is called on the person object and pass that result to the Java rule implementor.

You must choose one of the following:

**Pass firing parameters from trigger point unchanged**

The parameters specified in the trigger point of the application are passed to the Java rule implementor without being altered. This is the default value.

**Specify firing parameters**

The values specified in the table are passed to the Java rule implementor.

To add a new firing parameter to the list, click **Add** and fill in the fields in the Add Firing Parameter window.

To edit an existing firing parameter, highlight the firing parameter, click **Change**, and fill in the fields in the Change Firing Parameter window.

To delete a parameter, highlight the firing parameter and click **Delete**.

To change the order of the firing parameters, highlight one and click the up or down arrows to move it to a new location.

**Add Firing Parameter window:** Use the Add Firing Parameter window to add a firing parameter to a rule. The firing parameters contain values passed from the trigger point in the application to the Java rule implementor at run time. You can alter the parameters coming from the application before passing them to the Java rule implementor. Typically, these parameters are left unaltered.

To add a firing parameter, enter a field description, select an appropriate option, and click **Add**. The parameter is added and the window remains open to specify additional parameters. When you finish specifying initialization parameters, click **Close**. The following fields and options are available in this window:

*Description:* Use the **Description** field to type a description of the firing parameter.

*Specify a type and value:* Use the **Specify a type and value** option to specify a constant value to pass to the Java rule implementor.

*Get value from method call:* Use the **Get value from method call** option to call the specified method on the target object.

*Get value from trigger point firing parameters:* Use the **Get value from trigger point firing parameters** option to get a specific value from the firing parameters that were specified in the trigger method in the application. An index to the original firing parameter must be specified. This index starts with 0; thus, specify the value 0 to pass the first firing parameter. Specify the trigger point parameter number.

**Change Firing Parameter window:** Use the Change Firing Parameter window to edit an existing firing parameter. The firing parameters contain values passed from the trigger point in the application to the Java rule implementor at run time. You can alter the parameters coming from the application before passing them to the Java rule implementor. Typically, these parameters are left unaltered.

To change a firing parameter, enter a field description, select an appropriate option, and click **Change**. The parameter is changed and the window remains open to specify additional parameters. When you finish specifying initialization parameters, click **Close**.

The following fields and options are available in this window:

*Description:* Use the **Description** field to type a description of the firing parameter. There are three types of firing parameters that can be specified.

*Specify a type and value:* Use the **Specify a type and value** option to specify a constant value to pass to the Java rule implementor.

*Get value from method call:* Use the **Get value from method call** option to call the specified method on the target object.

*Get value from trigger point firing parameters:* Use the **Get value from trigger point firing parameters** option to pass a specific value from the firing parameters that were specified on the trigger method in the application. An index to the original firing parameter must be specified. This index starts with 0; thus, specify the value 0 to pass the first firing parameter.

### **Rule properties window: Description tab**

Use the **Rule properties window: Description** tab to define the purpose and intent of the rule. All of the fields in this panel are optional and none are used by the Business Rule Beans run-time environment. The following fields are available on this tab:

**Business Intent:** Use the **Business Intent** field to describe the business intent of this rule.

**Description:** Use the **Description** field to define a general description of the rule and its purpose.

**Original requirement:** Use the **Original requirement** field to compose a description of the original requirement that created this rule.

### **Rule properties window: Dependent Rules tab**

Use the **Rule properties window: Dependent Rules** tab to specify the rules that the newly created rule will depend upon.

To add names to the **Dependent rule names** field, proceed as follows:

1. Locate the dependent rule. You can do this in one of two ways:

#### **Browse for a rule**

If you are familiar with the location of the dependent rule, then click **Browse**. Navigate to the rule's location and highlight it.

#### **Find a rule**

If you are unfamiliar with the location of the rule, then click **Find**. This launches a Find Rules window in which you can specify options and then initiate a search. When you have located the rule, highlight it.

2. Click **Add**.

To change the name of a rule in the **Dependent rule names** field, highlight one or more rules and click **Edit**. Specify the new name for the rule and click **OK**.

To change the folder name of a rule in the **Dependent rule names** field, highlight one or more rules and click **Change Folder**. Fill-in the fields in the Change Folder window. All selected rules are updated with the newly specified values.

To delete a rule from the **Dependent rule names** field, highlight the rule and click **Delete**.

To change the order of the rules in the **Dependent rule names** field, highlight a rule and click the up or down arrows to move it to a new location.

**Change Folder window:** Use the Change Folder window to change the folder name for all selected dependent rules. There are two options for changing the folder name:

*Specify a new folder name:* Use the **Name** field to specify the new folder name for all selected rules. All selected dependent rule names are updated to contain the new folder, exactly as specified.

*Replace common portion of the folder name:* Use this option to change the portion of the folder name that is common to all selected rules.

For example, suppose the following two rules exist:

- com/acme/insurance/health/ruleA
- com/acme/insurance/life/ruleB

You want to change the `com/acme/insurance` portion of the name to `com/acme/ins`. The `com/acme/insurance` portion will be changed while leaving the remaining portion of the rule name intact.

The **Common folder** field is set to the common portion of the folder name. In the preceding example, this field is set to `com/acme/insurance`. This value cannot be changed.

Specify the new folder name in the **Replace with** field. For the preceding example, specify `com/acme/ins`.

### Rule properties window: Other tab

Use the **Rule properties window: Other** tab to establish precedence and enter information that is relevant to you, but does not fit into any other category. The following fields are available in this window:

**Precedence:** Use the **Precedence** field to specify the relative priority when firing the rule. This value is used to order the rules from lowest to highest.

**User defined data:** Use the **User defined data** field to enter any additional text that you want to store. The Business Rule Beans run-time environment does not use this field.

### Validate Rules

Use the **Validate** option to verify the correctness of the selected rules or folder. A report is generated and displayed in system's browser window. You can use the browser functionality to view, save, and print the results. The following items are validated:

#### Start and End dates

A valid start date must be specified. The end date must be empty (never expires) or be later than the start date.

#### Java rule implementor name

A valid and existing Java rule implementor name must be specified. The specified class must implement the `RuleImplementor` interface.

#### Dependent rules

The existence of each specified dependent rule is verified.

You can specify a Java classpath to use to validate rule implementor classes for the rules. To add individual JAR files or directories containing classes to the **Classpath** field, click **Add** or **Browse**.

To specify the full name of a jar file or directory to be added to the classpath, click **Add**.

To search through the file system for a JAR file or directory to be added to the classpath, click **Browse**.

To change an existing classpath entry, highlight the entry and click **Edit**. Specify the new name for the classpath entry and click **OK**.

To remove a classpath entry from the list, highlight one or more entries and click **Remove**.

To change the order of the classpath entries, highlight one or more entries and click the Up or Down arrows to move it to a new location.

After specifying the classpath, click **OK** to generate the report.

### Edit menu

This menu describes the options available on the Edit menu window. The following options are available in this window:

#### Cut

Use the **Cut** option to move rules and rule folders.

## Copy

Use the **Copy** option to copy rules and rule folders. The following tasks can be accomplished using the **Copy** option:

- **Copying rules**

Copy or move a rule from one folder to another by either cutting and pasting it or dragging and dropping it.

- **Cutting and pasting**

- Use menu commands (**Edit > Copy**, **Edit > Cut** and **Edit > Paste**) or keyboard commands (**CTRL-C**, **CTRL-V** and **CTRL-X**) to copy or move a rule.

- **Dragging and dropping**

- Highlight the rule you want to copy. Then, press and hold the right mouse button, drag the cursor to the target location, and release. Select **Copy** or **Move** from the list.

**Note:** You also can copy a rule so that the copy replaces the existing rule at a specified date. This is referred to as a Quick Copy.

- **Copying rule folders**

Copy or move a rule folder and all its contents by either cutting and pasting it or dragging and dropping it.

- **Cutting and pasting**

- Use menu commands (**Edit > Copy**, **Edit > Cut** and **Edit > Paste**) or keyboard commands (**CTRL-C**, **CTRL-V** and **CTRL-X**) to copy or move a rule.

- **Dragging and dropping**

- Press and hold the right mouse button on the folder to be copied. Drag the cursor to the target location and release the mouse button. Select **Copy** or **Move** from the list.

## Paste

Use the **Paste** option to add cut or copied rules and rule folders.

## Find

Use the **File** option to search for a rule. A window opens in which you can specify your search criteria. If you would like to search a specific folder, right-click the folder and select **Find** from the list. For more information, click the **Find Rules window** link under Related reference.

- **Search the whole directory**

- To search the whole directory, complete the following steps:

1. Click **Edit > Find** from the main menu of the Rule Browser.
2. Determine your search criteria in the Find Rules window.

- **Search a specific folder**

- To search a specific folder, complete the following steps:

1. Right-click the folder and select **Find** from the list.
2. Determine your search criteria in the Find Rules window.

The results of your search are displayed in a Search Results window.

## Quick Copy

Use the **Quick Copy** option to make a copy of a rule that will replace the existing one on a specified date. You can modify the copy so that a new value goes into effect on the desired date and time while the old rule expires. For more information, see the **Quick Copy window** link in Related reference.

## Select All

Use the **Select All** option to facilitate rule selection.

## Deselect All

Use the **Deselect All** option to deselect rules.

## Quick Copy window

Use the Quick Copy window to make a copy of a rule that replaces the existing one on a specified date.

For example, suppose that you have an "isSeniorCitizen" rule. Currently, a person is considered a senior citizen if they are 62 years of age or older. Starting on January 1, 2002, you must change this to 65. Use Quick Copy to specify the new date and to change the age from 62 to 65. The current rule is set to expire on the same date that the new rule takes effect. The new senior citizen age is defined as 65.

**Note:** Use the **Quick Copy** function for simple changes only.

In the following fields, specify how the copy differs from the original:

**Start Date For New Rule:** Use the **Start Date For New Rule** field to enter the date that the new rule replaces the existing rule. Use the date and time format that is shown. For example, the format might be the following:

M/d/yy h:mm a.

**Change parameter values for new rule:** Use the **Change parameter values for new rule** field to add new parameter values.

## Automatically Update References window

Use the Automatically Update References window to indicate what you would like to do with rules that contain references to the rules being moved, copied, or renamed. You can choose whether to update references and whether to view the references before updating the rules. When the rule references are displayed, you can choose which references to update. The following options are available in this window:

**Automatically update references:** Select **Automatically update references** to indicate that references should be updated.

**Display the updates before changing the rules option:** Select **Display the updates before changing the rules option** to indicate whether to show the changes before updating the references. When you choose this option, the Update Dependent Rule References window is displayed, allowing you to select which references to update.

## Update Dependent Rule References window

Use the Update Dependent Rule References window to select the dependent rule references that must be updated as a result of the move, copy, or rename operation.

Each row in the table represents one dependent rule reference. The following information is shown:

### Rule Name

Specifies the name of the rule containing the dependent rule reference.

### Folder Name

Specifies the folder containing the rule specified by **Rule Name**.

### Dependent Rule Old Name

Specifies the name of the dependent rule that is to be changed as a result of this move, copy, or rename operation.

### Dependent Rule New Name

Specifies the new name to be given to the dependent rule as a result of this move, copy, or rename operation.

### Status

Specifies the status of the rule; in effect, scheduled, expired, or invalid.

### Start Date

Specifies the date and time when this rule will begin being used.

### End Date

Specifies the date and time of when this rule will expire (no longer be used).

The check box to the left of the rule name indicates whether the dependent rule reference will be updated. Select the check box to change the selection which indicates that the reference should be updated.

Use the **Select All** button to indicate that all dependent rule references should be updated.

Use the **Deselect All** button to clear the dependent rule references selection.

Click **Continue** after reviewing the list of dependent rule references and indicating which references to update. Click **Cancel** to cause the move, copy, or rename operation to be cancelled completely.

### References To Rules Being Deleted window

Use the References To Rules Being Deleted window to view dependent rule references when a rule or folder is deleted. Each row in the table represents one dependent rule reference. The following information is shown:

**Rule Name**

Specifies the name of the rule containing the dependent rule reference.

**Folder Name**

Specifies the name of the folder containing business rules.

**Dependent Rule Reference**

Specifies the name of the dependent rule that is being deleted.

**Start Date**

Specifies the date and time when this rule is implemented.

**End Date**

Specifies the date and time when this rule expires.

Click **Continue** to delete. Click **Cancel** to abort.

### Rule Names Already Exist window

The Rule Names Already Exist window displays when one or more rules are copied into a folder and existing rules are found with the same name. This window enables you to rename the rules before you proceed with the copy operation. The conflicting rule names do not need to be changed; you can create multiple rules with the same name.

Each line of the table represents one rule for which a name conflict has occurred. The table shows the following fields:

**Rule Name**

Specifies the name of the rule being copied which is the same as the name of a rule that already exists in the destination folder.

**Folder Name**

Specifies the folder containing the rule specified by Rule Name

**Status**

Specifies the status of the rule; in effect, scheduled, expired, or invalid

**Start Date**

Specifies the date and time when this rule will begin being used

**End Date**

Specifies the date and time when this rule will expire (no longer be used)

To change the name of the rule being copied, click on the Rule Name in the table and specify a new name for the rule.

Click **OK** when you are finished reviewing or changing the rule names. Click **Cancel** to abort the copy operation.

### View menu

This article describes the options available in the View menu window. The following options are available in this window:

## Status Bar

Use the **Status Bar** option to toggle the status bar on or off. The status bar is shown along the bottom of the Rule Browser window.

## Specify Columns

Use the **Specify Columns** option to adjust the type and order of the columns that display in your window.

In the window that opens, the following tasks can be accomplished:

### Add a new column

Select one or more entries in the **Available columns** list and click the **Add** button. The selected entries are added to the end of the **Columns displayed** list.

### Remove a column

Select one or more entries in the **Columns displayed** and click the **Remove** button. The selected entries are added to the end of the **Available columns** list.

### Reorder columns

Select one or more entries in the **Columns displayed** list. To move the entries towards the top of the list, click the Up arrow; to move the entries towards the bottom, click the Down arrow.

## Specify Date/Time Format

Use the **Specify Date/Time Format** option to adjust the format used when displaying dates and times. For more information, click the **Specify Date/Time Format window** link under Related reference.

## Refresh

Use the **Refresh** option to update the contents of the folder hierarchy and the rule table.

## Specify Date/Time Format window

Use the Specify Date/Time Format window to change the date and time format. Choose one of the following radio button options and then click **OK**:

**Use default format for this locale:** Use the **Use default format for this locale** option to adjust the date and time format to match the default setting of your current locale.

**Select a predefined format for the date and time:** Use the **Select a predefined format for the date and time** option to select one of several existing date and time formats.

**Specify a custom format for the date and time:** Use the **Specify a custom format for the date and time** option to determine your own format for your date and time display. Choose one of the date and time formats from the two menus.

## Find Rules window

Use the Find Rules window to specify search criteria to locate rules. The search combines your queries using a logical "AND" operation. For example, if you specify both a folder name and a rule name, the search finds rules that match both the folder name and rule name. It displays the results in a Search Results window.

**Note:** All of the fields in this window are optional.

## Main menu

The main menu has the following options:

- **File**

- Save As**

- Use the **Save as** option to open a Save Search window and store the current search criteria.

- Open** Use the **Open** option to open the Open Saved Search window and load a previously saved set of search criteria into the Find Rules window.

- Close** Use the **Close** option to close the Find Rules window.

- **View**

- Show Search**

- Use the **Show Search** option to display a text description of your search criteria on one screen.

- Specify Date/Time Format**

- Use the **Specify Date/Time Format** option to adjust the format used when displaying dates and times. For more information, see the **Specify Date/Time Format window** link in Related reference.

## **Tabs**

The following tabs are displayed in this window:

**Name** Use the **Name** tab to specify the basic search criteria. For more information, click the **Find Rules window: Name tab** link under Related reference.

**Date** Use the **Date** tab to specify the date-related search criteria. For more information, click the **Find Rules window: Date tab** link under Related reference.

**Classification**

Use the **Classification** tab to specify the search criteria related to a rule's classification. For more information, click the **Find Rules window: Classification tab** link under Related reference.

**Implementation**

Use the **Implementation** tab to specify the search criteria that is based on the manner in which the rule is implemented. For more information, click the **Find Rules window: Implementation tab** link under Related reference.

**Description**

Use the **Description** tab to specify the text-based search criteria related to a rule's description. For more information, click the **Find Rules window: Description tab** link under Related reference.

**Other** Use the **Other** tab to specify the search criteria based on precedence and user-defined data. For more information, click the **Find Rules window: Other tab** link under Related reference.

## **Find Rules window: Name tab**

Use the **Find Rules window: Name** tab to specify the basic search criteria. The following fields and options are available on this tab:

**Name:** Use the **Name** field to search for a specific rule name.

**Note:** This is case-sensitive.

**Drop-down search option list:** Use the one of the following options in the **Drop-down search option list** to narrow your search:

**equal** Use the **equal** selection to look for an *exact* match.

**starting with**

Use the **starting with** selection to find rules whose name *starts* with the specified value.

**ending with**

Use the **ending with** selection to find rules whose name *ends* with the specified value.

**containing**

Use the **containing** selection to find rules that *contain* the specified value.

**Location:** Use the **Location** field to specify the folder that you want to search. Click the **ellipses** button to the right of the field if you want to browse for the folder.

**Note:** The folder names are case-sensitive.

**Include subfolders:** Select **Include subfolders** to include the folder's subfolders in the search.

**Status:** Use the **Status** menu to specify a search criteria that is based on a rule's availability.

## Find Rules window: Date tab

Use the **Find Rules window: Date** tab to specify date-related search criteria. A rule always has a start date and a range of time in which it is in effect. The end date is optional and if it is not specified, the rule never expires. The following options are available on this tab:

**Find Rules for any date:** Use the **Find Rules for any date** option to remove the date from consideration in the search criteria.

**Find Rules that are:** Use the **Find Rules that are** option to search for rules in one of the following states:

### currently in effect

The **currently in effect** selection finds rules that are active at this point in time.

### scheduled

The **scheduled** selection finds rules that go into effect at a future date.

### expired

The **expired** selection finds previously active rules that are beyond the rule's end date.

**Find Rules:** Use the **Find Rules** option to specify the dates you want to search. Modify the following criteria to narrow your search:

1. Select one of the following rule states from the menu:

- in effect
- starting
- ending

2. Select **Query on date only** if you would like your search to ignore time-specific information.

3. Select one of the following three methods by which to search:

**on x** Select the **on x** option to find rules that are in the desired state (as chosen in Step 1) on the specified date. If the **Query on date only** check box is clear, then midnight is used for the time.

#### anytime between x and y

Select the **anytime between x and y** option to find rules that are in the desired state (as chosen in Step 1) *anytime* between the given dates. Specify a start date (represented by x) and an end date (represented by y). If the **Query on date only** check box is clear, then midnight of each day is used for the time.

#### anytime during the next x days

Select the **anytime during the next x days** option to find rules that are in the desired state (as chosen in Step 1) within this period of time and specified in days.

## Find Rules window: Classification tab

Use the **Find Rules window: Classification** tab to specify search criteria related to a rule's classification. The following options are available on this tab:

**Show all:** Use the **Show all** option if you do not want to include the classification information in the search criteria.

**Show rules that are not classified and do not perform classification:** Use the **Show rules that are not classified and do not perform classification** option to find rules that you do not need to classify.

**Show rules that perform classification:** Use the **Show rules that perform classification** option to find rules that return a classification such as "Gold", "Silver", or "Bronze".

**Show rules that are classified:** Use the **Show rules that are classified** option to find rules that are classified with the specified classification. The specified classification is case-sensitive. Enter a specific classification into the field that is provided.

## Find Rules window: Implementation tab

Use the **Find Rules window: Implementation** tab to specify search criteria that is based on the manner in which the rule is implemented. The following options are available on this tab:

**Java rule implementor:** Use the **Java rule implementor** option to search for rules that use the specified Java rule implementor. You can use one of the values in the list or type in your own.

**Firing location:** Use the **Firing location** option to search for the location in which the rule implementor is run. Choose one of the following values from the check box:

**Local** Use the **Local** option to search locally for the location in which the rule implementor is run.

**Remote**

Use the **Remote** option to search the server for the location in which the rule implementor is run.

**Anywhere**

Use the **Anywhere** option to search both locally and on the server for the location in which the rule implementor is run.

**Firing parameters:** Use the **Firing parameters** option to search for rules that alter the firing parameters passed from the trigger point to the Java rule implementor. For more information, see the **Add Firing Parameter window** link in Related reference.

The following selections are available for the firing parameter option:

- show rules that alter firing parameters
- show rules that do not alter firing parameters

### Find Rules window: Description tab

Use the **Find Rules window: Description** tab to specify text-based search criteria related to a rule's description. The following fields and options are available on this tab:

**Business intent:** Use the **Business intent** field to search for rules with a given business intent.

**Description:** Use the **Description** field to search for rules with a given description.

**Original requirement:** Use the **Original requirement** field to search for rules with a given original requirement.

**Drop-down search option list:** Use the following options in the **Drop-down search option list** to narrow your search in the **Business intent**, **Description**, and **Original requirements** fields:

**equal** Use the **equal** selection to look for an *exact* match.

**starting with**

Use the **starting with** selection to find rules whose name *starts* with the specified value.

**ending with**

Use the **ending with** selection to find rules whose name *ends* with the specified value.

**containing**

Use the **containing** selection to find rules that *contain* the specified value.

### Find Rules window: Other tab

Use the **Find Rules window: Other** tab to specify search criteria based on precedence and user-defined data. The following options are available on this tab:

**Precedence:** Use the **Precedence** option to search for rules with given precedence. The precedence is an integer value that specifies the relative priority of this rule when it is fired.

**Drop-down search option list:** Use the **Drop-down search option list** to narrow your search by using one of the following options:

- equal
- less than
- less than or equal
- greater than
- greater than or equal
- not equal

**User defined data:** Use the **User defined data** option to search for rules with given user defined data.

**Drop-down search option list:** Use one of the following options from the **Drop-down search option list**:

**equal** Use the **equal** selection to look for an *exact* match.

**starting with**

Use the **starting with** selection to find rules whose name *starts* with the specified value.

**ending with**

Use the **ending with** selection to find rules whose name *ends* with the specified value.

**containing**

Use the **containing** selection to find rules that *contain* the specified value.

## Search Results window

This window contains the results of a search from a Find Rules window. It is nearly identical to the Rule Browser in terms of form and function. Use the options in the main menu to perform many of the same administrative actions, with a few differences:

- Rules cannot be imported into the Search Results window.
- Rules cannot be pasted into the Search Results window.
- The **Open Containing Folder** menu item opens a new browser window showing the contents of the folder for the selected rule.

## Save Search window

Use the Save Search window to store the current search criteria for later retrieval. Follow the following steps to save your search:

1. Type in a name for your search or replace a previously saved search from the list.
2. Click **OK**.

The saved search criteria is loaded into the Find Rules window.

## Open Saved Search window

Use the Open Saved Search window to open a previously saved search. Follow these steps to open your saved search:

1. In the Select a Search window, highlight the name of the search you want to open.
2. Click **OK**.

The saved search criteria is loaded into the Find Rules window.

---

## Business rule beans: Resources for learning

Use the following links to find relevant supplemental information about business rule beans. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

View links to additional information about:

## Chapter 18. Using asynchronous beans

The asynchronous beans feature adds a new set of APIs that enable Java 2 Platform Enterprise Edition J2EE applications to run asynchronously inside an Integration Server. This topic provides a brief overview of the tasks involved in using asynchronous beans. For a more detailed description of the asynchronous beans model, review the conceptual topic Asynchronous beans.

1. Configure work managers.
2. Assemble applications that use work managers.
3. Develop work objects to run code in parallel.
4. Develop event listeners.
5. Develop asynchronous scopes.

---

### Asynchronous beans

An asynchronous bean is a Java object or enterprise bean that can be executed asynchronously by a Java 2 Platform Enterprise Edition (J2EE) application, using the J2EE context of the asynchronous bean creator.

Asynchronous beans can improve performance by enabling a J2EE program to decompose operations into parallel tasks. Asynchronous beans support the construction of stateful, active J2EE applications. These applications address a segment of the application space that J2EE has not previously addressed (that is, advanced applications that require application threading, active agents within a server application, or distributed monitoring capabilities).

Asynchronous beans can run using the J2EE security context of the creator J2EE component. These beans also can run with copies of other J2EE contexts. For example:

- Internationalization context
- Application profiles
- Work areas

### Asynchronous bean interfaces

Three types of asynchronous bean exist:

#### Work object

A work object implements the `com.ibm.websphere.asynchbeans.Work` interface. A work object runs parallel to its caller using the `WorkManager.startWork()` method. Applications implement work objects to run code blocks asynchronously. For more information on the `Work` interface, see the Related reference section at the end of this article.

#### Alarm listener

An alarm listener is an object that implements the `com.ibm.websphere.asynchbeans.AlarmListener` interface. Alarm listeners are called when a high-speed transient alarm expires. For more information on the `AlarmListener` interface, see the Related reference section at the end of this article.

#### Event listener

An event listener can implement any interface. An event listener is a lightweight, asynchronous notification mechanism for asynchronous events within a single Java virtual machine (JVM). An event listener typically enables J2EE components within a single application to notify each other about various asynchronous events.

### Supporting interfaces

#### Work manager

A work manager is a thread pool that administrators create for J2EE applications. The administrator specifies the properties of the thread pool and a policy that determines which J2EE contexts the asynchronous bean inherits.

## Event source

An event source implements the `com.ibm.websphere.asynchbeans.EventSource` interface. An event source is a system-provided object that supports a generic, type-safe asynchronous notification server within a single JVM. The event source enables event listener objects, which implement any interface to be registered. For more information on the `EventSource` interface, see the Related reference section at the end of this article.

## Event source events

Every event source can generate events of its own. Event sources also can generate their own events such as listener count changed. An application can register an event listener object that implements the class `com.ibm.websphere.asynchbeans.EventSourceEvents`. This action enables the application to catch events such as listeners being added or removed, or a listener throwing an unexpected exception. For more information on the `EventSourceEvents` class, see the Related reference section at the end of this article.

Additional interfaces, including alarms and subsystem monitors, are introduced in the topic *Developing Asynchronous scopes*, which discusses some of the advanced applications of asynchronous beans.

## Transactions

Every asynchronous bean method is called using its own transaction, much like container-managed transactions in typical enterprise beans. It is very similar to the situation when an Enterprise Java Beans (EJB) method is called with `TX_NOT_SUPPORTED`. The run-time environment starts a local transaction before invoking the method. The asynchronous bean method is free to start its own global transaction if this transaction is possible for the calling J2EE component. For example, if an enterprise bean creates the component, the method that creates the asynchronous bean must be `TX_BEAN_MANAGED`.

When you call an entity bean from within an asynchronous bean, for example, you must have a global transactional context available on the current thread. Because asynchronous bean objects start local transactional contexts, you can encapsulate all entity bean logic in a session bean that has a method marked as `TX_REQUIRES` or equivalent. This process establishes a global transactional context from which you can access one or more entity bean methods.

If the asynchronous bean method throws an exception, any local transactions are rolled back. If the method returns normally, any incomplete local transactions are completed according to the unresolved action policy configured for the bean. EJB methods can configure this policy using their deployment descriptor. If the asynchronous bean method starts its own global transaction and does not commit this global transaction, the transaction is rolled back when the method returns.

## Access to J2EE component meta data

If an asynchronous bean is a J2EE component, such as a session bean, its own meta data is active when a method is called. If an asynchronous bean is a simple Java object, the J2EE component metadata of the creating component is available to the bean. Like its creator, the asynchronous bean can look up the `java:comp` namespace. This look up enables the bean to access connection factories and enterprise beans, just as it would if it were any other J2EE component. The environment properties of the creating component also are available to the asynchronous bean.

The `java:comp` namespace is identical to the one available for the creating component; the same restrictions apply. For example, if the enterprise bean or servlet has an EJB reference of `java:comp/env/ejb/MyEJB`, this EJB reference is available to the asynchronous bean. In addition, all of the connection factories use the same resource-sharing scope as the creating component.

## Connection management

An asynchronous bean method can use the connections that its creating J2EE component obtained using `java:comp` resource references. (For more information on resource references, see *References*). However,

the bean method must access those connections using a get, use, close pattern. There is no connection caching between method calls on an asynchronous bean. The connection factories or datasources can be cached, but the connections must be retrieved on every method call, used, and then closed. While the asynchronous bean method can look up connection factories using a global Java Naming and Directory Interface (JNDI) name, this is not recommended for the following reasons:

- The JNDI name is hard coded in the application (for example, as a property or string literal).
- The connection factories are not shared because there is no way to specify a sharing scope.

For code examples that demonstrate both the correct and the incorrect ways to access connections from asynchronous bean methods, see the topic [Example: Asynchronous bean connection management](#).

## Deferred start of Asynchronous Beans

Asynchronous Beans supports deferred execution by allowing serialization of J2EE service context information. The `WorkWithExecutionContext` `createWorkWithExecutionContext(Work r)` method on the `WorkManager` interface will create a snapshot of the J2EE service contexts enabled on the `WorkManager`. The resulting `WorkWithExecutionContext` object can then be serialized and stored in a database or file. This is useful when it is necessary to store J2EE service contexts such as the current security identity or `Locale` and later inflate them and execute some work within this context. The `WorkWithExecutionContext` object can be executed using the `startWork()` and `doWork()` methods on the `WorkManager` interface.

All `WorkWithExecutionContext` objects must be deserialized by the same application that serialized it. All EJBs and classes must be present in order for Java to successfully inflate the objects contained within.

## Deferred Execution and Security

The asynchronous beans security service context might require Common Secure Interoperability Version 2 (CSIv2) identity assertion to be enabled. Identity assertion is required when a `WorkWithExecutionContext` object is deserialized and executed to Java Authentication and Authorization Service (JAAS) subject identity credential assignment. Review the following topics in the Information Center to better understand if you need to enable identity assertion, when using a `WorkWithExecutionContext` object:

- [Configuring Common Secure Interoperability Version 2 and Security Authentication Service authentication protocol](#)
- [Identity Assertion](#)

There are also issues with interoperating with `WorkWithExecutionContext` objects from different versions of the product. See [Interoperating with asynchronous beans](#).

## Example: Asynchronous bean connection management

An asynchronous bean method can use the connections that its creating Java 2 Platform Enterprise Edition (J2EE) component obtained using `java:comp` resource references. (For more information on resource references, see the topic [References](#).) The following is an example of an asynchronous bean that uses connections correctly:

```
class GoodAsynchBean
{
 DataSource ds;
 public GoodAsynchBean()
 throws NamingException
 {
 // ok to cache a connection factory or datasource
 // as class instance data.
 InitialContext ic = new InitialContext();
 // it is assumed that the created J2EE component has this
 // resource reference defined in its deployment descriptor.
 ds = (DataSource)ic.lookup("java:comp/env/jdbc/myDataSource");
 }
}
```

```

// When the asynchronous bean method is called, get a connection,
// use it, then close it.
void anEventListener()
{
 Connection c = null;
 try
 {
 c = ds.getConnection();
 // use the connection now...
 }
 finally
 {
 if(c != null) c.close();
 }
}
}

```

The following example of an asynchronous bean that uses connections illegally:

```

class BadAsynchBean
{
 DataSource ds;
 // Do not do this. You cannot cache connections across asynch method calls.
 Connection c;

 public BadAsynchBean()
 throws NamingException
 {
 // ok to cache a connection factory or datasource as
 // class instance data.
 InitialContext ic = new InitialContext();
 ds = (DataSource)ic.lookup("java:comp/env/jdbc/myDataSource");
 // here, you broke the rules...
 c = ds.getConnection();
 }
 // Now when the asynch method is called, illegally use the cached connection
 // and you likely see J2C related exceptions at run time.
 // close it.
 void someAsynchMethod()
 {
 // use the connection now...
 }
}

```

---

## Configuring work managers

If you are not familiar with work managers, review the conceptual topic [Work managers](#).

A work manager acts as a thread pool for application components that use asynchronous beans. Use the administrative console to configure work managers. You can define multiple work managers for each cell. Each work manager is bound to a unique place in Java Naming and Directory Interface (JNDI).

**Note:** The work manager service is only supported from within the Enterprise Java Beans (EJB) Container or Web Container. Looking up and using a configured work manager from a J2EE application client container is not supported.

1. Start the administrative console.
2. Select **Resources > Work Managers**.
3. Click **New**.
4. Specify the following required properties:
  - Name** The display name for the work manager.

**JNDI Name**

The JNDI name for the work manager. This name is used by asynchronous beans that need to look up the work manager. Each work manager must have a unique JNDI name within the cell.

**Number of Alarm Threads**

The maximum number of threads to use for processing alarms. A single thread is used to monitor pending alarms and dispatch them. An additional pool of threads is used for dispatching the threads. All alarm managers on the asynchronous beans associated with this work manager share this set of threads. A single alarm thread pool exists for each work manager, and all of the asynchronous beans associated with the work manager share this pool of threads.

**Minimum Number Of Threads**

The initial number of threads to be created in the thread pool.

**Maximum Number Of Threads**

The maximum number of threads to be created in the thread pool. The maximum number of threads can be exceeded temporarily if the **Growable** check box is selected. These additional threads are discarded when the work on the thread completes.

**Thread Priority**

The order of the priority for threads available in the thread pool.

5. [Optional] Specify a **Description** and a **Category** for the work manager.
6. [Optional] Select the **Service Names** (J2EE contexts) on which you want this work manager to be made available. Any asynchronous beans that use this work manager then inherit the selected J2EE contexts from the component that creates the bean. The list of selected services also is known as the "sticky" context policy for the work manager. Selecting more services than are actually required might impede performance.
7. Save your configuration.

The work manager is now configured and ready for access by application components that need to manage asynchronous code execution.

## Work managers

A work manager is a thread pool created for J2EE applications that use asynchronous beans.

Using the administrative console, an administrator can configure any number of work managers. The administrator specifies the properties of the work manager, including the inheritance context policy for any asynchronous beans that use the work manager. The administrator binds each work manager to a unique place in Java Naming and Directory Interface (JNDI).

When writing a Web or EJB component that uses asynchronous beans, the developer should include a resource reference in each component that needs access to a work manager. (For more information on resource references, see the topic [References](#).) The component looks up a work manager using a logical name in the component's `java:comp` namespace, just as it looks up a data source, enterprise bean, or connection factory.

The deployer binds physical work managers to logical work managers when the application is deployed.

For example, if a developer needs three thread pools to partition work between bronze, silver, and gold levels, the developer writes the component to pick a logical pool based on an attribute in the client application profile. The deployer has the flexibility to decide how to map this request for three thread pools. The deployer might decide to use a single thread pool on a small machine. In this case, the deployer binds all three resource references to the same work manager instance (that is, the same JNDI name). A larger machine might support for three thread pools, so the deployer binds each resource reference to a different work manager. Work managers can be shared between multiple J2EE applications installed on the same server.

An application developer can use as many logical work managers as necessary; the deployer chooses whether to map one physical work manager or several to the logical work manager defined in the application.

All J2EE components that need to share asynchronous scope objects must use the same work manager. These scope objects have an affinity with a single work manager so an application that uses `AsynchScopes` should verify that all of the components using scope objects use the same work manager.

When multiple work managers are defined, the underlying thread pools are created in a JVM only if an application within that Java virtual machine (JVM) looks up the work manager. For example, there might be ten thread pools (work managers) defined, but none are actually created until an application looks these pools up.

### How to look up a work manager

An application can look up a work manager as follows. Here, the component contains a resource reference named `wm/myWorkManager`, which was bound to a physical work manager when the component was deployed:

```
InitialContext ic = new InitialContext();
WorkManager wm = (WorkManager)ic.lookup("java:comp/env/wm/myWorkManager");
```

### Inheritance J2EE contexts

Asynchronous beans can inherit the following J2EE contexts.

#### Internationalization context

#### Work area

#### Application profile

#### Security

The asynchronous bean can be run as anonymous or as the client authenticated on the thread that created it. This is useful because the asynchronous bean can do only what the caller can do.

This is more useful than a `RUN_AS` mechanism, for example, which prevents this kind of behavior.

#### Component meta data

Component meta data is relevant only when the asynchronous bean is a simple Java object. If the bean is a J2EE component, such as an enterprise bean, the component's meta data is active.

The contexts that can be inherited depends on the work manager used by the application that creates the asynchronous bean. Using the administrative console, the administrator defines the sticky context policy of a work manager by selecting the services on which the work manager is to be made available.

## Work manager collection

Use this page to view the configuration properties of work managers.

A work manager contains a pool of threads bound into JNDI.

To view this administrative console page, click **Resources > Work Managers** .

### Name

The name by which the work manager is known for administrative purposes.

**Data type** String

### JNDI Name

The JNDI name used to look up the work manager in the namespace.

**Data type** String

## Service Names

A list of service names on which this work manager is made available.

The context information of each selected service is propagated to each work or alarm that is created using this work manager. Selecting services that are not needed can negatively impact performance.

**Data type** Integer

## Number of Alarm Threads

The number of threads used to execute concurrent alarms.

**Data type** Integer

## Minimum Number of Threads

The minimum number of threads available in this work manager for running works.

**Data type** Integer

## Maximum Number of Threads

The maximum number of threads available in this work manager for running works.

**Data type** Integer

## Work manager settings

Use this page to modify work manager settings.

A work manager contains a pool of threads bound into JNDI.

To view this administrative console page, click **Resources > Work Managers > *workmanager\_name***.

### **Name:**

The name by which the work manager is known for administrative purposes.

**Data type** String

### **JNDI Name:**

The JNDI name used to look up the work manager in the namespace.

**Data type** String

### **Description:**

A description of this work manager for administrative purposes.

**Data type** String

### **Category:**

A string that can be used to classify or group this work manager.

**Data type** String

***Number of Alarm Threads:***

The number of threads used to execute concurrent alarms.

**Data type** Integer

***Minimum Number of Threads:***

The minimum number of threads available in this work manager for running works.

**Data type** Integer

***Maximum Number of Threads:***

The maximum number of threads available in this work manager for running works.

**Data type** Integer

***Thread Priority:***

The priority of the threads available in this work manager.

**Data type** Integer

***Growable:***

Specifies whether the number of threads in this work manager can be increased.

***Service Names:***

A list of service names on which this work manager is made available.

The context information of each selected service is propagated to each work or alarm that is created using this work manager. Selecting services that are not needed can negatively impact performance.

**Data type** Integer  
**Range** Application Profiling Service  
Work Area  
Security  
Internationalization

## **Work manager service settings**

Use this page to enable or disable the work manager service, which manages work manager resources used by the server.

To view this administrative console page, click **Servers > Application Servers > *server\_name* > Work Manager Service** .

### **Startup**

Specifies whether the server will attempt to start the work manager service.

**Default  
Range**

**Selected  
Selected**

When the application server starts, it attempts to start the work manager service automatically.

**Cleared**

The server does not try to start the work manager service. If work manager resources are to be used on this server, the system administrator must start the work manager service manually or select this property then restart the server.

---

## Assembling applications that use work managers

Your administrator needs to configure at least one work manager using the administrative console.

If your application references one or more logical work managers, the logical work managers must be bound to one or more physical work managers using the Application Assembly Tool (AAT) Assembly Toolkit.

1. Declare a resource reference for each work manager (required action by the application developer). This forms an EAR file. (For more information on resource references, see the topic [References](#).)
2. Using the Application Assembly Tool (AAT) Assembly Toolkit, bind each resource reference to a physical work manager.
3. Add a resource reference with the type 'com.ibm.websphere.asynchbeans.WorkManager' to the application's descriptor. The application then can look up this work manager using its resource reference name in java:comp. The assembly tool or WebSphere Studio Application Developer Integration Edition then can specify which resource references are bound to a physical work manager.

**Note:** The previous steps is the same process used for data sources.

---

## Developing work objects to run code in parallel

Your administrator must have configured at least one work manager using the administrative console.

To run code in parallel, or in a different J2EE context, wrap the code in a work object.

1. Create a work object.

A work object implements the `com.ibm.websphere.asynchbeans.Work` interface. For example:

```
class SampleWork implements Work
```

2. Determine the number of work managers needed by this application component.
3. Look up the work manager or managers using the work manager resource reference (or logical name) in the `java:comp` namespace. (For more information on resource references, see the topic [References](#).)

```
InitialContext ic = new InitialContext();
WorkManager wm = (WorkManager)ic.lookup("java:comp/env/wm/myWorkManager");
```

The resource reference for the work manager (in this case, `wm/myWorkManager`) must be declared as a resource reference in the application deployment descriptor.

4. Call the `WorkManager.startWork()` method using the work object as a parameter. For example:

```
Work w = new MyWork(...);
WorkItem wi = wm.startWork(w);
```

The `startWork()` method can take a `startTimeout` parameter. This specifies a hard time limit for the Work object to be started. The `startWork()` method returns a work item object. This object is a handle that provides a link from the component to the now running work object.

5. [Optional] If your application component needs to wait for one or more of its running work objects to complete, call the `WorkManager.join()` method. For example:

```
WorkItem wiA = wm.start(workA);
WorkItem wiB = wm.start(workB);
ArrayList l = new ArrayList();
l.add(wiA);
l.add(wiB);
if(wm.join(l, wm.JOIN_AND, 5000)) // block for up to 5 seconds
{

 // both wiA and wiB finished
}
else
{

 // timeout

 // we can check wiA.getStatus or wiB.getStatus to see which, if any, finished.
}
```

This method takes an array list of work items which your component wants to wait on and a flag that indicates whether the component will wait for one or all of the work objects to complete. You also can specify a timeout value.

6. Use the `release()` method to set a variable in a synchronized block. For example:

```
public synchronized void release()
{
 released = true;
}
```

The `Work.run()` method can periodically examine this variable to check whether the loop exits or not.

## Work objects

A work object is a type of asynchronous bean used by application components to run code in parallel or in a different J2EE context.

A work object implements the `com.ibm.websphere.asynchBeans.Work` interface. A work object is essentially a `java.lang Runnable` object that is serializable and provides additional methods. For details, see the Interface `Work` in the Javadoc.

A component wanting to run work in parallel, or in a different J2EE context, locates a work manager in JNDI, then calls the `WorkManager.startWork()` method using the work object as a parameter.

The `startWork()` method returns a work item object. This object is a handle that provides a link from the component to the now running work object. The work item object is typically used when the component needs to wait for one or more of its running work objects to complete. The `WorkManager.join()` method takes an array list of work items that the component wants to wait on, and a flag indicating whether the component will wait for all or one of the work objects to complete. A timeout can be specified, which prevents the component from waiting indefinitely.

Why not have the application create Java 2 SDK threads? The threads created by the Java 2 SDK are not managed threads and hence know nothing about the J2EE environment and are unusable inside an application server. In addition, these threads have no J2EE context (for example, a `java:comp`) and are not authenticated when they fire. Work object threads are fully supported by the application server and have the same properties as any other asynchronous bean.

## Example: Work object

The following is an example of a work object that dynamically subscribes to a topic:

```
class SampleWork implements Work
{
 boolean released;
 Topic targetTopic;
 EventSource es;
 TopicConnectionFactory tcf;
 public SampleWork(TopicConnectionFactory tcf, EventSource es, Topic targetTopic)
 {
 released = false;
 this.targetTopic = targetTopic;
 this.es = es;
 this.tcf = tcf;
 }
 synchronized boolean getReleased()
 {
 return released;
 }
 public void run()
 {
 try {
 // setup our JMS stuff.
 TopicConnection tc = tcf.createConnection();
 TopicSession sess = tc.createSession(false, Session.AUTOACK);
 tc.start();

 MessageListener proxy = es.getEventTrigger(MessageListener.class, false);
 while(!getReleased())
 {
 // block for up to 5 seconds.
 Message msg = sess.receiveMessage(5000);
 if(msg != null)
 {
 // fire an event when we get a message
 proxy.onMessage(msg);
 }
 }
 tc.close();
 } catch (JMSEException ex)
 {
 // handle the exception here
 throw ex;
 }
 finally
 {
 if (tc != null)
 {
 try{
 tc.close();
 } catch (JMSEException ex1)
 { // handle exception }
 }
 }
 }
 // called when we want to stop the Work object.
 public synchronized void release()
 {
 released = true;
 }
}
```

As a result, any component that has access to the event source can add an event on demand, which allows components to subscribe to a topic in a more scalable way than by simply giving each client subscriber its own thread. The previous example is fully explored in the WebSphere Trader Sample. See your Samples Gallery for details.

---

## Developing event listeners

Application components that listen for events can use the `EventSource.addListener()` method to register an event listener object (a type of asynchronous bean) with the event source to which the events will be published. An event source also can fire events in a type-safe manner using any interface.

Notifications between components within a single EAR file are handled by a special event source. See the topic, [Using the application notification service](#).

1. Create an event listener object, which can be any type. For example, see the following interface code:

```
interface SampleEventGroup
{
 void finished(String message);
}

class myListener implements SampleEventGroup
{
 public void finished(String message)
 {
 // This will be called when we 'finish'.
 }
}
```

2. Register the event listener object with the event source. For example, see the following code:

```
InitialContext ic = ...;
EventSource es = (EventSource)ic.lookup("java:comp/websphere/ApplicationNotificationService");
myListener l = new myListener();
es.addListener(l);
```

This enables the `myListener.finished()` method to be called whenever the event is fired. The following code example shows how this event might be fired:

```
InitialContext ic = ...;
EventSource es = (EventSource)ic.lookup("java:comp/websphere/ApplicationNotificationService");
myListener proxy = es.getEventTrigger(myListener.class);
// fire the 'event' by calling the method
// representing the event on the proxy
proxy.finished("done");
```

## Using the application notification service

During the application lifetime, individual J2EE components (servlets or enterprise beans) within a single EAR file might need to signal each other. There is an event source in the `java:comp` namespace that is bound into all components within an EAR file. The JNDI name for this event source is:

```
java:comp/websphere/ApplicationNotificationService
```

Components within the same application can fire asynchronous events and register event listeners using this application notification service. Startup beans can be used to register these event listeners at application startup or they can be registered dynamically at run time.

To have your enterprise bean or servlet use the application notification service, write code similar to the following example:

```
InitialContext ic = new InitialContext();
EventSource appES = (EventSource)
 ic.lookup("java:comp/websphere/ApplicationNotificationService");
// now, the application can add a listener using the EventSource.addListener method.
// MyEventType is an interface.
MyEventType myListener = ...;
AppES.addListener(myListener);

// later another component can fire events as follows
InitialContext ic = new InitialContext();
EventSource appES = (EventSource)
ic.lookup("java:comp/websphere/ApplicationNotificationService");

// This highlights a constant string on the EventSource interface which
// specifies the 'java:comp/websphere/ApplicationNotificationService' string.
ic.lookup(appES.APPLICATION_NOTIFICATION_EVENT_SOURCE)
// now, the application can add a listener using the EventSource.addListener method.
MyEventType proxy = appES.getEventTrigger(MyEventType.class, false);
proxy.someEvent(someArguments);
```

## Example: Event listener

The following code example demonstrates how to fire a listenerCountChanged event:

```
// imagine this snippet inside an EJB or servlet method.
// Make an inner class implementing the required event interfaces.
EventSourceEvents listener = new Object() implements EventSourceEvents.class
{
 void listenerCountChanged(EventSource es, int old, int newCount)
 {
 try
 {
 InitialContext ic = new InitialContext();
 // here, the asynch bean can access an environment variable of
 // the component which created it.
 int i = (Integer)ic.lookup("java:comp/env/countValue").intValue();
 if(newCount == i)
 {
 // do something interesting
 }
 // call this event when the following code executes:
 }
 catch(NamingException e)
 {
 }
 }
 void listenerExceptionThrown(EventSource es, Object listener,
 String methodName, Throwable exception)
 {
 }
 void unexpectedException(EventSource es, Object runnable, Throwable exception)
 {
 }
}
// register it.
es.addListener(listener);

...

// now fire an event which the previous listener receives.
EventSourceEvents proxy = (EventSourceEvents)
 es.getEventTrigger(EventSourceEvents.class, false);
```

```
proxy.listenerCountChanged(es, 0, 1);

// now, fire another event, you can call any of the methods.
proxy.listenerCountChanged(es, 4, 5);
```

In this example, you get a proxy for the interface that we want to fire a method on. Then, call the method corresponding to the event on the proxy. This action causes the same method with the same parameters to be called on any event listeners that implement the `EventSourceEvents` interface and that were previously registered with the EventSource "es". The same proxy can be used to send multiple events simultaneously.

The boolean parameter on the `getEventTrigger()` method is named "sameTransaction". When the `sameTransaction` parameter is `false`, a new transaction is started for each event listener invoked and these event listeners can be called in parallel to the caller. However, the `event()` method always is blocked until all of the event listeners are notified. If the `sameTransaction` parameter is `true`, the current transaction, if any, on the thread is used for all of the event listeners; that is, the event listeners share the transaction of the method that fired the event. For that reason, all event listeners must run serially in an undetermined order. That is, the order in which the listeners are called is undefined and the order in which listeners are registered does not act as a guide for the order used at run time. The method on the proxy does not return until all of the event listeners are called; that is, it is a synchronous operation.

The parameters that are passed by reference and listeners do not interfere with these references unless the method that fired the event has purposefully designed such interaction. For example, event listeners can be used as collaborators and add data to a map, which was a parameter. Each event listener runs on its own transaction, independent of any transaction that is active on the thread. Extreme care must be taken when the `sameTransaction` parameter is `false` because the parameters can be accessed by multiple threads.

---

## Developing asynchronous scopes

Asynchronous scopes are units of scoping that comprise a set of alarms, subsystem monitors, and child asynchronous scopes. Using asynchronous scopes can involve some or all of the following steps:

1. Create asynchronous scopes Create a parent asynchronous scope object by calling the `AsynchScopeManager.createAsynchScope()` method using a unique name as the parameter. You can store properties in an asynchronous scope object. This storage provides Java 2 Enterprise Edition (J2EE) applications with a way to store a non-serializable state that otherwise cannot be stored in a session bean. You also can create child asynchronous scopes, which is useful for scoping data beneath the parent.
2. Listen for alarm notifications
  - a. Create a listener object by implementing the `AlarmListener` interface. For more information, see the `AlarmListener` interface in the Javadoc.
  - b. Supply this object to the `AlarmManager.create()` method, as the target for the alarm. The `create()` method takes the following parameters:

### Target for the alarm

The target on which the `fired()` method is called when the alarm is fired.

### Context

The context object for the alarm. This object is useful for supplying alarm-specific data to the listener and supports a single listener for multiple alarms.

### Interval

The number of milliseconds before the alarm fires.

After the specified interval, the alarm fires and the `fired()` method of the listener is called with the firing alarm as a parameter. The alarm object is returned. By calling methods on this object, you can cancel or reschedule the alarm.

3. Monitor remote systems.

- a. Implement a mechanism for detecting messages sent from the remote system. For example, publish and subscribe messaging.
- b. Create a subsystem manager object by calling the `SubsystemMonitorManager.create()` method with the following parameters:
  - Name** Each subsystem monitor must have a unique name.
  - Heartbeat interval**  
The expected interval, in milliseconds, between heartbeats.
  - Missed heart beats until stale or suspect**  
The number of heartbeats that can be missed before the subsystem is marked as stale.
  - Missed heart beats until dead**  
The number of heartbeats that can be missed before the system is marked as dead.
- c. Create an object that implements the `SubsystemMonitorEvents` interface. For more information, see the `SubsystemMonitorEvents` in the Javadoc.
- d. Add an instance of this object to the subsystem monitor using the `SubsystemMonitor.addListener()` method.
- e. Whenever a heartbeat message arrives from the remote system, call the `SubsystemMonitor.ping()` method.

The subsystem monitor configures alarms to track the heartbeat status of the remote system. When the `ping()` method is called, the alarms are reset. If an alarm fires, the `ping()` method is not called; that is, the application did not receive a heartbeat from the monitored subsystem.

Asynchronous scopes are useful in stateful server applications. An application can have a startup bean that creates an asynchronous scope on a named work manager. The application also might create subsystem monitors to monitor the health of any remote systems on which the application is dependent.

When a client attaches to the server, the application creates a child asynchronous scope that is owned by the application asynchronous scope for the client and named using the client ID. A subsystem monitor for monitoring the client might be created on the client asynchronous scope. If the client times out, a callback can clean up the client state on the server. Callbacks can be attached to the application subsystem monitors, on behalf of the client. When a remote system becomes unavailable, the client code in the server is notified and an event is sent to the client to warn that a critical remote system has failed. For example, the failure might be a data feed in an electronic trading application.

## Asynchronous scopes

An asynchronous scope (`AsynchScope` object) is a unit of scoping provided for use with asynchronous beans.

Asynchronous scopes are collections of alarms, subsystem monitors, and child asynchronous scopes that enable a relationship to form. Each asynchronous scope uses a single work manager.

Each `AsynchScope` object owns and controls the life cycle of the following objects:

### Child asynchronous scopes

Each `AsynchScope` object extends the `AsynchScopeManager` interface, which is a factory for `AsynchScope` objects. (For more information on the `AsynchScopeManager` interface, see the Javadoc). Any asynchronous scope can therefore create named asynchronous scopes (children). Child asynchronous scopes can be useful for scoping data underneath the parent. All of the child asynchronous scopes must be uniquely named. These children are destroyed if the parent asynchronous scope is destroyed.

### Alarms

Each asynchronous scope has an associated alarm manager. All of the alarms created by the alarm manager are automatically cancelled if the associated asynchronous scope is destroyed.

### Subsystem monitors

Each asynchronous scope has a subsystem monitor manager, which manages a set of subsystem

monitors associated with the asynchronous scope. When the asynchronous scope is destroyed, all of the associated subsystem monitors also are destroyed.

To summarize, asynchronous scopes can be organized into an acyclic tree. The life cycle of each asynchronous scope is directly coupled to that of its parent asynchronous scope. Each asynchronous scope is associated with a set of alarms and subsystem monitors, and an optional set of child asynchronous scopes. These objects are cancelled and destroyed when the asynchronous scope is destroyed.

### **Asynchronous scope state**

Each asynchronous scope has an associated map, in which applications can store their state in the form of name and value pairs.

### **Asynchronous scope events**

Each asynchronous scope is also an event source. Applications can therefore register event listeners against the asynchronous scope. The event listeners can receive notification if, for example, the `AsynchScope` object is about to be destroyed.

Applications also can use this event source to fire events only to listeners of this asynchronous scope. For example, an `AsynchScope` object created for a client session might be used to fire asynchronous events to parties interested in that client.

## **Alarms**

An alarm executes Java 2 Enterprise Edition (J2EE) context-aware code at a given time interval. Alarm objects are fine-grained, non-persistent, transient, and can fire at millisecond intervals.

Alarms are executed using a thread pool associated with the work manager that owns the associated asynchronous scope.

The `AlarmManager.createAlarm()` method takes an application-written object that implements the `AlarmListener` interface. (For more information on the `AlarmListener` interface, see the Javadoc) The `fire` method is called when the alarm expires. The `createAlarm()` method returns a non-serializable handle, which can be used to cancel or reset the alarm. All of the pending alarms are cancelled when its associated `AsynchScope` object is destroyed.

The Java 2 Software Development Kit (SDK) already has a timer mechanism, so why create a new one? The Java 2 SDK is a Java 2 Platform Standard Edition (J2SE) feature that knows nothing about the J2EE environment. Timers fired by the J2SE feature do not run on a managed thread and are therefore unusable inside an application server. These timers also lack a J2EE context (that is, a `java:comp` value) and are not authenticated when they fire. The asynchronous scope alarms are fully supported by the product and have the same properties as any other asynchronous bean.

### **Alarm performance**

The alarm subsystem is designed to handle a large number of alarms. However, do not have alarms undertake heavy processing when they are firing because this activity slows the processing of later alarms. If an alarm needs to process a heavy load, design a work object that is activated by a work manager. This procedure moves the heavy processing to a different thread and enables the alarm threads to process alarms unhampered. All of the alarms owned by asynchronous scopes that are owned by a single work manager, share a common thread pool. The properties of this thread pool can be tuned at the work manager level using the administrative console.

## Subsystem monitors

A subsystem monitor is an object that monitors the health of a remote system. It uses an event source to inform all registered listeners of the health of the system.

Advanced Java 2 Platform Enterprise Edition (J2EE) applications often rely on remote, non-managed, non-J2EE systems. These remote systems can periodically send clients a message to indicate that they are working. A subsystem monitor is essentially a set of alarms that track indicators messages or heartbeats from a remote system.

An application creates a subsystem monitor by calling the `SubsystemMonitorManager.create()` method with the following parameters:

**Name** Each subsystem monitor must be uniquely named.

**Heart beat interval**

The time period, in milliseconds, between arriving heartbeat messages.

**Missed heart beats until stale or suspect**

The number of heartbeats that can be missed before the subsystem is marked as stale. This designation indicates that the subsystem might be having problems.

**Missed heart beats until dead**

The number of heartbeats that can be missed before the system is considered down. The system then is marked as dead.

The subsystem monitor configures alarms to track the heartbeat status. Whenever the `ping()` method is called, the alarms are reset. If an alarm fires, the `ping()` method has not been called; that is, the application did not receive a heartbeat from the monitored subsystem. When the number of **Missed heart beats until stale** value has elapsed without a ping, a stale event is fired. Later, if the number of **Missed heart beats until dead** value elapses without a ping, a dead event is fired. If a ping is received after a stale or dead notification, a fresh event is sent, which indicates that the subsystem is alive again.

Make the **Missed heart beats until dead** value greater or equal to the **Missed heart beats until stale** value. If **Missed heart beats until stale** value equals the **Missed heart beats until dead** value, then a stale event is not published. Only a dead event is published.

Applications wanting to be informed of these events can register a listener that implements the `SubsystemMonitorEvents` interface. For more information on the `SubsystemMonitorEvents` interface, see the Javadoc.

Heart beat messages can be transmitted using a variety of mechanisms. The application must call the `SubsystemMonitor ping()` method whenever a heartbeat message arrives from a remote system, but the method used to detect these messages is up to the application. For example, you might use a Java Message Service (JMS) publish or subscribe implementation or even a third-party Java messaging product that does not implement JMS.

## Asynchronous scopes: Dynamic message bean scenario

Java 2 Platform Enterprise Edition (J2EE) now supports message-driven beans, but the beans are static. All of the message sources must be known in advance and bound at deployment time. This action is not always viable, especially in fluid messaging environments such as those found in brokerages. Some environments have publish-subscribe topic spaces that are continually changing and clients need servers that can subscribe on demand to an arbitrary topic.

An asynchronous bean application can create a work object that performs a blocking receive on a Java Messaging Service (JMS) topic and then publishes the message as an event on an application-defined event source. Clients requiring a subscription to that message can add an event listener to the event source. The event source can inform the work object when there are no listeners. Then, the event source can shut down and make the JMS and thread resources available. The work object registers a listener with its own event source. When the count is one again, the work object knows that it is the only listener

and it is time to shut down the work object. The WebSphere Trader Sample (see your installed Samples Gallery) uses this pattern to dynamically subscribe to JMS topics at run time to gather stock prices. For more information, see an overview of the samples in the Information Center.

How does the server catch clients that disconnect or crash? It creates a subsystem monitor to watch the client and adds an event listener to catch dead events. When a dead event occurs, the server application can clean up the client server state. For example, the server application can remove the client event listener from the dynamic message bean, thereby allowing the server to subscribe to a dynamic topic only when it is needed.

---

## Interoperating with asynchronous beans

The WebSphere Application Server Enterprise Edition asynchronous beans Version 5 service has interoperability problems that affect how the dependent services behave in a clustered environment with mixed WebSphere product versions and mixed platforms. Read the Serialized Asynchronous beans interoperability article and the JMX MBean interoperability issues article to determine whether you need to complete the following general recovery steps.

1. If the Serialized Asynchronous beans interoperability issues apply to you, then apply interim fix PQ72742 or PTF 1 to bring all affected servers up to the appropriate Version `WorkWithExecutionContext` level. If any of the security problems apply to you, then all data must be reserialized. For example, modify the existing Enterprise Java Bean (EJB) or servlet used to serialize the `WorkWithExecutionContext`, so that it rewrites the object using a `java.io.ObjectOutputStream`:

```
ObjectInputStream ois = new ObjectInputStream(...);
ObjectOutputStream oos = new ObjectOutputStream(...);
Object in = ois.readObject();
oos.writeObject(in);
oos.flush();
```

2. If the JMX MBean interoperability issues apply to you:
  - a. Apply interim fix PQ80354 to allow Version 5.0.2 servers to create `ThreadPool` MBeans that are compatible with subsequent versions.
  - b. Change the `mbeanIdentifier` or name fields in all affected scripts and program source to use the new MBean name format rules, if any scripts or programs look up `ThreadPool` MBeans for a `WorkManager`.

## Serialized Asynchronous beans interoperability

Asynchronous beans support taking snapshots of Java 2 Platform Enterprise Edition (J2EE) contextual information from the current servlet or Enterprise Java Beans (EJB) method. This information can include security information, and can be stored using the `WorkManager.create(Work r)` method to get a serializable `WorkWithExecutionContext` object.

If this `WorkWithExecutionContext` object is serialized and stored with customer data, the following information must be reviewed to determine if any steps must be taken to avoid problems.

### Affected products

Both the scheduler and process choreographer services that are included with the WebSphere Application Server Enterprise Edition Version 5 are affected by the problems described in this document. Review the respective sections of each service in the Version 5.0.1 Release Notes, or in one of the following interim fix options for further information:

- PQ72885 - Scheduler Version 5 Interoperability Issues
- PQ72886 - Process Choreographer Version 5 Interoperability Issues

## Asynchronous beans security errors

The asynchronous beans `WorkWithExecutionContext` object created with the 5.0 version of asynchronous beans stores security information incorrectly, which can cause deserialization errors and ASYN9999E errors to appear in the WebSphere Application Server log files. This happens if the interoperating versions of WebSphere Application Server have different implementations of Java Authentication and Authorization Service (JAAS). This error most likely occurs when interoperating between two different platforms, but may occur on the same platform if the JAAS implementation is updated on any of the servers.

Security information is stored with the `WorkWithExecutionContext` object only when the following conditions are true:

- The `WorkManager` resource used to create the `WorkWithExecutionContext` object has the *security* context policy attribute enabled.
- Global Security is enabled on the WebSphere Application Server.

If either of the previous conditions are false, then there should be no interoperability issues.

If the JAAS implementation JAR files have already been updated or changed such that all servers are already experiencing ASYN9999E errors, then apply the original version of the JAAS implementation JAR files that were used to serialize the `WorkWithExecutionContext` data, or follow the Recovery and interoperability steps in the article, *Interoperating with asynchronous beans*, on each platform that is having the problem to ensure all data is reserialized to the appropriate version.

## Asynchronous beans interoperability errors

To avoid further problems interoperating between releases or platforms of asynchronous beans, the serialization mechanisms within asynchronous beans have been updated such so that a 5.0 version of the asynchronous beans object, `WorkWithExecutionContext`, is not able to deserialize a `WorkWithExecutionContext` object that is serialized with a Version 5.0.1 release or later.

## Interoperability and recovery

If any of the conditions described in the *Asynchronous beans security errors* section of this document are true, then all data with the serialized Version 5 `WorkWithExecutionContext` object must be reserialized with the updated format.

Regardless of whether any of the conditions described in the "Asynchronous beans security errors" section of this document are true, apply interim fix, PQ72742, to all WebSphere Application Server Enterprise 5 servers that expect to interoperate with Version 5.0.1 and later servers or expect to interoperate with other Version 5 servers that have PQ72742 applied.

Servers with interim fix, PQ72742, or Version 5.0.1 applied are able to read `WorkWithExecutionContext` data serialized with Version 5, but servers at the Version 5 level are not able to read data serialized in the PQ72742 or Version 5.0.1 format. If this problem occurs, errors such as the following appear: ASYN9999E: Unexpected Exception Occurred: `java.io.OptionalDataException`.

For more information on completing the steps for recovery and interoperability, see the article, *Interoperating with asynchronous beans*.

## Internationalization interoperability issues

There are internationalization interoperability issues with the Asynchronous Beans `WorkWithExecutionContext` object. Read this section and the *Internationalization Interoperability* section of the Version 5.0.1 Release Notes for details on how to determine if this issue affects your work environment, and if so, how to resolve the problems.

Affected customers are those who store Internationalization service context information with the `WorkWithExecutionContext` object. Internationalization information is stored with the `WorkWithExecutionContext` object only when the following conditions are true:

- The `WorkManager` resource used to create the `WorkWithExecutionContext` object has the **com.ibm.ws.i18n** context policy attribute enabled.
- The Internationalization service is enabled on the WebSphere Application Server.

If either of the previous conditions are false on either the application server that *serializes* the `WorkWithExecutionContext` or the application server that *deserializes* the `WorkWithExecutionContext`, no interoperability issue exists.

If both of the previous conditions are true on either of the application servers, then follow the instructions in the Internationalization Interoperability section of the Version 5.0.1 Release Notes or interim fix PQ73371.

## Java Management Extension MBean interoperability

WebSphere Application Server Enterprise Edition Asynchronous Beans service creates several MBeans. Two of these MBeans control the thread pools associated with each configured `WorkManager` object -- the `WorkManager` thread pool and the `AlarmManager` thread pool. Both of these pools can be modified at run time by using a Java Management Extension (JMX) MBean. Each pool has an MBean that can be looked up independently and are named: "`WorkManager:<Workmanager_name>`" and "`<Workmanager_name>:Alarm Pool`" respectively, where, `<WorkManager_name>` is the name field of the configured `WorkManager`.

Because the name for the MBean is not a legal JMX 1.2 `ObjectName`, `AsynchBeans` and the `ThreadPool` manager have been updated to automatically convert all illegal characters to periods ("."). For example, if a `WorkManager` name is **Central WorkManager: Finance,Admin**, the actual MBean name and `mbeanIdentifier` becomes **Central WorkManager. Finance.Admin**.

When looking up a `WorkManager ThreadPool` MBean, all queries for these objects change from:

```
wsadmin>$AdminControl queryNames "WebSphere:*,type=ThreadPool,name=WorkManager:Central WorkManager: Finance,Admin"
```

or

```
wsadmin>$AdminControl queryNames "WebSphere:*,mbeanIdentifier=WorkManager:Central WorkManager: Finance,Admin"
```

to

```
wsadmin>$AdminControl queryNames "WebSphere:*,type=ThreadPool,name=WorkManager.Central WorkManager. Finance.Admin"
```

or

```
wsadmin>$AdminControl queryNames "WebSphere:*,mbeanIdentifier=WorkManager.Central WorkManager. Finance.Admin"
```

---

## Chapter 19. Using object pools

An object pool helps an application avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports pooling, while waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity (JDBC) connections or Java Messaging Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To use an object pool, the product administrator must define an *object pool manager* using the administrative console. Multiple object pool managers can be created in an Application Server cell.

**Note:** The Object pool manager service is only supported from within the EJB container or Web container. Looking up and using a configured object pool manager from a Java 2 Platform Enterprise Edition (J2EE) application client container is not supported.

1. Start the administrative console.
2. Click **Resources > Object Pools**.
3. Define the name of the object pool manager. This name can be up to 30 ASCII characters long.
4. Assign the object pool manager a Java Naming and Directory Interface (JNDI) name.
5. Provide a description of this object pool manager.
6. Categorize the object pool manager.

After completing this steps, applications can find the object pool manager by doing a JNDI lookup using the specified JNDI name.

The following code illustrates how an application can find an object pool manager object:

```
InitialContext ic = new InitialContext();
ObjectPoolManager opm = (ObjectPoolManager)ic.lookup("java:comp/env/pool");
```

When the application has an ObjectPoolManager, it can cache an object pool for classes of the types it wants to use. The following is an example:

```
ObjectPool arrayListPool = null;
ObjectPool vectorPool = null;
try
{
 arrayListPool = opm.getPool(ArrayList.class);
 vectorPool = opm.getPool(Vector.class);
}
catch(InstantiationException e)
{
 // problem creating pool
}
catch(IllegalAccessException e)
{
 // problem creating pool
}
```

When the application has the pools, the application can use them as in the following example:

```
ArrayList list = null;
try
{
 list = (ArrayList)arrayListPool.getObject();
 list.clear(); // just in case
 for(int i = 0; i < 10; ++i)
 {
 list.add("" + i);
 }
}
```

```

// do what ever we need with the ArrayList
}
finally
{
 if(list != null) arrayListPool.returnObject(list);
}

```

This example presents the basic pattern for using object pooling. If the application does not return the object, then the only adverse effect is that the object cannot be reused.

---

## Object pool managers

Object pool managers control the reuse of application objects and Developer Kit objects, such as Vectors and HashMaps.

Multiple object pool managers can be created in an Application Server cell. Each object pool manager has a unique cell-wide Java Naming and Directory Interface (JNDI) name. Applications can find a specific object pool manager by doing a JNDI lookup using the specific JNDI name.

The Object pool manager and its associated objects implement the following interfaces:

```

public interface ObjectPoolManager
{
 ObjectPool getPool(Class aClass)
 throws InstantiationException, IllegalAccessException;
 ObjectPool createFastPool(Class aClass)
 throws InstantiationException, IllegalAccessException;
}

public interface ObjectPool
{
 Object getObject();
 void returnObject(Object o);
}

```

Each object pool manager can be used to pool any Java object with the following characteristics:

- The object must be a public class with a public default constructor.
- Each pooled object class must have its own object pool.
- An application gets an object pool for a specific object using either the `ObjectPoolManager.getPool()` method or the `ObjectPoolManager.createFastPool()` method. The difference between these methods is that the `getPool()` method returns a pool that can be shared across multiple threads. The `createFastPool()` method returns a pool that can only be used by a single thread.

If in a Java virtual machine (JVM), the `getPool()` method is called multiple times for a single class, the same pool is returned. A new pool is returned for each call when the `createFastPool()` method is called. Basically, the `getPool()` method returns a pool that is thread-synchronized.

The pool for use by multiple threads is slightly slower than a fast pool because of the need to handle thread synchronization. However, extreme care must be taken when using a fast pool. Consider the following interface:

```

public interface PoolableObject
{
 void init();
 void returned();
}

```

If the objects placed in the pool implement this interface and the `ObjectPool.getObject()` method is called, the object returned has the `init()` method called on it. When the `ObjectPool.returnObject()` method is called, the returned method is called on the object before it is returned to the object pool. Using this method objects can be pre-initialized or cleaned up.

It is not always possible for an object to implement `PoolableObject`. For example, an application might want to pool `ArrayList` objects. The `ArrayList` object needs clearing each time the application reuses it. The application might extend the `ArrayList` object and have the `ArrayList` object implement a poolable object. For example, consider the following:

```
public class PooledArrayList extends ArrayList implements PoolableObject
{
 public PooledArrayList()
 {
 }

 public void init() {
 }

 public void returned()
 {
 clear();
 }
}
```

If the application uses this object, in place of a true `ArrayList` object, the `ArrayList` object is cleared automatically when it is returned to the pool.

Clearing an `ArrayList` object simply marks it as empty and the array backing the `ArrayList` object is not freed. Therefore, as the application reuses the `ArrayList`, the backing array expands until it is big enough for all of the application requirements. When this point is reached, the application stops allocating and copying new backing arrays and achieves the best performance.

It might not be possible or desirable to use the previous procedure. An alternative is to implement a custom object pool and register this pool with the object pool manager as the pool to use for classes of that type. The class is registered by the WebSphere administrator when the object pool manager is defined in the cell. Take care that these classes are packaged in Java Archive (JAR) files available on all of the nodes in the cell where they might be used.

---

## Object pool manager collection

Use this page to manage object pool managers.

To view this administrative console page, click **Resources > Object Pools**.

### Name

The name by which the object pool manager is known for administrative purposes.

<b>Data type</b>	String
<b>Range</b>	1 through 30 ASCII characters

### JNDI Name

The Java Naming and Directory Interface (JNDI) name for the object pool manager.

<b>Data type</b>	String
------------------	--------

## Description

A description of the object pool manager.

**Data type** String

## Category

A category string used to classify or group this object pool manager.

**Data type** String

## Object pool manager settings

Use this page to modify object pool manager settings.

To view this administrative console page, click **Resources > Object Pools > *objectpoolmanager\_name***

### Name

The name by which the object pool manager is known for administrative purposes.

**Data type** String  
**Range** 1 through 30 ASCII characters

### JNDI Name

The Java Naming and Directory Interface (JNDI) name for the object pool manager.

**Data type** String

### Description

A description of the object pool manager.

**Data type** String

### Category

A category string used to classify or to group this object pool manager.

**Data type** String

## Custom object pool collection

Use this page to manage object pools.

To view this administrative console page, click **Resources > Object Pools > *objectpoolmanager\_name* > Object Pools**.

### ***Pool Class Name:***

The fully qualified class name of the objects that are stored in the object pool.

**Data type** String

### ***Pool Impl Class Name:***

The fully qualified class name of the CustomObjectPool implementation class for this object pool.

**Data type** String

### **Custom object pool settings:**

Use this page to modify custom object pool settings.

An object pool manages a pool of arbitrary objects.

To view this administrative console page, click **Resources > Object Pools > objectpoolmanager\_name > Object Pools > objectpool\_name**.

#### *Pool Class Name:*

The fully qualified class name of the objects that are stored in the object pool.

**Data type** String

#### *Pool Impl Class Name:*

The fully qualified class name of the CustomObjectPool implementation class for this object pool.

**Data type** String

---

## **Object pool service settings**

Use this page to enable or disable the object pool service, which manages object pool resources used by the server.

To view this administrative console page, click **Servers > Application Servers > server\_name > Object Pool Service**.

## **Startup**

Specifies whether the server attempts to start the object pool service.

**Default**  
**Range**

Selected  
**Selected**

When the application server starts, it attempts to start the object pool service automatically.

**Cleared**

The server does not try to start the object pool service. If object pool resources are used on this server, then the system administrator must start the object pool service manually or select this property, and then restart the server.

---

## **Object pools: Resources for learning**

Use the following links to find relevant supplemental information about object pools. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links

are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Furthermore, these links provide guidance on using object pools. Since object pooling is a general topic and the WebSphere Application Server product implementation is only one way to use it, you must understand when object pooling is necessary. These articles help you make that decision.

### **Programming model and decisions**

- Java performance programming, Part 1: Smart object-management saves the day
- Build your own ObjectPool in Java to boost app speed
- Improve the robustness and performance of your ObjectPool
- Java Tip 78: Recycle broken objects in resource pools

---

## **Object pool performance considerations**

Object pools are designed to pool and reuse instances of objects that are both complex and frequently instantiated during run time. To use an object pool, you must define an object pool manager using the administrative console. The object pool manager is available in the Java Naming Directory Interface (JNDI) and can provide object pool instances for any class implementing the PoolableObject interface. The PoolableObject interface defines methods for releasing resources when an object is to be pooled and initializes the internal state when an object is retrieved from the pool. The objects are obtained by methods available on the ObjectPool object.

You should use an object pool when objects are needed repeatedly that are expensive to instantiate. This expense can be gauged through the complexity of the object, as well as the size of the data inside the object. Another consideration is the viability of efficiently cleaning out an object. If the members of an object are large or complex, but cannot be quickly restored to defaults for future use, pooling these objects proves effective. The key to seeing a benefit from using an object pool is to make sure that the total time to retrieve the object from the pool, initialize the internal members, and clear the object for reuse and return it to the pool, is less than the time it takes to instantiate the object, initialize internal members, and subsequently clean up the object when heap space runs out. Retrieving an object from the pool and returning it to the pool have been streamlined as much as possible, but the tasks of member initialization and clearing must fall to the developer to implement and evaluate.

An important issue to consider is when implementing an object pool thread contention. There are two types of object pools to choose from: one is thread-safe and other is not. The latter is not synchronized, allowing for faster access and reduction in contention, but is not recommended in a multithreaded environment. If there is a chance that two threads are operating on a pool at the same time, use the thread-safe object pool. However, be sure to consider how many threads are accessing the pool at the same time and how frequently. If it is more than a few on a regular basis, the single point of contention created in this scenario can sometimes cancel out all benefits with an otherwise well conceived poolable object. A thread-safe pool accessed by multiple threads creates a bigger pool of ready object instances, but lining up to retrieve these instances through synchronization can decrease performance.

When attempting to maximize performance with an object pool, cache the ObjectPoolManager instance wherever it is accessed. By looking up an object once and keeping a reference to it for the future, you can reduce the amount of time spent looking it up in JNDI, which, because of its remote nature, tends to be costly.

Another performance consideration is in the implementation of a poolable returned() method object. Preserve the member to be cleared, if it is needed for next use. This reduces even more clean up and avoids the re-initialization of this member upon reuse. Also, if a member has a more efficient way to clear its state, other than simply destroying it, try to utilize the poolable object returned() method. For example, calling the clear() method on a member Vector is much more efficient than destroying the Vector and instantiating a new one upon reuse.

Using an object pool significantly reduces the amount of memory that applications use and the amount of clean up. Through an intelligent choice of pooled objects and pool types, performance improvements can be achieved by avoiding unnecessary object allocation and clean up.

---

## Chapter 20. Using startup beans

A startup bean is a stateful session bean that is loaded when an application starts. Startup beans enable Java 2 Platform Enterprise Edition (J2EE) applications to execute business logic automatically, whenever an application starts or stops normally.

Startup beans are especially useful when used in with asynchronous bean features. For example, a startup bean might create an alarm object that uses Java Messaging Service (JMS) to periodically publish heartbeat messages on a well-known topic. This enables clients or other server applications to determine whether the application is available.

1. Use the home interface, `com.ibm.websphere.startupservice.AppStartUpHome`, to designate a bean as a startup bean
2. Use the remote interface, `com.ibm.websphere.startupservice.AppStartUp`, to define a `start()` and `stop()` method on the bean.

The startup bean `start()` method is called when the application starts. The startup bean implements any business logic that must run at application start time.

The `start()` method returns a boolean. `True` indicates normal application startup and `false` indicates that the application start process should be aborted. The `start()` and `stop()` methods should not use a `TX_MANDATORY` attribute because there never is a transaction on the thread when the `start()` or `stop()` methods are invoked. Any other `TX_*` attribute can be used. If `TX_MANDATORY` is used, an exception is logged (need a transaction for mandatory) and the application does not start.

The startup bean `stop()` method is called when the application stops and implements any business logic that needs to run. Any exception thrown by a `stop()` method is ignored, but logged to trace.

The `start()` and `stop()` methods on the remote interface use **Run-As** mode. **Run-As** mode specifies the credential information to be used by the security service to determine the permissions that a principal has on various resources. If security is on, the **Run-As** mode needs to be defined on all of the methods called. The identity of the bean without this setting is undefined.

There are no restrictions on what code the `start()` and `stop()` methods can run, since the full Enterprise Application Server programming model is available to these methods.

3. Use an *optional* environment property integer, `wasStartupPriority`, to specify the start order of multiple startup beans in the same Java Archive (JAR) file. If the environment property is found and is the wrong type, application startup is aborted. If no priority value is specified, a default priority of 0 is used. It is recommended that you specify the priority property. Beans that have specified a priority are sorted using this property. Beans with numerically lower priorities are executed first. Beans that have the same priority are executed in an undefined order. All priorities must be positive integers. The priority is used to order beans within an EJB JAR file. The order in which this process happens is applied to different EJB JAR files in a single EAR file is undefined. Beans are stopped in the opposite order to their start priority.

---

## Chapter 21. Using the scheduler service

The scheduler service enables tasks to execute at a requested time. You can schedule the following tasks:

- Invoke a session bean method.
- Send a Java Message Service (JMS) message on a queue or topic.

The scheduler service performs the task, repeating as necessary, according to the metadata for that task.

1. Manage the scheduler service. This article includes instructions for creating and configuring a database for the scheduler, configuring a scheduler instance, and enabling or disabling the scheduler service (the service is enabled by default).
2. Develop and schedule tasks. This article includes instructions for developing various types of tasks, receiving notifications from a scheduler, submitting tasks to a scheduler, and managing tasks.

**Note:** Creating and manipulating scheduled tasks through the Scheduler interface is only supported from within the Enterprise Java Beans (EJB) container or Web container (EJB containers or servlets). Looking up and using a configured scheduler from a Java 2 Platform Enterprise Edition (J2EE) application client container is not supported.

3. Interoperate with the scheduler service. This article explains how to manage the Scheduler service in a clustered environment with mixed WebSphere Application Server product versions and mixed platforms.

---

### Managing the scheduler service

Schedulers are configured using the administrative console and are available to all servers on which the scheduler service is enabled.

1. Create the database for a scheduler.
2. Configure a scheduler.
3. Enable the scheduler service.

The scheduler service is enabled by default.

### Creating the database for a scheduler

Your database system must be installed and available.

It is important to realize that the scheduler uses this database for storing tasks and then executing them. The performance of the scheduler is ultimately limited by the performance of the database. If you need more tasks per second, you can run the scheduler daemons on larger systems or you can use clusters for the session beans used by the tasks. Eventually, however, the task database becomes saturated and you then need a larger or better-tuned database system.

Multiple applications can share a scheduler database. This sharing can lower the cost of administering the scheduler database.

The scheduler requires a database, a Java Database Connectivity (JDBC) provider and a data source.

1. Create the database according to the description for your database system:
  - Creating a Cloudscape database for scheduler.
  - Creating a DB2 database for scheduler.
  - Creating a DB2 database for z/OS for scheduler.
  - Creating an Informix database for scheduler.
  - Creating a Microsoft SQL Server database for scheduler.

- Creating an Oracle database for scheduler.
  - Creating a Sybase 12.0 database for scheduler.
2. If the database is not on the same machine as your IBM WebSphere Application Server, verify that you can access the database from your application server machine.
  3. Configure your JDBC provider and data source. For details, see the topic "Creating and configuring a JDBC provider and data source" in the Information Center.

## Creating a Cloudscape database for scheduler

Cloudscape is a database system implemented in Java code. It is delivered with WebSphere Application Server as three Java Archive (JAR) files. The Cloudscape license that comes with WebSphere Application Server is only for development and testing purposes and not for production purposes.

1. Open a command-line window.
2. Make sure that you have administrator rights for the database system.
3. If you want to use an existing database, skip to step 5. Make sure that the database supports Unicode (UTF-8). Otherwise, it cannot store all characters that can be handled in Java code, and you can run into code page conversion problems when a client uses an incompatible code page.
4. Use the Cloudview utility supplied with the Cloudscape system to create the database, scheddb. Cloudscape supports only one local connection. If WebSphere Application Server is running and accessing a Cloudscape database, then attempts to open a second connection to the database from the command line are rejected.
5. Create the schema.
  - a. Using a text editor, edit the script %WAS\_HOME%\Scheduler\createSchemaCloudscape.ddl according to the instruction at the top of the file.
  - b. Enter one of the following commands (shown on multiple lines for publication): On Windows:

```
%install_root%\java\jre\bin\java -Djava.ext.dirs=%install_root%/lib
-Dij.protocol=jdbc:db2j: -Dij.database=scheddb com.ibm.db2j.tools.ij
%install_root%\Scheduler\createSchemaCloudscape.ddl
```

On UNIX:

```
%install_root%/java/jre/bin/java -Djava.ext.dirs=%WAS_HOME%/lib
-Dij.protocol=jdbc:db2j: -Dij.database=scheddb com.ibm.db2j.tools.ij
%WAS_HOME%/Scheduler/createSchemaCloudscape.ddl
```

The Cloudscape database for the scheduler service exists.

## Creating a DB2 database for scheduler

1. Open a DB2 command-line window.
2. Make sure that you have administrator rights for the database system.
3. If you want to use an existing database, skip to Step 5.

**Note:** Verify that the database supports Unicode (UTF-8). Otherwise, it cannot store all the characters that can be handled in Java code, and you could run into codepage conversion problems when a client uses an incompatible codepage.

To avoid deadlocks, be sure that the DB2 isolation level is set to "read stability". If necessary, enter the command db2set DB2\_RR\_TO\_RS=YES then restart the DB2 instance to activate the change.

4. In the DB2 command line processor, enter this command to create the database:

```
db2 CREATE DATABASE scheddb USING CODESET UTF-8 TERRITORY en-us
```

A DB2 database named scheddb has been created.

5. Create the table space and schema.

- a. Analyze the results of your experiences during development and system testing. The size of your database depends on many factors. If possible, distribute tablespace containers across different logical disks, and implement an appropriate security policy. Consider the performance implications of your choices for buffer pools and log file settings.
- b. Using a text editor, edit the following scripts according to the instruction at the top of each file: %WAS\_HOME%\Scheduler\createTablespaceDB2.dd1, %WAS\_HOME%\Scheduler\createSchemaDB2.dd1, %WAS\_HOME%\Scheduler\dropSchemaDB2.dd1, and %WAS\_HOME%\Scheduler\dropTablespaceDB2.dd1.
- c. Make sure that you are attached to the correct instance. Check the environment variable DB2INSTANCE.
- d. To connect to a database named scheddb, enter the command:

```
db2 connect to scheddb
```

- e. To create the table space, enter the command:

```
db2 -tf createTablespaceDB2.dd1
```

Make sure that the script's output contains no errors. If there were any errors, you can drop the table space using the script dropTablespaceDB2.dd1.

- f. To create the schema (tables and indices), in the DB2 command line processor, enter the command:

```
db2 -tf createSchemaDB2.dd1
```

Make sure that the script's output contains no errors. If there were any errors, you can use the dropSchemaDB2.dd1 file to drop the schema.

The DB2 database for the scheduler exists.

## Creating a DB2 for z/OS database for scheduler

This topic describes how to create a DB2 for z/OS database for the scheduler and how to verify that it is reachable from the application server machine.

1. You must have already installed WebSphere Application Server WebSphere Business Integration Server Foundation on a UNIX or Windows machine.
2. On the z/OS machine that hosts the database:
  - a. Log on to the native z/OS environment.
  - b. If multiple DB2 systems are installed, then decide which subsystem you want to use.
  - c. Make a note of the Internet Protocol (IP) port to which the DB2 subsystem is listening.
  - d. Using the DB2 administration menu, create a new database named SCHEDDB, for example. Note the database name.
  - e. Create a storage group and note the name.
  - f. Decide which user ID is used to connect to the database from the remote machine running the product. Normally, for security reasons, this user ID is not the one you used to create the database.
  - g. Grant the user ID the rights to access the database and storage group. The user ID must also have permission to create new tables for the database.
3. On the server machine:
  - a. Make sure that you have DB2 Connect Gateway (Version 8.1 fix pack 3 or higher) installed. This component is part of the DB2 UDB ESE package, however, you can also install it separately.
  - b. Catalog the remote database using the following commands, either in a script or in a DB2 command line window:

```
catalog tcpip node zosnode remote hostname server IP_port ostype mvs;
catalog database subsystem as subsystem at node zosnode authentication dcs;
catalog dcs database subsystem as subsystem parms ',,INTERRUPT_ENABLED'
```

An important difference exists between DB2 UDB and DB2 for z/OS. DB2 UDB does not have the concept of a subsystem, but DB2 for z/OS does have subsystems. To avoid confusion between Database name and Subsystem name, it is important to understand that because DB2 for z/OS runs in a subsystem, the catalog node and catalog database commands must identify the appropriate subsystem. On DB2 UDB, the subsystem name is not a known concept, and the database name to which it connects is actually the name of the DB2 for z/OS subsystem.

- c. Verify that you can establish a connection to the remote subsystem by entering the following command: `db2 connect to subsystem user userid using password`
- d. Change to the *Scheduler* subdirectory in the application server installation root directory.
- e. Edit the `createTablespaceDB2ZOS.dd1` script. Replace `@STG@` with the storage group name. Replace `@DBNAME@` with the database name (not the subsystem name), and replace `@SCHED_TABLESPACE@` with the name of a valid tablespace.
- f. Run your customized version of `createTablespaceDB2ZOS.dd1`, as described in the header of the script. If this script does not work, or if you want to remove the tablespace, edit and run the `dropTablespaceDB2ZOS.dd1` script.
- g. Edit the `createSchemaDB2ZOS.dd1` script. Replace `@STG@` with the storage group name. Replace `@DBNAME@` with the database name (not the subsystem name). Replace `@TABLE_PREFIX@` with the Table Prefix in the configured scheduler resource, and replace `@SCHED_TABLESPACE@` with a valid tablespace that was created by the `createTablespaceDB2ZOS.dd1` script.
- h. Run your customized version of the `createSchemaDB2ZOS.dd1` script, as described in the header of the script. If this script does not work, or if you want to remove the tables and views, use `dropSchemaDB2ZOS.dd1` to drop the schema.
- i. To avoid deadlocks, verify that the `DB2_RR_TO_RS` DB2 flag is set to **YES**. If necessary, restart the DB2 instance to activate the change.

The DB2 for z/OS database for the scheduler service is created.

## Creating an Informix database for scheduler

1. Open a command-line window.
2. Make sure that you have administrator rights for the database system.
3. If you want to use an existing database, skip to step 5.

**Note:** Make sure that the database supports Unicode (UTF-8) . Otherwise, it cannot store all characters that can be handled in the Java code, and you could run into codepage conversion problems when a client uses an incompatible codepage.

4. If you want to create a new database named `scheddb`, enter the command:

```
dbaccess CREATE DATABASE scheddb with log
```

5. Create the schema.
  - a. Using a text editor, edit the script `%WAS_HOME%\Scheduler\createSchemaInformix.sql` according to the instruction at the top of the file.
  - b. Enter the command:

```
dbaccess scheddb createSchemaInformix.sql
```

The Informix database for scheduler exists.

## Creating a Microsoft SQL Server database for scheduler

1. Open a command-line window.

2. Change to the directory where the configuration scripts for scheduler are located. This is the Scheduler subdirectory of the IBM WebSphere Application Server installation directory. On Windows, enter:

```
cd %WAS_HOME%\Scheduler
```

On UNIX, enter:

```
cd $WAS_HOME/Scheduler
```

3. Using a text editor, edit the schema creation script (createSchemaMSSQL.sql for SQL Server 2000 and createSchemaMSSQL7.sql for SQL Server 7), according to the instructions at the beginning of the file.
4. If you want to use an existing database, skip to step 6.

**Note:** Make sure that the database supports Unicode (UTF-8) . Otherwise, it cannot store all characters that can be handled in the Java code, and you could run into codepage conversion problems when a client uses an incompatible codepage.

5. If you want to create a new database named scheddb:
  - a. Make sure that you are using a user ID that has administrator rights for the database system.
  - b. In the **Enterprise Manager**, expand a server group, then expand a server.
  - c. Right-click **Databases**, then click **New Database**.
  - d. Type the name scheddb.
  - e. Modify any default values, as desired, then save.

A Microsoft SQL Server database named scheddb is created.

6. To create the schema:
  - a. Make sure that you have administrator rights for the database system. The user ID you use to create the schema must be the one that you tell WebSphere Application Server to use when accessing the database.
  - b. Run the script to create the schema (tables and views):

```
isql -S <serverName> -U<userid> -P<password> -D<databaseName> -i <script name>
```

The Microsoft SQL Server database for scheduler exists.

## Creating an Oracle database for scheduler

1. Open a command-line window.
2. Make sure that you have administrator rights for the database system.
3. If you want to use an existing database, skip to step 5.

**Note:** Make sure that the database supports Unicode (UTF-8). Otherwise, it cannot store all characters that can be handled in the Java code, and you could run into codepage conversion problems when a client uses an incompatible codepage.

4. Use the Database Configuration Assistant to create a database named scheddb. Make sure that you select the JServer option for the database. It is recommended to use a Unicode codepage when creating the database. The text data you pass to the APIs must be compatible with the selected codepage.
5. Create the table space and schema.
  - a. Using a text editor, edit the scripts %WAS\_HOME%\Scheduler\createTablespaceOracle.ddl and %WAS\_HOME%\Scheduler\createSchemaOracle.ddl according to the instruction at the top of the files.
  - b. If you do not want the schema to be created in the default instance, set the environment variable ORACLE\_SID
  - c. To create the table space, run the script createTablespaceOracle.ddl. For test purposes you can use the same location for all table spaces and pass the path as a command line argument to the

script, for example, on Windows, user ID scheduser, password schedpwd, database name scheddb, and table space path d:\mydb\ts, enter the command:

```
sqlplus scheduser/schedpwd@scheddb @createTablespaceOracle.ddl d:\mydb\ts
```

If you get any errors creating the table space, you can use dropTablespaceOracle.ddl to drop the table space.

- d. To create the schema, run the script createSchemaOracle.ddl. For example, on Windows systems, enter:

```
sqlplus scheduser/schedpwd@scheddb @createSchemaOracle.ddl
```

If you get any errors creating the schema (tables and views), you can use dropSchemaOracle.ddl to drop the schema.

The Oracle database for scheduler exists.

## Creating a Sybase database for scheduler

1. Open a command-line window.
2. Make sure that you have administrator rights for the database system.
3. Make sure that you have the DTM option for Sybase ASE installed.
4. If you want to use an existing database, skip to step 6.

**Note:** Make sure that the database supports Unicode (UTF-8). Otherwise, it cannot store all characters that can be handled in the Java code, and you could run into codepage conversion problems when a client uses an incompatible codepage.

5. Use the Sybase isql utility to create a database named scheddb. See your Sybase product documentation for details.
6. Create the schema:
  - a. Using a text editor, edit the following script <install\_root>\Scheduler\createSchemaSybase12.ddl according to the instruction at the top of the file.
  - b. Enter the command:

```
isql -S <serverName> -U<userid> -P<password> -D scheddb -i createSchemaSybase12.ddl
```

The Sybase database for the scheduler exists.

## Configuring a scheduler

Before your application can make use of the scheduler service, you need to configure a scheduler instance using the administrative console. Conceptually, a scheduler is similar to a datasource: you specify various configuration attributes, including a JNDI name where the instance will be bound. Once defined, an application using the scheduler API can look up the scheduler object and call various methods to manage tasks.

1. Start the administrative console.
2. Select **Resources > Scheduler Configurations**.
3. Click **New**.
4. Specify configuration settings. Fields marked with an asterisk (\*) are required. The settings are described in detail in the topic Scheduler configuration settings.

## Scheduler configuration collection

Use this page to manage scheduler configurations.

To view this administrative console page, click **Resources > Scheduler Configurations** .

### **Name:**

The name by which this scheduler is known for administrative purposes.

**Data type** String

### **JNDI Name:**

The JNDI name for the scheduler.

The JNDI name specifies where this scheduler instance is bound in the namespace. Clients can look this name up directly, although the use of resource references is recommended.

**Data type** String

### **Description:**

A description of this scheduler for administrative purposes.

**Data type** String

### **Category:**

A string that can be used to classify or group this scheduler.

**Data type** String

### **Datasource JNDI Name:**

Datasource where persistent tasks will be stored.

Any datasource available in the name space can be used with a scheduler. Multiple schedulers can share a single datasource while using different tables by specifying a table prefix.

**Data type** String

### **Datasource Alias:**

Alias to a user name and password used to access the datasource.

**Data type** String

### **Table Prefix:**

String prepended to the table name TASK.

Multiple independent schedulers can share the same database if each instance specifies a different prefix string.

**Data type** String

***Poll Interval:***

The interval at which the scheduler daemon polls the database. Each scheduled, repeating task's minimum repeat interval will be equal to this value regardless of what is specified on the task.

Each poll operation can be expensive. If the interval is extremely small and there are many scheduled tasks, polling can consume a large portion of system resources.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	30
<b>Range</b>	Any positive long integer

***Work Manager:***

Specifies the work manager used by this scheduler.

The Work Manager is a server object that serves as a logical thread pool for the scheduler. Each repeating task that is created using this scheduler will use the "Number Of Alarm Threads" specified in the Work Manager which will affect the number tasks that can run concurrently. Use the Work Manager's "Service Names" property to limit the amount of context information that is propagated to the task when it executes.

When a task fires, the task is run in the Work Manager associated with the scheduler instance. Configuring a scheduler with a specific Work Manager enables you to control how many tasks are actively running at a given time.

***Scheduler configuration settings:***

Use this page to modify scheduler settings.

To view this administrative console page, click **Resources > Scheduler Configurations > scheduler\_name**.

*Name:*

The name by which this scheduler is known for administrative purposes.

**Data type** String

*JNDI Name:*

The JNDI name for the scheduler.

The JNDI name specifies where this scheduler instance is bound in the namespace. Clients can look this name up directly, although the use of resource references is recommended.

**Data type** String

*Description:*

A description of this scheduler for administrative purposes.

**Data type** String

*Category:*

A string that can be used to classify or group this scheduler.

**Data type** String

*Datasource JNDI Name:*

Datasource where persistent tasks will be stored.

Any datasource available in the name space can be used with a scheduler. Multiple schedulers can share a single datasource while using different tables by specifying a table prefix.

**Data type** String

*Datasource Alias:*

Alias to a user name and password used to access the datasource.

**Data type** String

*Table Prefix:*

String prepended to the table name TASK.

Multiple independent schedulers can share the same database if each instance specifies a different prefix string.

**Data type** String

*Poll Interval:*

The interval at which the scheduler daemon polls the database. Each scheduled, repeating task's minimum repeat interval will be equal to this value regardless of what is specified on the task.

Each poll operation can be expensive. If the interval is extremely small and there are many scheduled tasks, polling can consume a large portion of system resources.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	30
<b>Range</b>	Any positive long integer

*Work Manager:*

Specifies the work manager used by this scheduler.

The Work Manager is a server object that serves as a logical thread pool for the scheduler. Each repeating task that is created using this scheduler will use the "Number Of Alarm Threads" specified in the

Work Manager which will affect the number tasks that can run concurrently. Use the Work Manager's "Service Names" property to limit the amount of context information that is propagated to the task when it executes.

When a task fires, the task is run in the Work Manager associated with the scheduler instance. Configuring a scheduler with a specific Work Manager enables you to control how many tasks are actively running at a given time.

## Creating a scheduler resource reference

When a scheduler has been defined in the server configuration, the object instance is bound into the global name space under the configured JNDI name. A resource reference can be used to avoid hardcoding this JNDI name into your application.

You can alternatively create a scheduler resource reference by editing the XML directly. A scheduler resource reference is a (Java 2 Platform Enterprise Edition (J2EE) compliant resource that uses the class `com.ibm.websphere.scheduler.Scheduler` as the object type. For information regarding the XML file format, see the J2EE Specification.

1. Start the Application Assembly Tool Assembly Toolkit.
2. Select your application.
3. In the left-hand panel, right-click on **Resource References** and select **New**.
4. On the **General** tab, complete the following fields:
  - Name** Specify the name suffix. For example, if the scheduler name is *MyScheduler*, the reference JNDI name is **`java:comp/env/MyScheduler`**
  - Type** From the drop-down list select **`com.ibm.websphere.scheduler.Scheduler`**
5. (Optional) You can also specify the global JNDI name to which this resource reference is bound by entering the JNDI name on the **Bindings** tab.

## Scheduler daemon

A scheduler daemon is a background thread that searches for events in the persistent store.

A scheduler daemon is started for each scheduler defined on each server. If "Scheduler 1" is configured on server1, then there will only be one scheduler daemon running on server1 unless it is cloned. If "Scheduler 1" is defined at the node scope level, then the scheduler will run on each server within that node.

The poll interval determines the frequency at which the persistent store is queried. By default, this value is set to 30 seconds. When a task is found that is scheduled to fire within the current poll interval, an alarm is set. The task then runs as close to this time as possible using an alarm thread from the scheduler's associated work manager. Thus, the number of alarm threads configured on the work manager determines how many concurrent tasks are executed. No tasks are lost. If we reach this limit, then new tasks are simply queued to be executed when an alarm thread becomes available. The actual firing time is dictated by server load and availability of free threads in the alarm thread pool of the associated work manager.

## Scheduler daemons in a cluster

When multiple scheduler daemons are configured to the same table (as is the case in a clustered environment), any of the daemons can find a task and set the timer in its Java virtual machine (JVM). The task is executed in the virtual machine where the timer first fires.

## Enabling the scheduler service

Before an application can make use of the scheduler service, you need to configure a scheduler.

The scheduler service manages all schedulers used by a given server. The scheduler service can be enabled and disabled on a server-by-server basis using the administrative console. The service is enabled by default. If you disable the service on a server, all schedulers configured on that server are no longer available. All lookups fail and all scheduler daemons are inactive.

1. Start the administrative console.
2. Select **Servers** > *server\_name* > **Scheduler Service**.
3. Select or clear the **Startup** check box to enable or disable the service.
4. Click **Save** on the menu bar to save your configuration.

The change takes effect on the next server restart.

## Scheduler service settings

Use this page to enable or disable the scheduler service, which manages scheduler resources used by the server.

To view this administrative console page, click **Servers** > **Application Servers** > *server\_name* > **Scheduler Service**.

### Startup:

Specifies whether the server will attempt to start the scheduler service.

**Default**  
**Range**

Selected

**Selected**

When the application server starts, it attempts to start the scheduler service automatically.

**Cleared**

The server does not try to start the scheduler service. If scheduler resources are to be used on this server, the system administrator must start the scheduler service manually or select this property, then restart the server.

---

## Developing and scheduling tasks

1. Developing a task.

The scheduler API supports different implementations of the TaskInfo interface, each of which can be used to schedule a particular type of work. Refer to one of the following topics for details:

- Developing a task that calls a session bean.
- Develop a task that sends a Java Messaging Service (JMS) message. This task object can send a JMS message to either a queue or a topic.

**Note:** Create and manipulate scheduled tasks through the Scheduler interface is only supported from within the EJB container or Web container (enterprise beans or servlets). Looking up and using a configured scheduler from a J2EE application client container is not supported.

2. Receiving scheduler notifications. A notification sink is set on a task in order to receive the notification events that are generated by a scheduler when it performs an operation on the task.
3. Submitting a task to a scheduler. After a TaskInfo object has been created, it can be submitted to the scheduler for task creation by calling the Scheduler.create() method.
4. Managing tasks with a scheduler.

## Developing a task that calls a session bean

The scheduler API supports different implementations of the `TaskInfo` interface, each of which can be used to schedule a particular type of work. This topic describes how to call a method on a task handler session bean using the `BeanTaskInfo` implementation.

1. Create a stateless session bean that implements the `process()` method in the `com.ibm.websphere.scheduler.TaskHandler` remote interface. Place the business logic you want created in the `process()` method. The `process()` method is called when the task fires. The `Home` and `Remote` interfaces must be set as follows in the bean's deployment descriptor:
  - `com.ibm.websphere.scheduler.TaskHandlerHome`
  - `com.ibm.websphere.scheduler.TaskHandler`
2. In a java server page (JSP), servlet or session bean, create an instance of the `BeanTaskInfo` interface by using the following `Scheduler.createBeanTaskInfo()` method:

```
//lookup the scheduler instance to be used
Scheduler scheduler = (Scheduler)new InitialContext.lookup("java:comp/env/Scheduler");

BeanTaskInfo taskInfo = (BeanTaskInfo) scheduler.createTaskInfo(BeanTaskInfo.class)
```

**Note:** Creating a `BeanTaskInfo` object does not add the task to the persistent store. Rather, it creates a placeholder for the necessary data. The task is not added to the persistent store until the `create()` method is called on a `Scheduler` instance, as described in the topic [Submitting a task to a scheduler](#).

3. Now, set parameters on the `BeanTaskInfo` object. These parameters define which task is to run, which session bean is called, and so on.

The `TaskInfo` interface contains various `set()` methods that you can use to control execution of the task, including when the task will fire and what work the task will do when it fires. For example:

```
//create a date object which represents 30 seconds from now
java.util.Date startDate = new java.util.Date(System.currentTimeMillis()+30000);

//find the session bean to be called when the task executes
Object o = new InitialContext().lookup("java:comp/env/ejb/MyTaskHandlerHome");
TaskHandlerHome home = (TaskHandlerHome)javax.rmi.PortableRemoteObject.narrow(o,TaskHandlerHome.class);

//now set the start time and task handler to be called in the task info
taskInfo.setTaskHandler(home);
taskInfo.setStartTime(startDate);
```

The `TaskInfo` interface specifies additional control points, as documented in Javadoc.

A `TaskInfo` object has been created that contains all of the relevant data for a task.

Submit the task to a scheduler instance for creation, as described in the topic [Submitting a task to a scheduler](#).

## Developing a task that sends a JMS message

The scheduler API supports different implementations of the `TaskInfo` interface, each of which can be used to schedule a particular type of work. This topic describes how to use the `MessageTaskInfo` implementation, which sends a JMS message to either a queue or a topic.

1. Create an instance of the `MessageTaskInfo` interface by using the following `Scheduler.createMessageTaskInfo()` method:

```
//lookup the scheduler instance to be used
Scheduler scheduler = (Scheduler)new InitialContext.lookup("java:comp/env/Scheduler");

MessageTaskInfo taskInfo = (MessageTaskInfo) scheduler.createTaskInfo(MessageTaskInfo.class);
```

**Note:** Creating a `MessageTaskInfo` object does not add the task to the persistent store. Rather, it creates a placeholder for the necessary data. The task is not added to the persistent store until the `create()` method is called on a `Scheduler` instance, as described in the topic `Submitting a task to a scheduler`.

2. Set parameters on the `MessageTaskInfo` object.

The `TaskInfo` interface contains various `set()` methods that can be used to control execution of the task, including when the task will fire and what work the task will do when it fires. For example:

```
//create a date object which represents 30 seconds from now
java.util.Date startDate = new java.util.Date(System.currentTimeMillis()+30000);
```

```
//now set the start time and the JNDI names for the queue connection factory and the queue
taskInfo.setConnectionFactoryJndiName("jms/MyQueueConnectionFactory");
taskInfo.setDestination("jms/MyQueue");
taskInfo.setStartTime(startDate);
```

The `TaskInfo` interface specifies additional control points, as documented in Javadoc.

A `TaskInfo` object has been created that contains all of the relevant data for a task.

Submit the task to a scheduler instance for creation, as described in the topic `Submitting a task to a scheduler`.

## Receiving scheduler notifications

Various notification events are generated by a scheduler when it performs an operation on a task. These events include:

### **Scheduled**

A task has been scheduled.

### **Purged**

A task has been permanently deleted from the persistent store.

### **Suspended**

A task was suspended.

### **Resumed**

A task was resumed.

### **Complete**

A task has run completely. If it was a repeating task, all repeats have been performed.

### **Cancelled**

A task has been cancelled. It will not run again.

**Fired** A task fired successfully.

### **Fire Failed**

A task could not fire successfully.

To receive notification events, call the `setNotificationSink()` method on the `TaskInfo` interface before creating the event. The `setNotificationSink()` method enables you to specify the session bean that is to act as the callback, and a mask that restricts which events are generated.

1. Create a notification sink session bean. Create a stateless session bean that implements the `handleEvent()` method in the `com.ibm.websphere.scheduler.NotificationSink` remote interface. The `handleEvent()` method is called when the notification is fired. The `Home` and `Remote` interfaces can be set as follows in the bean's deployment descriptor:

```
com.ibm.websphere.scheduler.NotificationSinkHome
com.ibm.websphere.scheduler.NotificationSink
```

The notification sink bean must exist in the same application (EAR file) that is used to create the task. The `NotificationSink` interface defines the following method:

```
public void handleEvent(TaskNotificationInfo task) throws java.rmi.RemoteException;
```

The transactional context used by the session bean is defined by the assembler.

2. Specify the notification sink session bean to be used as the callback. The following code illustrates how to set this option:

```
TaskInfo taskInfo = ...
Object o = new InitialContext().lookup("java:comp/env/ejb/NotificationSink");
NotificationSinkHome home =
 (NotificationSinkHome)javax.rmi.PortableRemoteObject.narrow(o,NotificationSinkHome.class);
taskInfo.setNotificationSink(home,TaskNotificationInfo.ALL_EVENTS);
```

3. Specify the event mask. The event mask is specified as an integer mask. You can either use an individual mask such as `TaskNotificationInfo.CREATED` to receive specific events, `TaskNotificationInfo.ALL_EVENTS` to receive all events or a combination of specific events.. For example:

```
int eventMask = TaskNotificationInfo.CREATED+TaskNotificationInfo.PURGED;
```

## Submitting a task to a scheduler

This task assumes that you have already configured a scheduler instance using the administrative console.

Once you have developed a `TaskInfo` object that contains all relevant data for a task, submit the task to a scheduler instance for creation. For example:

```
//lookup the scheduler instance to be used
Scheduler scheduler = (Scheduler)new InitialContext.lookup("java:comp/env/Scheduler");
```

```
TaskStatus status = scheduler.create(taskInfo);
```

When you configure a scheduler, it is bound to a global JNDI name. Although the desired scheduler instance can be found by performing a lookup on that JNDI name, it is better to create a resource reference, which allows for more flexibility in configuring the scheduler.

**5.1 +** The scheduler service utilizes the asynchronous beans deferred start mechanism to propagate Java 2 Enterprise Edition (J2EE) service context information to a task when it runs. The service context information captured when the task is created and later applied to the task is controlled by the Service Context settings on the `WorkManager` configuration object, which the scheduler configuration references. For example, security and internationalization can be enabled. See asynchronous beans for details on how to configure the Application Server to propagate these service contexts.

**5.1 +** To secure your application using the global security mechanism built into the product, create each task with the correct credentials on the thread. When each task has the correct credentials, you can disable and re-enable security without causing any security problems. If you do not set the security context when the scheduler task is created and you later enable security in the target application, then a security exception or error message might display.

**5.1 +** The security context is not set if any of the follow conditions are true:

- Global security is disabled.
- The security context policy is disabled on the configured `WorkManager` for the associated scheduler instance configuration.
- A credential is not set on the thread. For example, enterprise beans or the servlet that is used to create the scheduled task is not secured.

**5.1 +** If any of the previously mentioned conditions are true when you create your task, and you need to enable security on your application server or application, then you must complete the following steps:

1. Cancel the task with security disabled.

2. Recreate each scheduled task with security enabled. Recreating each task enables the scheduler to store the desired security context with the task.

**Note:** The scheduler interface is a local interface. It can only be used by server-side code; that is, J2EE applications.

Once the call to the `create()` method is complete, the task exists in the persistent store and is run at the time specified in the `TaskInfo` object. This call is transactional. If a transactional context is present on the thread when the `create()` method rolls back or is aborted, the task does not run.

The status object, which has been returned by the call to the `create()` method, contains information about the state of the task, as well as the task ID. The task ID is the unique identifier for this task, and is required if the task is to be suspended, resumed, cancelled, and so on, at a later time.

**Note:** The status object is only a snapshot of the current state of the task. Use the `Scheduler.getStatus()` method to receive the current state when needed.

## Managing tasks with a scheduler

When a task is created by calling the `create()` method on a scheduler instance, a `TaskStatus` object is returned to the caller. The status object contains the task ID, which is a unique identifier. The scheduler API defines several additional methods that pertain to the management of tasks, each of which accepts the task ID as a parameter. The following task management methods are defined:

### **suspend()**

Suspends a task. The task does not run until it has been resumed.

### **resume()**

Resumes a previously suspended task.

### **cancel()**

Cancels a task. The task is not run.

### **purge()**

Permanently deletes the task from the persistent store.

### **getStatus()**

Returns the current status of the task.

For example, the following code creates and cancels a task:

```
//Create the task.
TaskInfo taskInfo = ...
TaskStatus status = scheduler.create(taskInfo);

//Get the task ID
String taskId = status.getTaskId();

//Cancel the task. Specify the purgeAlso flag so that the task does not remain in the persistent store
scheduler.cancel(taskId,true);
```

**Transactionality.** All methods of the scheduler API are transactional. If a global transactional context is present, it is used to perform the operation. If an unexpected exception is thrown, the transaction is marked to roll back. If an expected or declared exception is thrown, the transaction remains intact and the caller must choose to roll back or to commit the transaction. If the transaction is rolled back at some point, all scheduler operations performed within the transaction were also rolled back.

If a local transactional context is present, it is suspended and a new global transactional context begins. Likewise, if no transactional context is active, a global transactional context begins. In both cases, if an unexpected exception is thrown, the transaction rolls back. If a declared exception is thrown, the transaction is committed.

If another thread is concurrently modifying the task in question, a `TaskPending` exception is thrown. This is because schedulers lock the database optimistically. The calling application can then retry the operation.

All methods defined by the scheduler API are described in Javadoc.

## Transactions and the scheduler service

### Transactions and the scheduler daemon

Scheduled `BeanTaskInfo` and `MessageTaskInfo` objects are guaranteed to execute only once. This is accomplished by grouping all of the work done in the task as a single unit of work. When each task fires, the following events occur in a single global transactional context:

1. The context of the application that created the task is applied to the thread.
2. A global transactional context is started.
3. The next fire time and start-by time are calculated using the `UserCalendar` bean or the `DefaultUserCalendar`.
4. The task database task record is updated in the database with the state of the next task or deleted if the task is complete and the task's auto-purge setting is true.
5. The `BeanTaskInfo` or `MessageTaskInfo` object is executed.
6. If the task fails and the `NotificationSink` bean is set, a `FIRE_FAILED` notification is fired on a separate transaction.
7. If the task's `NotificationSink` bean is set, then the various notifications are fired as required.
8. The global transaction is committed.

Because all of a task's events are executed in a single global transactional context, you need to consider the following points in order to avoid transaction-related errors:

- Each resource participating in the task's transaction must be 2-phase XA capable.  
This includes the JDBC datasource configured for the scheduler, any JMS services used by the `MessageTaskInfo` objects, and any resources used within any of the `UserCalendar`, `TaskHandler`, or `NotificationSink` beans that have a transaction setting of "Requires".
- One resource can be single-phase, if last participant support is enabled for the application that created the transaction.

All unexpected exceptions are logged to the activity log and all events participating in the task's global transaction are rolled back. This includes changes to the task's database record, which force the task to be executed again when the scheduler daemon polls the database during the next poll cycle. The `UserCalendar`, `TaskHandler`, and `NotificationSink` beans can choose not to participate in the global transaction by setting the bean's transaction setting to "Requires new".

### Transactions and the scheduler interface

All Scheduler interface methods participate in a single global transactional context. If a global transactional context is already present on the thread when the `create()`, `suspend()`, `resume()`, `cancel()`, and `purge()` methods are executed, the existing global transaction is used. Otherwise, a new global transaction begins.

If the method participates in the caller's global transaction and an unexpected error occurs, the transaction is marked to roll back. If the exception is a declared exception, then the exception is rethrown to the caller, and the transaction is left alone for the caller to commit or roll back.

If the method starts its own global transaction and any exception occurs, the transaction is rolled back, and the exception is rethrown to the caller.

## Scheduler interface

A scheduler object exists in the JNDI namespace for each scheduler configuration. A reference to a scheduler can be obtained by performing a lookup on the JNDI name; however, the lookup is valid only

from the server process where the scheduler instance exists. Once a reference has been obtained, tasks can be created, suspended, cancelled, and so on, if the caller has access to the scheduler instance.

For details, see the Interface Scheduler in the Javadoc.

#### **Task creation**

The task is created in the persistent store using the caller's global transactional context if present. See the topic "Transactions and the scheduler service" on page 1110 for more details. Since this is a transactional operation, the task cannot be run or modified from another thread until the current transaction commits.

#### **Task modification**

Tasks that have been created can be modified with the `suspend()`, `resume()`, `cancel()`, and `purge()` methods. These methods take a Task Identifier string as a parameter, which is generated by the `create()` method and can be found in the `TaskStatus` object. If a task is currently running or being modified by another thread, an operation that attempts to modify the state of the task does not block on the attempt, but a `TaskPending` exception is thrown. The operation can be reattempted at another time. Tasks can only be modified by the same application (EAR file) that was used to create the task.

#### **Task execution**

Tasks are executed in the thread pool specified by the configuration's work manager, under the security ID of the task creator. If multiple schedulers are configured to share the same database table, the tasks found in the table can be executed on any of the schedulers, whether or not they are in the same server, node, or cell.

#### **Task lookup**

Tasks can be located using the Name property that was assigned at creation time. This is useful when you need to modify a group of tasks and tracking individual task ID's is not convenient.

### **TaskInfo interface**

`TaskInfo` objects contain the information that can be used to create a task. Several implementations of this class exist, one for each type of task that can be run. Available `TaskInfo` implementations include:

#### **BeanTaskInfo**

Calls a stateless session bean.

#### **MessageTaskInfo**

Sends a JMS message to a queue or publishes a message to a topic.

For details, see the Interface `TaskInfo` in the Javadoc.

After a `TaskInfo` object is created, it can be submitted to the scheduler for task creation by calling the `Scheduler.create()` method.

**Specifying time intervals.** `setStartTimeInterval()`, `setStartByInterval()`, and `setRepeatInterval()` methods all take a `String` parameter that represents time interval. Time intervals are calculated using *user calendars*.

### **TaskHandler interface**

A task handler is a user-defined stateless session bean that is called by tasks created using a `BeanTaskInfo` object. A task handler bean uses the following home and remote interfaces, which are defined in the deployment descriptor using the Application Assembly Tool Assembly Toolkit or WebSphere Studio Application Developer:

```
com.ibm.websphere.scheduler.TaskHandlerHome
com.ibm.websphere.scheduler.TaskHandler
```

The bean itself needs to implement the `process()` method defined in the remote interface. For details, see the Interface `TaskHandler` in the Javadoc.

If a task is created using a `BeanTaskInfo` object, the `process()` method on the `TaskHandler` session bean is called whenever the task runs. Because the `TaskStatus` object for the task is passed as a parameter, the handler can make use of the saved `UserContext` field, as well as determine information about the task, such as when it will fire next, the number of repeats remaining, and so on.

## NotificationSink interface

A notification sink is a user-defined stateless session bean that is called by tasks when their state changes throughout the bean's lifecycle. A notification sink bean uses the following home and remote interfaces, which are defined in the deployment descriptor using the Application Assembly Tool Assembly Toolkit or WebSphere Studio Application Developer::

```
com.ibm.websphere.scheduler.NotificationSinkHome
com.ibm.websphere.scheduler.NotificationSink
```

The bean itself needs to implement the `handleEvent()` method defined in the remote interface. For details, see the Interface `NotificationSink` in the Javadoc.

A `NotificationSink` provides an event notification callback on a task-by-task basis. A notification sink is set on the `TaskInfo` interface, using the `setNotificationSink()` method. If a notification sink is not specified on a task, all notifications are lost; however, the status of a task can be determined by calling the `getStatus()` method from the `Scheduler` interface. A notification callback is made for each of the following events:

- Scheduled
- Suspended
- Resumed
- Fired
- Fire Failed
- Complete
- Purged

## UserCalendar interface

A user calendar is a user-defined stateless session bean that is called by tasks when they need to calculate date-related values. A user calendar bean uses the following home and remote interfaces, which are defined in the deployment descriptor using the Application Assembly Tool Assembly Toolkit or WebSphere Studio Application Developer:

```
com.ibm.websphere.scheduler.UserCalendarHome
com.ibm.websphere.scheduler.UserCalendar
```

The bean itself needs to implement the `applyDelta()` and `validate()` methods defined in the remote interface. For details, see the Interface `UserCalendar` in the Javadoc.

User calendars can be used to calculate time intervals, such as the time between when a repeating task fires and the next time it fires. A user calendar takes a `java.util.Date` object and applies the interval string. The resulting object is a `java.util.Date` object that is an incremented date.

User calendars are set by the `setUserCalendar()` method on the `TaskInfo` interface, and called by the scheduler run-time code when a delta calculation is necessary.

The following methods on the `TaskInfo` interface specify delta strings that use the user calendar for calculation:

- `setStartTimeInterval`
- `setStartByInterval`
- `setRepeatInterval`

### Default user calendar

If a user calendar has not been specified using the `TaskInfo.setUserCalendar()` method, a default

user calendar is used. The default calendar allows for simple delta specifications, such as seconds, minutes, hours, days, and months. See the Javadoc for details on the default calendar.

### Calendar specifiers

A single user calendar can contain logic for multiple calendars. Which calendar is used is determined by a string that acts as the specifier. For example, a bean might be implemented to recognize the interval "day", with a specifier that determines whether to calculate "day" as a standard calendar day, or as a business day.

### Internationalization and time zones

Scheduler makes use of the `java.util.Date` class when storing and processing dates. Internally, this class saves the time as milliseconds since the Epoch, Greenwich Mean Time. Since the `Date` is not converted to local time until converted to a string, the scheduler respects the time zone where the date was created.

### Writing user calendars

Because the user calendar is a stateless session bean, the same Java 2 Platform Enterprise Edition (J2EE) programming model available to other session beans is available to the user calendar as well.

---

## Interoperating with the Scheduler service

The WebSphere Application Server Enterprise Edition Scheduler Version 5.0 service has several interoperability problems that affect how the Scheduler behaves in a clustered environment with mixed WebSphere versions and/or mixed platforms. Specifically, there are two issues that cause interoperability problems:

1. The EJB HomeHandle format has changed between the Versions 5.0 and 5.0.1 of the product. See interim fix PQ72184 or the Interoperability section of the Version 5.0.1 Release Notes.
2. The asynchronous beans serialization mechanism has changed between Versions 5.0 and 5.0.1 of the product. See interim fix PQ72742 or the asynchronous beans section of the Version 5.0.1 Release Notes.

To avoid problems interoperating between Version 5.0 and 5.0.1 and or higher, all Version 5.0 scheduler service customers must first apply the Version 5.0 fix packs associated with interim fixes PQ72184 and PQ72742 and remove all scheduled tasks that were created prior to applying these fix packs.

Be aware that removing all scheduled tasks involves removing data from your scheduler service databases. Follow these procedures for each scheduler instance defined on the affected server.

1. Recreate all scheduler tasks. Use this method if you wish to programmatically recreate your scheduled tasks.
2. Delete all scheduler tasks. Use this method to remove all of your Scheduler tasks and recreate them manually.
3. Recreate all scheduler tables. Use this method to drop and recreate the scheduler tables.

## Recreating Scheduler tasks

This step requires advanced knowledge of developing J2EE Applications and the Scheduler programming interfaces.

1. Use the administrative console to locate each Scheduler resource that was used in WebSphere Application Server Version 5.0. For each Scheduler resource, note the JNDI name.
2. Back up the Scheduler database.
3. Create a new or modify an existing EJB or servlet J2EE application to implement as a method that you intend to use as the Scheduler update program.
4. Create a method similar to the included example. This action finds all existing Scheduler tasks, deletes them and creates new ones with the same parameters. ***If Global Security is enabled in the WebSphere Application Server and the "security" context is enabled on the WorkManager***

*referenced by the Scheduler resource, the current security context is used (as well all other J2EE contexts that are enabled on the creating EJB or servlet thread).* See the following as an example:

```
public void recreateTasks(String schedulerJNDIName)
 throws Exception
{
 InitialContext ctx = new InitialContext();
 Scheduler s = (Scheduler)ctx.lookup(schedulerJNDIName);

 Iterator tasks = null;;
 try
 {
 tasks = s.findTasksByName("%");
 }
 catch (SchedulerNotAvailableException e)
 {
 e.printStackTrace();
 throw e;
 }

 // Iterate through each task and recreate it.
 while(tasks.hasNext())
 {
 TaskInfo curTask = (TaskInfo) tasks.next();

 int retries=0;
 boolean deleted=false;
 TaskStatus status=null;

 // It's best to include each cancel/create
 // in it's own transaction (not shown here).
 while(!deleted && retries < 5)
 {
 try
 {
 // Delete the task.
 s.cancel(curTask.getTaskId(), true);
 deleted = true;

 // Create a new one.
 int createRetries = 0;
 boolean created = false;
 while(!created && createRetries<5)
 {
 try
 {
 s.create(curTask);
 created = true;
 }
 catch (Exception e)
 {
 ++createRetries;
 Thread.sleep(5000);
 }
 }
 }
 }
 }
}
```

```

 if (!created)
 {
 System.out.println("Task Not Created: " + curTask.getTaskId());
 }
 }
 catch (Exception se)
 {
 ++retries;
 Thread.sleep(5000);
 }
}
if (!deleted)
{
 System.out.println("Task Not Deleted: " + curTask.getTaskId());
}
}
}
}

```

## Deleting Scheduler tasks

Use this method to remove *all* of your Scheduler tasks and recreate them manually.

1. Use the administrative console to locate each Scheduler resource that was used in WebSphere Application Server Version 5.0. For each Scheduler resource, note the following:
  - JDBC DataSource JNDI Name
  - Table Prefix
2. Use the administrative console to locate each JDBC DataSource, and note the connection and location parameters.
3. Back up the Scheduler database.
4. Using the native database utilities, remove all of the records for each Scheduler resource for each database noted in steps 1 and 2. The following SQL query template can be used to remove all records. Substitute TBLPFX with the actual Table Prefix.

```
DELETE FROM<TBLPFX>TASK
```

Once the tasks are deleted, new tasks can be created immediately. In addition, the Scheduler service can be active while executing the DELETE SQL command in step 4. However, the operation might take longer to execute or even time out if the Scheduler has database records locked.

## Recreating Scheduler tables

Use this method to drop and recreate the Scheduler tables.

1. Use the administrative console to locate each Scheduler resource that was used in WebSphere Application Server Version 5.0. For each Scheduler resource, note the following:
  - JDBC DataSource JNDI Name
  - Table Prefix
2. Use the administrative console to locate each JDBC DataSource, and note the connection and location parameters.
3. Back up the Scheduler database.
4. For each database and Table Prefix identified in the previous steps, execute the dropSchemaXXX.ddl and createSchemaXXX.ddl scripts located in the <install\_root>/Scheduler directory of your WebSphere Application Server, where <install\_root>, is the directory where the WebSphere Application Server is installed. Each DDL script has instructions (located at the beginning of the

respective script and in the form of a comment) on how to edit and execute the script. Refer to the Creating the database for scheduler article for more information.

---

## Chapter 22. Using shared work areas

The work area service enables application developers to implicitly propagate information beyond the information passed in remote calls. Applications can create a work area, insert information into it, and make remote invocations. The work area is propagated with each remote method invocation, eliminating the need to explicitly include an appropriate argument in the definition of each method. The methods on the server side can use or ignore the information in the work area as appropriate.

Before proceeding with the steps to implement work areas, as described below, review the topic `WorkArea service: Overview`.

1. Developing applications that use work areas. Applications interact with the work area service by implementing the `UserWorkArea` interface.
2. Managing work areas. The work area service is managed using the administrative console.

---

### WorkArea service - Overview

One of the foundations of distributed computing is the ability to pass information, typically in the form of arguments to remote methods, from one process to another. When application-level software is written over middleware services, many of the services rely on information beyond that passed in the application's remote calls. Such services often make use of the implicit propagation of private information in addition to the arguments passed in remote requests; two typical users of such a feature are security and transaction services. Security certificates or transaction contexts are passed without the knowledge or intervention of the user or application developer. The implicit propagation of such information means that application developers do not have to manually pass the information in method invocations, which makes development less error-prone, and the services requiring the information do not have to expose it to application developers. Information such as security credentials can remain secret.

The `WorkArea` service gives application developers a similar facility. Applications can create a work area, insert information into it, and make remote invocations. The work area is propagated with each remote method invocation, eliminating the need to explicitly include an appropriate argument in the definition of every method. The methods on the server side can use or ignore the information in the work area as appropriate. If methods in a server receive a work area from a client and subsequently invoke other remote methods, the work area is transparently propagated with the remote requests. When the creating application is done with the work area, it terminates it.

There are two prime considerations in deciding whether to pass information explicitly as an argument or implicitly by using a work area. These considerations are:

- **Pervasiveness:** Is the information used in a majority of the methods in an application?
- **Size:** Is it reasonable to send the information even when it will not be used?

When information is sufficiently pervasive that it is easiest and most efficient to make it available everywhere, application programmers can use the `WorkArea` service to simplify programming and maintenance of code. The argument does not need to go onto every argument list. It is much easier to put the value into a work area and propagate it automatically. This is especially true for methods that simply pass the value on but do nothing with it. Methods that make no use of the propagated information simply ignore it.

Work areas can hold any kind of information, and they can hold an arbitrary number of individual pieces of data, each stored as a property.

### Work area property modes

The information in a work area consists of a set of properties; a property consists of a key-value-mode triple. The key-value pair represents the information contained in the property; the key is a name by which the associated value is retrieved. The mode determines whether the property can be removed or modified.

## Property modes

There are four possible mode values for properties, as shown in the following code example:

### Code example: The PropertyModeType definition

```
public final class PropertyModeType {
 public static final PropertyModeType normal;
 public static final PropertyModeType read_only;
 public static final PropertyModeType fixed_normal;
 public static final PropertyModeType fixed_readonly;
};
```

A property's mode determines three things:

- Whether the value associated with the key can be modified
- Whether the property can be deleted
- Whether the mode associated with the key-value pair can be modified

The two read-only modes forbid changes to the information in the property; the two fixed modes forbid deletion of the property.

The WorkArea service does not provide methods specifically for the purpose of modifying the value of a key or the mode associated with a property. To change information in a property, applications simply rewrite the information in the property; this has the same effect as updating the information in the property. The mode of a property governs the changes that can be made. Modifying key-value pairs describes the restrictions each mode places on modifying the value and deleting the property. Changing modes describes the restrictions on changing the mode.

## Changing modes

The mode associated with a property can be changed only according to the restrictions of the original mode. The read-only and fixed read-only properties do not permit modification of the value or the mode. The fixed normal and fixed read-only modes do not allow the property to be deleted. This set of restrictions leads to the following permissible ways to change the mode of a property within the lifetime of a work area:

- If the current mode is normal, it can be changed to any of the other three modes: fixed normal, read-only, fixed read-only.
- If the current mode is fixed normal, it can be changed only to fixed read-only.
- If the current mode is read-only, it can be changed only by deleting the property and re-creating it with the desired mode.
- If the current mode is fixed read-only, it cannot be changed.
- If the current mode is not normal, it cannot be changed to normal. If a property is set as fixed normal and then reset as normal, the value is updated but the mode remains fixed normal. If a property is set as fixed normal and then reset as either read-only or fixed read-only, the value is updated and the mode is changed to fixed read-only.

**Note:** The key, value, and mode of any property can be effectively changed by terminating (completing) the work area in which the property was created and creating a new work area. Applications can then insert new properties into the work area. This is not precisely the same as changing the value in the original work area, but some applications can use it as an equivalent mechanism.

## Nested work areas

Applications can nest work areas. When an application creates a work area, a work area context is associated with the creating thread. If the application thread creates another work area, the new work area is nested within the existing work area and becomes the current work area. Nested work areas allow applications to define and scope properties for specific tasks without having to make them available to all

parts of the application. All properties defined in the original, enclosing work area are visible to the nested work area. The application can set additional properties within the nested work area that are not part of the enclosing work area.

An application working with a nested work area does not actually see the nesting of enclosing work areas. The current work area appears as a flat set of properties that includes those from enclosing work areas. In the figure below, the enclosing work area holds several properties and the nested work area holds additional properties. From the outermost work area, the properties set in the nested work area are not visible. From the nested work area, the properties in both work areas are visible.

Figure 25. Defining new properties in nested work areas

Nesting can also affect the apparent settings of the properties. Properties can be deleted from or directly modified only within the work areas in which they were set, but nested work areas can also be used to temporarily override information in the property without having to modify the property. Depending on the modes associated with the properties in the enclosing work area, the modes and the values of keys in the enclosing work area can be overridden within the nested work area.

The mode associated with a property when it is created determines whether nested work areas can override the property. From the perspective of a nested work area, the property modes used in enclosing work areas can be grouped as follows:

- Modes that permit a nested work area to override the mode or the value of a key locally. The modes that permit overriding are:
  - Normal
  - Fixed normal
- Modes that do not permit a nested work area to override the mode or the value of a key locally. The modes that do not permit overriding are:
  - Read-only
  - Fixed read-only

If an enclosing work area defines a property with one of the overridable modes, a nested work area can specify a new value for the key or a new mode for the property. The new value or mode becomes the value or mode seen by subsequently nested work areas. Changes to the mode are governed by the

restrictions described in Changing modes. If an enclosing work area defines a property with one of the modes that cannot be overridden, no nested work area can specify a new value for the key.

A nested work area can delete properties from enclosing work areas, but the changes persist only for the duration of the nested work area. When the nested work area is completed, any properties that were added in the nested area vanish and any properties that were deleted from the nested area are restored.

The following figure illustrates the overriding of properties from an enclosing work area. The nested work area redefines two of the properties set in the enclosing work area. The other two cannot be overridden. The nested work area also defines two new properties. From the outermost work area, the properties set or redefined in the nested work are not visible. From the nested work area, the properties in both work areas are visible, but the values seen for the redefined properties are those set in the nested work area.

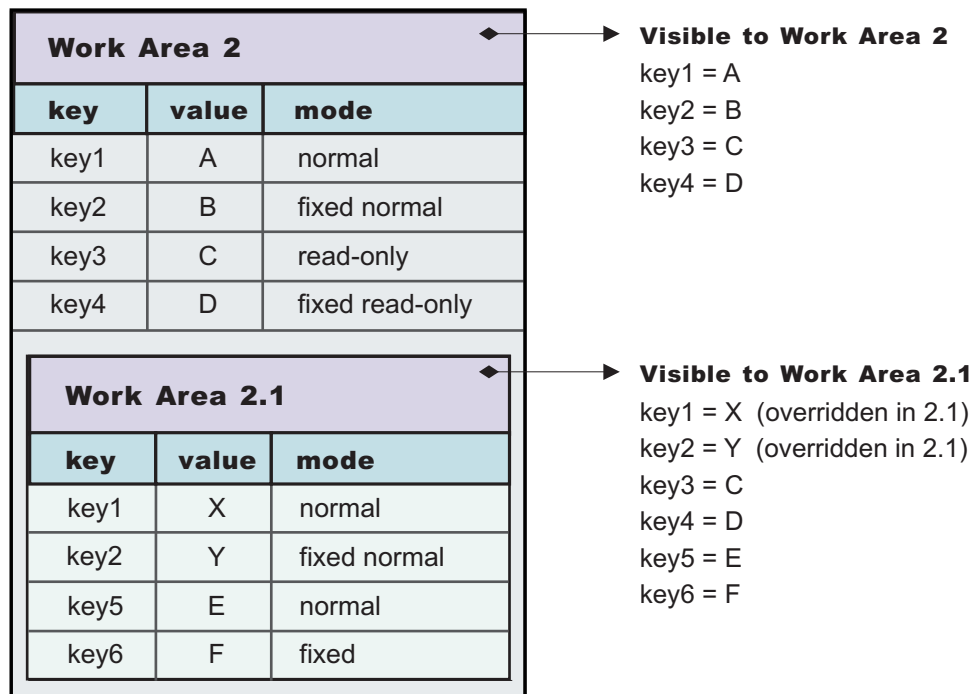

Figure 26. Redefining existing properties in nested work areas

## Distributed work areas

**5.1 +** The propagation of work area context operates differently depending on whether a work area partition is defined as bidirectional or not. In either case all work area context propagates to a target object on a remote invocation. However, whether the context propagates from a target object back to the originator depends on whether a partition is defined as bidirectional.

### Non-bidirectional work area partitions (UserWorkArea partition)

If a remote invocation is issued from a thread associated with a work area, a copy of the work area is automatically propagated to the target object, which can use or ignore the information in the work area as necessary. If the calling application has a nested work area associated with it, a copy of the nested work area and all its ancestors is propagated to the target. The target application can locally modify the information, as allowed by the property modes, by creating additional nested work areas; this information will be propagated to any remote objects it invokes. However, no changes made to a nested work area on a target object are propagated back to the calling object. The caller's work area is unaffected by changes made in the remote method.

## **Bidirectional work area partitions** 5.1+

If a remote invocation is issued from a thread associated with a work area, a copy of the work area is automatically propagated to the target object, which can use or ignore the information in the work area as necessary. If the calling application has a nested work area associated with it, a copy of the nested work area and all its ancestors is propagated to the target. The target application can locally modify the information, as allowed by the property modes, this information is propagated to any remote objects it invokes. In a partition that is not defined as bidirectional, a target application must begin a nested work area before making changes to the imported work area. However, if a partition is defined as bidirectional, a target application need not begin a nested work area before operating on an imported work area. By not beginning a nested work area, any new context set into the work area, or any context changes made by the target application, will not only propagate on future remote invocations but will also propagate back to the originating application (that is, the one who initiated the remote invocation) thus allowing bidirectional propagation of work area context. If the target application does not want new or changed context to propagate back to the originating application, then the target application must begin a nested work area to scope the context to its process. However, the new or changed context in the nested work area will propagate on any future remote invocation the target application may make.

## **WorkArea service: Special considerations**

Developers who use work areas should consider the following issues that could potentially cause problems: interoperability between the EJB and CORBA programming models; and the use of work areas with Java's Abstract Windowing Toolkit.

### **EJB and CORBA interoperability**

Although the WorkArea service can be used across the EJB and CORBA programming models, many composed data types cannot be successfully used across those boundaries. For example, if a SimpleSampleCompany instance is passed from the WebSphere environment into a CORBA environment, the CORBA application can retrieve the SimpleSampleCompany object encapsulated within a CORBA Any object from the work area, but it cannot extract the value from it. Likewise, an IDL-defined struct defined within a CORBA application and set into a work area will not be readable by an application using the UserWorkArea class. Applications can avoid this incompatibility by directly setting only primitive types, like integers and strings, as values in work areas, or by implementing complex values with structures designed to be compatible, like CORBA valuetypes. Also, CORBA Anys that contains either the tk\_null or tk\_void typecode can be set into the work area by using the CORBA interface, but the work-area specification cannot allow the J2EE implementation to return null on a lookup that retrieves these CORBA-set properties without incorrectly implying that there is no value set for the corresponding key. If a J2EE application tries to retrieve CORBA-set properties that are non-serializable, or contain CORBA nulls or void references, the `com.ibm.websphere.workarea.IncompatibleValue` exception is raised.

### **Using work areas with Java's Abstract Windowing Toolkit (AWT)**

Work areas must be used cautiously in applications that use Java's Abstract Windowing Toolkit (AWT). The AWT implementation is multithreaded, and work areas begun on one thread are not available on another. For example, if a program begins a work area in response to an AWT event, such as pressing a button, the work area might not be available to any other part of the application after the execution of the event completes.

## **Work area service performance considerations**

The work area service is designed to address complex data passing patterns that can quickly grow beyond convenient maintenance. A work area is a note pad that is accessible to any client capable of looking up Java Naming Directory Interface (JNDI). Once a work area is established, data can be placed there for future use in any subsequent method calls to both remote and local resources.

You can utilize a work area when a large number of methods require common information or if information is only needed by a method that is significantly further down the call graph. The former avoids the need for complex parameter passing models where the number of arguments passed becomes excessive and hard to maintain. You can improve application function by placing the information in a work area and subsequently accessing it independently in each method, eliminating the need to pass these parameters from method to method. The latter case also avoids unnecessary parameter passing and helps to improve performance by reducing the cost of marshalling and de-marshalling these parameters over the Object Request Broker (ORB) when they are only needed sparsely throughout the call graph.

When attempting to maximize performance by using a work area, cache the `UserWorkArea` retrieved from JNDI wherever it is accessed. You can reduce the amount of time spent looking up information in JNDI by retrieving it once and keeping a reference for the future. JNDI look up takes time and can be costly.

Additional caching mechanisms available to a user defined partition are defined by the configuration property, "Deferred Attribute Serialization". This mechanism will attempt to minimize the number of serialization and deserialization calls. See "Work area partition service" on page 1133 for further explanation of this configuration attribute.

Other configuration parameters that may affect the performance of the work area server are "maxSendSize" and "maxReceiveSize". Setting these two values to 0 (zero) effectively turns off the policing of the size of context that can be sent in a work area. This may enhance performance depending on the number of nested work areas an application uses. In applications that use only one work area, the performance enhancement may be negligible. In applications that have a large number of nested work areas, there may be a performance enhancement. However, a user must note that by turning off this policing it is possible that an extremely large amount of data might be sent to a server.

Performance is degraded if you use a work area as a direct replacement to passing a single parameter over a single method call. The reason is that you incur more overhead than just passing that parameter between method calls. Although the degradation is usually within acceptable tolerances and scales similarly to passing parameters with regard to object size, consider this potential problem before utilizing the service. As with most functional services, intelligent usage of work areas yields the best results.

The work area service is a tool to simplify the job of passing information from resource to resource, and in some cases can improve performance by reducing the overhead associated with parameter passing when the information is only sparsely accessed within the call graph. Caching the instance retrieved from JNDI is important to effectively maximize performance during runtime.

---

## Developing applications that use work areas

Applications interact with the work area service by using the `UserWorkArea` interface and its implementation. This interface defines all of the methods used to create, manipulate, and complete work areas:

1. Access the partition by either:
  - "Accessing the WorkArea service" on page 1124, to access the `UserWorkArea` partition.
  - "Accessing a user defined work area partition" on page 1140, to access a user defined work area.

The following steps use the `UserWorkArea` partition as an example, however a user defined partition can be used in the same way.

2. Beginning a work area.
3. Setting properties in a work area.
4. Using a work area to manage local work.
5. Completing a work area.

An example application, the WorkArea SimpleSample application, is used throughout this documentation to illustrate these tasks

## UserWorkArea interface

Applications interact with the WorkArea service by implementing the UserWorkArea interface. This interface, shown below, defines all of the methods used to create, manipulate, and terminate work areas:

```
package com.ibm.websphere.workarea;

public interface UserWorkArea {
 void begin(String name);
 void complete() throws NoWorkArea, NotOriginator;

 String getName();
 String[] retrieveAllKeys();
 void set(String key, java.io.Serializable value)
 throws NoWorkArea, NotOriginator, PropertyReadOnly;
 void set(String key, java.io.Serializable value, PropertyModeType mode)
 throws NoWorkArea, NotOriginator, PropertyReadOnly;
 java.io.Serializable get(String key);
 PropertyModeType getMode(String key);
 void remove(String key)
 throws NoWorkArea, NotOriginator, PropertyFixed;
}
```

**Note:** EJB applications can use the UserWorkArea interface only within the implementation of methods in the remote interface; likewise, servlets can use the interface only within the service method of the HTTPServlet class. Use of work areas within any lifecycle method of a servlet or enterprise bean is considered a deviation from the work area programming model and is not supported.

### Exceptions

The WorkArea service defines the following exceptions for use with the UserWorkArea interface:

#### NoWorkArea

Thrown when a request requires an associated work area but none is present.

#### NotOriginator

Raised when a request attempts to manipulate the contents of an imported work area.

#### PropertyReadOnly

Raised when a request attempts to modify a read-only or fixed read-only property.

#### PropertyFixed

Raised by the remove method when the designated property has one of the fixed modes.

## Example: WorkArea SimpleSample application

In this example, the client creates a work area and inserts two properties into the work area: a site identifier and a priority. The site-identifier is set as a read-only property; the client does not allow recipients of the work area to override the site identifier. This property consists of the key company and a static instance of a SimpleSampleCompany object. The priority property consists of the key priority and a static instance of a SimpleSamplePriority object. The object types are defined as shown in the following code example

```
public static final class SimpleSampleCompany {
 public static final SimpleSampleCompany Main;
 public static final SimpleSampleCompany NewYork_Sales;
 public static final SimpleSampleCompany NewYork_Development;
 public static final SimpleSampleCompany London_Sales;
 public static final SimpleSampleCompany London_Development;
}

public static final class SimpleSamplePriority {
 public static final SimpleSamplePriority Platinum;
 public static final SimpleSamplePriority Gold;
}
```

```

 public static final SimpleSamplePriority Silver;
 public static final SimpleSamplePriority Bronze;
 public static final SimpleSamplePriority Tin;
}

```

The client then makes an invocation on a remote object. The work area is automatically propagated; none of the methods on the remote object take a work area argument. On the remote side, the request is first handled by the SimpleSampleBean; the bean first reads the site identifier and priority properties from the work area. The bean then intentionally attempts, and fails, both to write directly into the imported work area and to override the read-only site-identifier property.

The SimpleSampleBean successfully begins a nested work area, in which it overrides the client's priority, then calls another bean, the SimpleSampleBackendBean. The SimpleSampleBackendBean reads the properties from the work area, which contains the site identifier set in the client and priority set in the SimpleSampleBean. Finally, the SimpleSampleBean completes its nested work area, writes out a message based on the site-identifier property, and returns.

The implementation of this application is discussed in the topic, [Developing applications that use work areas](#).

## Accessing the WorkArea service

The WorkArea service provides a JNDI binding to an implementation of the UserWorkArea interface under the name `java:comp/websphere/UserWorkArea`. Applications that need to access the service can perform a lookup on that JNDI name, as shown in the following code example:

```

import com.ibm.websphere.workarea.*;
import javax.naming.*;

public class SimpleSampleServlet {
 ...

 InitialContext jndi = null;
 UserWorkArea userWorkArea = null;
 try {
 jndi = new InitialContext();
 userWorkArea = (UserWorkArea)jndi.lookup(
 "java:comp/websphere/UserWorkArea");
 }
 catch (NamingException e) { ... }
}

```

The next step is to use the `begin()` method to create a new work area and associate it with the calling thread, as described in the topic [Beginning a new work area](#).

## Beginning a new work area

Be sure that your client has a reference to the UserWorkArea interface, as described in the topic [Accessing the WorkArea Service](#) or a reference to a user defined partition as defined in “[Accessing a user defined work area partition](#)” on page 1140. The following steps use the UserWorkArea partition as an illustration. However a user defined partition can be used in the exact same way.

Use the `begin()` method to create a new work area and associate it with the calling thread. The `begin()` method takes a string as an argument; the string is used to name the work area. The argument must not be null, which causes the `java.lang.NullPointerException` to be raised. In the following code example, the application begins a new work area with the name SimpleSampleServlet:

```

public class SimpleSampleServlet {
 ...
 try {

```

```

 ...
 userWorkArea = (UserWorkArea)jndi.lookup(
 "java:comp/websphere/UserWorkArea");
}
...

userWorkArea.begin("SimpleSampleServlet");
...
}

```

The `begin()` method is also used to create nested work areas; if a work area is associated with a thread when the `begin()` method is called, the method creates a new work area nested within the existing work area.

The `WorkArea` service makes no use of the names associated with work areas; You can name work areas in any way that you choose. Names are not required to be unique, but the usefulness of the names for debugging is enhanced if the names are distinct and meaningful within the application. Applications can use the `getName()` method to return the name associated with a work area by the `begin()` method.

Using a work area

## Setting properties in a work area

An application with a current work area can insert properties into the work area and retrieve the properties from the work area. The `UserWorkArea` interface provides two `set()` methods for setting properties and a `get()` method for retrieving properties. The two-argument `set()` method inserts the property with the property mode of normal. The three-argument `set()` method takes a property mode as the third argument. (See "Setting property modes", later in this topic.)

Both `set()` methods take the key and the value as arguments. The key is a `String`; the value is an object of the type `java.io.Serializable`. None of the arguments can be null, which causes the `java.lang.NullPointerException` to be raised.

The `WorkArea` `SimpleSample` application uses objects of two classes, the `SimpleSampleCompany` class and the `SimpleSampleProperty` class, as values for properties. The `SimpleSampleCompany` class is used for the site identifier, and the `SimpleSamplePriority` class is used for the priority. These classes are shown in following code example:

```

public class SimpleSampleServlet {
 ...
 userWorkArea.begin("SimpleSampleServlet");

 try {
 // Set the site-identifier (default is Main).
 userWorkArea.set("company",
 SimpleSampleCompany.Main, PropertyModeType.read_only);

 // Set the priority.
 userWorkArea.set("priority", SimpleSamplePriority.Silver);
 }

 catch (PropertyReadOnly e) {
 // The company was previously set with the read-only or
 // fixed read-only mode.
 ...
 }

 catch (NotOriginator e) {
 // The work area originated in another process,
 // so it can't be modified here.
 ...
 }
}

```

```

catch (NoWorkArea e) {
 // There is no work area begun on this thread.
 ...
}

// Do application work.
...
}

```

The `get()` method takes the key as an argument and returns a Java Serializable object as the value associated with the key. For example, to retrieve the value of the company key from the work area, the code example above uses the `get()` method on the work area to retrieve the value.

**Setting property modes.** The two-argument `set()` method on the `UserWorkArea` interface takes a key and a value as arguments and inserts the property with the default property mode of normal. To set a property with a different mode, applications must use the three-argument `set()` method, which takes a property mode as the third argument. The values used to request the property modes are as follows:

- **Normal:** `PropertyModeType.normal`
- **Fixed normal:** `PropertyModeType.fixed_normal`
- **Read-only:** `PropertyModeType.read_only`
- **Fixed read-only:** `PropertyModeType.fixed_readonly`

## Using a work area to manage local work

Be sure that your client has a reference to the `UserWorkArea` interface, as described in the topic [Accessing the WorkArea Service](#) or a reference to a user defined partition as defined in “Accessing a user defined work area partition” on page 1140. The following steps use the `UserWorkArea` partition as an illustration. However a user defined partition can be used in the exact same way.

In a business application that uses work areas, server objects typically retrieve the work area properties and use them to guide local work.

1. Retrieving the name of the active work area This step determines whether the calling thread is associated with a work area.
2. Overriding work area properties. Server objects can override client work area properties by creating their own, nested work area.
3. Retrieving properties from a work area
4. Retrieving a list of all keys in a work area
5. Querying the mode of a work area property
6. Deleting a work area property
7. Completing a work area

The server side of the `WorkArea SimpleSample` application accepts remote invocations from clients. With each remote call, the server also gets a work area from the client if the client has created one. The work area is propagated transparently. None of the remote methods includes the work area on its argument list.

In the example application, the server objects use the work area interface for demonstration purposes only. For example, the `SimpleSampleBean` intentionally attempts to write directly to an imported work area, which triggers the `NotOriginator` exception. Likewise, the bean intentionally attempts to mask the read only `SimpleSampleCompany`, which triggers the `PropertyReadOnly` exception. The `SimpleSampleBean` also nests a work area and successfully overrides the priority property before invoking the `SimpleSampleBackendBean`. A true business application would extract the work area properties and use them to guide the local work. The `SimpleSampleBean` mimics this by writing a message that function is denied when a request emanates from a sales environment.

## Retrieving the name of the active work area

Applications use the `getName()` method on the `UserWorkArea` interface to retrieve the name of the current work area. This is the recommended method for determining whether the thread is associated with a work area; if the thread is not associated with a work area, the `getName()` method returns null. In the following code example, the name of the work area corresponds to the name of the class in which the work area was begun.

```
public class SimpleSampleBeanImpl implements SessionBean {

 ...

 public String [] test() {
 // Get the work-area reference from JNDI.
 ...

 // Retrieve the name of the work area. In this example,
 // the name is used to identify the class in which the
 // work area was begun.
 String invoker = userWorkArea.getName();
 ...
 }
}
```

## Overriding work area properties

Work areas are inherently associated with the process that creates them. In the sample application, the client begins a work area and sets into it the site-identifier and priority properties. This work area is propagated to the server when the client makes a remote invocation.

Applications nest work areas in order to temporarily override properties imported from a client process. The nesting mechanism is automatic; invoking `begin` on the `UserWorkArea` interface from within the scope of an existing work area creates a nested work area that inherits the properties from the enclosing work area. Properties set into the nested work area are strictly associated with the process in which the work area was begun; the nested work area must be completed within the process that created them. If a work area is not completed by the creating process, the work-area facility terminates the work area when the process exits. After a nested work area is completed, the original view of the enclosing work area is restored. However, the view of the complete set of work areas associated with a thread cannot be decomposed by downstream processes.

Applications set properties into a work area using property modes to ensure that a particular property is fixed (not removable) or read-only (not overrideable) within the scope of the given work area.

In the following code example, the server-side sample bean attempts to write directly to the imported work area; because the `UserWorkArea` partition is not defined to be bidirectional, this action is not permitted, and the `NotOriginator` exception is thrown. When the `UserWorkArea` partition is not defined as bidirectional, the sample bean must begin its own work area in order to override any imported properties, as shown in the second code example. If a work area in a user defined partition is used and is defined as bidirectional, this bean can set context into the work area before beginning another work area. This context set in the bidirectional case will propagate back to the caller. See "Bidirectional propagation" on page 1139 for additional information.

```
public class SimpleSampleBeanImpl implements SessionBean {

 public String [] test() {
 ...
 String invoker = userWorkArea.getName();

 try {
 userWorkArea.set("key", "value");
 }
 catch (NotOriginator e) {
 ...
 }
 }
}
```

```

 }
 ...
}
}

```

The following code example demonstrates beginning a nested work area, using the name of the creating class to identify the nested work area.

```

public class SimpleSampleBeanImpl implements SessionBean {

 public String [] test() {
 ...
 String invoker = userWorkArea.getName();
 try {
 userWorkArea.set("key", "value");
 }
 catch (NotOriginator e) {
 }

 // Begin a nested work area. By using the name of the creating
 // class as the name of the work area, we can avoid having
 // to explicitly set the name of the creating class in
 // the work area.
 userWorkArea.begin("SimpleSampleBean");

 ...
 }
}

```

In the example application, the client sets the site-identifier property as read-only; that guarantees that the request will always be associated with the client's company identity. A server cannot override that value in a nested work area. In the following code example, the SimpleSampleBean attempts to change the value of the site-identifier property in the nested work area it created.

```

public class SimpleSampleBeanImpl implements SessionBean {

 public String [] test() {
 ...

 String invoker = userWorkArea.getName();
 try {
 userWorkArea.set("key", "value");
 }
 catch (NotOriginator e) {
 }

 // Begin a nested work area.
 userWorkArea.begin("SimpleSampleBean");

 try {
 userWorkArea.set("company",
 SimpleSampleCompany.London_Development);
 }
 catch (NotOriginator e) {
 }
 ...
 }
}

```

## Retrieving work area properties

Properties can be retrieved from a work area by using the `get()` method. This method is intentionally lightweight; there are no declared exceptions to handle. If there is no active work area, or if there is no such property set in the current work area, the `get()` method returns null.

**Note:** The `get()` method can raise a `NotSerializableError` in the relatively rare scenario in which CORBA clients set composed data types and invoke enterprise-bean interfaces.

The following example shows the retrieval of the site-identifier and priority properties by the `SimpleSampleBean`. Recall that one property was set into an outer work area by the client, and the other property was set into the nested work area by the server-side bean; the nesting is transparent to the retrieval of the properties.

```
public class SimpleSampleBeanImpl implements SessionBean {

 public String [] test() {
 ...

 // Begin a nested work area.
 userWorkArea.begin("SimpleSampleBean");
 try {
 userWorkArea.set("company",
 SimpleSampleCompany.London_Development);
 }
 catch (NotOriginator e) {
 }

 SimpleSampleCompany company =
 (SimpleSampleCompany) userWorkArea.get("company");
 SimpleSamplePriority priority =
 (SimpleSamplePriority) userWorkArea.get("priority");
 ...
 }
}
```

## Retrieving a list of all keys in a work area

The `UserWorkArea` interface provides the `retrieveAllKeys()` method for retrieving a list of all the keys visible from a work area. This method takes no arguments and returns an array of strings. This method returns null if there is no work area associated with the thread. If there is an associated work area containing no properties, the method returns an array of size 0.

## Querying the mode of a work area property

The `UserWorkArea` interface provides the `getMode()` method for determining the mode of a specific property. This method takes the property's key as an argument and returns the mode as a `PropertyModeType` object. (See *Setting property modes* for more information on names of mode types.) If the specified key does not exist in the work area, the method returns `PropertyModeType.normal`, indicating that the property can be set and removed without error.

## Deleting a work area property

The `UserWorkArea` interface provides the `remove()` method for deleting a property from the current scope of a work area. If the property was initially set in the current scope, removing it deletes the property. If the property was initially set in an enclosing work area, removing it deletes the property until the current scope is completed. When the current work area is completed, the deleted property is restored.

The `remove()` method takes the property's key as an argument. Only properties with the modes `normal` and `read-only` can be removed. Attempting to remove a fixed property causes the `PropertyFixed` exception to be thrown. Attempting to remove properties in work areas that originated in other processes causes the `NotOriginator` exception to be thrown.

## Completing a work area

After an application has finished using a work area, it must complete the work area by calling the `complete()` method on the `UserWorkArea` interface. This terminates the association with the calling thread

and destroys the work area. If the complete method is called on a nested work area, the nested work area is terminated and the parent work area becomes the current work area. If there is no work area associated with the calling thread, a NoWorkArea exception is thrown.

Every work area must be completed, and work areas can be completed only by the originating process. For example, if a server attempts to call the complete() method on a work area that originated in a client, a NotOriginator exception is thrown. Work areas created in a server process are never propagated back to an invoking client process.

**Note:** The WorkArea service claims full local-remote transparency. Even if two beans happen to be deployed in the same server, and therefore the same JVM and process, a work area begun on an invocation from another is completed and the bean in which the request originated is always in the same state after any remote call.

The following code example shows the completion of the work area created in the client application.

```
public class SimpleSampleServlet {
 ...
 userWorkArea.begin("SimpleSampleServlet");
 userWorkArea.set("company",
 SimpleSampleCompany.Main, PropertyModeType.read_only);
 userWorkArea.set("priority", SimpleSamplePriority.Silver);
 ...

 // Do application work.
 ...

 // Terminate the work area.
 try {
 userWorkArea.complete();
 }

 catch (NoWorkArea e) {
 // There is no work area associated with this thread.
 ...
 }

 catch (NotOriginator e) {
 // The work area was imported into this process.
 ...
 }
 ...
}
```

The following code example shows the sample application completing the nested work area it created earlier in the remote invocation.

```
public class SimpleSampleBeanImpl implements SessionBean {

 public String [] test() {
 ...

 // Begin a nested work area.
 userWorkArea.begin("SimpleSampleBean");
 try {
 userWorkArea.set("company",
 SimpleSampleCompany.London_Development);
 }
 catch (NotOriginator e) {
 }

 SimpleSampleCompany company =
 (SimpleSampleCompany) userWorkArea.get("company");
 SimpleSamplePriority priority =
 (SimpleSamplePriority) userWorkArea.get("priority");
 }
}
```

```

 // Complete all nested work areas before returning.
 try {
 userWorkArea.complete();
 }
 catch (NoWorkArea e) {
 }
 catch (NotOriginator e) {
 }
}
}

```

---

## Managing the work area service

The WorkArea service is managed using the administrative console. There are two administrative tasks associated with work areas:

- Enabling the WorkArea service. The WorkArea Service is enabled by default on both clients and servers.
- Managing the size of work areas. Applications can set maximum sizes on each work area to be sent and to be accepted.

### Enabling the WorkArea service

For an application to take advantage of work areas, the WorkArea service must be enabled for both clients and servers. In both cases, the service is enabled by default.

1. Enable (or disable) the use of work areas on a server:
  - a. Start the administrative console.
  - b. Select **Servers > server\_name > WorkArea Service**.
  - c. Select or clear the **Startup** checkbox. This specifies whether or not the server should automatically start the WorkArea service when the server starts.
2. Enable (or disable) the use of work areas on a client: Set the `com.ibm.websphere.workarea.enabled` property to `TRUE` or `FALSE` before starting the client. For example, edit the `launchClient` script in the `$WAS_HOME/bin` directory and add the following to the Java invocation:

```
-Dcom.ibm.websphere.workarea.enabled=false
```

### WorkArea service settings

Use this page to manage the work area service.

The work area service manages the scope and implicit propagation of application context.

To view this administrative console page, click **Servers > Application Servers > server\_name > Work Area Service** .

#### **Startup:**

Specifies whether the server will attempt to start the work area service.

**Default**

Selected

**Range****Selected**

When the application server starts, it attempts to start the work area service automatically.

**Cleared**

The server does not try to start the work area service. If work areas are to be used on this application server, the system administrator must start the service manually or select this property then restart the server.

**Maximum Send Size:**

Specifies the maximum size of data that can be sent within a single work area.

<b>Data type</b>	Integer
<b>Units</b>	Bytes
<b>Default</b>	32767
<b>Range</b>	-1 to no limit
	<b>-1</b> Default.
	<b>0</b> No limit.

**Maximum Receive Size:**

Specifies the maximum size of data that can be received by a single work area.

<b>Data type</b>	Integer
<b>Units</b>	Bytes
<b>Default</b>	32767
<b>Range</b>	-1 to no limit
	<b>-1</b> Default.
	<b>0</b> No limit.

## Managing the size of work areas

Applications can set maximum sizes on each work area to be sent or received. By default, the maximum size of a work area that is sent by a client and received, then possibly re-sent, by a server is 32,768 bytes. You can change this size as described in this topic.

1. Change the size of the work area that can be sent or received by a server:
  - a. Start the administrative console.
  - b. Select **Servers > server\_name > WorkArea Service**.
  - c. Enter a new value in the **maxSendSize** field to modify the size of the work area that this server can send, or enter a new value in the **maxReceiveSize** field to modify the size of the work area that this server can accept.
2. Change the size of the work area that can be sent by a client: Set the `com.ibm.websphere.workarea.maxSendSize` property to the desired number of bytes before starting the client. This can be done in several ways. For example, to set the maximum size to 10,000 bytes, edit the `launchClient` script in the `$WAS_HOME/bin` directory and add the following to the Java invocation:

```
-Dcom.ibm.websphere.workarea.maxSendSize=10000
```

The maximum size that can be specified is determined by the maximum value expressible in the Java Integer data type, 2,147,483,647. The smallest maximum size that can be specified is 1. Using a maximum size of 1 byte effectively means that no requests associated with the work area can leave the

system or enter another system. A value of 0 means that no limit is imposed. A value of -1 means that the default value is to be honored. The default value is also used if an invalid value or a malformed property is specified.

---

## Configuring work area partitions on the server

The work area partition service extends the work area service by allowing the creation of multiple work areas with more configuration options. Follow these steps to create and configure a work area partition:

1. Start the administrative console.
2. Click **Servers > Application Servers > *server\_name* > Work Area Partition Service**.
3. Click **New**.
4. On the settings page for work area partitions, specify values such as the partition name, `maxSendSize` and `maxReceiveSize`, then click OK.
5. Save the new configuration and restart the server to apply the new configuration

You have created a work area partition

Retrieve the partition through the work area partition manager interface and use it as defined by the work area service and the work area service interface. See the topic, “Example: Work area partition manager” on page 1136, for an example.

## Work area partition service

The work area partition service is an extension of the work area service that allows the creation of multiple custom work areas. The work area partition service is an optional service to users. Any user that currently uses the work area service and the `UserWorkArea` partition can continue using it in the same manner. The `UserWorkArea` partition is created automatically (if it has not been disabled) by the work area partition service. By allowing a user the option to create their own work area partition through the work area partition service, they can have more control over configuration and access to their partition.

Unlike the `UserWorkArea` partition, which is publicly known, work areas created by the work area partition service are accessible to, and known only by the creator. However, the work area partition service does not strictly enforce that a partition is accessed and/or operated on exclusively by the partition creator. There are no limitations should the creator want to publish their work area partition and make it publicly available by binding their partition reference in java naming or by other means. However, the work area partition service does try to hide a partition as much as possible should a user not want others to know about a certain partition. The work area partition service does not allow a person to determine, or query the names of all the partitions that have been created; however, it does not restrict the partitions from being accessed by users other than the creator of that partition. The context of a partition, such as the `UserWorkArea` partition or a user defined partition, is scoped to a single thread and is not accessible by multiple threads.

The work area partition reference returned to a user implements `javax.naming.Referenceable` (as well as `com.ibm.websphere.UserWorkArea`), therefore a user can bind their partition into naming should they want to make their partition publicly available. An alternative to using java naming to bind and access the partition is to use the work area partition manager interface. Anyone can access the work area partition manager interface; therefore, if a user wants to make their partition publicly available, they simply need to publish their partition name. Other users can then call the `getWorkAreaPartition(..)` method on the work area partition manager interface with the published name.

The `WorkAreaPartitionManager.createWorkAreaPartition(..)` method can only be used from a J2EE client. To create a work area partition on the server side, one must use the administrative console. On the server side a work area partition must be created during server startup because each partition needs to be register with the appropriate web and EJB collaborators before the server has started. Custom work area partitions are created by the work area partition service and defined by the `UserWorkArea` interface.

The work area partition service also allows a user to configure partitions with additional properties that are not available on the UserWorkArea partition, such as bidirectional propagation of work area partition context and deferred attribute serialization. These properties are available as configuration properties when creating a partition. The properties are defined as follows:

### **Bidirectional propagation of WorkArea context**

If a remote invocation is issued from a thread associated with a work area, a copy of the work area is automatically propagated to the target object, which can use or ignore the information in the work area as necessary. If the calling application has a nested work area associated with it, a copy of the nested work area and all its ancestors are propagated to the target application. The target application can locally modify the information, as allowed by the property modes, by creating additional nested work areas; this information will be propagated to any remote objects that it invokes.

Whether context changes will propagate back to a calling application from a remote application depends on the configuration of the work area partition. If a user creates a partition to be bidirectional (selects the Bidirectional property during creation), changes made by a remote application will propagate back to the calling application, meaning that changes made to the work area context by a downstream process will propagate back up stream. The UserWorkArea partition is not configured (and can never be configured) to be bidirectional; therefore context changes will only flow to downstream processes and will not propagate back upstream. See “Bidirectional propagation” on page 1139 for further explanation.

### **Deferred attribute serialization of WorkArea context**

By default, on each set operation the attribute set into a work area is automatically serialized by the work area service. On each subsequent get operation on that same attribute it is deserialized and returned to the requester. This gives the work area service complete control of the attribute such that any changes to a mutable object are not reflected in the work area’s copy of the attribute unless a user specifically resets the attribute into the work area. However, this can potentially lead to excessive serialization and deserialization. Excessive serialization and deserialization can result in observable performance degradation under heavy load. The deferred attribute serialization configuration property is a caching feature that reduces serialization and deserialization operations. When deferred attribute serialization is enabled (by selecting the Deferred Attribute Serialization field during creation) in a client or server process, attributes set into the work area Service are not automatically serialized during the set operation. Rather, a reference to the attribute is stored in the work area. If the attribute is mutable, then changes to the object will be reflected in the work area’s reference to that attribute. When a get operation is performed on that attribute, the reference to that object is returned and no deserialization is performed. Attributes are not actually serialized until the thread with which the attribute is associated makes a remote IIOp invocation. At that point the attribute is serialized and the serialized form of the attribute is cached. If the attribute is not reset into the work area, changes to the original attribute are still reflected within the attribute contained within the work area because the work area still holds a cached reference to the original object. However, if the work area has not been told that the attribute has changed by resetting the attribute into the work area, subsequent remote requests continues to use the cached serialized version of the attribute and direct changes to the mutable attribute are not propagated. This is an important distinction between enabling and not enabling the deferred attribute serialization configuration property and a user must pay close attention to this difference and how mutable objects are handled when enabling deferred attribute serialization. The work area service releases cached references and cached serialized versions of attributes when any of the following occur:

- An attribute is reset or removed.
- The work area is explicitly completed by the application.
- Server component ends execution of the request during which the work area was begun.
- Client process which began the work area terminates.

## Partition context propagation across process boundaries

Work area context automatically propagates from client to server when a client makes a remote call to a server. If a client is configured with, for example, three different work area partitions when it makes a remote call to a server, server1; the context associated with each partition on the client thread propagates to server1. If the same three partitions reside (have been created) on server1, the context is demarshaled to the appropriate partition. However, if none or only a few of the three partitions have been created on server1, only the context associated with a partition that is resident on both the client and server is demarshaled. The context associated with a partition that is not resident on server1 is still resident on server1 but will not be accessible. The context associated with partitions that are not resident on server1 must remain resident on server1 in case another remote call is made to a different server. Going one step further, if server1 makes a call to yet another server, server2 and assume server2 has created all the same partitions that the client has, server2 receives the context for the partitions that were not resident on server1. Any partitions that reside on server1 that did not reside on the client, now have its context propagated to server2.

## WorkAreaPartitionManager interface

Applications interact with the work area partition service by using the WorkAreaPartionManager interface. A user can retrieve an instance of the WorkAreaPartitionManager out of naming and use the methods defined below. An implementation of the WorkAreaPartitionManager is bound in java naming at "java:comp/websphere/WorkAreaPartitionManager". This interface is responsible for creating, retrieving, and manipulating work area partitions:

```
package com.ibm.websphere.workarea;

import com.ibm.websphere.workarea.UserWorkArea;
import com.ibm.websphere.workarea.PartitionAlreadyExistsException;
import com.ibm.websphere.workarea.NoSuchPartitionException;
import java.util.Properties;

public interface WorkAreaPartitionManager {

 public UserWorkArea getWorkAreaPartition(String partitionName) throws NoSuchPartitionException;

 public UserWorkArea createWorkAreaPartition(String partitionName, Properties props) throws
 PartitionAlreadyExistsException, java.lang.IllegalAccessException;
}
```

Programmatically creating a work area partition (through the createWorkAreaPartition(..) method) is only available on the J2EE client. To create a work area partition on the server, one must use the WebSphere Administrative Console. All partitions in a server process must be created before server start up is complete to allow the work area service to register with the appropriate container collaborators. Therefore, calling createWorkAreaPartition(..) in a server process after the server has started results in a java.lang.IllegalAccessException. The createWorkAreaPartition(..) method can be called in a J2EE process at any time.

### Exceptions

The work area partition service defines the following exceptions for use with the WorkAreaPartitionManager interface:

#### **PartitionAlreadyExistsException**

This exception is raised by the createWorkAreaPartition(..) method on the WorkAreaPartitionManager implementation if a user tries to create a work area partition with a partition name that already exists. Partition names must be unique.

#### **NoSuchPartitionException**

This exception is raised by the getWorkAreaPartition(..) method on the WorkAreaPartitionManager implementation if a user requests a work area partition with a partition name that does not exist.

## java.lang.IllegalAccessException

This exception is raised by the createWorkAreaPartition(..) method on the WorkAreaPartitionManager implementation if a user tries to create a work area partition during runtime on a server process. This method can only be used on a J2EE client process. On the server process a partition must be created using the Administrative Console.

## Example: Work area partition manager

The example below demonstrates the use of the work area partition manager interface. The sample illustrates how to create and retrieve a work area partition programmatically. Please note that programmatically creating a work area partition is only available on the Java 2 platform, Enterprise Edition (J2EE) client. To create a work area partition on the server one must use the WebSphere administrative console. See "Work area partition service" on page 1133 for configuration parameters available to configure a partition.

```
import com.ibm.websphere.workarea.WorkAreaPartitionManager;
import com.ibm.websphere.workarea.UserWorkArea;
import com.ibm.websphere.workarea.PartitionAlreadyExistsException;
import com.ibm.websphere.workarea.NoSuchPartitionException;
import java.lang.IllegalAccessError;
import java.util.Properties;
import javax.naming.InitialContext;

//This sample demonstrates how to retrieve an instance of the
//WorkAreaPartitionManager implementation and how to use that
//instance to create a WorkArea partition and retrieve a partition.
//NOTE: Creating a partition in the way listed below is only available
//on a J2EE client. To create a partition on the server use the
//WebSphere administrative console. Retrieving a WorkArea
//partition is performed in the same way on both client and server.

public class Example {

 //The name of the partition to create/retrieve
 String partitionName = "myPartitionName";
 //The name in java naming the WorkAreaPartitionManager instance is bound to
 String jndiName = "java:comp/websphere/WorkAreaPartitionManager";

 //On a J2EE client a user would create a partition as follows:
 public UserWorkArea myCreate(){
 //Variable to hold our WorkAreaPartitionManager reference
 WorkAreaPartitionManager partitionManager = null;
 //Get an instance of the WorkAreaPartitionManager implementation
 try {
 InitialContext initialContext = new InitialContext();
 partitionManager = (WorkAreaPartitionManager) initialContext.lookup(jndiName);
 } catch (Exception e) { }

 //Set the properties to configure our WorkArea partition
 Properties props = new Properties();
 props.put("maxSendSize","12345");
 props.put("maxReceiveSize","54321");
 props.put("Bidirectional","true");
 props.put("DeferredAttributeSerialization","true");

 //Variable used to hold the newly created WorkArea Partition
 UserWorkArea myPartition = null;

 try{
 //This is the way to create a partition on the J2EE client. Use the
 //WebSphere Administrative Console to create a WorkArea Partition
 //on the server.
 myPartition = partitionManager.createWorkAreaPartition(partitionName,props);
 }
 catch (PartitionAlreadyExistsException e){ }
 }
}
```

```

 catch (IllegalAccessException e){ }

 return myPartition;
 }

 // . . .

 //In order to retrieve a WorkArea partition at some time later or
 //from some other class, do the following (from client or server):
 public UserWorkArea myGet(){
 //Variable to hold our WorkAreaPartitionManager reference
 WorkAreaPartitionManager partitionManager = null;
 //Get an instance of the WorkAreaPartitionManager implementation
 try {
 InitialContext initialContext = new InitialContext();
 partitionManager = (WorkAreaPartitionManager) initialContext.lookup(jndiName);
 } catch (Exception e) { }

 //Variable used to hold the retrieved WorkArea partition
 UserWorkArea myPartition = null;
 try{
 myPartition = partitionManager.getWorkAreaPartition(partitionName);
 }catch(NoSuchPartitionException e){ }

 return myPartition;
 }
}

```

## Work area partition collection

Use this page to manage the work area service.

The work area partition service supports the definition of custom work area partitions.

To view this administrative console page, click **Servers > Application Servers > *server\_name* > Work Area Partition Service > Work Area Partitions**.

### Name

Specifies the name of the work area partition. This name must be unique and is used to retrieve the partition.

### Description

Specifies the description of the work area partition.

### Startup

Specifies whether the server attempts to start the specified service when the server starts.

### Bidirectional

Permits applications to modify a work area's context that is imported by a J2EE request; modified properties are propagated back to the requestor's environment. This option is disabled by default.

### Maximum send size

The maximum size of data that can be sent within a single work area. (0 = no limit; -1 = default)

### Maximum receive size

The maximum size of data that can be received within a single work area. (0 = no limit; -1 = default)

### Deferred attribute serialization

Specifies whether attribute serialization is deferred until the work area is propagated on a remote invocation.

## Work area partition settings

Use this page to modify the work area service settings.

The work area partition service supports the definition of custom work area partitions.

To view this administrative console page, click **Servers > Application Servers > server\_name > Work Area Partition Service > Work Area Partitions > Work\_area\_partion\_name**.

### **Name:**

Specifies the name of the work area partition. This unique name is used to retrieve the partition.

Extended information about the field, if needed, can be added here.

**Data type** String

### **Description:**

Specifies the description of the work area partition.

**Data type** String

### **Startup:**

Specifies whether the server attempts to start the specified service when the server starts.

**Data type** Check box  
**Default** Selected

### **Bidirectional:**

Permits applications to modify a work area's context that is imported by a J2EE request; modified properties are propagated back to the requestor's environment. This option is disabled by default.

**Data type** Check box  
**Default** Cleared

### **Maximum send size:**

The maximum size of data that can be sent within a single work area. (0 = no limit; -1 = default)

**Data type** Integer  
**Units** Milliseconds|Seconds|Hours|Etc.  
**Default** 32768  
**Range** 0 (no limit) to -1 (default)

### **Maximum receive size:**

The maximum size of data that can be received within a single work area. (0 = no limit; -1 = default)

**Data type** Integer  
**Units** Milliseconds|Seconds|Hours|Etc.  
**Default** 32768

Range

0 (no limit) to -1 (default)

**Deferred attribute serialization:**

Specifies whether attribute serialization is deferred until the work area is propagated on a remote invocation. This option is disabled by default.

Data type

Check box

Default

Cleared

## Bidirectional propagation

### Example: Bidirectional propagation of work area context

Whether context changes propagate back to a calling application from a remote application depends on the configuration of the work area partition. If a user creates a bidirectional partition, changes made by a remote application propagate back to the calling application. In other words, changes made to the work area context by a downstream process propagate back up stream. Figure 1 illustrates distribution of work area context on a remote call when the partition containing the given work area is configured for bidirectional propagation of its work area context. For this illustration, the client and server must have created a partition with the same name.

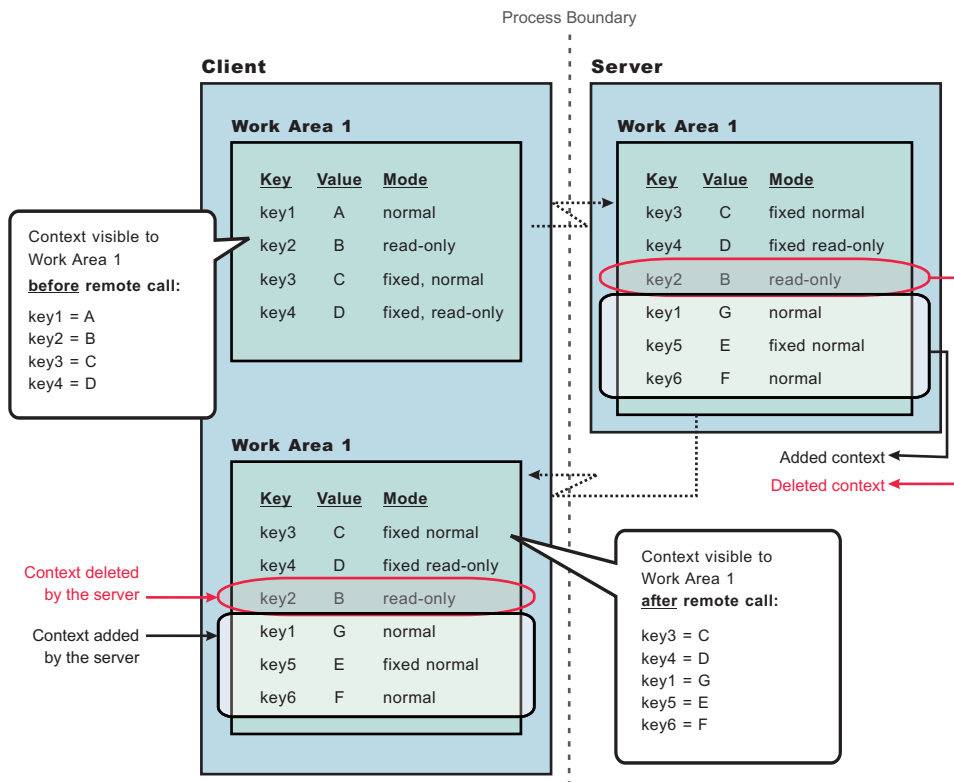

Figure 27. Figure 1

As Figure 1 shows, when the client makes a remote call to the server, the server receives the context set by the client process. The server then can make changes to this context or add to it. In this illustration, the server overwrites the value at **key1**, removes the property at **key2**, and adds two new properties at **key5** and **key6**. When the server application returns to the client, the work area context is propagated back to

the client and demarshalled. The current work area is then updated with the new context. Note, that if the partition is not configured as bidirectional, and the server tries to change or remove context in work area, "Work Area 1", it will receive a `com.ibm.websphere.workarea.NotOriginator` exception since the client was the originator of the work area. The server can retrieve the context in "Work Area 1". This is the main distinction between bidirectional propagation of context and non-bidirectional propagation.

### Bidirectional propagation of nested work area context

If a remote application needs to add context to a work area that is only used by itself or any other remote objects, the remote application should begin another work area. By beginning a new work area, the new context added is scoped to that application and does not flow back to the calling application. The major benefit of nesting work areas is that nesting work areas allows an application to scope work area context to a given application. Taking the above illustration one step further, if the server has begun a work area before overwriting the value at **key1**, removing the property at **key2**, or adding new properties at **key5** and **key6**; those changes would not have propagated back to the client. This is shown in Figure 2. You can also see from this figure that the client does not receive the context from the nested work area started by the server.

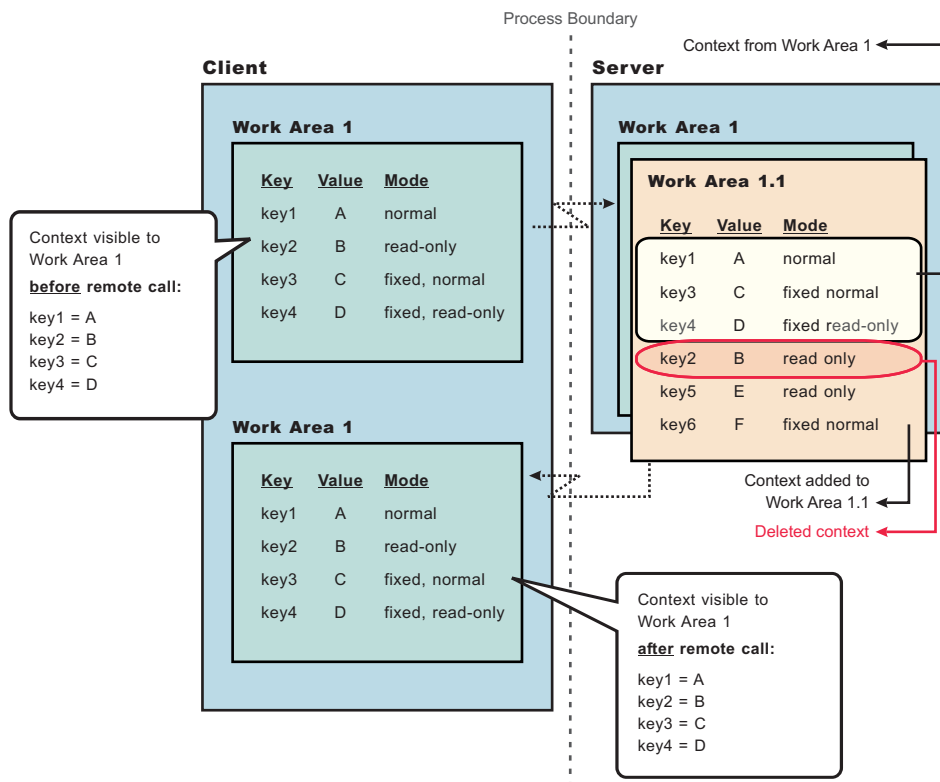

Figure 28. Figure 2

### Accessing a user defined work area partition

The work area partition service provides a Java Naming and Directory Interface (JNDI) binding to an implementation of the work area partition manager interface under the name `java:comp/websphere/WorkAreaPartitionManager`. Applications that need to access their partition can perform a lookup on that JNDI name and then use the `getWorkAreaPartition()` method on the work area partition manager, as shown in the following code example:

```

import com.ibm.websphere.workarea.*;
import javax.naming.*;

public class SimpleSampleServlet {
 ...

 //Variable to hold our WorkAreaPartitionManager implementation
 WorkAreaPartitionManager partitionManager = null;
 try {
 InitialContext initialContext = new InitialContext();
 partitionManager = (WorkAreaPartitionManager)
 initialContext.lookup("java:comp/websphere/UserWorkArea");
 } catch (Exception e) {...}

 //Variable used to hold the retrieved WorkArea Partition
 UserWorkArea myPartition = null;
 try{
 myPartition = partitionManager.getWorkAreaPartition(partitionName);
 }catch(NoSuchPartitionException e){...}
}

```

The next step is to use the `begin()` method to create a new work area and associate it with the calling thread, as described in the topic [Beginning a new work area](#).

---

## Chapter 23. Working with the Event Programming Model in WebSphere

How to use the Common Event Infrastructure in the WebSphere programming environment.

The Event Programming Model is part of the wider programming model in WebSphere. The Event Programming Model provides a standard mechanism for the actions of applications to be recorded as events, or to trigger work in other applications. Events can also be generated at significant points from within processes, providing a powerful tool for analyzing the execution of the process. The Event Programming Model provides the following facilities :

- Standard interfaces and services for WebSphere applications to create event objects, store them and retrieve them later. There are also facilities that pass event objects to registered applications either directly, in the context of the producing (source) application, or indirectly via JMS.
- The ability to fill an event object with additional data needed to correlate events together. This data has to describe the complete execution and business environment to allow different types of users retrieving events to specify queries to satisfy their own data needs.
- A simple event browser (Event browser) for browsing the events that have been stored.

The Event Programming Model exploits the Common Event Infrastructure, a shared component that can be exploited by different types of middleware. The Common Event Infrastructure provides the means to store, update and distribute events to event consumers listening on JMS topics.

**Note:** This information set provides enough information for you to make full use of the Event Programming Model but, if you wish to know more about the Common Event Infrastructure, you can read the developers' guide here: "Common Event Infrastructure Developer's Guide" on page 1173

---

### The Common Event Infrastructure in WebSphere

This topic describes how WebSphere takes advantage of the Common Event Infrastructure to work with application events.

The Common Event Infrastructure provides the runtime environment to persistently store and retrieve events from many different programming environments. See Introduction to the common event infrastructure for more information about the common event infrastructure.

An application creates an event object whenever something happens that either should be recorded for later analysis or which may require additional work to be triggered. This event object describes event type, when the application generated the event and a small number of properties that are relevant to the event.

The application creating the event object is called the event source. The event source passes the event object to the common event infrastructure where data from the event object is aggregated with information from the execution environment and an event catalog before being passed to the Common Event Infrastructure.

The Common Event Infrastructure is a shared component that can either be inside or outside WebSphere Application Server. It provides the means to store, update and distribute events to event consumers listening on JMS topics. Event consumers process events outside the environment of the event source. In fact they are typically processing events from a number of event sources. This has two consequences:

- All event sources need to use a common structure for the event. The accepted standard for such a structure is called the Common Base Event. This defines common fields, the values they can take and the exact meanings of these values.

- The Common Base Event needs to contain all of the information needed by the consumers to understand the event. This includes information about the runtime environment, the business environment and the instance of the application object that created the event. See The Common Base Event model for more information.

## Events and Common Base Events

Understanding the relationship between application events and Common Base Events

An **event** occurs when something significant happens in the IT system. An application processing a new customer order or a failure occurring in a critical part of the system are examples of events.

Information about the event is captured in an event object. This event object describes that the event has occurred, when this happened and any data that is relevant to the event.

The Common Base Event is an XML schema defined as part of the Autonomic Computing initiative IBM Autonomic Computing Initiative. It is used to describe a situation that has occurred in the IT system which may be of interest elsewhere. This includes a precise description of what happened and the environment in which it occurred.

There are two major benefits of adopting the Common Base Event model consistently across systems:

- it saves the expense of creating, documenting and maintaining many record structures
- it makes it possible to manage and process data from a variety of subsystems using common utilities.

In addition to structure, the Common Base Event specification provides guidelines on how to set the attributes and elements of the Common Base Event. This consistency is critical to enabling autonomic correlation of Common Base Events relating to a single situation detected by a number of subsystems.

## The structure of the Common Base Event

The different elements of the Common Base Event, and their structure and values.

A Common Base Event has five logical sections:

1. Attributes for the CommonBaseEvent element. See Attributes for the CommonBaseEvent element.
2. Event classification, describing the situation element. The Common Base Event instance can be one of twelve situation categories. See Event classification elements.
3. Source component identity. For Common Base Events generated within WebSphere, this contains the attributes associated with the sourceComponentId element that describe the IT stack that was executing when the situation occurred. See Common Base Event data describing WebSphere as the source.
4. Context Data Fields. For WebSphere Common Base Events, these fields contain context data used to correlate Common Base Event instances together. See Additional Common Base Event context and application data added by BCDS.
5. Application data. Any additional data supplied by a WebSphere application, and its format. See Additional Common Base Event context and application data added by BCDS.

### Attributes for the CommonBaseEvent element

The meaning of each field in the CommonBaseEvent element of the Common Base Event.

The CommonBaseEvent tag groups the data for a Common Base Event instance together. It has a number of attributes that are common to all instances of Common Base Events. The example below shows the typical use of these attributes in WebSphere.

```
<CommonBaseEvent extensionName="HighValueOrder"
 globalInstanceId="A44486D00A4511D7A5F99C9202ABA117"
 creationTime="2003-05-09T14:28:16.410000-05:00"
 sequenceNumber="0"
```

```

 severity="10"
 priority="50">
 :
 :
</CommonBaseEvent>

```

Each field is described below:

- **extensionName** - this is the type, or class, or the Common Base Event instance. It indicates which extended data elements will be included.
- **globalInstanceid** - a globally unique identifier for the Common Base Event instance.
- **creationTime** - when the Common Base Event instance was created. Its format follows the XML schema dateTime format, which includes a time zone offset and means nanosecond accuracy is possible. However, WebSphere will extract the data and time from the JVM and so is limited to millisecond accuracy. Common Base Events generated within a millisecond can be sequenced automatically.
- **sequenceNumber** - this field counts the number of Common Base Events generated so far within a millisecond interval. It is used by some technologies that need to sequence events within a millisecond time period. The use of the sequenceNumber is optional.
- **severity** - a number between 0 and 70 which describes the impact that the event has had on the creator of the record. Its data type is short. The higher the number the more negative the impact. The predefined severity levels, in order of increasing severity, are:
  - UNKNOWN (0)
  - INFORMATION (10) - used when the event record does not relate to an error.
  - HARMLESS (20) - strictly speaking this is an error but will not cause harm.
  - WARNING (30) - should be used when it's appropriate to let the user decide if action is needed.
  - MINOR (40) - should be used to indicate action is needed, but the situation is not serious at this time.
  - CRITICAL (50) - should be used to indicate action is needed NOW and the scope is broad (perhaps an imminent outage to a critical resource will result).
  - FATAL (60) - should be used to indicate an error occurred, but it's too late to take remedial action. The severity attribute is optional.
- **priority** - this indicates the relative order that the records should be processed in. Its data type is short and valid values are between 0 and 100. Their meanings are:
  - FIRST (100) - This is the highest priority possible. Process this record first.
  - URGENT (90) - This record describes a situation that needs to be resolved or processed as soon as possible.
  - HIGH (70) - This is an important record.
  - MEDIUM (50) - This record is of average importance.
  - LOW (10) - This record does not need to be processed immediately
  - LAST (0) - This is the lowest priority possible. Process this record last

The priority is an optional attribute. Where specified, it takes precedence over the severity. (For example, a record with a priority of 70 and a severity of 40 is processed before a record with a priority of 10 and a severity of 50.)

In addition, components from the WebSphere environment may use these attributes.

- **localInstanceid** - an instance id that is meaningful to the creator and consumer of the Common Base Event but is not necessarily globally unique across all uses of the Common Base Event. This instance id can be up to 128 characters long.
- **msg** - used to document a fully formatted user message.
- **repeatCount** - a counter that is used in conjunction with elapsedTime below.

- **elapsedTime** - the elapsed time documents in seconds the time period over which a situation has repeatedly occurred. The repeatCount attribute documents the number of times the situation occurred within the period. This pair of attributes condenses the number of Common Base Event instances required to describe repeating situations.

The attributes for the CommonBaseEvent tag give some very basic information about a Common Base Event instance. Only the creationTime attribute is required. WebSphere will fill this in automatically if the application does not specify a value.

## Event classification elements

The meaning of each field in the Situation element.

Nested within the CommonBaseEvent element are elements giving more detail about the situation. The first of these is the situation element, a standardized classification of the situation. Classification involves adding fields to the Common Base Event instance that describes why the event was created and how it relates to other activity. The purpose is to simplify event filtering and correlation.

Each Common Base Event instance must contain a valid situation element. This classifies the event into one of twelve situation categories so it can be sorted by common utilities. The categories are as follows:

- StartSituation - a component is starting up
- StopSituation - a component is stopping
- ConnectSituation - a component is connecting to another component
- ConfigureSituation - a component is being configured
- RequestSituation - details the progress of a request issued against a component
- FeatureSituation - indicates the status of a particular feature or service
- DependencySituation - details the availability of a dependent component
- CreateSituation - a component is being created
- DestroySituation - a component is being destroyed
- ReportSituation - details report data from a component
- AvailableSituation - details a component's operational state and availability
- OtherSituation - something else

The Common Base Event specification defines additional sub-elements specific to each category. This is an example of a situation element used by the WebSphere Process Choreographer in an event that documents a new process starting.

```
<situation categoryName="StartSituation">
 <situationType reasoningScope="EXTERNAL" xsi:type="Common Base Event:StartSituation">
 <situationQualifier>START_INITIATED</situationQualifier>
 <successDisposition>SUCCESSFUL</successDisposition>
 </situationType>
</situation>
```

If the application does not supply a situation element, WebSphere adds a default one of category "OtherSituation".

```
<situation categoryName="OtherSituation">
 <situationType reasoningScope="EXTERNAL" xsi:type="Common Base Event:OtherSituation">
 <any>Application Event</any>
 </situationType>
</situation>
```

In addition, WebSphere makes use of extended data elements to define two further classification schemes that reflect the use it makes of the Common Base Event. These are the event domain and the event purpose.

The event domain describes the part of the WebSphere platform stack that the Common Base Event instance comes from. It can take one of the following values:

- **Business** -the Common Base Event instance represents an event in the business world, for example, a late payment by a customer, or a contract being signed.
- **Container** - the Common Base Event instance was created by a WebSphere container as a result of processing events in the application. For example, when a method is invoked, or a Business Process Execution Language (BPEL) activity completes. The control of when a process Common Base Event is generated is defined in deployment descriptors. Knowledge of the application design will allow the reader to extract the business significance of the event.
- **System** - the Common Base Event instance represents an event in the underlying infrastructure, such as when a subsystem is initialized or fails unexpectedly.
- **Debug** - the Common Base Event instance is describing information used for problem determination.

Here is an example of an extended data element showing the event domain:

```
<extendedDataElements name="eventDomain" type="string">
 <values>Business</values>
</extendedDataElements>
```

The **event purpose** describes the purpose of the event within the domain. The event purpose values are as follows:

- **Information** - The Common Base Event instance contains useful information about the operation within the domain.
- **Audit** - The Common Base Event instance records a decision made by someone or something within the domain.
- **Exception** - The Common Base Event instance describes an unexpected event within the domain. This may be an error condition or a situation that needs special processing (for example, the receipt of an extremely valuable customer order).
- **Alert** - The Common Base Event instance records a plea for help by the domain since it may need intervention to resolve a situation.
- **Correlation** - The Common Base Event instance records an association between either a number of events, or a number of data items from the domain.
- **Trace** - The Common Base Event instance is recording a point in the processing of the domain.

This is an example of the event purpose extended data element.

```
<extendedDataElements name="eventPurpose" type="string">
 <values>Audit</values>
</extendedDataElements>
```

**Note:** An **event source category** is an arbitrary name that an application can use to group events. For example, an event source in the category "DomesticClaimsCallCentreAgents" might generate events named "insurance\_claim\_start\_auto" and "insurance\_claim\_start\_home". The Common Base Event may have details of the relevant event source categories active when the Common Base Event instance was created. Notice there may be more than one event source category:

```
<extendedDataElements name="eventSourceCategories" type="string">
 <values>OrderProcessing</values>
 <values>WebSphereProcessChoreographer</values>
</extendedDataElements>
```

## Common Base Event data describing WebSphere as the source

The event data describing WebSphere as the source that is automatically provided in the Common Base Event

## Reference section

By default, Common Base Event instances from WebSphere contain the sourceComponentId and no reporterComponentId. The "component" referred to in this tag is the WebSphere server where the situation occurred. This XML fragment shows the structure of sourceComponentId.

```
<sourceComponentId componentIdType="ProductName"
 component="Platform 5.1 [BASE 5.1.0.1 cf10405.01] [PME 5.1.0 a0405.03]"
 componentType="WebSphereApplicationServer"
 subComponent="Workflow_Engine"
 locationType="Hostname"
 location="9.20.227.85"
 instanceId="alexhome\alexhome\server1"
 executionEnvironment="Windows XP[x86]#5.1"
 processId="1003550944522"
 threadId="Servlet.Engine.Transports : 2" />
```

All of these values are set automatically by the WebSphere runtime unless the caller provides the value explicitly. The attributes are defined as follows:

- **componentIdType** - a fixed value set to "ProductName"
- **component** - the identifiers for the products in the WebSphere platform stack. For example: Platform 5.1 [BASE 5.1.0.1 cf10405.01] [PME 5.1.0 a0405.03]
- **componentType** - a fixed value set to "WebSphereApplicationServer". This value is defined in the Web Application Server Component Types ([http://www.ibm.com/namespaces/autonomic/WebAppServer\\_componentTypes](http://www.ibm.com/namespaces/autonomic/WebAppServer_componentTypes)).
- **subComponent** - the name of the subcomponent within the server that created the event. The values in use are:
  - J2EE\_Application - the default value
  - WebAppServer\_EJB\_Container - generated by a deployment descriptor
  - Workflow\_Engine - generated by the WebSphere Process Choreographer These values are defined in the Web Application Server Component Types ([http://www.ibm.com/namespaces/autonomic/WebAppServer\\_componentTypes](http://www.ibm.com/namespaces/autonomic/WebAppServer_componentTypes)).
- **locationType** - a fixed value set to "Hostname"
- **location** - the hostname of the server (or server region for zOS)
- **instanceId** - the cell name, node name and server name separated by "." characters. It is possible to omit the cell name. It is possible to omit the node name provided the cell name is also omitted. This gives three alternatives:
  - **cell.node.server**
  - **node.server**
  - **server**
- **executionEnvironment** - a string describing the operating system that the application server is running in. This is extracted from the JVM system properties:
  - **os\_name** - Name of the operating system
  - **os\_arch** - Machine architecture
  - **os.version** - Operating system version as follows:

```
String osEnv = new String(System.getProperty("os.name") + "[" +
 System.getProperty("os.arch") + "]"# +
 System.getProperty("os.version"));
```
- **processId** - this is the jvm\_id extracted from the JVM
- **threadId** - this is the identifier for the thread where the Common Base Event instance was created.

## Additional Common Base Event context and application data added by BCDS

The additional context and application data that is added to the Common Base Event by the BCDS.

A Common Base Event instance may contain references to one or more "contexts". An instance of a context gathers - or groups - related types of work together while the application is executing. There are many types of context each managing a different type of work grouping. Some context types, such as transactions and security, are managed by system services that wish to act consistently across a grouping of work. Others are for information purposes only.

The WebSphere Business Context Data Service (BCDS) offers a generic context service to applications. It also adds details of the active BCDS contexts into each Common Base Event instance created so that events from a single instance of a context can be correlated together.

A ContextDataElements element records

- the context **type**
- the context **identifier**

for each active context instance. The example below shows a fragment of a Common Base Event that describes a BCDS context. The WebSphere Process Choreographer has set up an instance of this type of context for each BPEL process.

```
<contextDataElements name="WebSphereProcessChoreographer" type="string">
 <contextValue>OrderCreationTemplate/37471839182</contextValue>
</contextDataElements>
```

Any **application data fields** added to the Common Base Event by an application are saved in extended data elements, as name/value children of the context data. The example below shows three such data fields called customerNo, orderNo, and orderValue.

```
<extendedDataElements name="BusinessTask" type="noValue">
 <children name="customerNo" type="string">
 <values>C03738927</values>
 </children>
 <children name="orderNo" type="string">
 <values>056232-2003-May</values>
 </children>
 <children name="orderValue" type="string">
 <values>1394000</values>
 </children>
</extendedDataElements>
```

## Components you should know about

Event Programming Model components that are important for generating and using events in WebSphere.

There are four components that you should know about to make best use of the Event Programming Model capabilities:

- State observer plugin
- Business Context Data Services (BCDS)
- Common Base Event content handler
- Event browser

### State observer plugin

The state observer plugin processes events triggered from WebSphere Process Choreographer.

The state observer plugin (SOP) accepts events generated from BPEL processes run in WebSphere Process Choreographer and creates events to be passed to the Common Event Infrastructure.

Events will be sent to the state observer plugin if the businessRelevant flag is turned on. This flag can be set for at the process level and also for individual variables and activity instances. See Generating a Common Base Event in BPEL for further information on the businessRelevant flag and working with WebSphere Process Choreographer to generate events.

## Business Context Data Services

BCDS translates between real-world business models and their implementation in IT systems.

The Business Context Data Service (BCDS) makes it possible to define how a running application relates to a conceptual business model. This data provides important content for events generated by the application. The BCDS has two important functions:

- It populates the Common Base Event with relevant data about the business context that caused the event to be generated.
- It manages the data relating to the business model. The data is stored in a temporary area during the lifetime of the process and the BCDS will generate messages if the data is invalid or compromised.

## Common Base Event content handler

Completing event content automatically.

In some situations, you might want some event property data to be automatically set for every event you create. This can be useful if you want to fill in certain standard values that do not change (such as the application name), or if you want to set some properties based on information available from the execution environment (such as creation time or thread information). You might also want to set policies that govern event content according to business rules; for example, you might require that any event with a particular extension name have its severity set to a certain value.

The Common Event Infrastructure provides a content handler mechanism to accomplish this. A content handler is an object that automatically sets the property values of each event based on any arbitrary policies you want to use. The event infrastructure imposes no restrictions on how a content handler modifies event data, so long as the event still conforms to the Common Base Event specification.

The Event Programming Model in WebSphere provides a standard content handler to complete the runtime and context data in the event. You can see the data value mapping in Common Base Event data describing WebSphere as the source.

Common Event Infrastructure also allows you to develop content handlers to implement your own policies. For more information, see [Completing event content automatically](#).

## Event browser

The event browser is a Web application for retrieving events held in the Common Event Infrastructure data store.

Events are saved to a collection of database tables called the event data store. The event browser is a Web application (supplied with the Event Programming Model) that you can use to query and report on the events in the Common Event Infrastructure data store.

The Common Event Infrastructure makes it possible to query the contents of the event data store through a session bean called the Event Access interface: see in the [Common Event Infrastructure information](#), [Creating an event access bean](#).

---

## Starting to use the Event Programming Model

Installing, configuring and designing for the Event Programming Model.

1. Plan how you'll make use of events in your IT systems. See [Planning to use the Event Programming Model](#)
2. Install the Event Programming Model. (The Event Programming Model is installed automatically at the same time as the Common Event Infrastructure.) See [Installing the Event Programming Model](#)
3. Configure services associated with the Event Programming Model. See [Configuring the Event Programming Model using the Administration console](#)

## Planning to use the Event Programming Model

Defining the architecture of your event generation and consumption.

The Common Event Infrastructure provides facilities for generation, propagation, persistence, and consumption of events, but it does not define the events themselves. You should provide the semantics of event management by defining event types and event groups, in the context of an architecture of event sources and event consumers.

1. Identify each **event source** - the application creating the event. The event source passes the event object to the event infrastructure. The event infrastructure will also store the event object in a database for later retrieval. The event infrastructure's role is to pass the event object onto any applications that have expressed an interest in receiving it.
2. Identify each **event consumer** - each application that can make use of the information contained in the event object. Event consumers typically process events from a number of event sources.
3. Identify each **event group**. To recognize that events are a generic concept of use in a variety of situations, the event infrastructure introduces the concept of an event group. This defines the characteristics (property values) that all events of interest to a particular type of consumer would contain. Policies, such as access controls and distribution rules, are assigned to the event groups to customize the behavior of the event infrastructure for each user group.

**Note:** WebSphere supplies a default event group that is defined to include all events. This event group is called "Event groups list" and has a JNDI name of **com/ibm/events/configuration/event-groups/Default**

This figure shows the relationship between these topics:

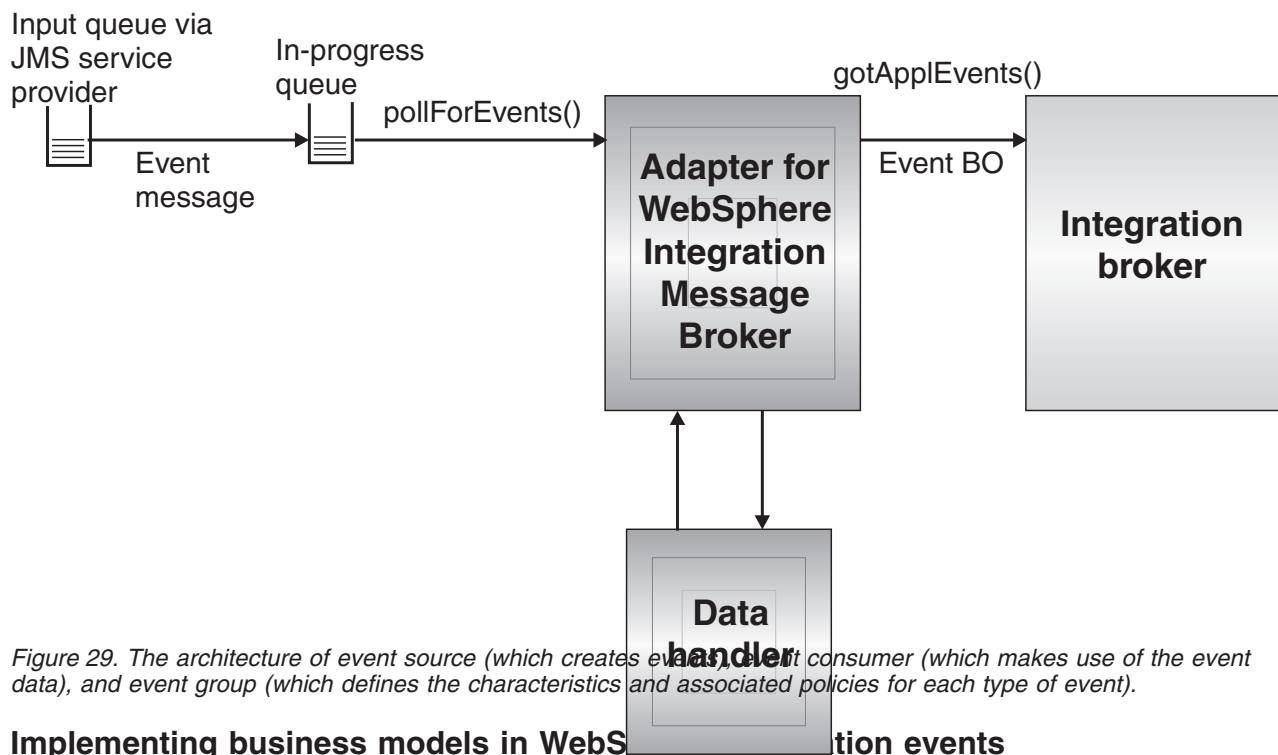

Figure 29. The architecture of event source (which creates event data), event consumer (which makes use of the event data), and event group (which defines the characteristics and associated policies for each type of event).

## Implementing business models in WebSphere Integration events

Things you need to know when designing applications to use the Event Programming Model.

When planning how to use the event infrastructure in your system design, you'll need to understand the business concepts that are relevant, and map them into the appropriate components of your system design.

1. Read about the business model concepts that are relevant to BCDS in Business model concepts.
2. Use the business model concepts to review your WebSphere applications to identify which components implement the concepts you identified. See Using the BCDS in a WebSphere application.

**Business model concepts:**

Things you need to understand before using Business Context Data Services (BCDS).

You need to understand four concepts that appear repeatedly in the many different types of business models.

The first concept is a **business solution**. This describes all of the processing performed by an IT system to support a significant part of the business (for example, order processing). In WebSphere, a solution would include a number of J2EE applications.

There are three more fine-grained concepts:

- The **business task**. This describes the processing to complete a small independent piece of work. (For example, the processing of a single customer order.)
- The **business conversation**. This is the processing performed on behalf of a single person or business partner over a particular period. (For example, the requests made by a single warehouse worker during a single day.)
- The **business data**. This describes the processing that affects a particular collection or instance of some business data. (For example, a single stock item record.)

In a typical IT system, each of these concepts is implemented by one or more components.

Here is an example of a business model that describes part of an order processing solution. Each box is a step in the business task, or process. Part of a warehouse worker’s business conversation involves processing orders (shown in the central lane) and the “Update stock” step updates a single record in the stock database.

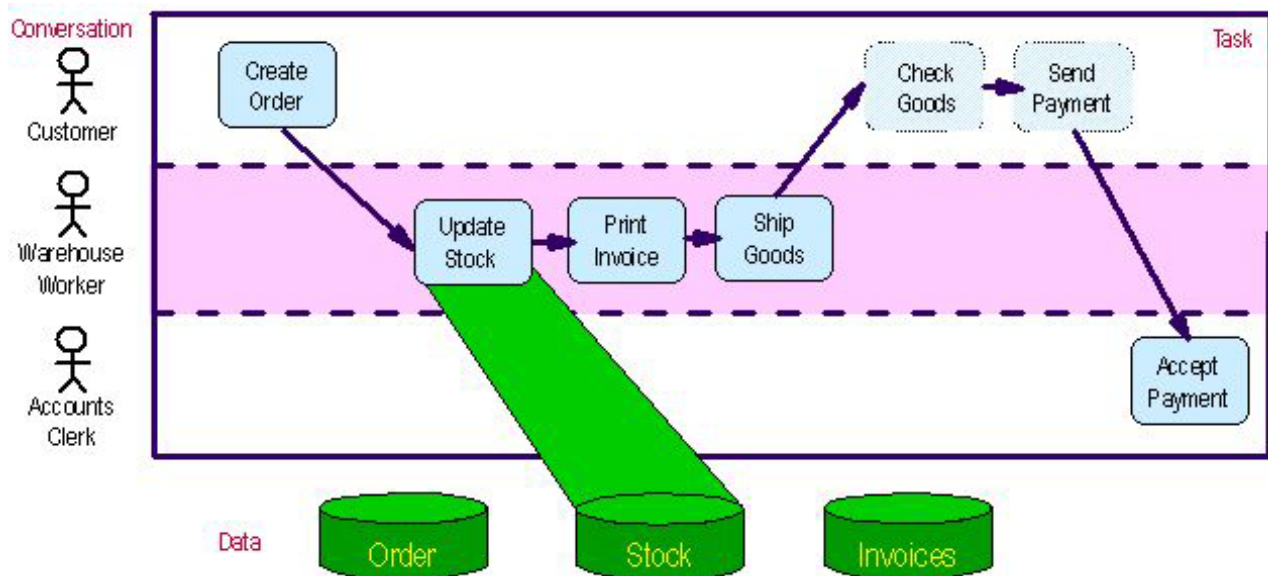

Figure 30. Example business model extract for an order processing solution

During the "Update Stock" activity, you can see that all four of these business concepts (solution, task, conversation and data) intersect. However, during the overall processing of the IT system they change independently of one another.

The BCDS provides the means for an application to create instances of **business context**. Each business context instance has a type (for example, business solution, business conversation, business task or business data), an instance identifier and an optional set of name-value pair properties. The business context instances are associated with the thread so they are available to all components processing a particular request. These components may update and change them at any time. Using the BCDS Java API describes how to use the BCDS to work with the business contexts

**Using the BCDS in a WebSphere application:**

The different ways of using the BCDS in a WebSphere application

1. Work through the business model, or high-level design, and identify the key concepts that are relevant to the application's users. In particular, identify the key user roles, the business tasks that the IT system performs and the key data entities that the business owns. See Business model concepts to read about the business concepts involved: Customer, Warehouse Worker, Accounts Clerk, Fulfil Order Process, Order, Stock, Invoices.
2. Group the business concepts into related types. These groupings will form the basis of your business context types. For example, in Business model concepts the concepts involved are: Customer, Warehouse Worker, Accounts Clerk, Fulfil Order Process, Order, Stock, Invoices (see table below).
3. For each business concept, decide on what the life span of an instance is and how each instance is identified. For example, if there is a business task to "fulfil an order" then there could be a new business task context instance for every order. The order identifier could be the context instance identifier.
4. Review the design of the WebSphere applications to identify which component (or method on a component) implements each of the business concepts identified. You would typically expect servlets, JSPs and portlets to represent the user roles, session beans and/or BPEL process to represent the business tasks and entity beans to represent business entities.
5. Use the BCDS Java programming interface (see Using the BCDS Java API) to update the application components so that a BCDS context instance is active while the application executes the function for an instance of a business concept.

User roles/Conversations	Business Tasks	Business entities/data
Customer	Fulfill order process	Order
Warehouse worker		Stock
Accounts clerk		Invoices

## Installing the Event Programming Model

Installing the Event Programming Model component of WebSphere Business Integration Server Foundation 5.1

You need to have administrator access to the WebSphere Business Integration Server Foundation 5.1 install process.

By choosing to install the Common Event Infrastructure, you also install the Event Programming Model.

To install Common Event Infrastructure and the Event Programming Model in WebSphere, complete the following steps:

1. Use the WebSphere Business Integration Server Foundation 5.1 install program to install the software
  - a. Start the WebSphere Business Integration Server Foundation 5.1 install program

- b. Select the Custom install panel
  - c. Select **Event Infrastructure**, and ensure none of the samples are selected.
  - d. Finish the install program.
2. Configure the Common Event Infrastructure event database.
    - a. Change directory to <WAS\_HOME>/event/dbconfig
    - b. Execute the following command: `config_event_database.bat CloudscapeResponseFile.txt`

The file called CloudscapeResponseFile.txt in this command is a sample response file that will apply to most users. If you have any special circumstances, review the parameters listed in Configuring the event database in the Common Event Infrastructure information, and edit the supplied file.

**Note:** You will need to restart the server after you run the Common Event Infrastructure event database configuration command.

3. Deploy the Common Event Infrastructure EJB.
  - a. Change directory to <WAS\_HOME>/event/application
  - b. Execute the following command: `<WAS_HOME>/bin/wsadmin -f event-application.jacl -action install -earfile event-application.ear -node <nodename> -server <servername>`

**Note:** if your server was started before you issued the above command then you need to start the application from the Admin Console.

You can review the meaning of the parameters listed in the command in Deploying the event infrastructure application in the Common Event Infrastructure information.
4. Install and start the Event Programming Model sample Monitor from the administrative console
  - a. Select **Applications > Install New Application**
  - b. Browse for <WAS root>\eventbrowser\CBEViewer.ear
  - c. Click **Next**.
  - d. Accept the defaults on the next panel titled "Choose default bindings and mappings" and click **Next**.
  - e. Accept the defaults on the first four steps under the panel titled "Allow installation of enterprise applications and modules" by clicking **Next**.
  - f. Review the summary of install options on Step 5 panel, and click **Finish**.
  - g. Check that the message Application CBEViewer is installed successfully appears on the next screen and click **Save to Master Configuration**.
  - h. On the Save panel, click **Save**.

## Configuring the Event Programming Model using the Administration console

You can start and modify the different services you need for the Event Programming Model.

You should have administrator access for the Admin panel

1. Start the Common Event Infrastructure service. See Configuring the Common Event Infrastructure Service.
2. Start the BCDS Service. See Configuring the Business Context Data Service.
3. Start the Application Events Service. See Configuring the Application Events Service.
4. Consider if you need to modify the size of the work area. See Configuring the size of the work area.

## Configuring the Common Event Infrastructure Service

Complete this task to switch the Common Event Infrastructure service on or off for an application server.

The Common Event Infrastructure service provides the ability to process events in WebSphere applications and processes.

You can use the Common Event Infrastructure Service **Startup** property to specify whether or not the service is started automatically for an application server.

To configure the Common Event Infrastructure service **Startup** property for an application server, use the Administrative console to complete the following steps:

1. Start the Administrative console.
2. In the navigation pane, expand **Servers-> Manage Application Servers** This displays a list of the application servers in the content pane.
3. In the Content pane, select the application server that you want to configure. This displays the properties for the application server in the content pane.
4. In the Additional Properties table, select **Common Event Infrastructure service**. This displays the Common Event Infrastructure properties in the content pane.
5. Select or clear the **Startup** property as needed:

**Selected**

[Default] The Common Event Infrastructure service is started when the application server is started. This enables applications that generate events to run on such an application server.

**Cleared**

The Common Event Infrastructure service is not started when the application server is started. Applications that generate events cannot start on such an application server. The BCDS is unaffected. The state observer plugin will not send any events, but will still set business contexts.

Any attempt to start an application that uses Common Event Infrastructure is rejected and a message issued.

If this happens during server startup, the server continues to start without the application.

6. Click **OK**.
7. To save your configuration, click **Save** on the task bar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

## Configuring the Business Context Data Service

Complete this task to switch the Business Context Data service on or off for an application server.

The Business Context Data service defines how a running application relates to a conceptual business model. This data provides important content for events generated by applications to achieve end-to-end correlation across a business service, and allows you to define event groups.

You can use the Business Context Data Service **Startup** property to specify whether or not the service is started automatically for an application server.

**Note:** Since there are performance implications in using the BCDS, you may not want to start the BCDS service if:

- event groupings are not important to you, and
- you want to optimize performance potential.

To configure the Business Context Data Service **Startup** property for an application server, use the Administrative console to complete the following steps:

1. Start the Administrative console.
2. In the navigation pane, expand **Servers-> Manage Application Servers** This displays a list of the application servers in the content pane.
3. In the Content pane, select the application server that you want to configure. This displays the properties for the application server in the content pane.
4. In the Additional Properties table, select **Business Context Data Service**. This displays the Business Context Data Service properties in the content pane.

5. Select or clear the **Startup** property as needed:

**Selected**

[Default] The Business Context Data service is started when the application server is started. This enables applications that specify use of Business Context Data in their deployment descriptors to run on such an application server.

**Cleared**

The Business Context Data service is not started when the application server is started. Applications that specify use of Business Context Data in their deployment descriptors cannot start on such an application server.

Any attempt to start an application that uses Business Context Data is rejected and a message issued.

If this happens during server startup, the server continues to start without the application.

6. Click **OK**.
7. To save your configuration, click **Save** on the task bar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

### ***Business Context Data Service settings:***

Use this page to administer the runtime properties of the Business Context Data service.

The Business Context Data service defines how a running application relates to a conceptual business model. This data provides important content for events generated by applications to achieve end-to-end correlation across a business service.

To view this administrative console page, click **Servers > Application Servers > *server\_name* > Business Context Data Service**.

#### *Startup:*

Specifies whether the server attempts to start the Business Context Data service automatically.

**Default  
Range**

**Selected  
Selected**

When the application server starts, it attempts to start the Business Context Data service automatically.

**Cleared**

The server does not try to start the Business Context Data service. If applications that run on this server need to use the service, the system administrator must start the service manually or select this property then restart the server.

## **Configuring the Application Events Service**

Complete this task to switch the Application Events service on or off.

The Application Events service provides access to the Common Event Infrastructure for WebSphere applications using the Event Programming Model. It ensures that information about the WebSphere server is automatically included in each event passed to the Event Infrastructure.

You can use the Events Service **Startup** property to specify whether or not the service is started automatically for an application server.

To configure the Events Service **Startup** property for an application server, use the Administrative console to complete the following steps:

1. Start the Administrative console.
2. In the navigation pane, expand **Servers-> Manage Application Servers** This displays a list of the application servers in the content pane.
3. In the Content pane, select the application server that you want to configure. This displays the properties for the application server in the content pane.
4. In the Additional Properties table, select **Application Events Service**. This displays the Events Service properties in the content pane.
5. Select or clear the **Startup** property as needed:
  - Selected**  
 [Default] The Application Events Service is started when the application server is started. This enables applications that specify use of the Common Event Infrastructure in their deployment descriptors to run on such an application server.
  - Cleared**  
 The Application Events Service is not started when the application server is started. Applications that specify use of the Common Event Infrastructure in their deployment descriptors cannot start on such an application server. The state observer plugin will be stopped.  
  
 Any attempt to start an application that uses Events is rejected and a message issued.  
  
 If this happens during server startup, the server continues to start without the application.
6. Click **OK**.
7. Review the JNDI name of the Event Emitter Profile factory that will be used to submit events to the Events Infrastructure. The name provided is of the WebSphere default profile. Unless you have generated an alternative profile, accept the default name.
8. To save your configuration, click **Save** on the task bar of the Administrative console window.
9. To have the changed configuration take effect, stop then restart the application server.

***Application Event service settings:***

Use this page to administer the runtime properties of the Application Event service.

The Application Event service provides access to the Common Event Infrastructure for WebSphere applications and ensures that information about the WebSphere server is automatically included in each event passed to the Common Event Infrastructure.

To view this administrative console page, click **Servers > Application Servers > *server\_name* > Application Events Service**.

*Startup:*

Specifies whether the server attempts to start the Application Event service automatically.

**Default Range**

Selected  
**Selected**

When the application server starts, it attempts to start the Application Event service automatically.

**Cleared**

The server does not try to start the Application Event service. If applications that run on this server need to use the service, the system administrator must start the service manually or select this property then restart the server.

*Event Emitter Factory JNDI Name:*

The JNDI name for the factory that is used to create event emitters.

The Event Submitter first passes the event to its Listener Registry and then (as a Common Base Event) on to the Event Emitter. The event emitter filters the event and if required, passes it on to be stored in the event data store and distributed to the consumers through JMS.

**Data type** String

## Configuring the size of the work area

Configuring the size of the work area to allow greater numbers of contexts.

The BCDS uses the work area to store context data. The default size of the work area is 10,000 and, typically, if there are more than about 15 contexts, this limit is reached with a CORBA.IMP\_LIMIT exception (property group too large). Since the size of a context can vary depending on the data, if you expect to have more than 10 concurrent contexts you should set the size of the work area to expand as necessary.

1. Start the Administrative console.
2. In the navigation pane, expand **Servers-> Manage Application Servers** This displays a list of the application servers in the content pane.
3. In the Content pane, select the application server that you want to configure. This displays the properties for the application server in the content pane.
4. In the Additional Properties table, select **Work Area Service**. This displays the work area properties in the content pane.
5. Select the **Startup** property
6. Set the values of the maxSendSize and the maxReceiveSize fields to **zero**. This has the effect of allowing the work area size to expand with an increasing number of contexts.
7. To save your configuration, click **Save** on the task bar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

---

## Generating Common Base Events

Generating Common Base Events from an event source in WebSphere.

An event source is any application that submits events for persistence and distribution to event consumers. The following applications are examples of event sources:

- An adapter or monitor that generates events related to monitored resources
- An application that generates notification events
- An application that forwards events from other sources

An event source must submit valid events conforming to the Common Base Event model. (See The Common Base Event model for more information.) Each event is represented as a Java object.

In general, an event source must follow these high-level steps:

1. Obtain an **emitter**. The emitter is the interface between an event source and the event server. See Emitters and emitter factories.
2. Create an instance of **CommonBaseEvent** (Common Base Event), either by using an event factory through a Java API or from within a process flow described in BPEL, and populate the event with data. See Event creation from WebSphere applications.
3. Submit the event to the event server through the emitter interface. See Send an event.

**Note:** Although it is possible for an application to specify all of the data for a Common Base Event instance, it is only necessary to specify the extensionName. WebSphere is able to fill in the rest of

the details automatically ensuring consistent formatting of this data - but only for events that have occurred within WebSphere. (The Event Programming Model cannot handle events that have been passed to a WebSphere application from another source, like DB2.) For more information about mapping the information in the Common Base Event, see “The structure of the Common Base Event” on page 1144 and, particularly for the information that is filled in by the BCDS, see, “Common Base Event data describing WebSphere as the source” on page 1147 and “Additional Common Base Event context and application data added by BCDS” on page 1148

## Obtain an emitter

How to get an emitter, the first step to creating CBEs.

Before you can obtain an emitter, there must be at least one emitter factory profile configured. See *Configuring the Application Events Service* for information about configuring the emitter factory profile. You can find more information about emitters and emitter factories and the default factory profile in *Emitters and emitter factories*.

To obtain the default emitter, follow these steps:

1. Perform a JNDI lookup specifying the name of the emitter factory you want to use for your emitter. The returned object is the emitter factory
2. Call the `getEmitter()` method of the emitter factory. The returned object is an emitter,

The following example obtains the default emitter:

```
import javax.naming.*
import com.ibm.events.*

Context context = new InitialContext();
EmitterFactory emitterFactory =
 (EmitterFactory) context.lookup("com/ibm/events/configuration/emitter/Default");
Emitter emitter = emitterFactory.getEmitter();
```

## Event creation from WebSphere applications

The different ways to create Common Base Events from within WebSphere applications.

An application creates an event object whenever it performs some processing that could be of interest to an external application. This event object describes event name, when the event happened and some properties that are relevant to the event. There are two different ways of generating events from within WebSphere:

- You can generate an event explicitly from within a WebSphere Java application. See *Using the Java API*.
- You can generate events at different points in application process flows specified in Business Process Flow Language (BPEL). See *Generating a Common Base Event in BPEL*.

Although it is possible for an application to specify all of the data for a Common Base Event instance, it is only necessary to specify the `extensionName`. WebSphere is able to fill in the rest of the details automatically ensuring consistent formatting of this data. For more information about mapping the information in the Common Base Event, see *Common Base Event data describing WebSphere as the source*.

## Using the Java API

Creating a Common Base Event instance from within a Java application.

The example below shows how to create a Common Base Event instance from a J2EE component such as a servlet or EJB.

```
import com.ibm.events.cbe.*;
import javax.naming.Context;

Context ctx = new InitialContext();
EventFactory factory = (EventFactory)ctx.lookup("com/ibm/websphere/events/factory");
```

The code above uses JNDI to obtain the WebSphere-provided event factory; configured with a content handler. (See [Populating events with event context data](#) for more information about content handlers.)

```
CommonBaseEvent event = factory.createCommonBaseEvent("NewOrderReceived");
event.setExtendedDataElement("OrderStatus", "NEW");
event.setExtendedDataElement("CustomerNumber", "C03738927");
```

This code sets three application properties as extended data elements.

The WebSphere event factory will create Common Base Event instances that are capable of automatically filling out the "situation", "sourceComponentId", "contextDataElements" and "extendedDataElements" elements that describe the WebSphere environment whenever the complete() method is called. This may be called explicitly by the application: event.complete();

Alternatively the event emitter (from WebSphere's Event Infrastructure) calls it automatically as part of the sendEvent() method processing.

## Generating a Common Base Event in BPEL

Generating Common Base Events from within BPEL process flows.

Events generated by BPEL are passed to the WebSphere state observer plugin (see [State observer plugin](#) for more information.) The state observer plugin uses the BCDS to convert the events into Common Base Events, the format processed by the Common Event Infrastructure.

WebSphere Process Choreographer can generate six different types of events during the lifetime of a process:

- ProcessTemplate
- ProcessInstance
- ActivityInstance
- ScopeInstance
- Variable
- Link

To activate each type of event, an attribute called wpc:businessRelevant must be set for the corresponding entity in the business model defined by the businessRelevant flag in the BPEL+ extensions supported by WebSphere Process Choreographer. It may be assigned to elements such as activities within the process definition. For further information on the use of the businessRelevant flag to generate events, see the [WebSphere Process Choreographer documentation at "Developing applications for BPEL-based processes"](#).

The example below shows a BPEL process called "purchaseOrderProcess" showing the businessRelevant attribute on the process and activity elements. The effect of this flag is to generate an event each time an instance of the element changes state. It is also possible to call the Common Event Infrastructure from Java snippets and any EJBs called from an activity.

```
<bpel:process name="OrderCreationTemplate" wpc:businessRelevant="yes|no" ...>
...
<bpel:sequence>
<bpel:receive wpc:businessRelevant="yes"
```

```

 bpel:partner="customer"
 bpel:portType="lms:purchaseOrderPT"
 bpel:operation="sendPurchaseOrder"
 bpel:container="PO"/>
...
<bpel:reply wpc:businessRelevant="yes"
 bpel:partner="customer"
 bpel:portType="lms:purchasePT"
 bpel:operation="sendPurchaseOrder"
 bpel:container="Invoice"/>
</bpel:sequence>
</bpel:process>

```

## Populating events with event context data

Completing business context data in an event.

Using the Business Context Data Service, or BCDS, WebSphere's event infrastructure automatically copies the business context data associated with an event into each Common Base Event instance that it creates. Read more about working with the BCDS and how the BCDS and the content handler relate to the Common Base Event in Introduction.

To work with the BCDS, see Using the BCDS Java API.

Using the BCDS Java API includes material on how to develop your own content handler if the WebSphere-supplied version doesn't meet your needs. The Event Mediator is part of the BCDS public API so that application developers can build their own event content handler and corresponding Event Factory to set any additional data in the Common Base Event and still have the business contexts and sourceComponentId element automatically added to the Common Base Event. For more information about the BCDS API, see the Javadoc.

### Introduction

How the Business Context Data Service and the content handler relate to the Common Base Event.

At the heart of the BCDS is the BusinessContextController. This object manages the data for a single business context type and its association with the current thread. This includes the identity of the context and a collection of properties contained in a BusinessContextProperties object. The BusinessContextFactory creates a BusinessContextController. The BusinessContextFactory can also return the types of business contexts active on the thread. The content handler provided by WebSphere adds details of the active business contexts to a Common Base Event

Provided the Event Programming Model event factory is used, the event infrastructure automatically copies the business contexts associated with the current thread into each Common Base Event instance it creates. See Common Base Event data describing WebSphere as the source for details of the data mapping performed when copying into the Common Base Event.

The fragment of a XML below shows the resulting elements in a Common Base Event instance that relates to a single business context instance. Each active context has a <contextDataElements> element with the name attribute set to the context type and the <contextValue> element containing the instance identifier. If there are properties associated with the context, these appear as <children> in an <extendedDataElement> element.

```

<contextDataElements name="BusinessTask" type="string">
 <contextValue>NewOrder-056232030516</contextValue>
</contextDataElements>

<extendedDataElements name="BusinessTask" type="noValue">
 <children name="customerNo" type="string">
 <values>C03738927</values>
 </children>
 <children name="orderNo" type="string">

```

```

 <values>056232-2003-May</values>
 </children>
 <children name="orderValue" type="string">
 <values>1394000</values>
 </children>
</extendedDataElements>

```

In addition, the Event Mediator will set the sourceComponentId element that describes the Event Programming Model. See Common Base Event data describing WebSphere as the source for details of the fields set in the sourceComponentId.

The business context instances associated with the current thread are automatically transported from one WebSphere server to another as calls pass directly between EJBs. However, there is no such automatic mechanism for JMS. If a business context instance needs to pass across JMS in an application message, you should format the active contexts and their properties into an XML document and send as a JMS header property. See Passing business context data across Java Messaging System.

## Using the BCDS Java API

Generating Common Base Events using the BCDS Java API.

The code block below shows how to extract the BusinessContextController for a business task from the current thread and then add some properties to it:

```

import com.ibm.websphere.bcds.*;
import javax.naming.Context;

String factoryName = "com/ibm/websphere/bcds/factory";
String contextType = BusinessContextType.BUSINESS_TASK.getContextType();

Context ctx = new InitialContext();
BusinessContextFactory factory = (BusinessContextFactory)ctx.lookup(factoryName);
BusinessContextController bcc = factory.getController(contextType);
BusinessContextProperties properties = bcc.getProperties();

```

This statement makes the context active in the stack of context instances in the workarea:

```
bcc.setContextId("NewOrder-056232030516");
```

These statements set example properties:

```

properties.setProperty("customerNo", "C03738927");
properties.setProperty("orderNo", "056232-2003-May");
properties.setProperty("orderValue", "1394000");

```

This is how to clear an instance of a business context from the thread:

```
bcc.clearContextId();
```

Since the thread maintains a stack of context instances for each context type, when clearContextId() is called, it restores the context instance for this context type that was on the thread when setContextId() was called.

For more information about the BCDS API, see the Javadoc.

### ***Passing business context data across Java Messaging System:***

How to export business contexts from WebSphere across Java Messaging System (JMS).

The life span of an event can span across several applications and servers. The business context instances associated with the current thread are automatically transported from one WebSphere server to

another as calls pass directly between EJBs. However, there is no such automatic mechanism for JMS. In this case, format the active contexts and their properties into an XML document and send as a JMS header property.

The XML below illustrates the recommended format of an XML document used to import and export business contexts from WebSphere. This XML is typically used to transport the business contexts over JMS in the `com.ibm.websphere.bcds.BusinessContexts` property.

```
<WebSphereBusinessContexts>

 <context typeName="businessSolution" id="Order Processing"/>

 <context typeName="businessConversation" id="JGB-030516">
 <property name="startTime" value="09:00"/>
 <property name="operator" value="Joe G Bloggs"/>
 </context>

 <context typeName="businessTask" id="NewOrder-056232030516">
 <property name="customerNo" value="C03738927"/>
 <property name="orderNo" value="056232-2003-May"/>
 <property name="orderValue" value="1394000"/>
 </context>

 <context typeName="businessData" id="Invoice-134252-030516">
 <property name="creationTime" value="2003-05-09T14:41:45.921000-05:00"/>
 </context>

</WebSphereBusinessContext>
```

The method used to import business contexts from WebSphere is `importContexts`. It sets up the current thread with the business contexts described in the XML document.

The method used to export business contexts from WebSphere is `exportContexts`. It returns an XML document describing the business contexts associated with the current thread. If there are no business contexts associated with the thread, a null is returned.

For more information about the BCDS API, see the Javadoc.

## Send an event

Sending the event to the data store, after it has been completed by BCDS.

To send an event, use the `sendEvent(CommonBaseEvent)` or `sendEvent(CommonBaseEvent, int, int)` method of the `Emitter` interface. You can send an event using the current default emitter settings, or you can specify different options that override the configured defaults for the current event.

To send an event using the current settings, use the `sendEvent(CommonBaseEvent)` method: `String eventId = emitter.sendEvent(event);`

For further information about the actions of the emitter when sending events, see [Sending events](#).

---

## Viewing events with the event browser

This topic describes how to use the event browser to select and review events in the event database.

1. Start the event browser.
  - a. Click on the **Enterprise applications** link in the navigation pane of the WebSphere admin console.
  - b. Click on the tick box beside `CBEViewer`, and click on the **Start** button.
  - c. Check that the status icon is green. Start the `CBEViewer` in your Web browser, using the server name and port 9080, in a URL like `http://<localhost>:9080/cbeviewer/`

2. Specify the events you wish to view. See [Specifying the events to view](#)
3. Select the view of the events returned. See [Working with the events returned](#)

## Specifying the events to view

This task describes how to use the event browser to specify a query.

This task assumes that you have already started the event browser. See [Viewing events with the event browser](#).

1. Specify the calendar period for the report. Enter the start and end dates.
2. Enter the maximum number of records that you want returned.
3. Select the event domains for inclusion, from **Business**, **Process** and **System**. **Note** that if you select none of the domains, then the search will return events for all domains, including events in which no domain is specified.
4. Select from the different types of event purpose, from: **Information**, **Audit**, **Exception**, and **Correlation**. **Note** that if you select none of the purpose types, then the search will return events for all purpose types, including events in which no event purpose is specified.
5. As appropriate, enter your search criteria in the writable fields. You can specify any of: **Solution** name, **Application** name, **Conversation** name, **Task** name, **Data** name, **Process** name, **Server** name, **Component** name, **Event group**, **Priority** and **Severity**.
6. Specify the data store to be searched. The field is a JNDI name, an EJB reference that can be configured in the Admin console. The WebSphere supplied default is `java:/comp/env/events/access`
7. And finally, click on the **Get data** button.

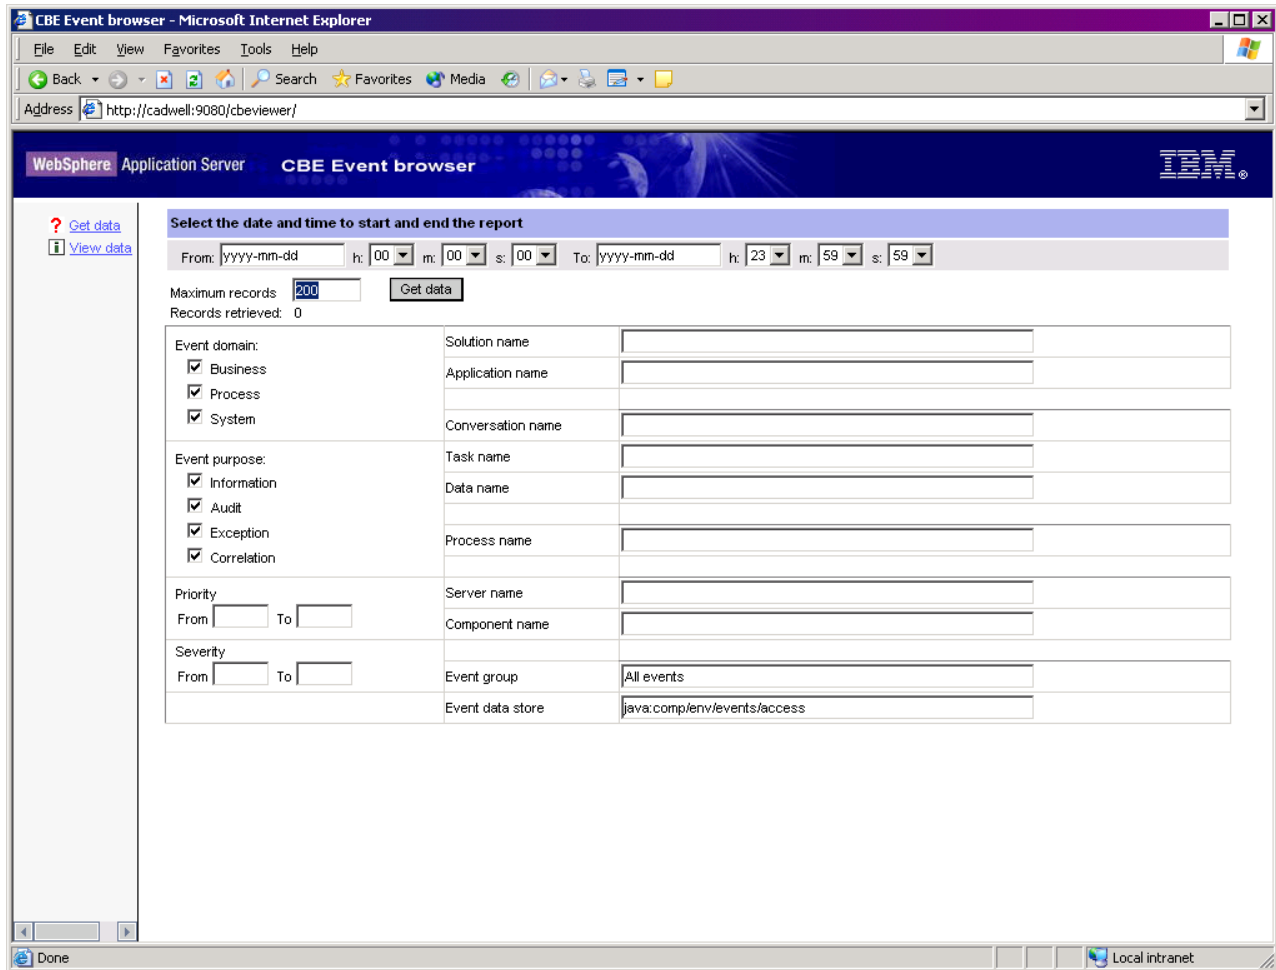

Figure 31. View of browser query screen.

For more information on the origin of these fields, see Origin of event browser fields.

## Origin of event browser fields

The technical details of where each event browser field comes from.

The table below shows the origin of all the fields displayed in the event browser, represented as an XPath expression.

**Note:** The XPath column does not show that all expressions begin with `"/CommonBaseEvent/"`. For example, the full XPath expression to select Creation Time would be `"/CommonBaseEvent/@creationTime"`.

Event Browser field	Position in CommonBaseEvent, as an XPath expression beginning <code>"/CommonBaseEvent/..."</code>
Creation Time	<code>@creationTime</code>
Event Domain	<code>extendedDataElements[@name="eventDomain"]/values</code>
Event Purpose	<code>extendedDataElements[@name="eventPurpose"]/values</code>
Priority	<code>@Priority</code>
Severity	<code>@Severity</code>
Solution Name	<code>contextDataElements[@name="businessSolution"]/contextValue</code>

Application Name	sourceComponentId/@application
Conversation Name	contextDataElements[@name="businessConversation"]/contextValue
Task Name	contextDataElements[@name="businessTask"]/contextValue
Data Name	contextDataElements[@name="businessData"]/contextValue
Process Name	extendedDataElements[@name="websphereProcessChoreographer"] /children[@name="processTemplateName"]/values
Server Name	sourceComponentId/@instanceId
Component Name	extendedDataElements[@name="j2eeComponent"]/children[@name="fullName"]/values
Name	@extensionName
Message	@msg
Instance (on processes tab)	extendedDataElements[@name="websphereProcessChoreographer"] /children[@name="processInstanceId"]/values
name/value properties (Solutions, Conversation, Task and Data tabs)	The complete collection of properties from every event in the collection, related to the selected item. extendedDataElements[@name="NAME"]/children where NAME is related to the currently selected tab (one of "businessSolution", "businessConversation", "businessTask" or "businessData".) And then for each children tag, returns its name and value: children/@name and children/values
name/value at bottom of screen	All values from selected event shown as name/value pairs. For nested properties names are "parentTagName / childTagName"

## Working with the events returned

This task describe show to use the event browser to view the events returned from a query.

This task acts on data returned by a query submitted, as described in Specifying the events to view.

The query returns all the records that meet your criteria. The initial view displayed if you click the **All** tab is shown in the following figure. Click on any event returned to see the event data displayed in the pane at the bottom of the window.

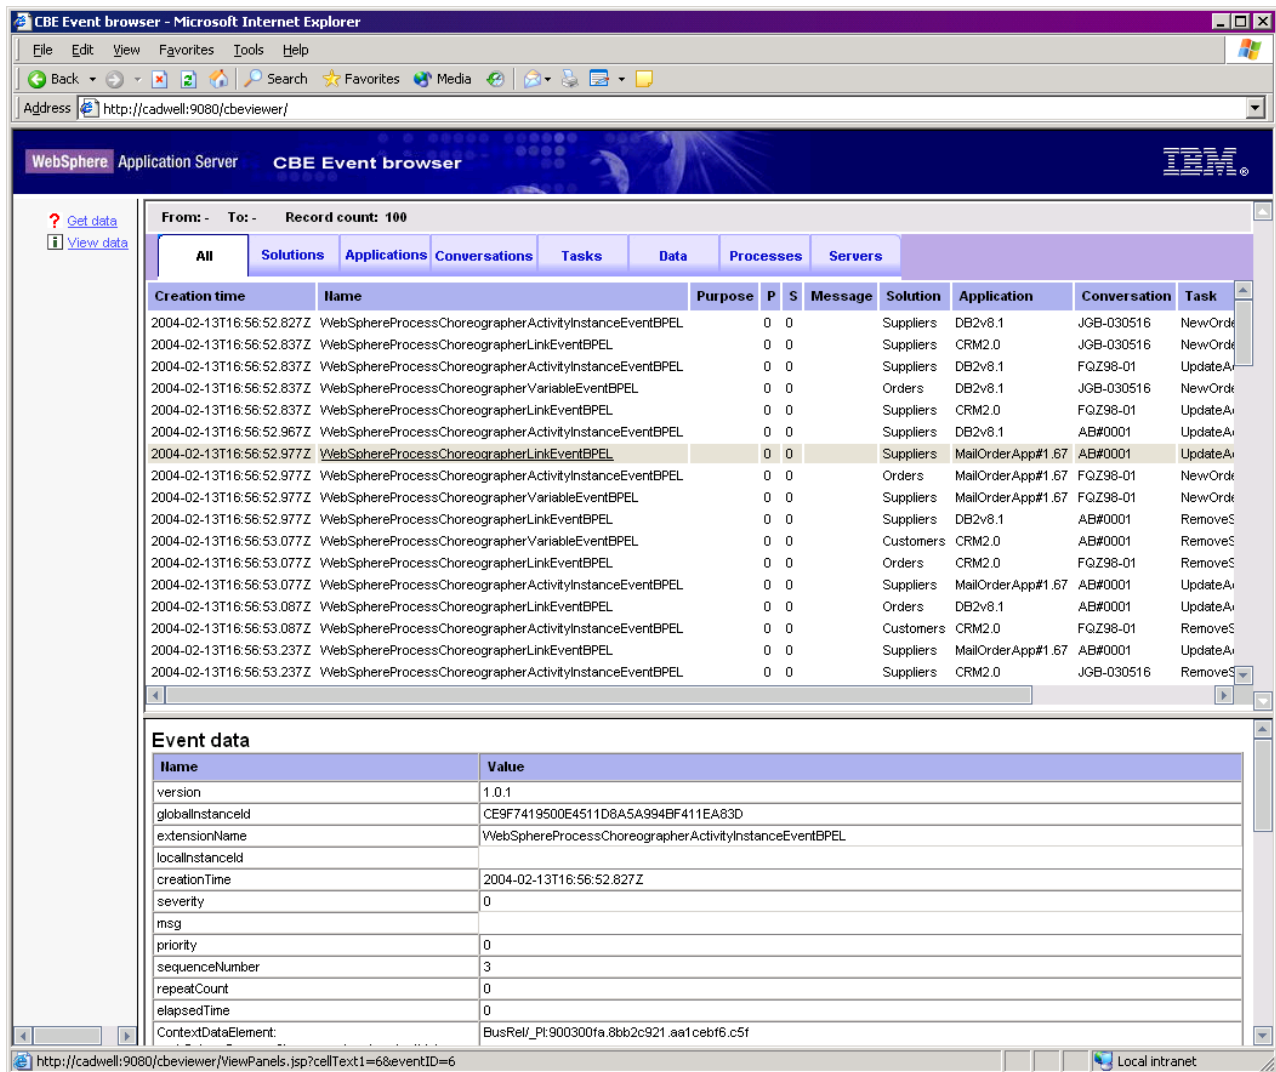

Figure 32. Initial view of event records displayed for an event query.

1. Refine your view of the events returned by clicking on one of the other tabs. These tabs correspond to the selection criteria that you worked with when specifying the query.
2. Further refine your view by selecting from the additional pane that appears when you click on a tab. For instance, if you select the **Solutions** tab, you will be able to select from the whole range of solutions that met your criteria, and selecting one will show you the event data that corresponds to your selection.

**Note:** If you click on the **Processes** tab, you'll be presented with an **Instances** pane when you select a process, to give an extra level of refinement to the search.

If you click on the **Solutions**, **Conversations**, **Tasks** and **Data** tabs, you will see an extra panel that contains any application data fields added to the Common Base Event by an application. They are saved in extended data elements, as name/value children of the context data. See Additional Common Base Event context and application data added by BCDS for more information. For instance, if you click on the **Conversations** tab and select a conversation, the pane will contain name/value pairs of the conversation, extracted from the listed events in that conversation.

---

## Working with WebSphere event infrastructure messages

The meaning of messages from BCDS and state observer plugin

1. If the message code is prefixed by ESOP then it comes from the state observer plugin. You can find the meaning of the messages in State observer plugin messages.
2. If the message code is prefixed by BCDS then it comes from BCDS.. You can find the meaning of the messages in Business context data services messages.

### State observer plugin messages

Messages emitted by the state observer plugin

#### ESOP0001E

The Initial Context for Naming is missing. No lookups are possible. See the nested exception for more information.

##### Explanation

The application is running in an environment where there is no JNDI service. Calls return null.

##### User action

The application needs to be run in a WAS environment where JNDI is available.

#### ESOP0002E

The value of parameter "{0}" is invalid:

##### Explanation

The named parameter has an invalid value. It is rejected. It cannot be null.

##### User action

Correct the calling application and try again.

#### ESOP0003E

The object associated with the BCDS factory JNDI lookup is incorrect. See the nested exception for more information.

##### Explanation

The wrong object has been bound into JNDI.

##### User action

The application needs to be run with the correct object bound into JNDI.

#### ESOP0004E

An exception occurred whilst submitting the event to the Common Event Infrastructure. See the nested exception for more information

**Explanation**

An error occurred with the event infrastructure.

**User action**

Consult the message log.

**ESOP0005E**

An exception occurred whilst obtaining a Common Event Infrastructure emitter. See the nested exception for more information.

**Explanation**

An error occurred with the Common Event Infrastructure.

**User action**

Consult the message log.

**ESOP0006E**

The object associated with the event factory JNDI lookup is incorrect. See the nested exception for more information.

**Explanation**

The wrong object has been bound into JNDI.

**User action**

The application needs to be run with the correct object bound into JNDI.

**ESOP0007E**

The object associated with the emitter factory JNDI lookup is null.

**Explanation**

"null" has been bound into JNDI.

**User action**

Consult the message log

**ESOP0008E**

Message content

**Explanation**

Object associated with the emitter factory JNDI lookup is incorrect. See the nested exception for more information.

**User action**

The application needs to be run with the correct object bound into JNDI.

**ESOP0009E**

An exception occurred whilst obtaining a Common Event Infrastructure emitter factory. See the nested exception for more information.

**Explanation**

An error occurred with the Common Event Infrastructure.

**User action**

Consult the message log

**ESOP0010E**

The object associated with the event factory JNDI lookup is null.

**Explanation**

"null" has been bound into JNDI.

**User action**

Consult the message log.

**ESOP0011E**

An exception occurred whilst obtaining a Common Event Infrastructure event factory. See the nested exception for more information

**Explanation**

An error occurred with the event infrastructure.

**User action**

Consult the message log

**ESOP0012E**

Cannot determine whether the event service is running. The event service is deemed to be running if an event factory can be obtained via JNDI. The object associated with the event factory JNDI lookup is incorrect. See the nested exception for more information

**Explanation**

The event service is deemed to be running if an event factory can be obtained via JNDI. However, the wrong object has been bound into JNDI.

**User action**

The application needs to be run with the correct object bound into JNDI.

## Business context data services messages

Messages issued by the business context data services

### BCDS0001E

No WebSphere work area support is available in this environment.

#### Explanation

The application is running in an environment where the WebSphere work area facility is not available. Calls return null.

#### User action

The application needs to be run in a WAS environment where the work area facility exists.

### BCDS0002E

The Initial Context for Naming is missing. No lookups are possible.

#### Explanation

The application is running in an environment where there is no JNDI service. Calls return null.

#### User action

The application needs to be run in a WAS environment where JNDI is available.

### BCDS0003E

The binding for the WebSphere work area interface was not found. BCDS is not available.

#### Explanation

The application is running in an environment where the WebSphere work area facility is not available. Calls return null.

#### User action

The application needs to be run in a WAS environment where the work area facility has not been disabled.

### BCDS0004E

No active context is associated with the current thread. The action fails.

#### Explanation

The application is unable to access the WebSphere work area facility because it has not been begun on the current thread.

#### User action

Determine how the application came to be executing on a thread where the work area facility has not been begun.

## **BCDS0005E**

The value of property "{0}" cannot be reset or cleared by this process.

### **Explanation**

The WebSphere work area facility only allows a property to be reset or cleared by the process that created it.

### **User action**

Change the application so that properties are reset or cleared only by the originating process.

## **BCDS0006E**

The mode for property "{0}" is read-only. Its value cannot be reset.

### **Explanation**

The WebSphere work area facility does not allow a property whose mode is read-only to be reset.

### **User action**

Check whether the application has corrupted contents of the WebSphere work area that belong to Event Programming Model.

## **BCDS0007E**

The mode for property "{0}" is fixed. Its value cannot be cleared.

### **Explanation**

The WebSphere work area facility does not allow a property whose mode is fixed to be reset.

### **User action**

Check whether the application has inadvertently corrupted contents of the WebSphere work area that belong to WebSphere event infrastructure.

## **BCDS0009E**

The value of parameter "{0}" is invalid.

### **Explanation**

The named parameter has an invalid value. It is rejected.

### **User action**

Correct the application and try again.

## **BCDS0010E**

An error occurred while parsing this imported XML.

**Explanation**

The XML does not conform with the required XSD schema. There may have been a classloader error.

**User action**

Check the XML is valid by reading it into a browser. It may have been corrupted.

**BCDS0011E**

The value for key "{0}" is not serializable. It cannot be returned to the caller.

**Explanation****User action****BCDS0012E**

Identifier "{1}" already exists for business context type "{0}"

**Explanation**

The given identifier is a duplicate for the business context type. It is rejected.

**User action**

Correct the application to use unique business context type identifiers.

---

## Common Event Infrastructure Developer's Guide

Using the Common Event Infrastructure.

- "Introduction to the common event infrastructure"
- "Configuring the common event infrastructure" on page 1175
- "Developing an event source" on page 1180
- "Developing an event consumer" on page 1184
- "Working with events" on page 1188

### Introduction to the common event infrastructure

The common event infrastructure is an embeddable technology intended to provide basic event management services to applications that require those services. This common event infrastructure serves as an integration point for consolidation and persistence of raw events from multiple, heterogeneous sources, and distribution of those events to event consumers. Events are represented using the Common Base Event model, a standard, XML-based format defining the structure of an event. For more information, see The Common Base Event model.

By using this common event infrastructure, diverse products that are not tightly coupled with one another can integrate their management of events, providing an end-to-end view of enterprise resources and correlating events across domain boundaries. For example, events generated by a network monitoring application can be correlated with events generated by a security application. Such correlation can be difficult to achieve when each product uses its own approach to event management.

The common event infrastructure provides facilities for generation, propagation, persistence, and consumption of events, but it does not define the events themselves. Instead, application developers and administrators define event types, event groups, and correlation.

## Components

The common event infrastructure consists of the following major components:

### Common Base Event

The Common Base Event component supports the creation of events and access to their property data. Event sources use the Common Base Event APIs to create new events conforming to the Common Base Event model (see see The Common Base Event model); event consumers use them to read property data from received events. For more information about the Common Base Event component, see Working with .

### Emitter

The emitter component supports the sending of events. After an event source creates an event and populates it with data, it submits the event to an emitter. The emitter validates the event to ensure that it conforms to the Common Base Event specification. If the event is valid, the emitter sends the event to the event server. For more information about emitters, see Developing an event source.

### Event server

The event server is the conduit between event sources and event consumers. The event server receives events submitted to emitters by event sources, and it stores them in a persistent data store. Event consumers can then query the event server to retrieve events. For more information about receiving events from the event server, see Developing an event consumer.

In addition, an application or solution using the event infrastructure might also include the following components (which are not part of the infrastructure itself):

### Event source

An event source is any application that submits events to an emitter.

### Event consumer

An event consumer is any application that receives events from the event server.

## The Common Base Event model

The Common Base Event model is a standard defining a common representation of events that is intended for use by enterprise management and business applications. This standard, developed by the IBM Autonomic Computing Architecture Board, supports encoding of logging, tracing, management, and business events using a common XML-based format, making it possible to correlate different types of events that originate from different applications. For more information about the Common Base Event model, see the Common Base Event specification (*Canonical Situation Data Format: The Common Base Event V1.0.1*). The common event infrastructure currently supports version 1.0.1 of the specification.

The basic concept behind the Common Base Event model is the *situation*. A situation can be anything that happens anywhere in the computing infrastructure, such as a server shutdown, a disk-drive failure, or a failed user login. The Common Base Event model defines a set of standard situation types that accommodate most of the situations that might arise (for example, StartSituation and CreateSituation).

An *event* is a structured notification that reports information related to a situation. An event reports three kinds of information:

- The situation itself (what has happened)
- The identity of the affected component (for example, the server that has shut down)
- The identity of the component that is reporting the situation (which might be the same as the affected component)

The Common Base Event specification defines an event as an XML element containing properties that provide all three kinds of information. These properties are encoded as attributes and subelements of the root element, CommonBaseEvent.

The Common Base Event format is extensible. In addition to the standard event properties, an event can also contain extended data elements, which are application-specific elements that can contain any kind of information relevant to the situation. The *extensionName* attribute can be used to label an event with a classification name, which indicates to applications what sort of extended data elements to expect.

For complete details on the Common Base Event format, see the XML schema included in the Common Base Event specification document, at <ftp://www6.software.ibm.com/software/developer/library/ac-toolkitdg.pdf> .

## Configuring the common event infrastructure

Some configuration is required after the common event infrastructure is installed. This includes deploying the event infrastructure application in WebSphere Application Server and configuring the event database.

In addition, you can perform configuration that affects the runtime behavior of the event infrastructure.

### Post-installation configuration

This set of topics describe the configuration that is required after the common event infrastructure is installed. This includes deploying the event infrastructure application in WebSphere Application Server and configuring the event database.

1. Configuring the event database
2. Deploying the event infrastructure application

#### **Configuring the event database:**

After the event infrastructure application is installed, you must configure the event database and Java Database Connectivity (JDBC) provider. To configure the database, you must first create a response file specifying database parameters, and then use the **config\_event\_database** command to generate and run the required SQL scripts.

*Creating a Cloudscape database response file:* The first step in configuring the event database is creating a response file specifying the database configuration parameters.

**Note:** The database configuration parameters differ depending on the type of database being used. However, currently only the Cloudscape database is supported.

The following parameters are specified in the response file:

#### **SHARE\_DB=[server|node|cell]**

The scope at which the configured database will be shared. This parameter is optional; the default value is `server`.

#### **WAS\_SERVER=*was\_server***

The name of the WebSphere application server where the common event infrastructure application will be installed. This parameter is required only if `SHARE_DB` is set to `server`.

#### **DB\_NAME=*name***

The name of the event database. This parameter is optional; the default is `event`.

#### **DB\_SYSTEM\_DIR=*path***

The path to the directory where the event database will be created. This parameter is optional; the default value is `%WAS_HOME%\event\CloudScapeEventDB`.

#### **JDBC\_PROVIDER=*provider***

The name of the JDBC provider you are using. The value must be the name of a JDBC driver supported by WebSphere Application Server Version 5.1. The following drivers are recommended:

- Cloudscape JDBC Provider
- Cloudscape JDBC Provider (XA)
- Cloudscape Network Server Using Universal JDBC Driver

This parameter is required.

**DB\_TYPE=database**

The type of database being configured. Currently, the only supported value is CLOUDSCAPE. This parameter is required.

**PAGE\_CACHE\_SIZE=pages**

The number of memory pages to use for data caching. This parameter is optional; if it is not specified, the default value for the installed database type is used. (The default value for Cloudscape is 4000.)

**SCHEMA\_NAME=cei**

The schema name used for the event database. This parameter must match the schema name specified in the data store profile, which by default is *cei*. For more information about the data store profile, see Data store profile.

**LOG\_DEVICE=device**

The transaction log device to use. Using a separate device for logs can improve performance, although it complicates backup and recovery. This parameter is optional.

The response file can also include comments, indicated by a number sign (#) character in the first column of any line.

*Sample response file for Cloudscape:* The following is a sample response file for configuring a Cloudscape database:

```
#-----
Sample event database configuration response file for Cloudscape
#-----
SHARE_DB=server
WAS_SERVER = server1
DB_NAME=event
JDBC_PROVIDER="Cloudscape JDBC Provider"
DB_TYPE=CLOUDSCAPE
PAGE_CACHE_SIZE=4000
```

You can also find a sample response file called *CloudscapeResponseFile.txt* in the `%WAS_HOME%\event\dbconfig` directory. You can use this file as a starting point and modify it to create your response file.

*Generating and running the SQL scripts:*

After you have created the response file, you can run the **config\_event\_database** command to generate and run the required SQL scripts. Windows and UNIX versions of this command are provided in the `%WAS_HOME%\event\dbconfig` directory.

On a Windows system, run the following command:

```
config_event_database.bat response_file
```

On a UNIX system, run the following command:

```
config_event_database.sh response_file
```

The *response\_file* parameter is the name of the response file. If the response file is in a different directory, you can specify the complete path to the file.

The **config\_event\_database** command generates the appropriate script in the `%WAS_HOME%\event\dbcscripts\cloudscape` directory. It then automatically runs the script to configure the event database. The following scripts are created:

Database and operating system	Script
-------------------------------	--------

Cloudscape on Windows systems	cr_event_cloudscape.bat
Cloudscape on UNIX systems	cr_event_cloudscape.sh

If you later need to recreate the event database, you can run the appropriate script manually without having to regenerate it. These scripts do not require any parameters.

Similarly, the configuration command generates the appropriate script in the %WAS\_HOME%\event\dsscripts\cloudscape directory and then runs the script to configure the JDBC provider. If you later need to recreate the JDBC provider, you can run the appropriate script:

Database and operating system	Script
Cloudscape on Windows systems	cr_cloudscape_jdbc_provider.bat <i>scope</i> [ <i>server_name</i> ]
Cloudscape on UNIX systems	cr_cloudscape_jdbc_provider.sh <i>scope</i> [ <i>server_name</i> ]

The parameters are as follows:

**scope**

The WebSphere Application Server scope at which you want to create the JDBC provider. The valid values are cell, node, and server.

**server\_name**

The name of the WebSphere server where you want to create the JDBC provider, if **scope** is server. (If **scope** is cell or node, this parameter is not required.)

If an error occurs during database configuration, the created databases are removed, and error messages are written to the log file %WAS\_HOME%\logs\event\event\_db.log.

After you finish configuring the event database, you must restart the WebSphere server.

In addition to configuring the event database, you must also deploy the event infrastructure application in WebSphere Application Server. For more information, see Deploying the event infrastructure application.

**Removing the event database:**

When the event database is created, SQL scripts for database removal are also created and stored in %WAS\_HOME%\event\dbscripts\cloudscape. If you need to remove the event database, you can use the appropriate script:

Database and operating system	Script
Cloudscape on Windows systems	rm_event_cloudscape.bat
Cloudscape on UNIX systems	rm_event_cloudscape.sh

The installation also creates scripts for removing the JDBC provider. To uninstall the JDBC provider, go to the %WAS\_HOME%\event\dsscripts\cloudscape directory and run the appropriate script:

Database and operating system	Script
Cloudscape on Windows systems	rm_cloudscape_jdbc_provider.bat <i>scope</i> [ <i>server_name</i> ]
Cloudscape on UNIX systems	rm_cloudscape_jdbc_provider.sh <i>scope</i> [ <i>server_name</i> ]

The parameters are as follows:

**scope**

The WebSphere Application Server scope from which you want to remove the JDBC provider. The valid values are cell, node, and server.

**server\_name**

The name of the WebSphere server from which you want to remove the JDBC provider, if **scope** is server. (If **scope** is cell or node, this parameter is not required.)

**Note:** The event database can be shared among multiple event servers through the same JDBC provider resource configuration. Therefore, the JDBC provider configuration should be removed only if the associated event database has been uninstalled.

***Deploying the event infrastructure application:***

In addition to configuring the event database, you must also deploy the event infrastructure application in WebSphere Application Server. The installation provides a Jacl script you can use with the WebSphere **wsadmin** command to deploy the application.

To deploy the application on a Microsoft Windows system, go to the %WAS\_HOME%\event\application directory and run the following command (all on one line):

```
wsadmin.bat -f event-application.jacl -action install -earfile event-application.ear
-node node_name -server server_name [-trace]
```

On a UNIX system, go to the \$WAS\_HOME/event/application directory and run the following command (all on one line):

```
wsadmin.sh -f event-application.jacl -action install -earfile event-application.ear
-node node_name -server server_name [-trace]
```

The parameters of this command are as follows:

**node\_name**

The WebSphere Application Server node in which the event infrastructure is installed. You can find out the node name by running the following two commands on the target system:

1. %WAS\_HOME%\bin\setupCmdLine
2. echo %WAS\_NODE%

**server\_name**

The WebSphere server in which the event infrastructure is to be deployed.

If the event-application.ear file is in a different directory, you can specify the complete path to the file. The path should use forward slashes (/) on both Windows and UNIX systems.

The optional **trace** parameter causes additional debugging information to be displayed on the standard output.

***Manually removing the event infrastructure application:***

If you need to manually remove the event infrastructure application from WebSphere Application Server, you can use the **event-application.jacl** script.

To remove the application on a Windows system, go to the %WAS\_HOME%\event\application directory and run the following command (all on one line):

```
wsadmin.bat -f event-application.jacl -action uninstall -node node_name
[-server server_name] [-trace]
```

On a UNIX system, go to the \$WAS\_HOME/event/application directory and run the following command (all on one line):

```
wsadmin.sh -f event-application.jacl -action uninstall -node node_name
[-server server_name] [-trace]
```

The parameters of this command are as follows:

**node\_name**

The WebSphere Application Server node from which you want to remove the event infrastructure application.

**server\_name**

The WebSphere server from which you want to remove the event infrastructure. This parameter is optional; if you do not specify a server, the application is uninstalled from all servers in the node.

The optional **trace** parameter causes additional debugging information to be displayed on the standard output.

## Runtime configuration

The event infrastructure is installed as a set of WebSphere Application Server applications, services, and resources. To customize the event infrastructure, you can configure these resources using the WebSphere Application Server administrative console or the wsadmin tool. (For more information about the administrative console and the wsadmin tool, see "Welcome to System Administration" in the Information Center.)

To see the event infrastructure resources in the administrative console, expand the **Resources** list and click **Common Event Infrastructure Provider**. The types of event infrastructure resources are displayed in the **Additional Properties** list. From here you can navigate to the individual resources of each type (for example, you can view a list of all event group profiles or emitter factory profiles). To change the configuration of a resource, click it in the list and then edit the properties you want to change.

**Note:** Some resources and properties are intended to support functions that are not included in this release. These items are displayed in the administrative console, but they cannot currently be modified.

This chapter describes the event infrastructure resources and the typical configuration tasks you might need to perform. For complete information about these resources and their properties, refer to the administrative console and the HTML file %WAS\_HOME%\web\configDocs\index.html.

**Data store profile:** A data store profile defines properties used by the event data store, which is used to persistently store events received by the event server. A default data store profile is provided; usually, no configuration is necessary for this resource.

**Emitter factory profile:** An emitter factory profile defines properties used for an emitter factory, which event sources use to create emitters. The properties in an emitter factory profile affect the behavior of any emitter that is created using the associated emitter factory. You can use the default emitter factory profile or create additional profiles for your event sources to use. You might want to create an additional emitter factory profile to specify a different transaction mode or synchronous transmission profile. For more information about how these options affect the behavior of the emitter, see Emitters and emitter factories.

To create an emitter factory profile, click **Common Event Infrastructure Provider > Emitter Factory Profile > New**. Specify the properties of the new profile as follows:

**Name** The display name for the profile (this is the name that will be displayed in the list of emitter factory profiles).

**JNDI Name**

The JNDI name for the profile (for example, com/ibm/events/configuration/emitter/Default). This is the JNDI name an event source will use to obtain an emitter factory associated with the profile.

### Preferred Transaction Mode

The transaction mode you want to use. Select the check box if you want each event to be sent in a new transaction; otherwise each event is sent within the current transaction.

### Synchronous Transmission Profile JNDI Name

The JNDI name of the synchronous transmission profile you want to use. This must refer to an existing event bus transmission profile. For example, to use the default synchronous transmission profile, specify `com/ibm/events/configuration/bus-transmission/Default`.

Click **Apply** and then **Save** to save your changes.

**Event bus transmission profile:** An event bus transmission profile defines properties used by emitters to access the event server synchronously using Enterprise JavaBeans (EJB) calls; these profiles are used by emitter factory profiles. A default transmission profile is provided; usually, no configuration is necessary for this resource.

**Event group profile:** An event group profile defines an event group (a logical collection of events). Event groups are used to categorize events according to their content; when querying events from the event server, an event consumer can specify an event group to retrieve only the events in that group.

A default event group profile is provided; this profile defines an event group containing all events. You can create additional event group profiles specifying whatever event criteria are appropriate for your application.

To create an event group profile, click **Common Event Infrastructure Provider > Event Group Profile List > Event groups list > Event Group Profile > New**. Specify the properties of the new profile as follows:

#### Event Group Name

A unique descriptive name for the event group (for example, "Critical" or "Application Server"). This name will be used by event consumers when specifying the event group on a query.

#### Event Selector String

An event selector describing the events you want to include in the event group. An event selector is a regular expression defining a set of events based on their property data and written in a subset of XPath syntax. For more information about writing event selectors, see [Writing event selectors](#).

**Note:** Only one event groups list exists. Do not modify this list or create additional lists.

**Event server profile:** An event server profile defines properties affecting the behavior of the event server. A default event server profile is provided; usually, no configuration is necessary for this resource.

**Filter factory profile:** A filter factory profile defines a set of filter criteria used by event emitters. Currently, filtering is not available, so filter factory profiles cannot be created.

**JMS transmission profile:** A JMS transmission profile defines properties used by emitters to access the event server asynchronously using a Java Messaging Service queue. Currently, asynchronous transmission is not available, so JMS transmission profiles cannot be created.

## Developing an event source

An **event source** is any application that submits events for persistence and distribution to event consumers. The following applications are examples of event sources:

- An adapter or monitor that generates events related to monitored resources
- An application that generates notification events
- An application that forwards events from other sources

An event source is implemented in the Java programming language, using either the Java 2 Platform, Standard Edition (J2SE) or the Java 2 Platform, Enterprise Edition (J2EE). An event source must submit valid events conforming to the Common Base Event model (for more information, see The Common Base Event model). Each event is represented as a Java object.

In general, an event source must follow these high-level steps:

1. Obtain an emitter. The emitter is the interface between an event source and the event server. See *Emitters and emitter factories*.
2. Create an instance of `CommonBaseEvent` and populate the event with data. See *Working with events*.
3. Submit the event to the event server through the emitter interface. See *Sending events*.

## Emitters and emitter factories

An event source does not interact directly with the event server; instead, it interacts with an object called an emitter (an implementation of the `com.ibm.events.emitter.Emitter` interface). An emitter is a local object that provides methods for sending events.

In general, the emitter handles the details of event transmission; the developer of an event source does not need to be concerned about the event server location or the underlying transmission mechanism. Details such as these are governed by the *emitter factory profile*, a configuration object created by an administrator and bound in a Java Naming and Directory Interface (JNDI) namespace as an instance of the `com.ibm.events.emitter.EmitterFactory` interface. An emitter factory profile defines the behavior of an emitter by specifying the following settings (for a complete list, see *Emitter factory profile*):

- The preferred *transaction mode*. This setting specifies whether the emitter attempts to send each event in a new transaction or within the current transaction. An event source can change this setting for a particular emitter, but the profile specifies the default value. (This setting is valid only in a J2EE container; the J2SE platform does not provide transaction controls.)
- The preferred *synchronization mode*. This setting specifies whether events are sent using synchronous or asynchronous transmission. *Synchronous transmission* means that the `sendEvent()` method does not return control to the caller until the event has been processed; *asynchronous transmission* means that the method returns immediately after the event is submitted, and the caller has no further information about event processing. Again, an event source can change this setting for an emitter, but the default value is specified by the profile.

**Note:** Currently, only synchronous event transmission (using EJB calls) is supported.

- The *transmission profiles* to use. A transmission profile is a configuration object that defines a specific transmission mechanism for sending events to the event server. An emitter factory profile can specify two transmission profiles, one for synchronous transmission and one for asynchronous transmission. An event source cannot change the transmission profiles used by an emitter. For more information, see *Event bus transmission profile*.

**Note:** Currently, EJB calls are the only supported transmission mechanism.

An administrator can create multiple emitter factory profiles, each one defining a different emitter configuration. An event source obtains an emitter using the emitter factory associated with an existing emitter factory profile; therefore, all emitters created by a particular emitter factory will have the same default behavior. For more information, see *Obtaining an emitter*.

## Obtaining an emitter

Before you can obtain an emitter, there must be at least one emitter factory profile configured. For each emitter factory profile, an emitter factory is automatically created and is accessible using the JNDI name of the emitter factory profile. For more information, see *Configuring the common event infrastructure*.

To obtain an emitter, follow these steps:

1. Perform a JNDI lookup specifying the name of the emitter factory profile you want to use for your emitter. The returned object is the emitter factory associated with the specified profile. (An event source cannot directly access the profile itself.)
2. Call the *getEmitter()* method of the emitter factory. The returned object is an emitter configured with the profile you specified.

If the emitter factory is unable to obtain an emitter, it throws *EmitterException*.

The following example obtains an emitter configured with the profile *Default*:

```
import javax.naming.*
import com.ibm.events.*

Context context = new InitialContext();
EmitterFactory emitterFactory =
 (EmitterFactory) context.lookup("com/ibm/events/configuration/emitter/Default");
Emitter emitter = emitterFactory.getEmitter();
```

## Sending events

An event source sends events in the form of Java objects. Specifically, each event is an instance of a class implementing the *com.ibm.events.cbe.CommonBaseEvent* interface, which is a Java representation of the Common Base Event specification. For more information, see *The Common Base Event model*.

To create new events, you use an *event factory*, which is an object that returns new instances of *CommonBaseEvent* or of the various specialized classes representing event property data. For more information on event factories and event creation, see *Working with events*.

To send an event, use the *sendEvent(CommonBaseEvent)* or *sendEvent(CommonBaseEvent, int, int)* method of the *Emitter* interface. You can send an event using the current default emitter settings, or you can specify different options that override the configured default settings for the current event.

When you submit an event to an emitter, the following things happen:

1. The emitter calls the *complete()* method of the event, triggering optional content completion. See *Completing event content automatically* for more information.
2. The emitter assigns a sequence number and global instance identifier to any event that does not already have them. It then validates the event to ensure that it conforms to the Common Base Event specification.
3. Finally, if the event is valid, the emitter sends the event to the event server for persistence and distribution to event consumers.

If the event is not valid, or if the emitter encounters a problem when trying to send the event to the event server, an exception is thrown.

### **Using the current emitter settings:**

To send an event using the current settings, use the *sendEvent(CommonBaseEvent)* method:

```
String eventId = emitter.sendEvent(event);
```

In this example, *emitter* is an *Emitter* instance, while *event* is a *CommonBaseEvent* instance. The returned value, *eventId*, is the globally unique identifier of the event (the value of the *globalInstanceId* field of *CommonBaseEvent*). If the event does not have a *globalInstanceId* when you submit it, the emitter assigns one automatically.

### **Overriding the current emitter settings:**

When sending an event, an event source can specify options that override the current transaction mode or synchronization mode (or both) currently configured for the emitter. (The default values for these settings are initially those defined by the emitter factory profile; see Emitter factory profile for more information.)

**Note:** Currently, only synchronous mode is supported.

To override the emitter settings, use the `sendEvent(CommonBaseEvent, int, int)` method:

```
String eventId = emitter.sendEvent(event,
 synchronizationMode,
 transactionMode);
```

The parameters are as follows:

*event*

The event object (an instance of `CommonBaseEvent`) you want to send.

*synchronizationMode*

An integer constant defined by the interface `SynchronizationMode`. (Currently, only synchronous transmission is supported.) This should be one of the following constants:

- `SynchronizationMode.SYNCHRONOUS` (send the event synchronously)
- `SynchronizationMode.DEFAULT` (use the current emitter setting)

*transactionMode*

An integer constant defined by the interface `TransactionMode`:

- `TransactionMode.NEW` (send the event in a new transaction)
- `TransactionMode.SAME` (send the event in the current transaction)
- `TransactionMode.DEFAULT` (use the current emitter setting)

**Note:** An emitter might not support all synchronization and transaction modes. The synchronization modes supported by an emitter are defined by the emitter factory profile, and transactions are supported only in a J2EE container. If you attempt to use a mode that is not supported, the emitter throws `TransactionModeNotSupportedException` or `SynchronizationModeNotSupportedException`, as appropriate.

The following example overrides the emitter setting to send an event in a new transaction, but does not override the synchronization mode:

```
String eventId = sendEvent(event,
 SynchronizationMode.DEFAULT,
 TransactionMode.NEW);
```

Emitter options specified on `sendEvent()` apply only to the single event being sent; no changes are made to the emitter settings, and subsequent event submissions are not affected.

### **Changing the emitter settings:**

An event source can make changes to the transaction mode configured for the emitter. (This setting is initially defined by the emitter factory profile; see Emitter factory profile for more information.)

To change the transaction mode, use the `setTransactionMode(int)` method:

```
emitter.setTransactionMode(transactionMode);
```

The *transactionMode* is an integer constant defined by the interface `TransactionMode`:

- `TransactionMode.NEW` (send the event in a new transaction)
- `TransactionMode.SAME` (send the event in the current transaction)

You can also query the current transaction mode using the `getTransactionMode()` method:

```
int transactionMode = emitter.getTransactionMode();
```

The returned value is an integer corresponding to one of the transaction mode constants (either `TransactionMode.NEW` or `TransactionMode.SAME`).

**Note:** Transactions are supported only in a J2EE container.

## Freeing emitter resources

If your event source has finished sending events with a particular emitter, free the emitter resources using the `close()` method:

```
emitter.close();
```

This method releases all resources being used by the emitter.

## Developing an event consumer

An *event consumer* is any application that receives events from the event server. The event consumer receives events in the form of Java objects; it can then use the `CommonBaseEvent` interface to retrieve event property data.

An event consumer receives events by querying the event access interface. You can query events in either of two ways:

- You can specify a global instance identifier to retrieve a specific single event.
- You can specify an event group and retrieve events associated with that event group. You can optionally refine the query further by specifying an additional event selector, retrieving only events that match both the event group and event selector. For more information, see [Event group profile](#).

In addition to receiving events, an event consumer can also purge old events from the data store.

## Creating an event access bean

The event access interface is implemented as a stateless session bean using the Enterprise JavaBeans architecture. To query the event server using the event access interface, an event source must first create an instance of the event access session bean. The event access bean can be either local or remote.

To create an instance of the event access session bean, use the appropriate home interface (either `EventAccessHome` or `EventAccessLocalHome`):

```
// use home interface to create remote event access bean
InitialContext context = new InitialContext();
Object eventAccessHomeObj = context.lookup("ejb/com/ibm/events/access/EventAccess");
EventAccessHome eventAccessHome = (EventAccessHome)
 PortableRemoteObject.narrow(eventAccessHomeObj,
 EventAccessHome.class);
eventAccess = (EventAccess) eventAccessHome.create();
```

## Querying events by global instance identifier

The Common Base Event specification defines an event property called `globalInstanceId` which can be used as a primary key for event identification. The content of this property is a globally unique identifier, generated either by the application or by the event infrastructure. (Although the Common Base Event specification defines the `globalInstanceId` property as optional, the event emitter automatically assigns an identifier to any event that does not already have one. For more information, see [Sending events](#).)

You can retrieve a specific single event from the event server by querying with the `globalInstanceId` of the event you want to retrieve. This can be useful for testing purposes (to confirm that events are being stored in the event database), or to retrieve an event associated with one that was received previously.

To query an event by global instance identifier, use the `queryEventByGlobalInstanceId()` method of the event access bean:

```
CommonBaseEvent event = eventAccess.queryEventByGlobalInstanceId(eventId);
```

The parameter `eventId` is a string containing the identifier you are searching for. The returned value is an instance of `CommonBaseEvent` representing the event whose `globalInstanceId` matches the string you specified. If no event in the data store matches the specified identifier, the method returns null.

## Querying events by event group

An event can be associated with one or more *event groups*. An event group is a logical grouping of events that match a particular event selector; event groups are defined in the event infrastructure configuration. For more information, see [Event group profile](#).

You can use the event access interface to retrieve events that belong to a specified event group. You can further restrict the query results by specifying an additional event selector. The event access interface provides two methods for querying by event group; the first method returns a limited number of events, while the other returns all events belonging to the specified event group (which might be a large number of events).

To retrieve all of the events belonging to an event group, use the `queryEventsByEventGroup(String, String, boolean, int)` method:

```
CommonBaseEvent[] events = eventAccess.queryEventsByEventGroup(eventGroup,
 eventSelector,
 ascendingOrder,
 maxEvents);
```

The parameters of this method are as follows:

### *eventGroup*

A string containing the name of the event group you want to query events from. This must be the name of an existing event group defined in the event infrastructure configuration.

### *eventSelector*

A string containing an optional event selector that further refines the query. The query will return only events that match both the specified event group and the additional event selector. An event selector is specified in the form of an XPath expression (for more information, see [Writing event selectors](#)). If you do not want to specify an additional event selector, this parameter can be null.

### *ascendingOrder*

A boolean value specifying whether the returned events are to be sorted in ascending or descending order according to the value of the `creationTime` property. If this parameter is *true*, the events are sorted in ascending (chronological) order; if it is *false*, they are sorted in descending (reverse chronological) order.

### *maxEvents*

An integer specifying the maximum number of events you want returned.

To retrieve all of the events in an event group, use the `queryEventsByEventGroup(String, String, boolean)` method, which does not specify *maxEvents*.

**Note:** If the number of matching events exceeds the query threshold defined in the data store profile, `QueryThresholdExceededException` is thrown. The default query threshold is 100 000. For more information, see [Runtime configuration](#).

The following code fragment returns all events that belong to an event group called *critical\_hosts* and whose severity is greater than 30 (warning):

```

CommonBaseEvent[] events =
 eventAccess.queryByEventGroup("critical_hosts",
 "CommonBaseEvent[@severity > 30]",
 true);

```

The following example performs the same query, but specifies that no more than 5000 matching events should be returned:

```

CommonBaseEvent[] events =
 eventAccess.queryByEventGroup("critical_hosts",
 "CommonBaseEvent[@severity>30]",
 true,
 5000);

```

## Purging events from the data store

An event consumer or administrative tool can purge events from the data store using the event access interface. You can purge all events from the data store, or you can limit the purge by specifying event groups, event selectors, or both.

To purge events from the data store, use the `purgeEvents()` method of the event access bean:

```

int purged = eventAccess.purgeEvents(eventGroup,
 eventSelector,
 transactionSize);

```

The parameters are as follows:

### *eventGroup*

A string containing the name of the event group that includes the events you want to purge. This must be the name of an existing event group defined in the event infrastructure configuration. If you do not want to specify an event group, this parameter can be null.

### *eventSelector*

A string containing an optional event selector that identifies the events to purge. An event selector is specified in the form of an XPath expression (for more information, see [Writing event selectors](#)). If you do not want to specify an event selector, this parameter can be null.

### *transactionSize*

A nonzero integer specifying the number of events you want purged in a single database transaction. In most cases, you can use the constant `DEFAULT_PURGE_TRANSACTION_SIZE`, which is defined by the `EventAccess` interface.

The `purgeEvents()` method purges all of the events that match all of the criteria you specify. If *eventGroup* and *eventSelector* are both null, all events in the data store are purged. Events that arrive after the purge operation starts are not purged. The returned value is an integer specifying how many events were purged.

**Note:** If the number of matching events exceeds the maximum purge transaction size defined in the data store profile, `PurgeThresholdExceededException` is thrown and no events are purged. The default maximum purge transaction size is 100 000. For more information, see [Runtime configuration](#).

## Writing event selectors

An event selector is a regular expression that defines a set of events based on their property data (attributes or subelements). For example, an event selector might specify all events from a particular host whose severity is greater than 30 (warning). Event selectors are used to define event groups and query the event server.

Because the Common Base Event specification is based on XML, event selectors are written using a subset of XPath syntax. XPath is a standard language used to identify parts of an XML document; for more information, see the XPath specification at <http://www.w3.org/TR/xpath>.

Currently, an event selector can only specify attributes of the root `CommonBaseEvent` element; subelements and attributes of subelements are not supported. The attributes of `CommonBaseEvent` include the following:

- `version`
- `globalInstanceId`
- `extensionName`
- `creationTime`
- `localInstanceId`
- `severity`
- `priority`
- `msg`
- `sequenceNumber`
- `repeatCount`
- `elapsedTime`

A simple XPath event selector that specifies an attribute value takes the following form:

```
CommonBaseEvent[@attribute = value]
```

For example, the following event selector specifies events with the extension name *ApplicationStarted*:

```
CommonBaseEvent[@extensionName = 'ApplicationStarted']
```

You can also test for the presence of an attribute, regardless of its value:

```
CommonBaseEvent[@severity]
```

You can also perform other relational and equality comparisons using any of the following operators:

- `>` (greater than)
- `<` (less than)
- `=` (equal)
- `!=` (not equal)
- `>=` (greater than or equal)
- `<=` (less than or equal)
- `+` (plus)
- `-` (minus)
- `*` (multiplication)
- `div` (floating point division)
- `mod` (modulo)

**Note:** When used to compare times, these operators perform logical comparisons that recognize time zone differences.

You can form compound logical expressions by using the logical `and` and `or` operators to specify multiple conditions. The following example specifies events created before a particular time and with a severity greater than 30 (warning):

```
CommonBaseEvent[@creationTime < '2003-12-10T12:00:00-05:00' and @severity > 30]
```

When using XPath operators, keep the following rules in mind:

- Always specify logical operators using lowercase letters (for example, `and` rather than `AND`).
- Use spaces to separate operators from the surrounding attribute names and values (`@severity > 30` rather than `@severity>30`).

In addition, you can use the XPath string functions `starts-with`, `contains`, and `string-length`:

```
CommonBaseEvent[contains(@msg, 'disk full')]
```

## Working with events

The common event infrastructure represents events as Java objects. Specifically, each event is an instance of a class implementing the `CommonBaseEvent` interface, which is a Java representation of the Common Base Event specification. (For more information, see [The Common Base Event model](#)). At a high level, the life cycle of an event is as follows:

1. To send an event, an event source creates a new instance of `CommonBaseEvent`, populates it with property data, and then submits it to an emitter. (An optional content completion mechanism, if implemented, can populate events with required property data automatically; for more information, see [Completing event content automatically](#).)
2. The emitter validates the event against the Common Base Event specification. If the event is valid, the emitter sends the event to the event server. For more information about event processing by the emitter, see [Sending events](#).
3. The event server stores the event in a persistent data store.
4. An event consumer submits a query to retrieve the event from the data store, and then reads the event property data. For more information about querying events, see [Developing an event consumer](#).
5. When it is no longer needed, the event is purged from the data store.

The Common Base Event specification, which is based on XML, defines two kinds of event property data:

- Properties represented by simple data types, encoded in XML as attributes of the `CommonBaseEvent` element. These include properties such as *globalInstanceId*, *severity*, and *msg*. The `CommonBaseEvent` Java class represents these values as strings or integers, as appropriate.
- Properties represented by complex data types and encoded in XML as subelements of the `CommonBaseEvent` element. These include properties such as *situation*, *sourceComponentId*, and *extendedDataElements*, each of which has nested properties of its own. These complex types are represented by specialized Java objects; for example, the *sourceComponentId* property is represented by an instance of `ComponentIdentifier`.

The `CommonBaseEvent` interface defines getter and setter methods for each property, as well as helper methods to simplify creation of complex properties. An event source uses the setter methods (or the helper methods) to populate an event with property data before submitting it to an emitter; an event consumer uses the getter methods to retrieve the property data from a received event.

### Creating an event object

To create new events in your event source, you use an *event factory*, which is an object that returns new instances of `CommonBaseEvent` or of the specialized classes representing complex property data types.

There are two ways in which you might access an event factory:

- You can create a new event factory using the *event factory factory*. Use this approach if no appropriate event factory is already available. When you create an event factory, you can optionally specify a content handler to provide automatic content completion. For more information about content completion, see [Completing event content automatically](#).
- You can use an existing event factory that has been bound into a JNDI namespace. Use this approach if an event factory has been provided for you to use; this ensures that any events you create will conform to the appropriate business rules, since the event factory might be configured with a content handler.

#### **Creating a new event factory:**

To create a new event factory, use the event factory factory, implemented as the class `EventFactoryFactory`. This class has no instances; instead, it provides two static methods used to create event factories. The choice of which method to use depends upon whether you want to use a content handler to implement automatic content completion. For more information, see [Completing event content automatically](#).

To create a generic event factory with no content handler, use the `createEventFactory()` static method of `EventFactoryFactory`:

```
EventFactory eventFactory =
 (EventFactory) EventFactoryFactory.createEventFactory();
```

To create an event factory with a content handler, use the `createEventFactory(ContentHandler)` method, specifying the content handler you want to use:

```
EventFactory eventFactory =
 (EventFactory) EventFactoryFactory.createEventFactory(contentHandler);
```

In either case, the returned object is an event factory you can use to create new events.

### **Getting an event factory by JNDI lookup:**

If an event factory has already been provided and bound into a JNDI namespace for your event source to use, perform a standard JNDI lookup to retrieve the event factory:

```
import javax.naming.*
import com.ibm.events.*

Context context = new InitialContext();
EventFactory eventFactory =
 (EventFactory) context.lookup("com/ibm/events/EventFactory");
```

The returned object is the provided event factory; if the event factory is configured with a content handler, an instance of the content handler is also transparently created locally. For more information about content handlers and JNDI, see [Completing event content automatically](#).

### **Populating event data**

After you create an event, you must populate the event with property data. Most event properties are defined as optional by the Common Base Event specification, but four are required:

- *version* (a *string* attribute)
- *creationTime* (an XML *dateTime* attribute)
- *sourceComponentId* (a complex *ComponentIdentification* element)
- *situation* (a complex *Situation* element)

**Note:** The version attribute is defined as optional by the Common Base Event specification, but if it is not specified, the default value 1.0 is assumed. Because the event infrastructure supports only version 1.0.1 of the specification, this value must be specified.

If you try to send an event that is missing any of these properties, the emitter rejects the event and throws a `ValidationException`.

The following code fragment creates an event and populates it with the minimal required property data:

```
CommonBaseEvent event = eventFactory.createCommonBaseEvent();

event.setVersion("1.0.1"); //set version

long currentTime = System.currentTimeMillis(); // get current time
event.setCreationTimeAsLong(currentTime); // and set creationTime

// set sourceComponentId (a complex type)
event.setSourceComponentId("Windows", // application
 "svchost.exe", // component
 "tlntsvr.exe", // subcomponent
 "http://www.ibm.com/namespaces/autonomic/Windows", // componentType
 "win386_svc", // componentIdType
 "9.45.72.138", // location
```

```

 "IPV4" // locationType
);

 // create situation object
 Situation situation = eventFactory.createSituation();

 // set situationType to AvailableSituation (a complex type)
 situation.setAvailableSituation("EXTERNAL", // reasoningScope
 "NOT AVAILABLE", // availabilityDisposition
 "STARTABLE", // operationDisposition
 "FUNCTION_PROCESS"); // processingDisposition

 // set situation
 event.setSituation(situation);

```

This example first uses an event factory to create a new event instance, *event*. First it sets the version property; then it retrieves the current system time and uses the `setCreationTimeAsLong(long)` method to set the value of the *creationTime* property. This could also have been done using the `setCreationTime(String)` method, which sets the creation time using the XML *dateTime* format (for example, "1998-07-29T13:12:00-05:00").

The next required property, *sourceComponentId*, is a complex property represented by an instance of *ComponentIdentification*, which has properties of its own. However, it is not necessary to directly instantiate or interact with this object (although it is possible to do so). Instead, the next statement in the example uses a helper method, `setSourceComponentId()`, to specify the nested properties; the helper method uses these values to create an instance of *ComponentIdentification*, which it then uses to set the value of the *sourceComponentId* property of the event.

Similar helper methods exist for setting other complex properties (for example, `setMsgDataElement()`, `addAssociatedEvents`, and `addExtendedDataElement()`). Many of these methods exist in multiple versions with different signatures, making it possible to specify property values in numerous different ways. Refer to the Javadoc API documentation for complete information on these methods.

The last required property in the example, *Situation*, is another complex property. In this case the situation object must be instantiated directly using an event factory; the example then uses a helper method to set the *situationType* property, which is itself a complex subelement.

In an actual application, a useful event would need to include more information than is shown here, but this is the minimum required by the Common Base Event specification. The event is now valid and can be submitted to an emitter.

## Completing event content automatically

In some situations, you might want some event property data to be automatically set for every event you create. This can be useful if you want to fill in certain standard values that do not change (such as the application name), or if you want to set some properties based on information available from the execution environment (such as creation time or thread information). You might also want to set policies that govern event content according to business rules; for example, you might require that any event with a particular extension name have its severity set to a certain value.

You can accomplish this by creating a *content handler*. A content handler is an object that automatically sets the property values of each event based on any arbitrary policies you want to use. The event infrastructure imposes no restrictions on how a content handler modifies event data, so long as the event still conforms to the Common Base Event specification.

To create a content handler, you must create a new Java class implementing the `com.ibm.events.cbe.ContentHandler` interface. This interface defines a single method called `completeEvent(CommonBaseEvent)`; the parameter is the event whose content is to be completed. In your

implementation of this method, you can use the getter and setter methods of `CommonBaseEvent` to process the event property data in accordance with any policies that apply.

The following example is a simple content handler that automatically sets the extension name of each event:

```
import java.io.Serializable;
import com.ibm.events.cbe.CommonBaseEvent;
import com.ibm.events.cbe.CompletionException;
import com.ibm.events.cbe.ContentHandler;

public class BusinessContentHandler
 implements ContentHandler, Serializable {

 public void completeEvent(CommonBaseEvent event)
 throws CompletionException {
 event.setExtensionName("business");
 }
}
```

To use a content handler, you must associate it with an event factory. To do this, specify the content handler when creating the event factory:

```
EventFactory eventFactory =
 (EventFactory) EventFactoryFactory.createEventFactory(contentHandler);
```

The returned event factory is permanently associated with the specified content handler.

An event source does not need to do anything to enable content completion. If an event factory is associated with a content handler, each event it creates carries with it a reference to that content handler. When the event is submitted to an emitter, the event calls the `completeEvent()` method of the content handler, passing a reference to itself. This ensures that the correct policies are applied to the event after the event source has finished setting event-specific properties, but before the event is validated and processed by the emitter.

**Note:** When an event is transmitted from one process to another, the reference to the content handler is not transmitted with it. This is because content completion relies upon the execution environment where the event originated, and the necessary information might not be available elsewhere. This restriction does not affect calls between applications that are local to one another (for example, a call to an enterprise bean using its local interface).

If you want to ensure that all event sources comply with the same policies, you can create an event factory associated with a content handler (using `EventFactoryFactory`) and then bind the created event factory into a JNDI namespace. Instead of creating their own event factories, event sources can then perform JNDI lookups to access the event factory that already exists, without any knowledge of the content handler. If your business rules later change, you can modify the content handler in one place.

When an event source uses JNDI to retrieve an event factory, the content handler is returned along with the event factory. For this reason, the content handler must be serializable.

## Retrieving event data

When an event source receives an event, it can then use the getter methods of `CommonBaseEvent` to retrieve the event property data. For example, the following code fragment retrieves a single event and then reads the content of the `msg` property.

```
CommonBaseEvent event = eventAccess.queryEventByGlobalInstanceId(eventId);
String eventMessage = event.getMsg();
```

If the property you want to retrieve is a complex property (a subelement of `CommonBaseEvent` in the Common Base Event specification), the returned value is an instance of the specialized class representing

the complex data type. You can then use the getter methods of the returned object to retrieve the property data from that object. For example, the following code fragment retrieves the value of *componentId*, which is a complex property; it then retrieves the content of the nested *component* property, which is a string, to read the name of the source component.

```
CommonBaseEvent event = eventAccess.queryEventByGlobalInstanceId(eventId);
ComponentIdentification componentId = event.getSourceComponentId();
String componentName = componentId.getComponent();
```

## Accessing event metadata

The `com.ibm.events.cbe` package, which provides the classes and interfaces required for working with event objects, is based on the Eclipse Modeling Framework (EMF). EMF is a Java framework used to generate application code based on a structured data model; it also provides interfaces in the generated code that can be used to access metadata describing the data model. (Refer to the Eclipse Modeling Framework documentation at <http://www.eclipse.org/emf> for more information about EMF.)

By using these interfaces, EMF-compatible tools can interact with `CommonBaseEvent` event data without any prior knowledge of the data model or access to the implementation. This makes it possible for development tools to generate code that transfers data from other data models into the `CommonBaseEvent` model. Application developers can then focus on writing code that uses the data rather than code that builds the data.

For example, consider an event source that monitors network events and describes its own data model in terms of EMF. With access to both data models, a development tool could display the fields of the event source data model alongside the fields of the `CommonBaseEvent` data model. A developer could then use a graphical interface to indicate how the fields in the event source model are mapped to fields in the `CommonBaseEvent` model; for example, the field `Workstation.name` in the event source data model might correspond to the field `CommonBaseEvent.sourceComponentId.location` in the `CommonBaseEvent` data model. After this connection is made by the developer, the tool can generate code that handles the transfer of data between the two models.

The following code fragment is a simple example of how a development tool might use EMF interfaces to query information about the `CommonBaseEvent` data model and then use that information to interact with an event instance. This example could be part of a simple event consumer; it iterates through all of the fields of an event instance and, for each one, prints the name and value of the field.

```
// event is a valid CommonBaseEvent instance

// Get list of event instance structural features (fields)
List features = event.eClass().getEAllStructuralFeatures();

// iterate through list; print names and values
for (int i = 0 ; i < features.size() ; i++)
{
 EStructuralFeature feature = (EStructuralFeature)features.get(i);
 Object value = eObj.eGet(feature);
 System.out.println(feature.getName() + ":" + value);
}
```

The `CommonBaseEvent` data model is described in the EMF files `cbe.ecore` and `cbe.genmodel`. These files are included with the common event infrastructure development kit; you can import them into an Eclipse-based development environment and then use EMF to generate code that interacts with `CommonBaseEvent` objects.

---

## Message reference

### CEIC0001W

Event group profiles have been configured with duplicate event group names. Event group names: *event\_group\_names*

#### Explanation

Event group names must be unique in each event group profile. The first duplicated event group profile will be overwritten.

#### Administrator Response

Modify the event group names in the event group profile configuration to ensure that the event group names are unique.

### CEIC0002W

The Common Event Infrastructure service failed to start because the Common Event Infrastructure resources failed to bind into JNDI. Exception message: *binding\_error*

#### Explanation

See message.

#### Administrator Response

Consult the Common Event Infrastructure log files to ensure that the Common Event Infrastructure application is installed successfully. Also, see the exception message for additional information about the cause of the problem.

### CEIC0003W

The Common Event Infrastructure service failed to start because a Common Event Infrastructure object failed to bind into JNDI. Object type: *binding\_object* Exception message: *binding\_object\_error*

#### Explanation

See message.

#### Programmer Response

Consult the Common Event Infrastructure log files to ensure that installation of the Common Event Infrastructure application completed successfully. Also, see the exception message for additional information about the cause of the problem.

### CEIC0004W

The binding in JNDI could not be created. Exception message: *reference\_exception*

#### Explanation

See message.

### **Programmer Response**

Consult the Common Event Infrastructure log files to ensure that the installation of the Common Event Infrastructure application completed successfully. Also, ensure that the configuration settings are correct.

## **CEIC0005W**

The object to bind into JNDI could not be created. Exception message: *reference\_exception*

### **Explanation**

See message.

### **Programmer Response**

Consult the Common Event Infrastructure log files to ensure that the installation of the Common Event Infrastructure application completed successfully. Also, ensure that the configuration settings are correct.

## **CEIC0006I**

The Common Event Infrastructure application is started.

### **Explanation**

No additional information is available for this message.

## **CEIDS0001E**

The specified relational database management system is not supported. Database:*rdbms\_name* Version:  
*rdbms\_version*

### **Explanation**

See message.

### **Administrator Response**

Reconfigure the common event infrastructure data source to use a supported relational database management system.

## **CEIDS0002E**

The relational database management system reported the following error. SQL State: *sql\_state* Vendor code: *vendor\_code* Message: *message*

### **Explanation**

The SQL state is the standard JDBC error code for the reported problem. The vendor code is the database vendor specific error code. The message parameter is the localized error message that is returned by the relational database management system.

### **Administrator Response**

Refer to the appropriate relational database documentation for information about the SQL state, the vendor code, and the error message.

## CEIDS0003E

The mapping of a Common Base Event element or attribute to database tables and columns cannot be found. Attribute: *attribute\_name*

### Explanation

The data store stores metadata information in its database. This metadata information specifies how Common Base Event elements and attributes map to tables and columns in the database. Either an error occurred during the installation of the event database or the metadata table information is corrupted.

### Administrator Response

Reinstall the event database.

## CEIDS0004I

The data store is connecting to the specified relational database management system.  
Database:*rdbms\_name* Version: *rdbms\_version*

### Explanation

No additional information is available for this message.

## CEIDS0005E

The maximum purge transaction size of *purge\_threshold* has been exceeded. The purge operation has been stopped, and no events have been purged.

### Explanation

An event purge operation was attempting to delete a large number of events. Because this action can adversely affect system performance and event throughput, the purge operation was stopped.

### Programmer Response

To reduce the number of events to be purged in a single transaction, do one or both of the following:

- Add additional filters to the purge event selector expression.
- Set the maximum purge transaction size to a lower value.

## CEIDS0006E

The query threshold *query\_threshold* has been exceeded. The query operation has been stopped.

### Explanation

An event query attempted to return a very large number of events. Because this action can adversely affect system performance and event throughput, the query operation was stopped.

### Programmer Response

To reduce the number of events to be returned, do one or more of the following:

- Add additional filters to the event selector expression for the query.
- Specify the maximum number of events to be returned.

- If you have sufficient system resources, increase the query threshold value.

## **CEIDS0007E**

An event with the global instance identifier, *global\_id*, already exists in the database. The event was not stored in the database.

### **Explanation**

Each event instance must have a unique global instance identifier.

### **Programmer Response**

Create the event with a unique global instance identifier.

## **CEIDS0008E**

The WebSphere Application Server connection pooling system returned a database connection that is no longer valid.

### **Explanation**

See message.

### **Programmer Response**

Retry the operation.

## **CEIDS0009E**

A database connection could not be obtained from the connection pool after *maximum\_retries* attempts to obtain a connection.

### **Explanation**

The WebSphere Application Server connection pooling system was not able to return a database connection using the current configuration of the connection pool and the configured number of retries.

### **Administrator Response**

Do one or more of the following:

- Reconfigure the data source, increasing the maximum number of connections. This option improves performance and event throughput.
- Reconfigure the data source, increasing the connection timeout value.
- In the data store profile, increase the number of retries.

## **CEIDS0010I**

The *maxCacheEntries* configuration parameter must be greater than or equal to 0. However, *maximum\_statement\_cache\_size* was specified. The *maxCacheEntries* value has been set to 0.

## Explanation

The `maxCacheEntries` configuration parameter specifies how many translated event selector expressions can be cached by the data store. Caching translated event selector expressions can improve the performance of the event query and the event purge because event selector expressions in the cache do not need to be parsed and translated to SQL.

When the `maxCacheEntries` parameter is set to 0, no translated event selector expressions are cached. Therefore, each event selector expression specified in a call to the event query and the event purge methods must be parsed and translated to valid SQL.

## Administrator Response

In the data store profile, set the `maxCacheEntries` value to 0 or greater.

## CEIDS0011E

The data store cannot find the resource reference in JNDI. Resource reference: *resource\_reference\_name*

## Explanation

The data store uses resource references to obtain the data source that is used to obtain connections to the database and for the object that contains the configuration for the data store. The resource reference information specified at installation is not valid. For example, a JNDI name that is not valid was specified for the resource reference.

If the specified resource reference name is `java:comp/env/DefaultDataStoreProfileReference`, the data store cannot access its configuration data. If the specified resource reference name is `java:comp/env/EventDataSourceReference`, the data store cannot access its data source.

## Administrator Response

In the WebSphere Application Server Administrator's console, reconfigure the specified resource reference to a valid JNDI resource.

## CEIDS0013E

The attribute or element *name* specified in the event selector expression is not supported.

## Explanation

Only attributes in the `CommonBaseEvent` element are supported. The following attributes are supported:

- `globalInstanceid`
- `version`
- `extentionName`
- `localInstanceid`
- `creationTime`
- `severity`
- `msg`
- `priority`
- `sequenceNumber`

## Programmer Response

Specify an event selector expression that contains the supported elements and attributes.

## CEIDS0014E

The XPath location path *locationPath* is not valid, and it could not be translated to a valid SQL expression.

### Explanation

The most likely cause of this problem is specifying a location path that acts on an element or attribute in the `CommonBaseEvent` element that does not map directly to a table column in the event database.

## Programmer Response

Specify a location path that acts on elements and attributes that map directly to a table column in the event database.

The following example shows a valid event selector expression. Although the event selector expression is shown here on multiple lines, you must specify the expression on one line.

```
CommonBaseEvent[messageDataElement/
msgCatalogToken]
```

However, because the `msgCatalogToken` element cannot have data that is mapped directly to a column and table in the event database, it cannot be translated to an equivalent SQL expression.

Instead, use the following event selector expression to select all events from the event database that have at least one message catalog token. Although the event selector expression is shown here on multiple lines, you must specify the expression on one line.

```
CommonBaseEvent[messageDataElement/
msgCatalogToken/@value]
```

## CEIDS0015E

The type of the first argument of the `starts-with` or the `contains` function used in the event selector expression is not supported. Argument: *argument*

### Explanation

The first argument of the `starts-with` or the `contains` function must either be a string constant or a location path that can be translated to a column in the event database. The SQL equivalent to these functions, the `LIKE` function, requires that its first argument be either a table column or a string constant.

## Programmer Response

Specify a string constant or a location path that maps to a table column in the event database for the first argument of the `starts-with` or the `contains` function used in the event selector expression.

The following example shows a valid event selector expression using the `starts-with` function.

```
CommonBaseEvent[starts-with(@msg,'My message')]
```

## CEIDS0016E

The type of the second argument of the starts-with or the contains function used in the event selector expression is not supported. Argument: *argument*

### Explanation

The second argument of the starts-with or the contains function must be a string constant. The SQL equivalent to these functions, the LIKE function, requires that its second argument be a string constant.

### Programmer Response

Specify a string constant for the second argument of the starts-with or the contains function that is used in the event selector expression.

The following example shows a valid event selector expression using the starts-with function.

```
CommonBaseEvent[starts-with(@msg,'My message')]
```

## CEIDS0017E

The first argument of the starts-with or the contains function used in the event selector expression is a constant, but it is not a string constant. Argument: *argument*

### Explanation

If a constant is specified for the first argument of the starts-with or the contains function, the constant must be a string constant. The SQL equivalent to these functions, the LIKE function, requires that its first argument be either a string constant or a table column.

### Programmer Response

Specify a string constant or a location path that maps to a table column in the event database for the first argument of the starts-with or the contains function used in the event selector expression.

The following example shows a valid event selector expression using the starts-with function with a constant as the first argument.

```
CommonBaseEvent[starts-with('My','My message')]
```

## CEIDS0018E

The following division operation is not valid. Operation: *operation*

### Explanation

A zero is the second operand in the specified division operation. Division by zero is not valid.

### Programmer Response

Specify the division operation with a positive numeric value as the second operand.

The following example shows a valid event selector expression using the division operation.

```
CommonBaseEvent[@severity = 10 div 1]
```

## CEIDS0019E

No arguments were specified for the length function used in the event selector expression. Function:  
*function*

### Explanation

You must specify one argument for the length function. The SQL equivalent to the length function requires one argument.

### Programmer Response

Specify one argument for the length function.

The following example shows a valid event selector expression using the length function.

```
CommonBaseEvent[string-length(@msg)=10]
```

## CEIDS0020E

The event selector expression function used in the event selector expression is not supported. Function:  
*function*

### Explanation

The following event selector expression functions are supported:

- string-length()
- contains()
- starts-with()

### Programmer Response

Specify an event selector expression that uses a supported function.

## CEIDS0021E

The XPath expression type, *expression\_type*, is not supported.

### Explanation

The following expression types are supported:

- Constant

```
1,2,'thisString'
```

- Location Path

```
CommonBaseEvent[@severity=10]
```

- Operation

```
@severity+10=20
```

- Function

```
string-length(@msg)
```

## Programmer Response

Specify an XPath expression that uses a supported expression type.

## CEIDS0022E

The event selector expression *expression* is not valid. The event selector parsing tool returned the following message: *message*

### Explanation

The following are possible reasons for this exception:

- A predicate bracket is not closed. For example, `CommonBaseEvent[@severity='10` is missing a closing bracket, and it should be specified as `CommonBaseEvent[@severity='10']`.
- A function has the wrong number of arguments. For example, the `starts-with` and the `contains` function require two arguments.
- A quote on a string constant is not closed. For example, `CommonBaseEvent[@severity='10]` is missing a closing quote, and it should be specified as `CommonBaseEvent[@severity='10']`.
- An open parenthesis is not closed. For example, `CommonBaseEvent[(@severity+10=20]` is missing a closing parentheses, and it should be specified as `CommonBaseEvent[(@severity+10)=20]`.

## Programmer Response

Specify a valid event selector expression.

## CEIDS0023E

The event selector expression *expression* is not valid. The expression includes a step that references the `CommonBaseEvent` element, but it does not contain a predicate.

### Explanation

See message.

## Programmer Response

Specify an event selector expression with at least one predicate associated with the `CommonBaseEvent` element.

For example, the following event selector expression returns SQL that selects all events from the event database.

```
CommonBaseEvent[@globalInstanceId]
```

## CEIDS0024E

The function used in the event selector expression, such as the `starts-with` or the `contains` function, is not valid because it requires two arguments. Function: *function*

### Explanation

The specified function requires two arguments.

### **Programmer Response**

Specify two arguments for the specified function.

The following example shows a valid event selector expression using the starts-with function.

```
CommonBaseEvent[starts-with(@msg,'My message')]
```

## **CEIDS0025E**

The arithmetic operation contains an operand that is not a numeric value. Operation: *operation*

### **Explanation**

Only numeric operands are supported for the following arithmetic operators: +, -, \*, div, mod, <, >, <=, >=

### **Programmer Response**

Specify two numeric values for the operation.

The following example shows a valid event selector expression using the addition operation.

```
CommonBaseEvent[@severity = 10 + 1]
```

## **CEIDS0026E**

The operation contains operands that are not compatible. Operation:*operation*

### **Explanation**

The most likely cause of this problem is using a numeric value for one operand and a string value that cannot be converted to a numeric value for the other operand.

### **Programmer Response**

Specify operands with compatible types.

The following example shows a valid event selector expression using the equality operation.

```
CommonBaseEvent[@severity = '10']
```

Because the string value 10 can be converted to the numeric value 10, the operation is valid and the types are compatible.

## **CEIDS0027E**

An error occurred when writing the CommonBaseEvent any element to the database. The operation was stopped. Error: *io\_write\_error*

### **Explanation**

See message.

### **Administrator Response**

See message.

## **CEIDS0028E**

An error occurred when reading the CommonBaseEvent any element from the database. The operation was stopped. Error: *io\_read\_error*

### **Explanation**

See message.

### **Administrator Response**

See message.

## **CEIDS0029E**

An error occurred when writing a CommonBaseEvent extended data element that has a hexBinary data type to the database. The operation was stopped. Error: *io\_write\_error*

### **Explanation**

See message.

### **Administrator Response**

See message.

## **CEIDS0030E**

An error occurred when reading a CommonBaseEvent extended data element that has a hexBinary data type from the database. The operation was stopped. Error: *io\_read\_error*

### **Explanation**

See message.

### **Administrator Response**

See message.

## **CEIDS0031I**

The configuration value for connection retries, *connection\_retries*, is not valid. The value has been changed to 0.

### **Explanation**

The connection retries configuration setting specifies the number of times the data store attempts to obtain a database connection from the connection pool. If a connection cannot be obtained in the specified number of retries, the data store throws an exception. A value of 0 specifies that the data store does not retry the operation.

### **Administrator Response**

In the data store profile, set the connection retries value to 0 or greater.

## **CEIDS0032I**

The configuration value for query threshold, *query\_threshold*, is not valid. The value has been changed to 100 000.

### **Explanation**

The query threshold configuration setting specifies the maximum number of events that can be returned by the queryEvents methods. This value must be 1 or greater.

### **Administrator Response**

In the data store profile, set the query threshold value to 1 or greater.

## **CEIDS0033I**

The maximum purge transaction size, *purge\_threshold*, is not valid. The value has been changed to 100 000.

### **Explanation**

The maximum purge transaction size configuration setting specifies the maximum number of events that can be deleted in a single purgeEvents call. This value must be 1 or greater.

### **Administrator Response**

In the data store profile, set the maximum purge transaction size to 1 or greater.

## **CEIDS0034E**

The operator used in the the event selector expression operation *operation* is not supported.

### **Explanation**

The following event selector expression operators are supported:

- +, -, \*, div, mod
- =, !=, <, >, <=, >=
- and, or

### **Programmer Response**

Specify an event selector expression operation that uses a supported operator.

## **CEIEI0001E**

The reference obtained from the specified JNDI name is not a reference to an event factory. JNDI name: *JNDI\_name*

**Explanation**

An application attempted to look up an event factory from a JNDI namespace, but the object found in the specified location is not a reference to an event factory.

**Administrator Response**

Contact the owner of the application that is creating the event.

**Programmer Response**

Ensure that the specified JNDI name is a reference to an event factory.

**CEIEI0002E**

The event content handler referenced by this JNDI name cannot be converted back from its binary format. JNDI name: *JNDI\_name* Additional information, if any: *error\_message*

**Explanation**

See message.

**Administrator Response**

If you cannot resolve the problem from the additional information provided, contact IBM Customer Support.

**CEIEI0003E**

The event content handler cannot be converted to binary format. Additional information, if any: *error\_message*

**Explanation**

A problem was encountered when the event content handler was being converted to binary format.

**Administrator Response**

If you cannot resolve the problem from the additional information provided, contact IBM Customer Support.

**CEIEI0005E**

The event identifier in the specified Common Base Event property must start with an alphabetic character. ID: *id* Attribute: *attribute\_name* Property: *class\_name*

**Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification.

**Administrator Response**

Contact the owner of the application that is creating the event.

### **Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

## **CEIEI0007E**

The specified extended data element is a type that requires one element inside its array of values, but it contained multiple values. Extended data element: *extended\_data\_element\_name*  
Type: *extended\_data\_element\_type* Number of values: *count*

### **Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification.

### **Administrator Response**

Contact the owner of the application that is creating the event.

### **Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

## **CEIEI0008E**

The value in the extended data element cannot be converted to the specified type. Value: *value* Extended data element: *extended\_data\_element\_name* Type: *type*

### **Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification. An extended data element inside that event contains a value that does not match its type.

### **Administrator Response**

Contact the owner of the application that is creating the event.

### **Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

## **CEIEI0010E**

The extended data element has a type that is not valid. Extended data element: *extended\_data\_element\_name* Type: *extended\_data\_element\_type*

### **Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification.

### **Administrator Response**

Contact the owner of the application that is creating the event.

### **Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

## **CEIEI0011E**

The extended data element contains a null value inside its array of values. Extended data element:  
*extended\_data\_element\_name* Type:*extended\_data\_element\_type*

### **Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification.

### **Administrator Response**

Contact the owner of the application that is creating the event.

### **Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

## **CEIEI0015E**

The extended data element contains a string that is not a valid boolean string. Extended data element:  
*extended\_data\_element\_name* Type:*extended\_data\_element\_type* String: *string*

### **Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification. Valid values for a boolean string are: true, false, 0, and 1.

### **Administrator Response**

Contact the owner of the application that is creating the event.

### **Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

## **CEIEI0016E**

The extended data element contains a dateTime string that is not valid. Extended data element:  
*extended\_data\_element\_name* Type: *extended\_data\_element\_type* dateTime string: *string*

### **Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification. The following example shows a valid dateTime value that specifies 1:20 pm on May the 31st, 1999 for Eastern Standard Time which is 5 hours behind Coordinated Universal Time (UTC).

1999-05-31T13:20:00-05:00

### **Administrator Response**

Contact the owner of the application that is creating the event.

### **Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

## **CEIEI0017E**

The extended data element must contain an even number of characters in the hexValue property.  
Extended data element: *extended\_data\_element\_name* Type: *extended\_data\_element\_type*

### **Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification.

### **Administrator Response**

Contact the owner of the application that is creating the event.

### **Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

## **CEIEI0018E**

The extended data element must contain hexadecimal characters in the hexValue property. Extended data element: *extended\_data\_element\_name* Type: *extended\_data\_element\_type* Property value: *value*

### **Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification.

### **Administrator Response**

Contact the owner of the application that is creating the event.

### **Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

## **CEIEI0019E**

The CommonBaseEvent/situation/category attribute is not valid. Attribute: *situation\_type*

### **Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification.

### **Administrator Response**

Contact the owner of the application that is creating the event.

### **Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

## **CEIEI0020E**

The creationTime attribute for the specified attribute is not valid. creationTime attribute: *creation\_time*  
Attribute: *attribute\_name*

### **Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification. The following example shows a valid creationTime value that specifies 1:20 pm on May the 31st, 1999 for Eastern Standard Time which is 5 hours behind Coordinated Universal Time (UTC).

```
1999-05-31T13:20:00-05:00
```

### **Administrator Response**

Contact the owner of the application that is creating the event.

### **Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

## **CEIEI0021E**

The length of an element in the specified attribute exceeds the maximum number of characters. Element: *element*  
Attribute: *attribute\_name* Maximum length: *maximum\_length*

### **Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification.

### **Administrator Response**

Contact the owner of the application that is creating the event.

### **Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

## **CEIEI0022E**

The attribute value is outside the valid range. Attribute value: *attribute\_value* Attribute name: *attribute\_name*  
Valid range: *minimum\_value* through *maximum\_value*

**Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification.

**Administrator Response**

Contact the owner of the application that is creating the event.

**Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

**CEIEI0023E:**

An attribute is missing from the specified Common Base Event property. Attribute: *attribute\_name*  
Property: *class\_name*

**Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification.

**Administrator Response**

Contact the owner of the application that is creating the event.

**Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

**CEIEI0024E**

The attributes are mutually exclusive in the specified Common Base Event property. Attribute:  
*attribute\_name* Attribute: *attribute\_name* Property: *class\_name*

**Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification.

**Administrator Response**

Contact the owner of the application that is creating the event.

**Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

**CEIEI0025E**

The attribute value in the specified Common Base Event property is not valid. Attribute value: *value*  
Attribute: *attribute\_name* Property: *class\_name*

### **Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification. The value must be 1.0.1.

### **Administrator Response**

Contact the owner of the application that is creating the event.

### **Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

## **CEIEI0026E**

The length of the value in the specified Common Base Event property is outside the valid range of 32 to 64 characters. Value: *value* Attribute: *attribute\_name* Property: *class\_name*

### **Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification.

### **Administrator Response**

Contact the owner of the application that is creating the event.

### **Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

## **CEIEI0027E**

The length of an attribute in the specified Common Base Event property exceeds the maximum number of characters. Attribute length: *attribute\_length* Attribute: *attribute\_name* Property: *class\_name* Maximum number of characters: *maximum\_number*

### **Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification.

### **Administrator Response**

Contact the owner of the application that is creating the event.

### **Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

## **CEIEI0028E**

The length of an attribute value in the specified Common Base Event property is outside the valid range. Attribute length: *attribute\_length* Attribute: *attribute\_name* Property: *class\_name* Valid number of characters: *minimum\_maximum\_length*

**Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification.

**Administrator Response**

Contact the owner of the application that is creating the event.

**Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

**CEIEI0029E**

The attributes in the specified Common Base Event property must either all be set or all be unset.  
Attributes: *attribute\_list* Property: *class\_name*

**Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification.

**Administrator Response**

Contact the owner of the application that is creating the event.

**Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

**CEIEI0030E**

When the value of the following attribute in the specified Common Base Event property is equal to *attribute\_value*, the specified list of attributes must be unset. Property: *class\_name* Attribute: *attribute\_name* Attribute list: *attribute\_list*

**Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification.

**Administrator Response**

Contact the owner of the application that is creating the event.

**Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

**CEIEI0031E**

The situation type is not valid for the specified situation category. Situation type: *situation\_type* Situation category: *situation\_category*.

**Explanation**

An application has attempted to validate an event that does not conform to version 1.0.1 of the Common Base Event specification.

**Administrator Response**

Contact the owner of the application that is creating the event.

**Programmer Response**

Ensure that the event conforms to version 1.0.1 of the Common Base Event specification.

**CEIEM0001E**

The emitter failed to initialize because the configured synchronization mode *mode* is not valid.

**Explanation**

See message.

**Administrator Response**

Ensure that the synchronization mode specified in the emitter factory profile is valid.

**CEIEM0002E**

The emitter failed to start because the configured synchronization mode is not valid. A sender has not been configured for the synchronization mode.

**Explanation**

See message.

**Administrator Response**

Ensure that the synchronous transmission profile specified in the emitter factory profile is valid.

**CEIEM0003E**

The filter factory *filterFactory* failed to create a filter instance.

**Explanation**

See message.

**Administrator Response**

See the exception message that follows this message for additional information about the cause of the problem.

**CEIEM0004E**

The filter factory *filterFactory* failed to create a filter instance.

**Explanation**

See message.

**Administrator Response**

See the exception message that follows this message for additional information about the cause of the problem.

**CEIEM0005E**

A null event was passed to the `CommonBaseEvent` instance.

**Explanation**

The event parameter to the `Emitter.sendEvent(CommonBaseEvent event)` method must be a valid instance of `com.ibm.events.cbe.CommonBaseEvent`.

**Administrator Response**

Change the call to `Emitter.sendEvent(CommonBaseEvent)` to pass a valid `com.ibm.events.cbe.CommonBaseEvent` instance.

**CEIEM0006E**

The emitter failed to filter the event. Event: *event* Filter: *filter*

**Explanation**

See message.

**Administrator Response**

See the exception message that follows this message for additional information about the cause of the problem.

**CEIEM0007E**

The emitter failed to obtain the filter metadata from the filter factory.

**Explanation**

See message.

**Administrator Response**

See the exception message that follows this message for additional information about the cause of the problem.

**CEIEM0008E**

The filter failed to close. Resources held by the filter instance might not have been released. Filter: *filter*

**Explanation**

See message.

**Programmer Response**

See the exception message that follows this message for additional information about the cause of the problem.

**CEIEM0014E**

The emitter does not support the specified transaction mode *mode*.

**Explanation**

See message.

**Administrator Response**

Ensure that a valid transaction mode is configured.

**CEIEM0015E**

The emitter does not support the specified synchronization mode *mode*.

**Explanation**

See message.

**Administrator Response**

Ensure that the synchronization mode specified in the emitter factory profile is valid.

**CEIEM0020E:**

The emitter failed to initialize because the event bus could not be found. The event bus JNDI name is bound to null. JNDI name: *JNDI\_name* Namespace: *namespace*

**Explanation**

See message.

**Administrator Response**

Ensure that the JNDI name of the event bus as specified in the synchronous transmission profile is correct.

**CEIEM0021E**

The emitter failed to initialize because the event bus could not be found. The event bus JNDI name resolves to an instance of *class*. This name must resolve to an instance of *remoteEventBusClassName* or *localEventBusClassName*.

**Explanation**

See message.

**Administrator Response**

Ensure that the JNDI name of the event bus as specified in the synchronous transmission profile is correct.

**CEIEM0022E**

The emitter failed to initialize because the event bus could not be found. The event bus JNDI name defined in the event bus transmission profile does not exist. JNDI name: *JNDI\_name*

**Explanation**

See message.

**Administrator Response**

Ensure that the event bus JNDI name attribute of the event bus transmission profile is correct.

**CEIEM0023E**

The emitter failed to start because of a failure in the synchronous transmission sender. An exception occurred during initialization of the event bus sender. Exception: *exception*

**Explanation**

See message.

**Administrator Response**

See the exception message that follows this message for additional information about the cause of the problem.

**CEIEM0024E**

The emitter was unable to close due to a failure in the synchronous transmission sender. An exception occurred when attempting to close the emitter. A call to the *localOrRemote* event bus EJB `ejbRemove()` method failed. Exception: *exception*

**Explanation****Administrator Response**

See the exception message that follows this message to determine the exact cause of the failure.

**CEIEM0025E**

The *localOrRemote* event bus EJB on the event server failed during event processing, and the emitter failed to send the event to the event server. Event: *event* Transaction mode: *transaction\_mode*

**Explanation**

Either the server is unavailable or is not configured correctly, or an unexpected runtime error has occurred.

**Administrator Response**

See the exception message that follows this message for additional information about the cause of the problem.

**CEIEM0030E**

The lookup of a JNDI name failed. JNDI name: *JNDI\_name*

**Explanation**

See message.

**Administrator Response**

See the exception message that follows this message for additional information about the cause of the problem.

**CEIEM0031E**

The lookup of a JMS queue connection factory failed because the JNDI name defined in the emitter profile is not bound. JNDI name: *JNDI\_name*

**Explanation**

See message.

**Administrator Response**

Ensure that the configuration of the JMS queue connection factory asynchronous transmission profile for this event emitter is correct.

**CEIEM0032E**

The lookup of a JMS queue connection factory failed because the JNDI name does not resolve to an instance of `javax.jms.QueueConnectionFactory`. JNDI name: *JNDI\_name*

**Explanation**

See message.

**Administrator Response**

Ensure that the configuration of the JMS queue connection factory asynchronous transmission profile for this event emitter is correct.

**CEIEM0033E**

The lookup of a JMS queue connection factory failed because the JNDI name was bound to null instead of a valid `javax.jms.QueueConnectionFactory` instance. JNDI name: *JNDI\_name* failed.

**Explanation**

See message.

**Administrator Response**

Ensure that the configuration of the JMS queue connection factory asynchronous transmission profile for this event emitter is correct.

**CEIEM0034E**

The lookup of a JMS queue failed because the JNDI name defined in the emitter profile is not bound.  
JNDI name: *JNDI\_name*

**Explanation**

See message.

**Administrator Response**

Ensure that the configuration of the JMS queue and asynchronous transmission profile for this event emitter is correct.

**CEIEM0035E**

The lookup of a JMS queue failed because the JNDI name does not resolve to an instance of `javax.jms.Queue`. JNDI name: *JNDI\_name*

**Explanation**

See message.

**Administrator Response**

Ensure that the configuration of the JMS queue and asynchronous transmission profile for this event emitter is correct.

**CEIEM0036E**

The lookup of a JMS queue failed because the JNDI name was bound to null instead of a valid `javax.jms.Queue` instance. JNDI name: *JNDI\_name*

**Explanation**

See message.

**Administrator Response**

Ensure that the configuration of the JMS queue and asynchronous transmission profile for this event emitter is correct.

**CEIES0001E**

The event distribution received a null event when attempting to create the event notification.

**Explanation**

See message.

**Programmer Response**

Specify an event when creating the event notification.

**CEIES0002E**

The event distribution could not validate the event selector for the event group. Event selector: *event\_selector* Event group: *event\_group\_name* Exception message: *exception\_message*

**Explanation**

The event selector used by event distribution does not contain a valid XPath expression for filtering events.

**Administrator Response**

Ensure that the event group configuration for the event selector contains a valid XPath expression for filtering events.

**CEIES0003E**

The event distribution failed to initialize an event group because the specified destination could not be found in JNDI. Event group name: *event\_group\_name* Factory JNDI name: *destination\_factory\_jndi\_name* JNDI name: *destination\_jndi\_name* Exception message: *exception\_message*

**Explanation**

See message.

**Administrator Response**

Ensure that the event group definition contains a valid topic connection factory and topic or queue connection factory and queue as referenced in JNDI.

**CEIES0004E**

The event distribution failed to connect to the JMS destination with the specified JNDI name. Event group name: *event\_group\_name* Factory JNDI name: *destination\_factory\_jndi\_name* JNDI name: *destination\_jndi\_name* Exception message: *exception\_message*

**Explanation**

Events that are to be published to the event group will be rolled back until a connection can be made or until configuration of the event group is modified.

**Administrator Response**

Ensure that the event group definition contains a valid JMS destination.

## CEIES0005E

The event distribution failed to create a JMS message for an event notification being sent to the JMS destination with the specified JNDI name. Event group name: *event\_group\_name* Event: *event\_instance* Factory JNDI name: *destination\_factory\_jndi\_name* JNDI name: *destination\_jndi\_name* Exception message: *exception\_message*

### Explanation

See message.

### Administrator Response

Ensure that the event group definition contains a valid JMS destination.

## CEIES0006E

The event distribution failed to publish the event notification to the JMS destination with the specified JNDI name. Event group name: *event\_group\_name* Event: *event\_instance* JMS Message: *event\_instance* Factory JNDI name: *destination\_factory\_jndi\_name* JNDI name: *destination\_jndi\_name* Exception message: *exception\_message*

### Explanation

If this is the first destination configured for the event group, the event is rolled back to the sender. If this is not the first destination configured for the event group, event distribution attempts to publish the event to the other destinations for this event group.

### Administrator Response

Ensure that the event group definition contains a valid JMS destination.

## CEIES0007W

The event distribution failed to disconnect from the JMS destination with the specified JNDI name. Event group name: *event\_group\_name* Factory JNDI name: *destination\_factory\_jndi\_name* JNDI name: *destination\_jndi\_name* Exception message: *exception\_message*

### Explanation

No recovery is done because the JMS destination is closed.

## CEIES0008W

The event bus failed to store the event in the data store because the global instance ID in the event already exists in the data store. The event was not persisted in the configured data store, and it was not published to any message consumers. Event: *event\_instance* Exception message: *exception\_message*

### Explanation

The global instance ID uniquely identifies the event in the data store. It is assumed that the passed event is a duplicate of an event that already exists in the data store. Therefore, the event is not processed, and the current transaction is not marked for rollback.

### **Administrator Response**

If this is a recurring problem, inspect the source of the event to determine if the source is creating duplicate global instance IDs.

## **CEIES0009E**

The event bus failed to store the event in the data store because the data store could not be found using the specified JNDI name. The event was not persisted in the configured data store, and it was not published to any message consumers. Event: *event\_instance* JNDI name: *data\_store\_jndi\_name* Exception message: *exception\_message*

### **Explanation**

The event is not processed, and the current transaction is marked for rollback.

### **Programmer Response**

Ensure that the data store exists at the specified JNDI name. Also, see the exception message for additional information about the cause of the problem.

## **CEIES0010E**

The event bus failed to store the event in the data store referenced by the JNDI name. The event was not persisted in the configured data store, and it was not published to any message consumers. Event: *event\_instance* JNDI name: *data\_store\_jndi\_name* Exception message: *exception\_message*

### **Explanation**

The event is not processed, and the current transaction is marked for rollback.

### **Administrator Response**

See the exception message for additional information about the cause of the problem.

## **CEIES0011E**

The event bus failed to distribute the event. The event was not persisted in the configured data store, and it was not published to any message consumers. Event: *event\_instance* Exception message: *exception\_message*

### **Explanation**

The event is not processed, and the current transaction is marked for rollback.

### **Administrator Response**

See the exception message for additional information about the cause of the problem.

## **CEIES0012E**

The JMS type could not be found when processing a JMS message. JMS message: *message*

**Explanation**

See message.

**Administrator Response**

If this is a recurring problem, inspect the source of the event to determine if the source is creating JMS messages that are not valid.

**CEIES0013E**

The event could not be found when processing a JMS message. JMS message: *message*

**Explanation**

See message.

**Administrator Response**

If this is a recurring problem, inspect the source of the event to determine if the source is creating JMS messages that are not valid.

**CEIES0014W**

The event was not retrieved because the JMS message type is not valid. JMS message: *message*

**Explanation**

See message.

**Administrator Response**

If this is a recurring problem, inspect the source of the event to determine if the source is creating JMS messages that are not valid.

**CEIES0015E**

Creation of a JMS message for the event failed. Event: *event\_instance* Exception message: *exception\_message*

**Explanation**

See message.

**Administrator Response**

See the exception message for additional information about the cause of the problem.

**CEIES0016E**

The notification helper failed to set the event selector because the event selector is not in the correct format. Event selector: *event\_selector* Exception message: *exception\_message*

**Explanation**

See message.

**Administrator Response**

Ensure that the calling application is passing a valid event selector.

**CEIES0018E**

The event bus failed to process the event because the event server does not support the event version specified in the event. Event: *event\_instance* Event version: *event\_version* Event server version: *event\_server\_version*

**Explanation**

The event is not processed, and the current transaction is marked for rollback.

**Administrator Response**

If this is a recurring problem, inspect the source of the event to determine the cause of the problem.

**CEIES0019E**

The method *method* called by an event consumer on event access failed because the data store component is not enabled.

**Explanation**

See message.

**Administrator Response**

If the data store should be enabled, update the configuration of the Common Event Infrastructure application.

**CEIES0020E**

The method *method* called by an event consumer on event access failed. Exception message: *exception\_message*

**Explanation**

See message.

**Administrator Response**

See the exception message for additional information about the cause of the problem.

**CEIES0021E**

The home interface of the configured data store could not be found using the specified JNDI name. JNDI name: *jndi\_name* Exception message: *exception\_message*

**Explanation**

See message.

**Administrator Response**

Ensure that the correct JNDI name is configured for the data store. Also, ensure that the data store is deployed to the specified JNDI name.

**CEIES0023E**

The event server failed to create an instance of the configured data store because the data store version and the event server version are not compatible. Data store version: *datastore\_cbe\_version* Event server version: *eventserver\_cbe\_version*

**Explanation**

See message.

**Administrator Response**

The event server must use a data store that supports the same event version.

**CEIES0024E**

The event server failed to create an instance of the configured data store because the component metadata could not be retrieved from the data store. Exception message: *exception\_message*

**Explanation**

See message.

**Administrator Response**

See the exception message for additional information about the cause of the problem.

**CEIES0025E**

The event server failed to create an instance of the configured data store. Exception message: *exception\_message*

**Explanation**

See message.

**Administrator Response**

See the exception message for additional information about the cause of the problem.

**CEIES0026E**

The configuration of the event server is not valid because the data store is enabled, but the data store JNDI name is null. It is not valid to enable the data store and to have a null data store JNDI name. Event server JNDI name: *jndi\_name* Event server configuration object: *configuration\_object*

**Explanation**

See message.

**Administrator Response**

Update the configuration to either disable the data store or provide a valid data store JNDI name.

**CEIES0027E**

The configuration object for the event server at the specified JNDI name could not be found. JNDI name: *jndi\_name* Exception message: *exception\_message*

**Explanation**

See message.

**Administrator Response**

Verify that the Common Event Infrastructure server started. Also, ensure that the failing EJB has a correct EJB reference in the deployment descriptor to the event server configuration object.

**Programmer Response****CEIES0028E**

The configuration object for the event server could not be found when accessing configuration of event group list at the specified JNDI name. JNDI name: *jndi\_name* Exception message: *exception\_message*

**Explanation**

See message.

**Administrator Response**

Verify that the Common Event Infrastructure server started. Also, ensure that the failing EJB has a correct EJB reference in the deployment descriptor to the event server configuration object.

**Programmer Response****CEIES0029E**

The reference obtained from the specified JNDI name is not a reference to a notification helper factory. JNDI name: *jndi\_name* Exception message: *exception\_message*

**Explanation**

An application attempted to look up a notification helper factory from a JNDI namespace, but the object found in the specified location was not a reference to a notification helper factory.

**Administrator Response**

See the exception message for additional information about the cause of the problem.

## CEIES0030W

The event bus message driven bean failed to decode the JMS message because the message did not contain a valid message type. JMS message: *message* Message type: *message\_type*

### Explanation

The message is not processed, and the current transaction is marked for rollback causing the message to be returned to the JMS provider for handling.

### Administrator Response

If this is a recurring problem, check the source of the message to determine the cause of the problem.

## CEIES0031E

The event bus message driven bean failed to decode a JMS message. JMS message: *message* Exception message: *exception\_message*

### Explanation

The event is not processed, and the current transaction is marked for rollback.

### Administrator Response

See the exception message for additional information about the cause of the problem.

## CEIES0032E

The event bus message driven bean failed to submit an event to the event bus. Event: *event* Exception message: *exception\_message*

### Explanation

The event is not processed, and the current transaction is marked for rollback.

### Administrator Response

See the exception message for additional information about the cause of the problem.

## CEIES0033E

The event bus message driven bean failed to process a JMS message. JMS message: *message* Exception message: *exception\_message*

### Explanation

The message is not processed, and the current transaction is marked for rollback.

### Administrator Response

See the exception message for additional information about the cause of the problem.

## CEIES0034E

The event bus message driven bean failed because the home interface of the event bus could not be found using the specified JNDI name. JNDI name: *jndi\_name* Exception message: *exception\_message*

### Explanation

See message.

### Administrator Response

Ensure that the event bus message driven bean has a correct EJB reference in the deployment descriptor to the event bus.

## CEIES0035E

The event bus message driven bean failed to create an instance of the event bus. Exception message: *exception\_message*

### Explanation

See message.

### Administrator Response

See the exception message for additional information about the cause of the problem.

## CEIES0036E:

The event bus message driven bean failed to create an instance of the event bus. The event was not persisted, and it was not published to any message consumers. Event: *event\_instance* Exception message: *exception\_message*

### Explanation

The event is not processed, and the current transaction is marked for rollback.

### Administrator Response

See the exception message for additional information about the cause of the problem.

## CEIES0037E

The event selector parser failed to parse the event selector because it did not contain a valid XPath expression. Event selector: *event\_selector* Exception message: *exception\_message*

### Explanation

See message.

### Administrator Response

Ensure that the configuration setting for the event selector contains a valid XPath expression.

## CEIES0038E

The event selector does not represent a valid event selector for filtering events because it did not contain a valid XPath expression. Event selector: *event\_selector*

### Explanation

The event selector used by either event distribution or the notification helper must contain a valid XPath expression, it must select on `CommonBaseEvent`, and it must contain at least one predicate.

### Administrator Response

Ensure that the configuration setting for the event selector contains a valid XPath expression.

## CEIES0039E

The event selector subexpression is not valid because the `creationTime` property must be compared to a valid `xsd:datetime` value. Event selector: *event\_selector*

### Explanation

See message.

### Administrator Response

Ensure that the configuration setting for the event selector contains a valid XPath expression.

## CEIES0040E

The event selector subexpression is not valid because it contains an event selector expression that is not supported. Event selector: *event\_selector*

### Explanation

See message.

### Administrator Response

Ensure that the configuration setting for for the event selector contains a valid XPath expression.

## CEIES0041E

The event selector failed to parse using the XPath parser, and the notification helper failed to set the event selector. Event selector: *event\_selector* Exception message: *exception\_message*

### Explanation

See message.

### Administrator Response

Ensure that the configuration setting for the event selector contains a valid XPath expression.

## **CEIES0042E**

The notification helper failed because the event group configuration could not be found in JNDI. Event group: *event\_group* JNDI name: *jndi\_name* Exception message: *exception\_message*

### **Explanation**

See message.

### **Administrator Response**

Ensure that the event group is configured correctly.

## **CEIES0043E**

The notification helper failed because the event group configuration could not be found using the specified JNDI name. Event group: *event\_group* JNDI name: *jndi\_name* Exception message: *exception\_message*

### **Explanation**

See message.

### **Administrator Response**

Ensure that the event group is configured correctly.

## **CEIES0044E**

The home interface of the event distribution could not be found using the specified JNDI name. JNDI name: *jndi\_name* Exception message: *exception\_message*

### **Explanation**

See message.

### **Administrator Response**

Ensure that the event bus has a correct EJB reference in the deployment descriptor to the event distribution.

## **CEIES0045E**

The event server failed to create an instance of the event distribution. Exception message: *exception\_message*

### **Explanation**

See message.

### **Administrator Response**

See the exception message for additional information about the cause of the problem.

## **CEIES0046E:**

The event distribution failed because the configuration of the event group list could not be found using the specified JNDI name. JNDI name: *jndi\_name* Exception message: *exception\_message*

### **Explanation**

See message.

### **Administrator Response**

Ensure that the correct JNDI name is configured for the event group list.

## **CEIES0048E**

The event group is not defined in the event group list that the event server instance is using. Event group: *event\_group\_name*

### **Explanation**

See message.

### **Administrator Response**

Ensure that the event group is defined for this instance of the event server. Also, restart the application server that is running the instance of the event server to incorporate the latest configuration.

## **CEIES0049E**

The event group does not contain a valid event selector. Event group: *event\_group\_name* Event selector: *event\_selector*

### **Explanation**

See message.

### **Administrator Response**

Correct the specified event selector in the event group definition. Also, restart the application server that is running the instance of the event server to incorporate the latest configuration.

## **CEIES0050E**

The event selector is not valid. Event selector: *event\_selector*

### **Explanation**

See message.

### **Administrator Response**

Correct the event selector in the calling application.

## **CEIIN0001E**

The directory *directory\_name* failed to be created.

### **Explanation**

See message.

### **Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

## **CEIIN0002I**

The enterprise application was successfully deployed to the specified node. Application: *application\_name*  
Node: *node\_name* Server: *server\_name*

### **Explanation**

No additional information is available for this message.

## **CEIIN0003E**

The enterprise application failed to be deployed to the specified node. Application: *application\_name* Node:  
*node\_name* Server: *server\_name*

### **Explanation**

See message.

### **Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

## **CEIIN0004I**

The enterprise application was uninstalled successfully from the specified node. Application:  
*application\_name* Node: *node\_name*

### **Explanation**

No additional information is available for this message.

## **CEIIN0005E**

The enterprise application failed to be uninstalled from the specified node. Application: *application\_name*  
Node: *node\_name*

### **Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0006E**

The file *file\_name* was not found in the specified location.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0007E**

The Common Event Infrastructure database scripts for DB2 failed to be created.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0008E**

Creation of the DB2 database for the Common Event Infrastructure application failed.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0009E**

The DB2 data source for the Common Event Infrastructure database failed to be created.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

## **CEIIN0010E**

The Common Event Infrastructure database scripts for Oracle failed to be created.

### **Explanation**

See message.

### **Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

## **CEIIN0011E**

Creation of the Oracle database for the Common Event Infrastructure application failed.

### **Explanation**

See message.

### **Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

## **CEIIN0012E**

The Oracle data source for the Common Event Infrastructure database failed to be created.

### **Explanation**

See message.

### **Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

## **CEIIN0013E**

The Common Event Infrastructure database scripts for CloudScape failed to be created.

### **Explanation**

See message.

### **Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

## **CEIIN0014E**

Creation of the CloudScape database for the Common Event Infrastructure application failed.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0015E**

The CloudScape data source for the Common Event Infrastructure database failed to be created.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0016E**

The response file *file\_name* is not valid because it does not contain the required parameters, or it contains values that are not valid.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0017E**

A required parameter is missing from the response file. Required parameter: *parameter\_name*

**Explanation**

See message.

**Programmer Response**

Ensure that the response file contains the specified parameter.

**CEIIN0018I**

The Common Event Infrastructure configuration files were uninstalled successfully.

**Explanation**

No additional information is available for this message.

## **CEIIN0019W**

The directory *directory\_name* was not found in the specified location.

### **Explanation**

See message.

### **Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

## **CEIIN0020E**

The DB\_TYPE parameter is not specified in the response file *file\_name*.

### **Explanation**

See message.

### **Administrator Response**

Ensure that the DB\_TYPE parameter is specified in the response file.

## **CEIIN0021E**

The DB\_TYPE parameter does not contain a valid value. Valid values are: *validValues*

### **Explanation**

See message.

### **Administrator Response**

Ensure that the DB\_TYPE parameter that is specified in the response file contains a valid value.

## **CEIIN0022E**

The PAGE\_CACHE\_SIZE parameter in the response file contains a value that is not valid.

### **Explanation**

The PAGE\_CACHE\_SIZE parameter specifies the number of memory pages to use to cache data. Set the PAGE\_CACHE\_SIZE parameter to a number greater than 40.

### **Administrator Response**

Ensure that the PAGE\_CACHE\_SIZE parameter contains a numeric value.

## **CEIIN0023E**

The installation of the Common Event Infrastructure application completed, but errors occurred.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0024E**

The parameter *parameter\_name* in the response file contains a value *invalidValue*, which is not valid. Value values are: *validValues*.

**Explanation**

See message.

**Administrator Response**

Change the value of the specified parameter to a valid value.

**CEIIN0025E**

The CloudScape database already exists in the specified directory path. Database name: *dbName*  
Directory path: *path*

**Explanation**

See message.

**Administrator Response**

Remove the database before attempting to create a database with the same name.

**CEIIN0026I**

The enterprise application must be deployed to use the Common Event Infrastructure server. Application: *application\_name*

**Explanation**

See message.

**Administrator Response**

Deploy the specified application manually using the wsadmin tool.

**CEIIN0027E**

Creation of the Common Event Infrastructure database failed.

**Explanation**

See message.

### **Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

### **CEIIN0028E**

When running the Common Event Infrastructure installer from the command line, the correct command syntax was not provided.

#### **Explanation**

See message.

### **Programmer Response**

Provide the correct command syntax.

### **CEIIN0029E**

The response file *file\_name* does not exist.

#### **Explanation**

See message.

### **Administrator Response**

Ensure that you specify the correct response file name and location.

### **CEIIN0030E**

The Common Event Infrastructure server is not installed.

#### **Explanation**

No additional information is available for this message.

### **CEIIN0031E**

The directory *directory\_name* is not a valid WAS\_HOME directory.

#### **Explanation**

A WebSphere Application Server installation is not found in the specified directory.

### **Administrator Response**

Ensure that you have specified the correct location for the WebSphere Application Server installation.

### **CEIIN0032E**

The languages specified in the response file *file\_name* are not a valid or are not supported.

**Explanation**

See message.

**Programmer Response**

Ensure that you specify only supported languages in the response file.

**CEIIN0033E**

The WebSphere Application Server product version files *file\_name1* and *file\_name2* are not found.

**Explanation**

See message.

**Administrator Response**

Verify that the installation of the WebSphere Application Server product completed successfully.

**CEIIN0034E**

The Common Event Infrastructure server is already installed.

**Explanation**

No additional information is available for this message.

**CEIIN0035W**

The enterprise application has already been deployed to the specified node. Application: *application\_name*  
Node: *node\_name* Server: *server\_name*

**Explanation**

See message.

**CEIIN0036W**

The enterprise application has not been deployed to the specified node. Application: *application\_name*  
Node: *node\_name*

**Explanation**

No additional information is available for this message.

**CEIIN0037E**

The file *file\_name* could not be created.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0038E**

The file *file\_name1* could not be copied to file *file\_name2*.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0039E**

The file *file\_name* could not be placed in the directory *directory\_name*.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0040E**

The WebSphere Application Server configuration directory *directory\_name* was not found.

**Explanation**

See message.

**Administrator Response**

Verify that the installation of the WebSphere Application Server product completed successfully.

**CEIIN0041E**

The WebSphere Application Server configuration directory *directory\_name* does not contain any files.

**Explanation**

See message.

**Administrator Response**

Verify that the installation of the WebSphere Application Server product completed successfully.

## **CEIIN0042I**

The installation of the Common Event Infrastructure application completed successfully.

### **Explanation**

No additional information is available for this message.

## **CEIIN0043E**

The installation of the Common Event Infrastructure application failed.

### **Explanation**

See message.

### **Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

## **CEIIN0044E**

The enterprise application failed to uninstall because the uninstallation script was not found. Application: *application\_name* Script name: *script\_name*

### **Explanation**

See message.

### **Administrator Response**

Verify that the installation of the Common Event Infrastructure application completed successfully.

## **CEIIN0045I**

The installation of the Common Event Infrastructure configuration files completed successfully.

### **Explanation**

No additional information is available for this message.

## **CEIIN0046E**

Installation of the Common Event Infrastructure configuration files failed.

### **Explanation**

See message.

### **Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

## **CEIIN0047E**

Uninstallation of the Common Event Infrastructure configuration files failed.

### **Explanation**

See message.

### **Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

## **CEIIN0048E**

The WebSphere Application Server *server\_name* is stopped. Start the server to configure the Common Event Infrastructure JDBC provider and data source.

### **Explanation**

See message.

### **Administrator Response**

See message.

## **CEIIN0049I**

Version *version\_number* of the Common Event Infrastructure application is installed.

### **Explanation**

No additional information is available for this message.

## **CEIIN0050W**

Version *version\_number* of the Common Event Infrastructure application is installed, but this version is not valid.

### **Explanation**

See message.

### **Administrator Response**

Verify that the installation of the Common Event Infrastructure application completed successfully.

## **CEIIN0051I**

Installing version *version\_number* of the Common Event Infrastructure application.

### **Explanation**

No additional information is available for this message.

## **CEIIN0052I**

Uninstalling version *version\_number* of the Common Event Infrastructure application.

### **Explanation**

No additional information is available for this message.

## **CEIIN0053I**

The installation of the Common Event Infrastructure library files completed successfully.

### **Explanation**

No additional information is available for this message.

## **CEIIN0054E**

The installation of the Common Event Infrastructure library files failed.

### **Explanation**

See message.

### **Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

## **CEIIN0055I**

Uninstallation of the Common Event Infrastructure library files completed successfully.

### **Explanation**

No additional information is available for this message.

## **CEIIN0056E**

Uninstallation of the Common Event Infrastructure library files failed.

### **Explanation**

See message.

### **Administrator Response**

Consult the event infrastructure log files to determine the cause of the problem.

## **CEIIN0057I**

Installation of the Common Event Infrastructure tool files completed successfully.

**Explanation**

No additional information is available for this message.

**CEIIN0058I**

Installation of the Common Event Infrastructure tool files failed.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0059I**

Uninstallation of the Common Event Infrastructure tool files completed successfully.

**Explanation**

No additional information is available for this message.

**CEIIN0060E**

Uninstallation of the Common Event Infrastructure tool files failed.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0061W**

Setting execute permissions on some files in the directory *directory\_name* failed. Manually set the execute permissions for executable scripts before running the scripts.

**Explanation**

See message.

**Administrator Response**

See message.

**CEIIN0062I**

Uninstallation of the Common Event Infrastructure application completed successfully.

**Explanation**

No additional information is available for this message.

**CEIIN0063E**

Uninstallation of the Common Event Infrastructure application failed.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0064E**

The Common Event Infrastructure version file *file\_name* could not be deleted. Manually delete the specified file before reinstalling the Common Event Infrastructure application.

**Explanation**

See message.

**Administrator Response**

See message.

**CEIIN0065I**

Uninstallation of the common event infrastructure database completed successfully.

**Explanation**

No additional information is available for this message.

**CEIIN0066E**

Uninstallation of the Common Event Infrastructure database failed.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0067E**

The WebSphere Network Deployment Manager is not running. The WebSphere Network Deployment Manager must be running before configuring or uninstalling the Common Event Infrastructure application.

**Explanation**

See message.

**Administrator Response**

Start the WebSphere Network Deployment Manager.

**CEIIN0068E**

An error occurred when installing the Common Event Infrastructure application.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0069E**

An error occurred when uninstalling the Common Event Infrastructure application.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0070I**

Consult the log file *log\_file\_name* for more information.

**Explanation**

No additional information is available for this message.

**CEIIN0071I**

The installation of the Common Event Infrastructure administrative panel completed successfully.

**Explanation**

No additional information is available for this message.

**CEIIN0072E**

The installation of the Common Event Infrastructure administrative panel failed.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0073I**

The uninstallation of the Common Event Infrastructure administrative panel completed successfully.

**Explanation**

No additional information is available for this message.

**CEIIN0074E**

The uninstallation of the Common Event Infrastructure administrative panel failed.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0075I**

The Common Event Infrastructure administrative panel is not installed.

**Explanation**

No additional information is available for this message.

**CEIIN0076E**

The file *file\_name* could not be deleted.

**Explanation**

See message.

**Administrator Response**

Manually delete the specified file.

**CEIIN0077E**

The directory *directory* could not be deleted.

**Explanation**

See message.

**Administrator Response**

Manually delete the specified directory.

**CEIIN0078E**

Writing a file in EBCDIC format failed.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0079E**

Reading a file in EBCDIC format failed.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0083E**

The system could not determine if the WebSphere Application Server is operating in a standalone or a network environment.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0084E**

The enterprise application, *application\_name*, could not be uninstalled because WebSphere Application Server security is enabled.

**Explanation**

See message.

### **Administrator Response**

Manually uninstall the specified application.

### **CEIIN0085I**

The Common Event Infrastructure enterprise application could not be uninstalled. Manually uninstall the enterprise application *application\_name*, and then delete the directory *directory\_name*.

### **Explanation**

See message.

### **Administrator Response**

Consult the event infrastructure log files to determine the cause of the problem and manually uninstall the specified enterprise application.

### **CEIIN0086E**

The Common Event Infrastructure data source could not be uninstalled because WebSphere Application Server security is enabled.

### **Explanation**

See message.

### **Administrator Response**

Manually uninstall the Common Event Infrastructure data source.

### **CEIIN0087I**

The Common Event Infrastructure database or data source could not be uninstalled. Manually uninstall the Common Event Infrastructure database and data source. Then delete the directory *directory\_name*.

### **Explanation**

See message.

### **Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem. Manually uninstall the Common Event Infrastructure database and data source.

### **CEIIN0088E**

The LOG\_FILE\_SIZE parameter in the response file contains the value *value*, which is not valid.

### **Explanation**

The LOG\_FILE\_SIZE parameter defines the size of each primary and secondary log file in 4K pages. The log file size limits the number of log records that can be written to the log file before it becomes full and a new log file is required.

### **Administrator Response**

Enter a valid value in the response file for the LOG\_FILE\_SIZE parameter. Refer to the appropriate DB2 documentation for additional information.

## **CEIIN0089E**

The NUM\_PRIMARY\_LOG parameter in the response file contains the value *value*, which is not valid.

### **Explanation**

The primary log files establish a fixed amount of storage allocated to the recovery log files. Use the NUM\_PRIMARY\_LOG parameter to specify the number of primary log files to be preallocated.

### **Administrator Response**

Enter a valid value in the response file for the NUM\_PRIMARY\_LOG parameter. Refer to the appropriate DB2 documentation for additional information.

## **CEIIN0090E**

The NUM\_SECONDARY\_LOG parameter in the response file contains the value *value*, which is not valid.

### **Explanation**

The NUM\_SECONDARY\_LOG parameter specifies the number of secondary log files that are created and used for recovery log files, if needed.

### **Administrator Response**

Enter a valid value in the response file for the NUM\_SECONDARY\_LOG parameter in the response file. Refer to the appropriate DB2 documentation for more information.

## **CEIIN0091E**

An error occurred when running the PluginProcessor command.

### **Explanation**

See message.

### **Administrator Response**

Perform the following steps:

1. Manually delete the Common Event Infrastructure files that were not deleted.
2. Run the following command: **\$WAS\_HOME/bin/PluginProcessor -restore**

## **CEIIN0092I**

You must manually restore the Administrative console enterprise application.

### **Explanation**

See message.

## Administrator Response

Perform the following steps:

1. Delete the Common Event Infrastructure files that were not deleted.
2. Run the following command: **\$WAS\_HOME/bin/PluginProcessor -restore**

## CEIIN0093I

To restore the system, copy the file *source\_file\_name* manually to the file *destination\_file\_name*.

### Explanation

No additional information is available for this message.

## CEIIN0094I

To restore the system, manually collapse the enterprise application directory *directory\_name* to the temporary file *source\_file\_name* using the `$WAS_HOME/bin/EARExpander` command. Replace the file *destination\_file\_name* with the temporary file.

### Explanation

No additional information is available for this message.

## CEIIN0095E

The backup of the file *source\_file\_name* to the file *destination\_file\_name* failed.

### Explanation

See message.

## Administrator Response

Consult the Common Event Infrastructure log files to determine the cause of the problem.

## CEIIN0096E

The file *file\_name* cannot be restored from the backup copy of the file *backup\_file\_name*.

### Explanation

See message.

## Administrator Response

Consult the Common Event Infrastructure log files to determine the cause of the problem. Manually restore the file from the backup copy of the file.

## CEIIN0097E

Creation of a collapsed format of the Administrative console enterprise application in the directory *directory\_name* to the file *file\_name* failed.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem.

**CEIIN0098E**

The database configuration script file, *file\_name*, was not found.

**Explanation**

See message.

**Administrator Response**

Verify that the preceding steps in the installation of the Common Event Infrastructure application completed successfully.

**CEIIN0099I**

The installation of the Common Event Infrastructure database completed successfully.

**Explanation**

No additional information is available for this message.

**CEIIN0100E**

The installation of the Common Event Infrastructure database failed.

**Explanation**

See message.

**Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem. Manually create the Common Event Infrastructure database.

**CEIIN0101I**

Creation of the default Common Event Infrastructure database during installation is supported only in a WebSphere Application Server standalone environment.

**Explanation**

See message.

## **Administrator Response**

### **CEIIN0102I**

You must manually create the Common Event Infrastructure database using the database configuration scripts.

#### **Explanation**

No additional information is available for this message.

### **CEIIN0103I**

Deployment of the Common Event Infrastructure enterprise application during installation is supported only in a WebSphere Application Server standalone environment. Application: *application\_name*

#### **Explanation**

No additional information is available for this message.

### **CEIIN0104E**

Configuration of the default Common Event Infrastructure service failed.

#### **Explanation**

See message.

## **Administrator Response**

Consult the Common Event Infrastructure log files to determine the cause of the problem. Manually configure the Common Event Infrastructure service.

---

## Chapter 24. Using the transaction service

These topics provide information about using transactions with WebSphere applications

WebSphere applications can use transactions to coordinate multiple updates to resources as atomic units (as indivisible units of work) such that all or none of the updates are made permanent.

In WebSphere Application Server, transactions are handled by three main components:

- A transaction manager that supports the enlistment of recoverable XAResources and ensures that each such resource is driven to a consistent outcome either at the end of a transaction or after a failure and restart of the application server.
- A container in which the J2EE application runs. The container manages the enlistment of XAResources on behalf of the application when the application performs updates to transactional resource managers (for example, databases). Optionally, the container can control the demarcation of transactions for enterprise beans configured for container-managed transactions.
- An application programming interface (UserTransaction) that is available to bean-managed enterprise beans and servlets. This allows such application components to control the demarcation of their own transactions.

For more information about using transactions with WebSphere applications, see the following topics:

- Transaction support in WebSphere Application Server
- Using local transactions
- Developing a WebSphere application to use transactions
- Configuring transaction properties for an application server
- Managing active transactions
- Managing transaction logging for optimum server availability
- Interoperating transactionally between application servers
- Troubleshooting transactions
- Transaction service exceptions
- UserTransaction interface - methods available
- Coordinating access to 1-PC and 2-PC-capable resources within the same transaction
- Implementing WebSphere enterprise applications that use ActivitySessions

---

### Transaction support in WebSphere Application Server

A transaction is unit of activity within which multiple updates to resources can be made atomic (as an indivisible unit of work) such that all or none of the updates are made permanent. For example, multiple SQL statements to a relational database are committed atomically by the database during the processing of an SQL COMMIT statement. In this case, the transaction is contained entirely within the database manager and can be thought of as a resource manager local transaction (RMLT). In some contexts, a transaction is referred to as a logical unit of work (LUW).

The way that applications use transactions depends on the type of application component, as follows:

- A session bean can either use container-managed transactions (where the bean delegates management of transactions to the container) or bean-managed transactions (where the bean manages transactions itself).
- Entity beans use container-managed transactions.
- Web components (servlets) use bean-managed transactions.

WebSphere Application Server is a transaction manager that supports the coordination of resource managers through their XAResource interface and participates in distributed global transactions with other OTS 1.2 compliant transaction managers (for example J2EE 1.3 application servers). WebSphere applications can also be configured to interact with databases, JMS queues, and JCA connectors through their local transaction support when distributed transaction coordination is not required.

Resource managers that offer transaction support can be categorized into those that support two-phase coordination (by offering an XAResource interface) and those that support only one-phase coordination (for example through a LocalTransaction interface). The WebSphere Application Server transaction support provides coordination, within a transaction, for any number of two-phase capable resource managers. It also enables a single one-phase capable resource manager to be used within a transaction in the absence of any other resource managers, although a WebSphere transaction is not necessary in this case.

Under normal circumstances you cannot mix one-phase commit capable resources and two-phase commit capable resources in the same global transaction, because one-phase commit resources cannot support the prepare phase of two-phase commit. There are some special circumstances where it is possible to include mixed-capability resources in the same global transaction:

- In scenarios where there is only a single one-phase commit resource provider that participates in the transaction and where all the two-phase commit resource-providers that participate in the transaction are used in a read-only fashion. In this case, the two-phase commit resources all vote read-only during the prepare phase of two-phase commit. Because the one-phase commit resource provider is the only provider to actually perform any updates, the one-phase commit resource does not need to be prepared.
- In scenarios where there is only a single one-phase commit resource provider that participates in the transaction with one of more two-phase commit resource providers and where last participant support is available.

**5.1 +** Last participant support (of WBI Server Foundation) enables the use of a single one-phase commit capable resource with any number of two-phase commit capable resources in the same global transaction.

**5.1 +** The ActivitySession service (of WBI Server Foundation) provides an alternative unit-of-work (UOW) scope to that provided by global transaction contexts. It is a distributed context that can be used to coordinate multiple one-phase resource managers. The WebSphere EJB container and deployment tooling support ActivitySessions as an extension to the J2EE programming model. EJBs can be deployed with lifecycles that are influenced by ActivitySession context, as an alternative to transaction context. An application can then interact with a resource manager through its LocalTransaction interface for the period of a client-scoped ActivitySession rather than just the duration of an EJB method.

## Resource manager local transaction (RMLT)

A resource manager local transaction (RMLT) is a resource manager's view of a local transaction; that is, it represents a unit of recovery on a single connection that is managed by the resource manager.

Resource managers include:

- Enterprise Information Systems that are accessed through a resource adapter, as described in the J2EE Connector Architecture 1.0.
- Relational databases that are accessed through a JDBC datasource.
- JMS queue and topic destinations.

Resource managers offer specific interfaces to enable control of their RMLTs. J2EE connector resource adapters that include support for local transactions provide a LocalTransaction interface to enable applications to request that the resource adapter commit or rollback RMLTs. JDBC datasources provide a Connection interface for the same purpose.

The boundary at which all RMLTs must be complete is defined in WebSphere Application Server by a local transaction containment (LTC).

## Global transactions

If an application uses two or more resources, then an external transaction manager is needed to coordinate the updates to both resource managers in a global transaction.

Global transaction support is available to web and enterprise bean J2EE components. Enterprise bean components can be subdivided into beans that exploit container-managed transactions (CMT) or bean-managed transactions (BMT).

BMT enterprise beans and web components can use the Java Transaction API (JTA) UserTransaction interface to define the demarcation of a global transaction. The UserTransaction interface is obtained by a JNDI lookup of `java:comp/UserTransaction`. The UserTransaction is not available to the following components:

- CMT enterprise beans. Any attempt by such beans to obtain the interface results in an exception in accordance with the EJB specification.
- Client applications running outside the Web and EJB containers.

Ensure that programs that perform a JNDI lookup of the UserTransaction interface, use an InitialContext that resolves to a local implementation of the interface. Also ensure that such programs use a JNDI location appropriate for the EJB version.

Before the EJB 1.1 specification, the JNDI location of the UserTransaction interface was not specified. Each EJB container implementor defined it in an implementation-specific manner. Earlier versions of WebSphere Application Server, up to and including Version 3.5.x (without EJB 1.1), bind the UserTransaction interface to a JNDI location of `jta/usertransaction`. WebSphere Application Server Version 4, and later releases, bind the UserTransaction interface at the location defined by EJB 1.1, which is `java:comp/UserTransaction`. WebSphere Application Server, Version 5 no longer provides the `jta/usertransaction` binding within Web and EJB containers to applications at a J2EE level of 1.3 or later. For example, EJB 2.0 applications can use only the `java:comp/UserTransaction` location.

A web component or enterprise bean (CMT or BMT) can get the ExtendedJTATransaction interface through a lookup of `java:comp/websphere/ExtendedJTATransaction`. This interface provides access to the transaction identity and a mechanism to receive notification of transaction completion.

## Local transaction containment (LTC)

A local transaction containment (LTC) is used to define the application server behavior in an unspecified transaction context.

(Unspecified transaction context is defined in the Enterprise JavaBeans 2.0 Specification.)

A LTC is a bounded unit-of-work scope within which zero, one, or more resource manager local transactions (RMLTs) can be accessed. The LTC defines the boundary at which all RMLTs must be complete; any incomplete RMLTs are resolved, according to policy, by the container. An LTC is local to a bean instance; it is not shared across beans even if those beans are managed by the same container. LTCs are started by the container before dispatching a method on a J2EE component (such as an enterprise bean or servlet) whenever the dispatch occurs in the absence of a global transaction context. LTCs are completed by the container depending on the application-configured LTC boundary; for example at the end of the method dispatch. There is no programmatic interface to the LTC support; rather LTCs are managed exclusively by the container and configured by the application deployer through transaction attributes in the application deployment descriptor.

A local transaction containment cannot exist concurrently with a global transaction. If application component dispatch occurs in the absence of a global transaction, the container always establishes an LTC for J2EE components at J2EE 1.3 or later. The only exceptions to this are as follows:

- Where application component dispatch occurs without container interposition; for example, for a stateless session bean create or a servlet-initiated thread.
- J2EE 1.2 web components.
- J2EE 1.2 BMT enterprise beans.

A local transaction containment can be scoped to an `ActivitySession` context that lives longer than the enterprise bean method in which it is started, as described in `ActivitySessions` and transaction contexts.

## Local and global transaction considerations

Applications use resources, such as JDBC data sources or connection factories, that are configured through the Resources view of the WebSphere Application Server Administrative Console. How these resources participate in a global transaction depends on the underlying transaction support of the resource provider. For example, most JDBC providers can provide either XA or non-XA versions of a data source. A non-XA data source can support only resource manager local transactions (RMLTs), but an XA data source can support two-phase commit coordination, as well as local transactions.

If an application uses two or more resource providers that support only RMLTs, then atomicity cannot be assured because of the one-phase nature of these resources. To ensure atomic behavior, the application should use resources that support XA coordination and should access them within a global transaction.

If an application uses only one RMLT, the atomic behavior can be guaranteed by the resource manager, which can be accessed under a local transaction containment context.

An application can also access a single resource manager under a global transaction context, even if that resource manager does not support the XA coordination. An application can do this, because WebSphere Application Server performs an “only resource optimization” and interacts with the resource manager under a RMLT. Within a global transaction context, any attempt to use more than one resource provider that supports only RMLTs causes the global transaction to be rolled back.

At any moment, an instance of an enterprise bean can have work outstanding in either a global transaction context or a local transaction containment context, but never both. An instance of an enterprise bean can change from running under one type of context to the other (in either direction), if all outstanding work in the original context is complete. Any violation of this principle causes an exception to be thrown when the enterprise bean tries to start the new context.

## Extended JTA support

Extended JTA support provides application programming interfaces additional to the `UserTransaction` interface that is defined in the JTA as part of the J2EE specification. Specifically, the API extensions provide the following functionality:

- Access to global and local transaction identifiers associated with the thread.

The global id is based on the `tid` in `CosTransactions::PropagationContext`; and the local id identifies the transaction uniquely within the local JVM.

- A transaction synchronization callback that enables any J2EE component to register an interest in transaction completion.

This can be used by advanced applications to flush updates before transaction completion and clear up state after transaction completion. J2EE (and related) specifications position this function generally as the domain of the J2EE containers.

**5.1 +** The exception is for CMT session beans, for which the EJB specification defines the `SessionSynchronization` interface. WebSphere provides this WebSphere Application Server EnterpriseWBI Server Foundation functionality in recognition that more advanced applications can profit from the ability to receive such notifications.

An application uses a JNDI lookup of `java:comp/websphere/ExtendedJTATransaction` to get an `ExtendedJTATransaction` object, which it then uses as follows:

```
ExtendedJTATransaction exJTA = (ExtendedJTATransaction)ctx.lookup("
 java:comp/websphere/ExtendedJTATransaction");
SynchronizationCallback sync = new SynchronizationCallback();
exJTA.registerSynchronizationCallback(sync);
```

The `ExtendedJTATransaction` object supports the registration of one or more application-provided `SynchronizationCallbacks`. Each registered callback is called at the end of every transaction that runs on the application server (whether the transaction is started locally or imported).

The following information provides an overview of the interfaces provided by the Extended JTA support. For more detailed information, see the Javadoc provided with WBI Server Foundation.

### **SynchronizationCallback interface**

An object implementing this interface is enlisted once through the `ExtendedJTATransaction` interface, and receives notification of the completion of each subsequent transaction mediated by the transaction manager in the local JVM.

Although an object implementing this interface can run in a J2EE server, there is no specific J2EE component active when this object is called. So, the object has limited direct access to any J2EE resources. Specifically, it has no access to the `java:` namespace or to any container-mediated resource. Such an object can cache a reference to a J2EE component (for example, a stateless session bean) that it delegates to. The object would then have all the normal access to J2EE resources and could be used, for example, to acquire a JDBC connection and flush updates to a database during `beforeCompletion`.

### **ExtendedJTATransaction interface**

A WebSphere programming model extension to the J2EE JTA support. An object implementing this interface is bound, by WebSphere J2EE containers that support this interface, at `java:comp/websphere/ExtendedJTATransaction`. Access to this object, when called from an EJB container, is not restricted to bean-managed transactions.

---

## **Developing components to use transactions**

These topics provide information about developing WebSphere application components to use transactions

The way that applications use transactions depends on the type of application component, as follows:

- A session bean can either use container-managed transactions (where the bean delegates management of transactions to the container) or bean-managed transactions (where the bean manages transactions itself).
- Entity beans use container-managed transactions.
- Web components (servlets) use bean-managed transactions.

You configure whether a component uses container- or bean-managed transactions by setting an appropriate value on the `Transaction type` deployment attribute, as described in [Configuring transactional deployment attributes using the Assembly Toolkit](#). You can also configure other transactional deployment descriptor attributes.

If you want a session bean to manage its own transactions, you must write the code that explicitly demarcates the boundaries of a transaction as described in [Using bean-managed transactions](#).

Similarly, if you want a Web component to use transactions, you must write the code that explicitly demarcates the boundaries of a transaction as described in [Using bean-managed transactions](#).

## **Configuring transactional deployment attributes using the Assembly Toolkit**

Use this task to configure the transactional deployment descriptor attributes associated with an EJB or Web module, to enable a J2EE application to use transactions.

This topic describes the use of the Assembly Toolkit to configure the deployment attributes of an application. This task description assumes that you have an EAR file for an application component, that can be deployed in WebSphere Application Server. For more details about using the Assembly Toolkit, see *Assembling applications with the Assembly Toolkit*.

To set transactional attributes in the deployment descriptor for an application component (enterprise bean or servlet), complete the following steps:

1. Start the Assembly Toolkit.
2. Create or edit the application EAR file. For example, to change attributes of an existing application, use the import wizard to import the EAR file into the Assembly Toolkit. To start the import wizard:
  - a. Click **File-> Import-> EAR file**
  - b. Click **Next**, then select the EAR file.
  - c. Click **Finish**.
3. In the J2EE Hierarchy view, right-click the component instance, then click **Open With > Deployment Descriptor Editor**. For example:
  - For a session bean, expand **EJB Modules-> ejb\_module\_instance-> Session Beans** then select the bean instance.
  - For a servlet, expand **Web Modules-> web\_application-> web\_component** then select the servlet instance.

A property dialog notebook for the component is displayed in the property pane.

4. Set the **Transaction type** attribute, which defines the transactional manner in which the container invokes a method. You can set this attribute to Container or Bean, as follows:
  - For a session bean to use container-managed transactions, set Container
  - For a session bean to use bean-managed transactions, set Bean
  - For an entity bean, set Container
  - For a Web component (servlet), set Bean
5. In the property pane, select the IBM Extensions tab.
6. Under **WebSphere Extensions**, configure J2EE component extensions attributes for extended local transaction containment. To enable management of local transaction containments, configure the following EJB extensions attributes. These attributes configure, for the component, the behavior of the container's local transaction containment (LTC) environment that the container establishes whenever a global transaction is not present.

#### **Boundary**

Specifies the duration of a local transaction context. You can set this attribute to **Bean method** or **ActivitySession**.

**Note:** The ActivitySession option is not supported in the web container.

#### **Resolver**

Specifies how the local transaction is to be resolved before the local transaction context ends: by the application through user code or by the EJB container. You can set this attribute to either **Application** or **ContainerAtBoundary**.

#### **Unresolved action**

Specifies the action that the container must take when the local transaction context scope ends, if resources are uncommitted by an application in a local transaction and the **Resolution control** is set to Application. You can set this attribute to either **Commit** or **Rollback**.

For a value of **Commit**, the container will take the commit action only in the absence of an un-handled exception. If the application method executing under the local transaction context ends with an exception, then the local transaction context is rolled back by the container. (This is the same behavior as for global transactions.)

7. [For EJB components only] For container-managed transactions, configure how the container must manage the transaction boundaries when delegating a method invocation to an enterprise bean's business method:
  - a. In the navigation pane, click the Assembly Descriptor tab. The **Container Transactions** box displays a table of the methods for enterprise beans.
  - b. For each method of the enterprise bean set the **Transaction attribute** attribute to an appropriate value.

If the application uses ActivitySessions, how the container manages transaction boundaries when delegating a method invocation depends on both the **Transaction attribute** attribute, set here, and the **ActivitySession kind** attribute, as described in Configuring ActivitySession deployment attributes for an enterprise JavaBean. For more detail about the relationship between these two properties, see Combining transaction and ActivitySession container policies.
8. Save your changes to the deployment descriptor.
  - a. Close the deployment descriptor editor.
  - b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.
9. Verify the archive files.
10. Generate code for deployment for EJB modules or for enterprise applications that use EJB modules.
11. Optional: Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard. Note that **Run on Server** works on the Windows, Linux/Intel, and AIX operating systems only; you cannot deploy remotely from the Assembly Toolkit to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

### Important

**Important:** Use **Run On Server** for unit testing only. Assembly Server Toolkit controls the WebSphere Application Server installation and, when an application is published remotely, the Toolkit overwrites the server configuration file for that server. Do not use on production servers.

For instructions on remote testing, see the article "Setting Up a Remote WebSphere Application Server in WebSphere Studio V5" at

[http://www7b.boulder.ibm.com/wsdd/techjournal/0303\\_yuen/yuen.html](http://www7b.boulder.ibm.com/wsdd/techjournal/0303_yuen/yuen.html).

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that is to run the application; for example, using the administrative console as described in Deploying and managing applications.

## Using bean-managed transactions

This topic describes how to enable a session bean or servlet to use bean-managed transactions, to manage its own transactions directly instead of letting the container manage the transactions.

**Note:** Entity beans cannot manage transactions (so cannot use bean-managed transactions).

To enable a session bean or servlet to use bean-managed transactions, complete the following steps:

1. Set the **Transaction type** attribute in the component's deployment descriptor to Bean, as described in Setting transactional attributes in the deployment descriptor.
2. Write the component code to actively manage transactions. When writing the code required by a component to manage its own transactions, remember the following basic rules:
  - An instance of a stateless session bean cannot reuse the same transaction context across multiple methods called by an EJB client.
  - An instance of a stateful session bean can reuse the same transaction context across multiple methods called by an EJB client.

The following code extract shows the standard code required to obtain an object encapsulating the transaction context. There are three basic steps involved:

- The component class must set the value of the `javax.ejb.SessionContext` object reference in the `setSessionContext` method.
- A `javax.transaction.UserTransaction` object is created by calling a lookup on `"java:comp/UserTransaction"`.
- The `UserTransaction` object is used to participate in the transaction by calling transaction methods such as `begin` and `commit` as needed. If an enterprise bean begins a transaction, it must also complete that transaction either by invoking the `commit` method or the `rollback` method.

#### Code example: Getting an object that encapsulates a transaction context

```
...
import javax.transaction.*;
...
public class MyStatelessSessionBean implements SessionBean {
private SessionContext mySessionCtx =null;
...
public void setSessionContext (SessionContext ctx)throws EJBException {
mySessionCtx =ctx;
}
...
public float doSomething(long arg1)throws FinderException,EJBException {
 UserTransaction userTran = (UserTransaction)initCtx.lookup(
 "java:comp/UserTransaction");
 ...
 //User userTran object to call transaction methods
 userTran.begin ();
 //Do transactional work
 ...
 userTran.commit ();
 ...
}
...
}
```

---

## Configuring transaction properties for an application server

Use this task to configure the transaction properties for an application server; for example, to define the location of the directory that contains the transaction log or to change default timeouts associated with transactions.

To configure the transaction properties for an application server, complete the following steps:

1. Start the Administrative console
2. In the navigation pane, select **Servers-> Manage Application Servers-> *your\_app\_server*** This displays the properties of the application server, *your\_app\_server*, in the content pane.
3. Select the Transaction Service tab, to display the properties page for the transaction service, as two notebook pages:

#### Configuration

The values of properties defined in the configuration file. If you change these properties, the new values are applied when the application server next starts.

#### Runtime

The runtime values of properties. If you change these properties, the new values are applied immediately, but are overwritten with the Configuration values when the application server next starts.

4. Select the Configuration tab, to display the transaction-related configuration properties.
5. If you want to change the directory in which transaction logs are written, type the full pathname of the directory in the **Transaction log directory** field. You can check the current runtime value of **Transaction log directory**, by clicking the Runtime tab.

You can also specify a size for the transaction logs, as described in the following step.

**Note:** If you change the transaction log directory, you should apply the change and restart the application server as soon as possible, to minimize the risk of problems caused that might occur before the application server is restarted. For example, if a problem causes the server to fail (with in-flight transactions), the server next starts with the new log directory and is unable to automatically resolve in-flight transactions that were recorded in the old log directory.

6. If you want to change the default file size of transaction log files, modify the **Transaction log directory** field to include a file size setting, in the following format:

*directory\_name;file\_size*

Where

- *directory\_name* is the name of the transaction log directory
- *file\_size* is the new default size specified in bytes. The *nK* or *nM* suffix can be used to indicate kilobytes or megabytes. If you do not specify a file size value, the default value of 1M is used.

For example, `c:\tranlogs;2M` indicates the files are to be created with 2M bytes size and stored in the directory `c:\tranlogs`.

In a non-production environment, you can use the transaction log directory value of `;0` to disable transaction logging. (There must be no directory name element before the size element of 0.) You should not disable transaction logging in a production environment, because this prevents recovery after a system failure and, therefore, data integrity cannot be guaranteed.

7. In the **Total transaction lifetime timeout** field, type the number of seconds a transaction can remain inactive before it is ended by the transaction service. A value of 0 (zero) indicates that there is no timeout limit.
8. In the **Client inactivity timeout** field, type the number of seconds after which a client is considered inactive and the transaction service ends any transactions associated with that client. A value of 0 (zero) indicates that there is no timeout limit.
9. Click **OK**.
10. Stop then restart the application server.

If you change the transaction log directory configuration property to an incorrect directory name, the application server will restart but be unable to open the transaction logs. You should change the configuration property to a valid directory name, then restart the application server.

## Transaction service settings

Use this page to modify transaction service settings.

To view this administrative console page, click **Servers > Application Servers > server > Transaction Service**.

### Transaction log directory

Specifies the name of a directory for this server where the transaction service stores log files for recovery.

A blank value in the server configuration is expanded by the transaction log at startup as the directory `(install_root)/tranlog/(server_name)`.

When the application running on the WebSphere product accesses more than one resource, the WebSphere product stores transaction information to properly coordinate and manage the distributed transaction. In a higher transaction load, this persistence slows down performance of the application server due to its dependency on the operating system and the underlying storage systems.

To achieve better performance, move the transaction log files to a storage device with more physical disk drives, or preferably RAID disk drives. When the log files are moved to the file systems on the RAIDed disks, the task of writing data to the physical media is shared across the multiple disk drives. This allows more concurrent access to persist transaction information and faster access to that data from the logs. Depending upon the design of the application and storage subsystem, performance gains can range from 10% to 100%, or even more in some cases.

This change is applicable only to the configuration where the application uses distributed resources or XA transactions, for example, multiple databases and resources are accessed within a single transaction. Consider setting this property when the application server shows one or more of following signs:

- CPU utilization remains low despite an increase in transactions
- Transactions fail with several time outs
- Transaction rollbacks occur with *unable to enlist transaction* exception
- Application server hangs in middle of a run and requires the server to be restarted
- The disk on which an application server is running shows higher utilization

<b>Data type</b>	String
<b>Default</b>	Initial value is the <code>%WAS_HOME%/tranlog/(server_name)</code> directory and a default size of 1MB.
<b>Recommended</b>	Create a file system with at least 3-4 disk drives RAIDed together in a RAID-0 configuration. Then, create the transaction log on this file system with the default size. When the server is running under load, check the disk input and output. If disk input and output time is more than 5%, consider adding more physical disks to lower the value. If disk input and output is low, but the server is still high, consider increasing the size of the log files.

### Total transaction lifetime timeout

Specifies the maximum duration, in seconds, for transactions on this application server.

Any transaction that is not requested to complete before this time-out is rolled back. If set to 0, there is no time-out limit.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	120
<b>Range</b>	0 to 2 147 483 647

### Client inactivity timeout

Specifies the maximum duration, in seconds, between transactional requests from a remote client.

Any period of client inactivity that exceeds this timeout results in the transaction rolling back in this application server. If set to 0, there is no timeout limit.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	60
<b>Range</b>	0 to 2 147 483 647

### Enable logging for heuristic reporting

Select this property to enable the application server to log "about to commit one-phase resource" events from transactions that involve a one-phase commit resource and two-phase commit resources.

This property enables logging for heuristic reporting. If applications are configured to allow one-phase commit resources to participate in two-phase commit transactions, reporting of heuristic outcomes that occur at application server failure requires extra information to be written to the transaction log. If enabled, one additional log write is performed for any transaction that involves both one- and two-phase commit resources. No additional records are written for transactions that do not involve a one-phase commit resource.

<b>Data type</b>	String
------------------	--------

**Default  
Range**

Cleared

**Cleared**

The application server does not log "about to commit one-phase resource" events from transactions that involve a one-phase commit resource and two-phase commit resources.

**Selected**

The application server does log "about to commit one-phase resource" events from transactions that involve a one-phase commit resource and two-phase commit resources.

## Maximum Transaction Timeout

Specifies the maximum duration, in seconds, that transactions started by or propagated into this application server are allowed to execute.

**Data type**

Integer

**Units**

Seconds

**Default**

300

**Range**

0 to 2 147 040

---

## Using local transactions

Local transaction containment (LTC) support, and its configuration through local transaction extended deployment descriptors, gives IBM WebSphere Application Server application programmers a number of advantages. This topic describes those advantages and how they relate to the settings of the local transaction extended deployment descriptors. This topic also describes points to consider to help you best configure transaction support for some example scenarios that use local transactions.

### **Develop an enterprise bean or servlet that accesses one or more databases that are independent and require no coordination.**

If an enterprise bean does not need to use global transactions, it is often more efficient to deploy the bean with the Container Transaction deployment descriptor **Transaction** attribute set to Not supported instead of Required.

With the extended local transaction support of IBM WebSphere Application Server, applications can perform the same business logic in an unspecified transaction context as they can under a global transaction. An enterprise bean, for example, runs under an unspecified transaction context if it is deployed with a **Transaction** attribute of Not supported or Never.

The extended local transaction support provides a container-managed, implicit local transaction boundary within which application updates can be committed and their connections cleaned up by the container. Applications can then be designed with a greater degree of independence from deployment concerns. This makes using a **Transaction** attribute of Supports much simpler, for example, when the business logic may be called either with or without a global transaction context.

An application can follow a get-use-close pattern of connection usage regardless of whether or not the application runs under a transaction. The application can depend on the close behaving in the same way and not causing a rollback to occur on the connection if there is no global transaction.

There are many scenarios where ACID coordination of multiple resource managers is not needed. In such scenarios running business logic under a **Transaction** policy of Not supported performs better than if it had been run under a Required policy. This benefit is exploited through the **Local Transactions - Resolution-control** extended deployment setting of ContainerAtBoundary. With this setting, application interactions with resource providers (such as databases) are managed within implicit RMLTs that are both started and ended by the container. The RMLTs are committed

by the container at the configured **Local Transactions - Boundary**; for example at the end of a method. If the application returns control to the container by an exception, the container rolls back any RMLTs that it has started.

This usage applies to both servlets and enterprise beans.

#### **Use local transactions in a managed environment that guarantees clean-up.**

Applications that want to control RMLTs, by starting and ending them explicitly, can use the default **Local Transactions - Resolution-control** extended deployment setting of `Application`. In this case, the container ensures connection cleanup at the boundary of the local transaction context.

J2EE specifications that describe application use of local transactions do so in the manner provided by the default setting of **Local Transactions - Resolution-control**=`Application` and **Local Transactions - Unresolved-action**=`Rollback`. By configuring the **Local Transactions - Unresolved-action** extended deployment setting to `Commit`, then any RMLTs started by the application but not completed when the local transaction containment ends (for example, when the method ends) are committed by the container. This usage applies to both servlets and enterprise beans.

#### **Extend the duration of a local transaction beyond the duration of an EJB component method.**

The J2EE specifications restrict the use of RMLTs to single EJB methods. This restriction is because the specifications have no scoping device, beyond a container-imposed method boundary, to which an RMLT can be extended. In WBI Server Foundation, you can exploit the **Local Transactions - Boundary** extended deployment setting to give the following advantages:

- Significantly extend the use-cases of RMLTs
- Make conversational interactions with one-phase resource managers possible through `ActivitySession` support.

**5.1 +** An `ActivitySession` is a WBI Server Foundation programming model extension that provides a distributed context with a boundary that is longer than a single method. You can extend the use of RMLTs over the longer `ActivitySession` boundary, which can be controlled by a client. The `ActivitySession` boundary reduces the need to use distributed transactions where ACID operations on multiple resources are not needed. This benefit is exploited through the **Local Transactions - Boundary** extended deployment setting of `ActivitySession`. Such extended RMLTs can remain under the control of the application or be managed by the container depending on the use of the **Local Transactions - Resolution-control** deployment descriptor setting.

#### **Coordinate multiple one-phase resource managers.**

For resource managers that do not support XA transaction coordination, a client can exploit `ActivitySession`-bounded local transaction contexts. Such contexts give a client the same ability to control the completion direction of the resource updates by the resource managers as the client has for transactional resource managers. A client can start an `ActivitySession` and call its entity beans under that context. Those beans can perform their RMLTs within the scope of that `ActivitySession` and return without completing the RMLTs. The client can later complete the `ActivitySession` in a commit or rollback direction and cause the container to drive the `ActivitySession`-bounded RMLTs in that coordinated direction.

To determine how best to configure the transaction support for an application, depending on what you want to do with transactions, consider the following points.

#### **General points**

- You want to start and end global transactions explicitly in the application (BMT session beans and servlets only).

For a session bean, set the **Transaction type** to `Bean` (to use bean-managed transactions) in the component's deployment descriptor. (You do not need to do this for servlets.)

- You want to access only one XA or non-XA resource in a method.

In the component's deployment descriptor, set **Local Transactions - Resolution-control** to `ContainerAtBoundary`. In the Container transaction deployment descriptor, set **Transaction** to `Supports`.

- You want to access several XA resources atomically across one or more bean methods.

In the Container transaction deployment descriptor, set **Transaction** to Required, Requires new, or Mandatory.

- You want to access several non-XA resource in a method without having to worry about managing your own local transactions.

In the component's deployment descriptor, set **Local Transactions - Resolution-control** to ContainerAtBoundary. In the Container transaction deployment descriptor, set **Transaction** to Not supported.

- You want to access several non-XA resources in a method and want to manage them independently.

In the component's deployment descriptor, set **Local Transactions - Resolution-control** to Application and set **Local Transactions - Unresolved-action** to **Rollback**. In the Container transaction deployment descriptor, set **Transaction** to Not supported.

#### **Points specific to WBI Server Foundation**

- You want to access one of more non-XA resources across multiple EJB method calls without having to worry about managing your own local transactions.

In the component's deployment descriptor, set **Local Transactions - Resolution-control** to ContainerAtBoundary, **Local Transactions - Boundary** to ActivitySession, and **Bean Cache - Activate at** to ActivitySession. In the Container transaction deployment descriptor, set **Transaction** to Not supported and set **ActivitySession** attribute to Required, Requires new, or Mandatory.

- You want to access several non-XA resources across multiple EJB method calls and want to manage them independently.

In the component's deployment descriptor, set **Local Transactions - Resolution-control** to Application, **Local Transactions - Boundary** to ActivitySession, and **Bean Cache - Activate at** to ActivitySession. In the Container Transaction deployment descriptor, set **Transaction** to Not supported and set **ActivitySession** attribute to Required, Requires new, or Mandatory.

- You want to use a single non-XA resource and one or more XAResources.

Use the Last Participant Support of WBI Server Foundation.

---

## **Managing active transactions**

Use this task to manage transactions that are active on an application server.

You can use this task to display a snapshot of all the transactions currently running on an application server. For each transaction, the following properties are shown: its local ID, global ID, and current status. The transaction status is shown as an integer value. The values correspond to the following status:

- 0 - active
- 1 - marked for rollback
- 2 - prepared
- 3 - committed
- 4 - rolled back
- 5 - unknown
- 6 - none
- 7 - preparing
- 8 - committing
- 9 - rolling back

You can also choose to finish transactions manually.

Under normal circumstances, transactions should run and complete (commit or rollback) automatically, without the need for intervention. However, in some circumstances, you may need to finish a transaction manually. For example, you may want to finish a transaction that has become stuck polling a resource manager that you know will not become available again within the desired timeframe.

**Note:** If you choose to finish a transaction on an application server, it is recorded as having completed in the transaction service logs for that server, so will not be eligible for recovery during server start up. If you finish a transaction, you are responsible for cleaning up any in-doubt transactions on the resource managers affected.

To manage the active transactions for an application server, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers-> Manage Application Servers** This displays a list of application servers in the content pane.
2. In the content pane, click *your\_app\_server* This displays the properties of the application server, *your\_app\_server*.
3. In the content pane, click the **Runtime** tab. This displays the runtime properties of the application server.
4. In the Additional Properties table, select **Transaction Service** This displays the runtime properties of the Transaction Service.
5. Click **Manage Transactions**. This displays a snapshot of all the transactions currently running on the server. For each transaction, the following properties are shown: its local ID, current status, and global ID.
6. If you want to finish one or more transactions, select the checkbox provided on the entry for the transaction, then click **Finish**. Alternatively, to finish all transactions, select the checkbox in the header of the transactions table, then click **Finish**.

---

## Managing transaction logging for optimum server availability

This topic describes some considerations and actions that you can use to manage transaction logging to help ensure that the availability of your application servers is optimized.

The transaction service writes information to the transaction log for every global transaction which involves two or more resources or is distributed across multiple servers. The transaction log is stored on disk and is used by the transaction service for recovery after a system or server crash. The transaction log for each application server consists of multiple subdirectories and files held in a single directory. You can change the directory that an application server uses to store the transaction log, as described in Configuring transaction properties for an application server.

When a global transaction is completed, the information in the transaction log is not needed anymore so is marked for deletion. Periodically, this redundant information is garbage collected and the space reused by new transactions. The log files are created of fixed size at server startup, thus no further disk space allocation is required during the lifetime of the server. The default allocation is suitable for around 4000 concurrent transactions.

If all the log space is in use when a transaction needs to save information, the transaction is rolled back and the message WTRN0083W: The transaction log is full. Transaction rolled back. is reported to the system error log. No more transactions can commit until more log space is made available when existing active transactions complete.

You can monitor the number of concurrent global transactions by using the performance monitoring counters for transactions. The “Global transaction commit time” counter is a measure of how long a transaction takes to complete and, therefore, how long the log is in use by a transaction. If this value is high, then transactions are taking a long time to complete, which can be due to resource manager or network failures. If you ensure this value is low, the log is more efficiently used and unlikely to become full.

You can change the default size of log files by updating the transaction log settings as described in Configuring transaction properties for an application server.

## Configuring transaction aspects of servers for optimum availability

This topic describes some considerations and actions that you can take to configure transaction-related aspects of application servers for optimum availability.

To configure transaction-related aspects of application servers for optimum availability, complete the following steps:

1. Store the transaction log files on a fast disk in a highly-available file system, such as a RAID device. The transaction log may need to be accessed by every global transaction and be used for transaction recovery after a crash. Therefore, the disk the log files are being written to should be on a highly-available file system, such as a RAID device.

The performance of the disk also directly affects the transaction performance. In general, a global transaction makes two disk writes, one after the prepare phase when the outcome of the transaction is known (this information is forced to disk) and a further disk write at transaction completion. Therefore, the transaction logs should be placed on the fastest disks available and not make use of network mounted devices.

2. Mirror the transaction log files by using hardware disk mirroring or dual-ported disks. If log files have been mirrored or can be recovered, they can be used when restarting a failed server or moved to another machine and another server started there to perform recovery.

Hardware disk mirroring or dual-ported disks can be used by specifying the appropriate file system directory for the transaction logs using the WebSphere Administrative Console.

3. Specify the optimum location of the transaction log directory for application servers. By default, an application server places transaction log files in a subdirectory of the installed WebSphere Application Server, where the subdirectory name is the same as the server name. For example, the default directory for an application server named `server1` on Windows is `c:\WebSphere\AppServer\tranlog\server1`.

**Note:** The `TRANLOG_ROOT` variable was used in previous versions of WebSphere Application Server to override the default location of the transaction log, but is now deprecated. In a future version of WebSphere Application Server, transaction and compensation logs will move to a different default location and the variable `TRANLOG_ROOT` will be removed.

You can define a specific location for the transaction log directory for an application server by setting the **Transaction Log Directory** property for the server.

4. Never allow more than one application server to concurrently use the same set of log files. Because the transaction logs record the state of global transactions within a server, if the logs become lost or corrupt, then transactions that are in the prepared state before failure can leave resources in an in-doubt state and prevent further updates or access to the resources by other users or servers. These transactions may need to be manually resolved by either committing or rolling back the transactions at the affected resource managers. The failed server can then be cold-started, which creates new empty transaction logs.

If log files have been mirrored or can be recovered, they can be used when restarting the failed server or moved to an alternate server or machine and another server restarted to perform recovery, as described in the related tasks.

Never allow more than one application server to concurrently use the same set of log files, because each server will destroy the information recorded by the other, resulting in corrupt log files that are unusable for future recovery purposes.

5. Configure application servers to always use the same listening port address at each startup. If you are running distributed transactions between multiple application servers, the remote object references saved in the transaction log need to be redirected to the originating server on recovery.

On Application Server Network Deployment, the node agents automatically redirect such remote object references to the appropriate application servers on recovery. However, if the distributed transaction is between application servers that are not on Application Server Network Deployment, then you must handle the redirection of remote object references for transaction recovery to complete. For example,

you must do this is if an application server is deployed on WebSphere Application Server (not the Network Deployment edition) and runs distributed transactions with non-WebSphere EJB or Corba servers.

In particular, the default restart action of an application server not on Application Server Network Deployment is to use a different listening port address to the port when the server shut down. This prevents transaction recovery completing. To overcome this, you should always configure application servers to always use the same listening port address at each startup. See the ORB property `com.ibm.CORBA.ListenerPort` in ORB service settings that can be added to the administrative console. (See "Object Request Broker service settings" in the online help or Information Center.) You may need to make similar configuration changes to other application servers involved in transactions, to be able to access those servers during recovery.

## Moving a transaction log from one server to another

This topic describes some considerations and actions that you can take to move the transaction logs for an application server to another server.

To move transaction logs from one application server to another, consider the following steps:

1. Move all the transaction log files for the application server.

**5.1 +** The transaction log directory for each server contains a number of files and subdirectories. When moving transaction logs from one server to another you must move all of the files and subdirectories together as a single unit; otherwise recovery may not complete resulting in data inconsistency.

2. For a server configuration where there are no distributed transactions, move the transaction logs to any server that has access to the same resource managers. For a single server or network-deployed server configuration where it is known there are no distributed transactions present in the logs, the transaction logs can be moved to any server (on any node) that has access to the same resource managers as the original server. For example, the server needs communication and valid security access to databases or message queues.

All the transaction log files for the original server need to be moved to a directory accessible by the new server. This can be accomplished by either renaming the transaction log directory or copying all the contents to the new server's transaction log directory before starting the new server.

**Note:** To complete transaction recovery, the application server uses the resource manager configuration information in the transaction logs. However, for the application server to continue to do new work with the same resource managers, the server must have an appropriate resource manager configuration (as for the original server).

3. For a network-deployed server configuration where there are distributed transactions, move the transaction logs to a server that has the same name and host IP address, and access to the same resource managers. For a network-deployed server configuration, when it is known there are distributed transactions present in the logs, there are more restrictions. Distributed transactions that access multiple servers log information about each server involved in the transaction. This information includes the server name and the IP address of the machine on which the server is running. When recovery is taking place on server restart, the server uses this information to contact the distributed servers and similarly, the distributed servers try to contact the server with the same original name. So, if a server fails and the logs need to be recovered on an alternative server, that alternative server needs to have the same name and host IP address as the original server. The alternative server also needs to have access to the same resource managers as the original server. For example, the server needs communication and valid security access to databases or message queues.

**Note:** All servers within a cell must have unique names.

**Note:** To complete transaction recovery, the application server uses the resource manager configuration information in the transaction logs. However, for the application server to continue

to do new work with the same resource managers, the server must have an appropriate resource manager configuration (as for the original server).

## Restarting an application server on a different host

This topic describes some considerations and actions that you can take with transaction logs to restart an application server on a different host.

Moving transactions logs to a different host is similar to moving logs from one server to another, as described in *Moving transaction logs from one server to another*.

This involves moving an original application server on one host to an alternative server, which has access to the same resource managers, on another host. For a network-deployed server configuration, the alternative server must have the same name and host IP address as the original server.

**Note:** To complete transaction recovery, the application server uses the resource manager configuration information in the transaction logs. However, for the application server to continue to do new work with the same resource managers, the server must have an appropriate resource manager configuration (as for the original server).

To restart an application server on a different host, complete the following steps:

1. Ensure that the alternative application server is stopped.
2. Move all the transaction logs for the original server to the alternative application server, according to the considerations described in *Moving transaction logs from one server to another*.
3. Restart the alternative application server.

---

## Interoperating transactionally between application servers

This topic describes some considerations and actions that you can take to interoperate transactionally between different types of application servers.

To interoperate transactionally with a non-WebSphere application server, WebSphere Application Server switches dynamically between WebSphere-optimized native transaction contexts and interoperable OTS contexts depending on the capability of the partner with which it is interoperating.

**5.1+** To interoperate transactionally between WebSphere Application Server version 5.1 (or later) and WebSphere Application Server before version 5.0, you need to set the following system properties on application servers before version 5.0:

```
com.ibm.ejs.jts.jts.ControlSet.nativeOnly=false
com.ibm.ejs.jts.jts.ControlSet.interoperabilityOnly=true
```

For example, if you want to interoperate between application servers at WebSphere Application Server version 5.1 and WebSphere Application Server version 4.0.n, you need to set the system properties on the version 4.0.n application servers.

---

## Troubleshooting transactions

Use this overview task to help resolve a problem that you think is related to the Transaction service.

To identify and resolve transaction-related problems, you can use the standard WebSphere Application Server RAS facilities. If you encounter a problem that you think might be related to transactions, complete the following steps:

1. Check for transaction messages in the administrative console. The Transaction service produces diagnostic messages prefixed by “WTRN”. The error message indicates the nature of the problem and provides some detail. The associated message information provides an explanation and any user actions to resolve the problem.
2. Check for Transaction messages in the activity log. Activity log messages produced by the Transaction service are accompanied by Log Analyzer descriptions.
3. Check for more messages in the application server’s stdout.log. For more information about a problem, check the stdout.log file for the application server, which should contain more error messages and extra details about the problem.
4. Check for messages related to the application server’s transaction log directory when the problem occurred.

**Note:** If you changed the transaction log directory and a problem caused the application server to fail (with in-flight transactions) before the server was restarted properly, the server will next start with the new log directory and be unable to automatically resolve in-flight transactions that were recorded in the old log directory. To resolve this, you can copy the transaction logs to the new directory then stop and restart the application server.

---

## Transaction service exceptions

This topic lists the exceptions that can be thrown by the WebSphere Application Server transaction service. The exceptions are listed in the following groups:

- Standard exceptions
- Heuristic exceptions

If the EJB container catches a system exception from the business method of an enterprise bean, and the method is running within a container-managed transaction, the container rolls back the transaction before passing the exception on to the client. For more information about how the container handles the exceptions thrown by the business methods for beans with container-managed transaction demarcation, see the section *Exception handling* in the Enterprise JavaBeans 2.0 specification. That section specifies the container’s action as a function of the condition under which the business method executes and the exception thrown by the business method. It also illustrates the exception that the client receives and how the client can recover from the exception.

### Standard exceptions

The standard exceptions such as `TransactionRequiredException`, `TransactionRolledbackException`, and `InvalidTransactionException` are defined in the Java Transaction API (JTA) 1.0.1 Specification.

#### **InvalidTransactionException**

This exception indicates that the request carried an invalid transaction context.

#### **TransactionRequiredException exception**

This exception indicates that a request carried a null transaction context, but the target object requires an active transaction.

#### **TransactionRolledbackException exception**

This exception indicates that the transaction associated with processing of the request has been rolled back, or marked for roll back. Thus the requested operation either could not be performed or was not performed because further computation on behalf of the transaction would be fruitless.

### Heuristic exceptions

A heuristic decision is a unilateral decision made by one or more participants in a transaction to commit or rollback updates without first obtaining the consensus outcome determined by the Transaction Service. Heuristic decisions are an issue only after the participant has been prepared and the second phase of commit processing is underway. Heuristic decisions are normally made only in unusual circumstances, such as repeated failures by the transaction manager to communicate with a resource manager during

two-phase commit. If a heuristic decision is taken, there is a risk that the decision differs from the consensus outcome, resulting in a loss of data integrity.

The following list provides a summary of the heuristic exceptions. For more detail, see the Java Transaction API (JTA) 1.0.1 Specification.

**HeuristicRollback exception**

This exception is raised on the commit operation to report that a heuristic decision was made and that all relevant updates have been rolled back.

**HeuristicMixed exception**

This exception is raised on the commit operation to report that a heuristic decision was made and that some relevant updates have been committed and others have been rolled back.

---

## UserTransaction interface - methods available

For details about the methods available with the UserTransaction interface, see the WebSphere Application Server application programming interface reference information (Javadoc) or the Java Transaction API (JTA) 1.0.1 Specification.

---

## Using one-phase and two-phase commit resources in the same transaction

Use these topics to help you coordinate the use of a single one-phase commit capable resource with any number of two-phase commit capable resources in the same global transaction.

You can coordinate the use of a single one-phase commit capable resource with any number of two-phase commit capable resources in the same global transaction.

At transaction commit, the two-phase commit resources are prepared first using the two-phase commit protocol, and if this is successful the one-phase commit-resource is then called to `commit(one_phase)`. The two-phase commit resources are then committed or rolled back depending on the response of the one-phase commit resource.

For more information about using one-phase and two-phase commit resources within the same transaction, see the following topics:

- Coordinating use of one-phase and two-phase commit resources within the same transaction
- **5.1+** Assembling an application to use one-phase and two-phase commit resources in the same transaction (using WebSphere Studio or the Assembly Toolkit).
- Configuring an application server to allow logging for heuristic reporting

## Coordinating access to 1-PC and 2-PC-capable resources within the same transaction

Last participant support enables the use of a single one-phase commit capable resource with any number of two-phase commit capable resources in the same global transaction.

At transaction commit, the two-phase commit resources are prepared first using the two-phase commit protocol, and if this is successful the one-phase commit-resource is then called to `commit(one_phase)`. The two-phase commit resources are then committed or rolled back depending on the response of the one-phase commit resource.

**Note:** **5.1+** If the global transaction is distributed across multiple application servers *that are all running at WebSphere Application Server version 5.1 or later*, you can coordinate access to one-phase and two-phase commit capable resources within the same transaction.

**Note:** If the global transaction is distributed across multiple application servers *that are all running at WebSphere Application Server version 5.1 or later* then you can exploit last participant support to coordinate a one-phase commit capable resource and any number of two-phase commit capable resources within the same transaction, in a limited number of scenarios.

- The main scenario is where the one-phase commit resource provider is accessed in the application server process (the “transaction root” server) in which the transaction is started.  
In this scenario, last participant support can coordinate a one-phase commit capable resource and any number of two-phase commit capable resources within the same transaction.
- If the one-phase commit resource provider is accessed in a different application server (a “transaction subordinate” server) from the one in which the transaction was started; for example, as a result of a transactional invocation on a remote EJB interface where the EJB implementation accesses a one-phase commit resource provider.

In this scenario, the transaction typically cannot be committed. To be able to commit (as part of a global transaction) a one-phase commit resource enlisted on a transaction subordinate server, the transaction service must delegate coordination responsibility from the transaction root to the subordinate server. This occurs only if no other resources were registered with the transaction root server.

Last participant support introduces an increased risk of an heuristic outcome to the transaction. That is, the transaction manager cannot be sure that all resources were completed in the same direction (either committed or rolled back). For this reason, to enable an application to coordinate access to one-phase and two-phase commit capable resources within the same transaction, you configure the application to accept the increased risk of an heuristic outcome.

An heuristic outcome occurs if the transaction service (JTS) receives no response from the commit one-phase flow on the one-phase commit resource. In this situation the transaction service cannot determine whether changes for the one-phase commit resource were committed or rolled back, so cannot drive reliably the correct outcome of the global transaction on the other two-phase commit resources.

You can configure the transaction service for an application server to indicate whether or not to log that it is about to commit the one-phase commit resource. This does not reduce the heuristic hazard, but ensures that any failure, and subsequent recovery, of the application server during the one-phase commit phase occurs with knowledge of whether or not the one-phase commit resource was asked to commit:

- If the one-phase commit resource was asked to commit, a heuristic outcome is reported to the activity log.
- If the one-phase commit resource was not asked to commit, then the transaction is rolled back consistently.

## **Assembling an application to use one-phase and two-phase commit resources in the same transaction**

Use this task to assemble an application to use one-phase and two-phase commit resources within the same transaction.

To enable an application to use one-phase and two-phase commit capable resources within the same transaction, you must configure the deployment attributes of the application to accept the increased risk of an heuristic outcome.

You can configure the deployment attributes of an application by using the Deployment Descriptor Editor of WebSphere Studio Application Developer or the Assembly Toolkit.

This task description assumes that you have an EAR file for an application component, that can be deployed in WebSphere Application Server. For more details about using the Assembly Toolkit, see *Assembling applications with the Assembly Toolkit*.

To configure an application to indicate that you accept the increased risk of an heuristic outcome, complete the following steps:

1. Start the Assembly Toolkit.
2. Create or edit the application EAR file.

**Note:** Ensure that you set the target server as WBI Server Foundation v5.1.

For example, to change attributes of an existing application, use the import wizard to import the EAR file into the Assembly Toolkit. To start the import wizard:

- a. Click **File-> Import-> EAR file**
  - b. Click **Next**, then select the EAR file.
  - c. In the Target server field, select WBI Server Foundation v5.1
  - d. Click **Finish**
3. In the J2EE Hierarchy view, right-click the Enterprise Application instance, then click **Open With > Deployment Descriptor Editor**. A property dialog notebook for the component is displayed in the property pane.
  4. In the property pane, select the Extended Services tab.
  5. In the Last Participant Support section, select the **Last participant support** checkbox.
  6. Save your changes to the deployment descriptor.
    - a. Close the Deployment Descriptor Editor.
    - b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.
  7. Verify the archive files.
  8. Generate code for deployment for EJB modules or for enterprise applications that use EJB modules.
  9. Optional: Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard. Note that **Run on Server** works on the Windows, Linux/Intel, and AIX operating systems only; you cannot deploy remotely from the Assembly Toolkit to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

### **Important**

**Important:** Use **Run On Server** for unit testing only. Assembly Server Toolkit controls the WebSphere Application Server installation and, when an application is published remotely, the Toolkit overwrites the server configuration file for that server. Do not use on production servers.

For instructions on remote testing, see the article "Setting Up a Remote WebSphere Application Server in WebSphere Studio V5" at [http://www7b.boulder.ibm.com/wsdd/techjournal/0303\\_yuen/yuen.html](http://www7b.boulder.ibm.com/wsdd/techjournal/0303_yuen/yuen.html).

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that is to run the application; for example, using the administrative console as described in Deploying and managing applications.

## **Last participant support extension settings**

Use this page to configure last participant support extensions.

Last participant support is an extension to the transaction service to allow a single one-phase resource to participate in a two-phase transaction with one or more two-phase resources.

To view this administrative console page, click **Applications > Applications > *application\_name* > Last Participant Support Extension**.

### **Accept Heuristic Hazard:**

Specifies whether the application accepts the possibility of an heuristic hazard occurring in a two-phase transaction containing a one-phase resource.

**Default  
Range**

Cleared  
**Selected**

The application accepts the increased risk of an heuristic outcome.

**Cleared**

The application does not accept the increased risk of an heuristic outcome.

## Configuring an application server to log heuristic reporting

To enable an application server to log “about to commit one-phase resource” events from transactions that involve a one-phase commit resource and two-phase commit resources, use the Administrative console to complete the following steps:

1. Start the Administrative console
2. In the navigation pane, select **Servers-> Manage Application Servers-> *your\_app\_server*** This displays the properties of the application server, *your\_app\_server*, in the content pane.
3. Select the Transaction Service tab, to display the properties page for the transaction service, as two notebook pages:

### **Configuration**

The values of properties defined in the configuration file. If you change these properties, the new values are applied when the application server next starts.

### **Runtime**

The runtime values of properties. If you change these properties, the new values are applied immediately, but are overwritten with the Configuration values when the application server next starts.

4. Select the Configuration tab, to display the transaction-related configuration properties.
5. Select the **Enable logging for heuristic reporting** checkbox.
6. Click **OK**.
7. Stop then restart the application server.

## Exceptions thrown for transactions involving both single- and two-phase commit resources

The exceptions that can be thrown by transactions that involve single- and two-phase commit resources are the same as those that can be thrown by transactions involving only two-phase commit resources.

The exceptions that can be thrown are listed in the WebSphere API reference information (Javadoc).

## Last Participant Support: Resources for learning

Use the links in this topic to find relevant supplemental information about Last Participant Support. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

## Chapter 25. Using the ActivitySession service

These topics provide information about implementing WebSphere enterprise applications that use ActivitySessions.

The ActivitySession service provides an alternative unit-of-work (UOW) scope to that provided by global transaction contexts. ActivitySessions provide a scoping mechanism for units of work, and both an ActivitySession and a transaction has the same following characteristics:

- It can be bean-managed or container-managed
- It can be distributed across application servers
- It can be used as the context for managing EJB activation policy and lifecycle

An ActivitySession differs significantly from a transaction in the manner of its interaction with resource managers. An ActivitySession is used to scope or coordinate local transactions. That is, an ActivitySession can be used to request multiple one-phase resource managers to come to an application- or container-determined outcome. Unlike a transaction, an ActivitySession has no notion of a prepare phase or any notion of recovery at a service level.

The WebSphere EJB container and deployment tools support ActivitySessions as an extension to the J2EE programming model. Enterprise beans can be deployed with lifecycles that are influenced by ActivitySession context, as an alternative to transaction context. An enterprise bean with an ActivitySession-scoped lifecycle can participate in a resource manager local transaction (RMLT) that has a duration of the ActivitySession rather than an individual method on the bean (which is all that is possible under the standard J2EE model). Applications can then be composed of several enterprise beans with ActivitySession-based activation, with each bean participating in extended local transactions with one or more resource managers. At the end of the ActivitySession each of the local transactions can be directed to a common outcome by the ActivitySession manager.

You can configure the WebSphere containers and deployable applications to support enterprise beans that operate under application- or container-initiated ActivitySessions rather than, or in addition to, transactions.

For more information about implementing WebSphere enterprise applications that use ActivitySessions, see the following topics:

- The ActivitySession service
  - ActivitySessions and transaction contexts
  - Using ActivitySessions with HTTP sessions
- The ActivitySession service programming interfaces
- Developing a J2EE application to use an ActivitySession
- ActivitySessions samples
- Configuring EJB module ActivitySession deployment attributes with the Assembly Toolkit
- Configuring Web module ActivitySession deployment attributes with the Assembly Toolkit
- Disabling or enabling the ActivitySession service
- Configuring the default ActivitySession timeout
- Troubleshooting ActivitySessions

---

### The ActivitySession service

The ActivitySession service provides an alternative unit-of-work (UOW) scope to that provided by global transaction contexts. An ActivitySession context can be longer-lived than a global transaction context and can encapsulate global transactions.

Support for the ActivitySession service is shown in the following figure:

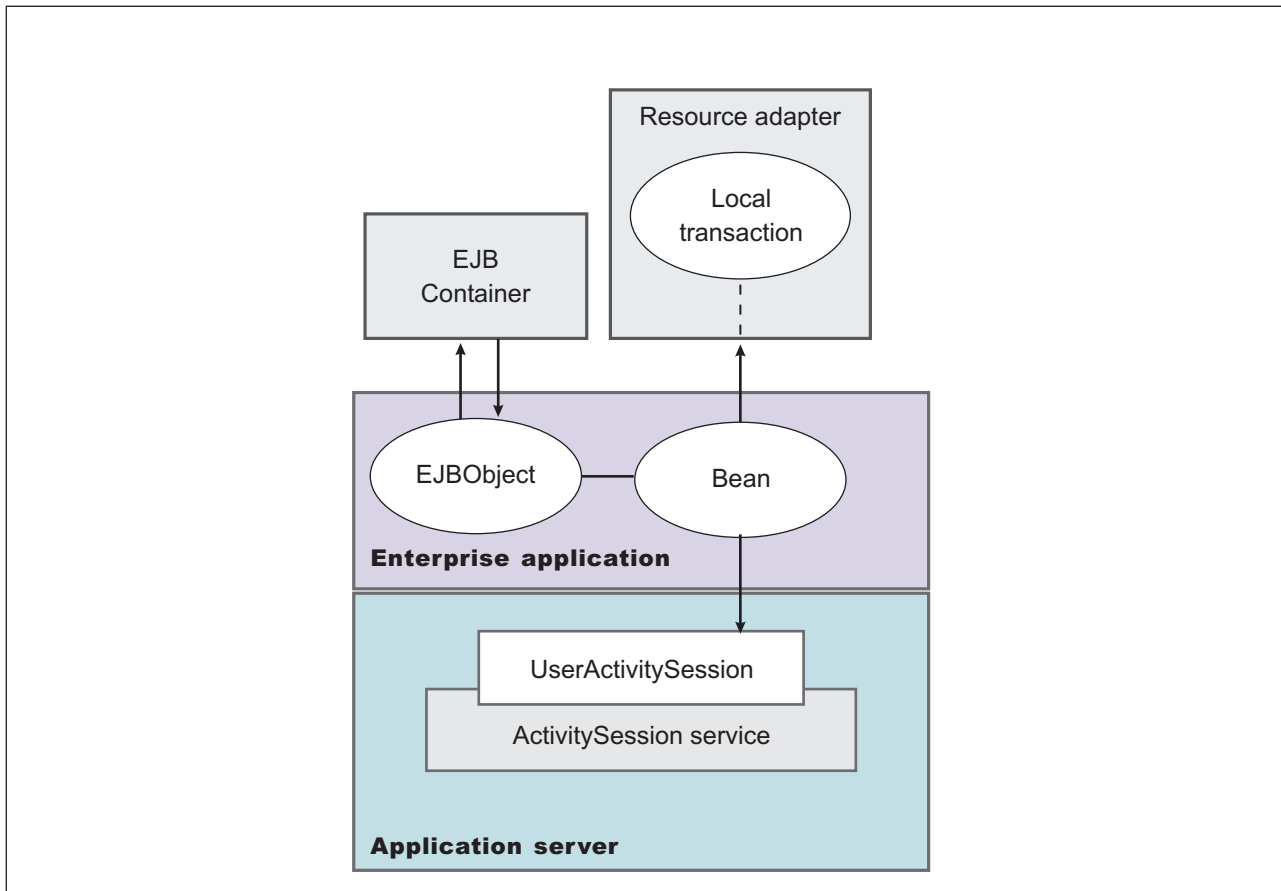

Figure 33. The ActivitySession service. This figure show the main components of the ActivitySession service within WebSphere Application server. For an overview of these components, see the text that accompanies this figure.

Although the purpose of a global transaction is to coordinate multiple resource managers, global transaction context is often used by J2EE applications as a “session” context through which to access EJB instances. An ActivitySession context is such a session context, and can be used in preference to a global transaction in cases where coordination of two-phase commit resource managers is not needed. Further, an ActivitySession can be associated with an HttpSession to extend a “client session” to an HTTP client.

ActivitySession support is available to Web, EJB, and J2EE-client components. EJB components can be divided into beans that exploit container-managed ActivitySessions and beans that use bean-managed ActivitySessions.

The ActivitySession service provides a UserActivitySession application programming interface available to J2EE components that use bean-managed ActivitySessions for application-managed demarcation of ActivitySession context. The ActivitySession service also provides a system programming interface for container-managed demarcation of ActivitySession context and for container-managed enlistment of one-phase resources (RMLTs) in such contexts.

The UserActivitySession interface is obtained by a JNDI lookup of `java:comp/websphere/UserActivitySession`. This interface is not available to enterprise beans that use container-managed ActivitySessions, and any attempt by such beans to obtain the interface results in a `NotFound` exceptions.

## Using ActivitySessions with HTTP sessions

This topic describes how a web application that runs in the WebSphere Web container can participate in an ActivitySession context.

If the web application is designed such that several servlet invocations occur as part of the same logical application, then the servlets can use the `HttpSession` to preserve state across servlet invocations. The `ActivitySession` context is one state that can be suspended into the `HttpSession` and resumed on a future invocation of a servlet that accesses the `HttpSession`.

An `ActivitySession` is associated automatically with an `HttpSession`, so can be used to extend access to the `ActivitySession` over multiple HTTP invocations, over inclusion or forwarding of servlets, and to support EJB activation periods that can be determined by the lifecycle of the web HTTP client. An `ActivitySession` context stored in an `HttpSession` can also be used to relate work for the `ActivitySession` back to a specific web HTTP client.

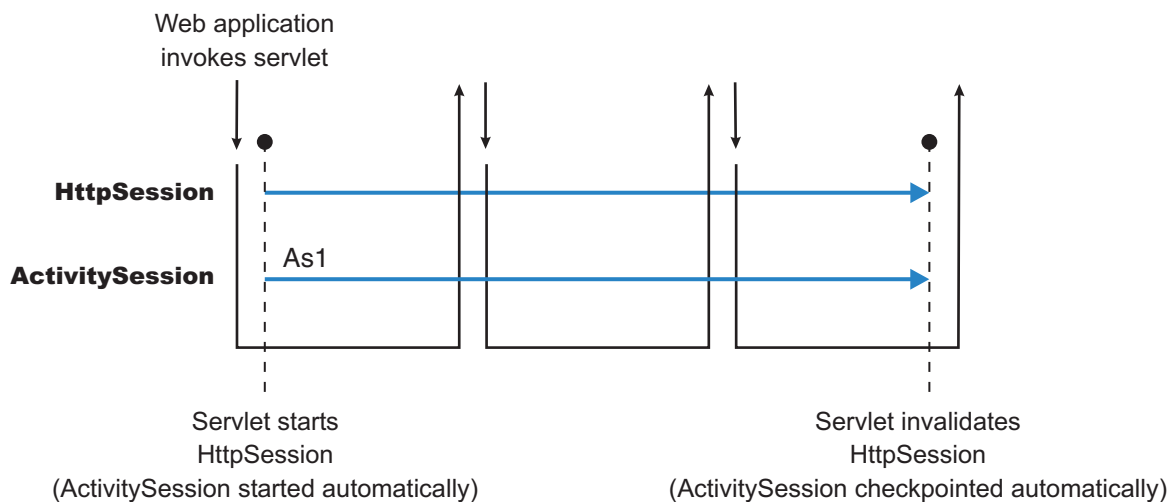

The Web container manages `ActivitySessions` based on deployment descriptor attributes associated with servlets in the Web application module. The two usage models are:

- The Web container starts and ends `ActivitySessions`.

The Web application invokes a servlet that has been configured for container control of `ActivitySessions`.

- If an `HttpSession` exists then it has an associated `ActivitySession`.
- If an `HttpSession` does not exist, the servlet can start an `HttpSession`, which causes an `ActivitySession` to be started automatically and associated with the `HttpSession`.

A servlet cannot start a new `HttpSession` until an existing `HttpSession` has been ended. Within an `HttpSession`, the Web application can invoke other servlets that can use the associated `ActivitySession` context. When the Web application invokes a servlet that ends the `HttpSession`, the `ActivitySession` is ended automatically. This is shown in the following diagram:

- The Web application starts and ends `ActivitySessions`.

The Web application invokes a servlet that has been configured for application control of `ActivitySessions`.

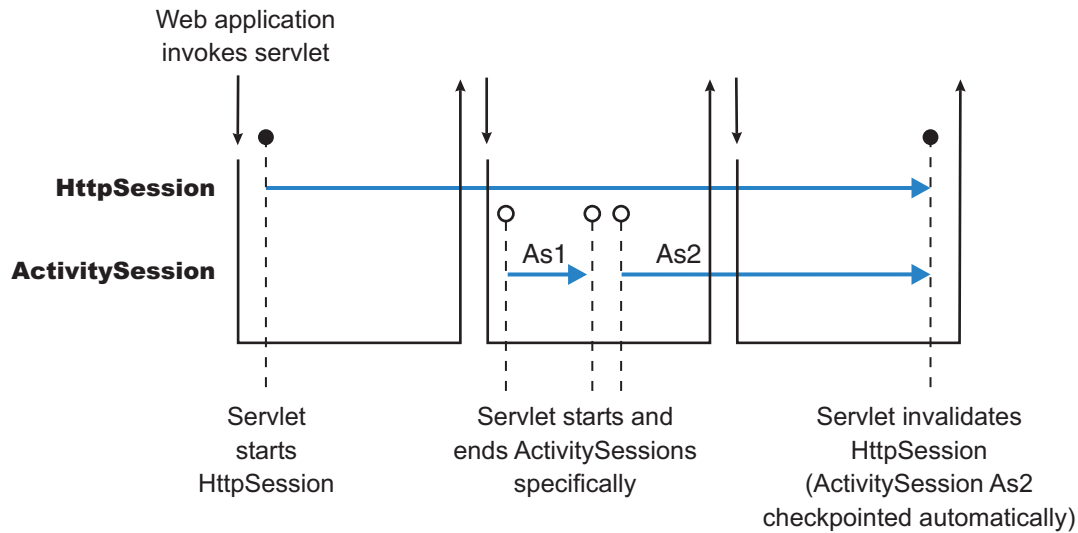

- If an `HttpSession` exists and has an associated `ActivitySession`, the servlet can use or end that `ActivitySession` context.
- If an `HttpSession` does not exist, the servlet can start an `HttpSession`, but this does not automatically start an `ActivitySession`.
- If an `HttpSession` exists but does not have an associated `ActivitySession`, the servlet can start a new `ActivitySession`. This automatically associates the `ActivitySession` with the `HttpSession`. The `ActivitySession` lasts either until the `ActivitySession` is specifically ended or until the `HttpSession` is ended.

The servlet cannot start a new `ActivitySession` until an existing `ActivitySession` has been ended. The servlet cannot start a new `HttpSession` until an existing `HttpSession` has been ended.

Within an `HttpSession`, the Web application can invoke other servlets that can use or end an existing `ActivitySession` context or, if no `ActivitySession` exists start a new `ActivitySession`. When the Web

application invokes a servlet that ends the HttpSession, the HttpSession is ended automatically. This is shown in the following diagram:

A Web application can invoke servlets configured for either usage model.

The following points apply to both usage models:

- To end an HttpSession (and any associated ActivitySession), the Web application must invalidate that session. This causes the ActivitySession to be checkpointed.
- Any downstream EJBs activated within the context of an ActivitySession can be held in memory rather than passivated between servlet invocations, because the client effectively becomes the web HTTP client.
- Web applications can be composed of many servlets, and each servlet in the Web application can be configured with a value for ActivitySessionControl. ActivitySessionControl determines whether the servlet or its container starts any ActivitySessions.
- An ActivitySession context that encapsulates an active transaction context cannot be associated with an HttpSession, because a transaction can hold database locks and should be designed to be shortlived. If an application moves an active transaction to an HttpSession, the transaction is rolled back and the ActivitySession is suspended into the HttpSession. In general, you should design applications to use ActivitySessions or other constructs as the long-lived entities and ACID transactions as short-duration entities within these.
- Only one ActivitySession can be associated with an HttpSession at any time, for the duration of the ActivitySession. An ActivitySession associated with an HttpSession remains associated for the duration of that ActivitySession, and cannot be replaced with another until the first ActivitySession is completed. The ActivitySession can be accessed by multiple servlets if they have shared access to the HttpSession.
- ActivitySessions are not persistent. If a persistent HttpSession exists longer than the server hosting it, any cached ActivitySession is terminated when the hosting server ends.
- If the HttpSession times out before the associated ActivitySession has ended, the ActivitySession is reset.
- If the ActivitySession times out, it is reset then the HttpSession is ended.

## ActivitySession and transaction contexts

This topic describes the hierarchical relationship between transaction and ActivitySession context, This relationship, defined by the ActivitySession service, requires that any transaction context be either wholly inside or wholly outside an ActivitySession context.

An `ActivitySession` context is very similar to a transaction context and extends the lifecycle choices for activation of enterprise beans; it can encapsulate one or more transactions. The `ActivitySession` context is a distributed context that, like the transaction context, can be bean- or container-managed. An `ActivitySession` context is used mainly by a client to scope the lifecycle of an enterprise bean that it uses either beyond or in the absence of individual transactions started by that client.

`ActivitySessions` have a lower overhead than transactions and can be used instead of transactions that are only used to scope the lifecycle of a called enterprise bean. For a bean with an activation policy of `ActivitySession`, the duration of any resource manager local transactions (RMLTs) started by that bean can be bounded by the duration of the `ActivitySession` instead of the bean method in which the RMLT was started. This provides flexibility and potential for using RMLTs in an enterprise bean beyond the scenarios described in the J2EE specifications. The J2EE specifications define that RMLTs need to be completed before the end of the bean method, because the bean method is the only containment boundary for local transactions available in those specifications.

The following rules defines the relationship between transactions and `ActivitySessions`.

- The EJB or Web container always uses a local transaction containment (LTC) if there is no global transaction present. An LTC can be method-scoped or `ActivitySession`-scoped.
- Before a method dispatch, the container ensures that there is always either an LTC or global transaction context, but never both contexts.
- `ActivitySessions` cannot be nested within each other. Any attempt to start a nested `ActivitySession` results in a `com.ibm.websphere.ActivitySession.NotSupportedException` on `UserActivitySession.beginSession()`.
- An `ActivitySession` can wholly encapsulate one or more global transactions.
- An `ActivitySession` cannot be encapsulated by a global transaction nor should `ActivitySession` and global transaction boundaries overlap. Any attempt to start an `ActivitySession` in the presence of a global transaction context results in a `com.ibm.websphere.ActivitySession.NotSupportedException` on `UserActivitySession.beginSession()`. Any attempt to call `endSession(EndModeCheckpoint)` on an `ActivitySession` that contains an incomplete global transaction results in a `com.ibm.websphere.ActivitySession.ContextPendingException`. Neither the global transaction nor the `ActivitySession` context are affected. If `endSession(EndModeReset)` is called then the `ActivitySession` is reset and the global transactions marked `rollback_only`.
- Each global transaction wholly encapsulated by an `ActivitySession` is independent of every other global transaction within that `ActivitySession`. A rollback of one global transaction does not affect any others or the `ActivitySession` itself.
- `ActivitySession` and global transaction contexts can coexist with an `ActivitySession` encapsulating one or more serially-executing global transactions.

## Combining transaction and `ActivitySession` container policies

This topic provides details about the relationship between the deployment descriptor properties that determine how the container manages `ActivitySession` boundaries.

If an enterprise bean uses `ActivitySessions`, how the EJB container manages `ActivitySession` boundaries when delegating a method invocation depends on both the **ActivitySession kind** and **Transaction attribute** deployment descriptor attributes configured for the enterprise bean. The following table lists the relationship between these two properties.

In each row, the final column describes the behavior that the EJB container takes with respect to global transaction and `ActivitySession` context, based on the following abbreviations:

**S<sub>n</sub>** An `ActivitySession`, where *n* indicates the `ActivitySession` instance.

**T<sub>n</sub>** A transaction, where *n* indicates the transaction instance.

In every case where the container does not start or leave a global transaction context associated with the thread, it starts (or obtains from the bean instance) a local transaction containment and associates that with the thread. The duration of the local transaction containment is determined by a combination of the

local-transaction boundary descriptor (configured as part of the application deployment descriptor, and not shown in the following table) and the presence or not of an ActivitySession context, as described in ActivitySessions and transaction contexts.

The rows highlighted in bold are not allowed.

Table 11. Container behavior for activitysession and transaction policies deployment settings

## Developing a J2EE application to use ActivitySessions

This topic provides an overview of the scenarios for which you would develop a J2EE application to use an ActivitySession.

The following common J2EE application scenarios make use of an ActivitySession:

- Developing a J2EE application to use one or more enterprise beans that are persisted to non-transactional datastores.

This scenario can be used by an application that needs to coordinate multiple one-phase resource managers; for example, for two or more entity EJBs whose persistence is delegated to LocalTransaction resource adapters.

In this scenario, the enterprise beans used by the application have an Activation policy of ActivitySession and a local transaction containment policy with a boundary of ActivitySession and resolution-control of ContainerAtBoundary. The synchronization of the EJB state data is synchronized, by the container, with the one-phase resource managers at ActivitySession completion and no application code is required to be aware of ActivitySession support.

- Developing a J2EE application in which an enterprise bean accesses a resource manager multiple times in different business methods.

This scenario can be used by an application that needs to extend a resource manager local transaction (RMLT) over several business methods of an enterprise bean instance.

In this scenario, the enterprise beans used by the application have an Activation policy of ActivitySession and a local transaction containment policy with a boundary of ActivitySession and resolution-control of Application. The application logic starts and ends the RMLTs, for example using the `javax.resource.cci.LocalTransaction` interface offered by a LocalTransaction Connector, but is not constrained to start and commit the LocalTransaction in the same method.

- Developing a J2EE client application to use an ActivitySession to scope EJB activation and load-balancing.

This scenario can be used by an application client that needs to access an entity bean instance several times in the same client session, either without needing to run under a transaction context, or with the need to run under a number of distinct and serially-executed transactions.

In this scenario, the enterprise beans used by the application client have an Activation policy of ActivitySession and a local transaction containment policy appropriate to the function of the enterprise bean. The J2EE client application can represent a period of user activity, for example a signon period, during which a number of interactions occur with one or more enterprise beans. If the J2EE client application begins an ActivitySession and invokes the enterprise beans within the scope of the UOW

represented by the `ActivitySession`, then the enterprise bean instances are activated by the container on the `ActivitySession` boundary and remain in the active state until passivated by the container at the end of the `ActivitySession`. Workload affinity management based on the `ActivitySession` is a platform quality of service. Global transactions can begin and end within the `ActivitySession`, if they are wholly encapsulated by the `ActivitySession` and run serially. EJB instances activated at the `ActivitySession` boundary remain active across the serial global transactions.

- Developing a Web application client to participate in an `ActivitySession` context.

A web application that runs in the WebSphere Web container can participate in an `ActivitySession` context. Web applications can use the `UserActivitySession` interface to begin and end an `ActivitySession` context. Also, the `ActivitySession` can be associated with an `HttpSession`, thereby extending access to the `ActivitySession` over multiple HTTP invocations and supporting EJB activation periods that can be determined by the lifecycle of the web HTTP client.

The Web container manages `ActivitySessions` based on deployment descriptor attributes associated with the Web application module.

#### **General considerations:**

- An application that is accessed under an `ActivitySession` context can receive a `javax.transaction.InvalidTransactionException RemoteException`, thrown by the EJB container when servicing any application method. This exception occurs when an instance of an enterprise bean that has an `ActivitySession`-based activation policy becomes involved with concurrent global and local transactions.
- To enable an enterprise bean to participate in an `ActivitySession` context and support `ActivitySession`-based operations, it must be configured with an `ActivationPolicy` of `ACTIVITY_SESSION`. A bean configured with `ActivationPolicy` of either `TRANSACTION` or `ONCE` cannot participate in `ActivitySession` context.
- A session bean can either use container-managed `ActivitySessions` or implement bean-managed `ActivitySessions`; entity beans can only use container-managed `ActivitySessions`. A bean is deployed to be bean-managed or container-managed with respect to `ActivitySession` management by setting its transaction type deployment attribute to be bean-managed or container-managed when deploying the enterprise bean. A bean that uses bean-managed transactions can use bean-managed `ActivitySessions`; a bean that uses container-managed transactions can use container-managed `ActivitySessions`.
- If you want a session bean or J2EE client to manage its own `ActivitySessions`, you must write the code that explicitly demarcates the boundaries of an `ActivitySession`, as described in *Developing an enterprise bean or J2EE client to manage ActivitySessions*.

For examples of using `ActivitySessions` in J2EE applications, see *ActivitySessions samples*.

---

## **Developing an enterprise bean or J2EE client to manage ActivitySessions**

Use this task to write the code needed by a session EJB or J2EE client application to manage an `ActivitySession`, based on the example code extract provided.

In most situations, an enterprise bean can depend on the EJB container to manage `ActivitySessions` within the bean. In these situations, all you need to do is set the appropriate `ActivitySession` attributes in the EJB module deployment descriptor, as described in *Configuring EJB module ActivitySession deployment attributes with the Assembly Toolkit*. Further, in general, it is practical to design your enterprise beans so that all `ActivitySession` management is handled at the enterprise bean level.

However, in some cases you may need to have a session bean or J2EE client participate directly in `ActivitySessions`. You then need to write the code needed by the session bean or J2EE client application to manage its own `ActivitySessions`.

**Note:** Session beans that use BMT and have an **Activate at** setting of Activity session can manage ActivitySessions. Entity beans cannot manage ActivitySessions; the EJB container always manages ActivitySessions within entity beans.

When preparing to write code needed by a session bean or J2EE client application to manage ActivitySessions, consider the points described in ActivitySessions and transaction contexts.

To write the code needed by a session EJB or J2EE client application to manage an ActivitySession, complete the following steps based on the example code extract below:

1. Get an initial context for the ActivitySession.
2. Get an implementation of the UserActivitySession interface, by a JNDI lookup of the URL `java:comp/websphere/UserActivitySession`. The UserActivitySession interface is used to begin and end ActivitySessions and to query various attributes of the active ActivitySession associated with the thread.
3. Set the timeout, in seconds, after which any subsequently started ActivitySessions are automatically completed by the ActivitySession service. If the session bean or J2EE client does not specifically set this value, the default timeout (300 seconds) is used.

The default timeout can also be overridden for each application server, on the **server-> Activity Session Service** panel of the administrative console.

4. Start the ActivitySession, by calling the `beginSession()` method of the UserActivitySession.
5. Within the ActivitySession, call business methods to do the work needed. You can also call UserActivitySession methods to manage the ActivitySession; for example, to get the status of the ActivitySession or to checkpoint all the ActivitySession resources involved in the ActivitySession.
6. End the ActivitySession, by calling the `endSession()` method of the UserActivitySession.

The following code extract provides a basic example of using the UserActivitySession interface:

```
// Get initial context
InitialContext ic = new InitialContext();
// Lookup UserActivitySession
UserActivitySession uas = (UserActivitySession)ic.lookup("java:comp/websphere/UserActivitySession");

// Set the ActivitySession timeout to 60 seconds
uas.setSessionTimeout(60);
// Start a new ActivitySession context
uas.beginSession();
// Do some work under this context
MyBeanA beanA.doSomething();
...
MyBeanB beanB.doSomethingElse();
// End the context
uas.endSession(EndModeCheckpoint);
```

---

## Setting EJB module ActivitySession deployment attributes with the Assembly Toolkit

Use this task to set the ActivitySession deployment attributes for an enterprise bean to enable the bean to participate in an ActivitySession context and support ActivitySession-based operations.

You can configure the deployment attributes of an application by using the Deployment Descriptor Editor of WebSphere Studio Application Developer or the Assembly Toolkit.

This topic describes the use of the Assembly Toolkit to configure the ActivitySession deployment attributes. These attributes are in addition to other deployment attributes, like Load at (which specifies when the bean loads its state from the database). This task description assumes that you have an EAR file, which contains an application enterprise bean that can be deployed in WebSphere Application Server. For more

details about using the Assembly Toolkit, see *Assembling applications with the Assembly Toolkit*. For more detail about the fields in the Assembly Toolkit, and for associated task help, see the help information provided with the toolkit.

To set the `ActivitySession` deployment attributes for an enterprise bean, use the Assembly Toolkit to complete the following steps:

1. Start the Assembly Toolkit.
2. Create or edit the application EAR file.

**Note:** Ensure that you set the target server as WBI Server Foundation v5.1.

For example, to change attributes of an existing application, use the import wizard to import the EAR file into the Assembly Toolkit. To start the import wizard:

- a. Click **File-> Import-> EAR file**
  - b. Click **Next**, then select the EAR file.
  - c. In the Target server field, select WBI Server Foundation v5.1
  - d. Click **Finish**
3. In the J2EE Hierarchy view of the J2EE perspective, right-click the EJB module for the enterprise bean instance, then click **Open With > Deployment Descriptor Editor**. A property dialog notebook for the enterprise bean instance is displayed in the property pane.
  4. In the property pane, select the Beans tab.
  5. Select the bean that you want to change.
  6. In the WebSphere Extensions section, under **Bean Cache**, set the **Activate at** attribute to **ActivitySession**:
- An enterprise bean with this activation policy is activated and passivated as follows:
- On an `ActivitySession` boundary, if an `ActivitySession` context is present on activation.
  - On a transaction boundary, if a transaction context, but no `ActivitySession` context, is present on activation.
  - Otherwise on an invocation boundary.
7. In the Local Transactions group box, set the **Boundary** attribute to **ActivitySession**: When this setting is used, the local transaction must be resolved within the scope of any `ActivitySession` in which it was started or, if no `ActivitySession` context is present, within the same bean method in which it was started.
  8. For entity beans, or session beans, set the `ActivitySessions` properties for each EJB method.

- a. In the property pane, select the `ActivitySession` tab.
- b. In the **Configure `ActivitySession` policies** field, click **Add** or **Edit** to set the **`ActivitySession` kind** attribute for methods of the enterprise bean. This specifies how the container must manage the `ActivitySession` boundaries when delegating a method invocation to an enterprise bean's business method:

**Never** The container invokes bean methods without an `ActivitySession` context.

- If the client invokes a bean method from within an `ActivitySession` context, the container throws an `InvalidActivityException` exception, which is a `javax.rmi.RemoteException`.
- If the client invokes a bean method from outside an `ActivitySession` context, the container behaves in the same way as if the **Not Supported** value was set. The client must call the method without an `ActivitySession` context.

#### **Mandatory**

The container always invokes the bean method within the `ActivitySession` context associated with the client. If the client attempts to invoke the bean method without an `ActivitySession` context, the container throws an `ActivityRequiredException` exception to the client. The `ActivitySession` context is passed to any EJB object or resource accessed by an enterprise bean method.

The `ActivityRequiredException` exception is `javax.rmi.RemoteException`.

#### **Requires new**

The container always invokes the bean method within a new `ActivitySession` context, regardless of whether the client invokes the method within or outside an `ActivitySession` context. The new `ActivitySession` context is passed to any enterprise bean objects or resources that are used by this bean method.

Any received `ActivitySession` context is suspended for the duration of the method and resumed after the method ends. The container starts a new `ActivitySession` before method dispatch and completes it after the method ends.

#### **Required**

The container invokes the bean method within an `ActivitySession` context. If a client invokes a bean method from within an `ActivitySession` context, the container invokes the bean method within the client `ActivitySession` context. If a client invokes a bean method outside an `ActivitySession` context, the container creates a new `ActivitySession` context and invokes the bean method from within that context. The `ActivitySession` context is passed to any enterprise bean objects or resources that are used by this bean method.

#### **Not supported**

The container invokes bean methods without an `ActivitySession` context. If a client invokes a bean method from within an `ActivitySession` context, the container suspends the association between the `ActivitySession` and the current thread before invoking the method on the enterprise bean instance. The container then resumes the suspended association when the method invocation returns. The suspended `ActivitySession` context is not passed to any enterprise bean objects or resources that are used by this bean method.

#### **Supports**

If the client invokes the bean method within an `ActivitySession`, the container invokes the bean method within an `ActivitySession` context. If the client invokes the bean method without a `ActivitySession` context, the container invokes the bean method without an `ActivitySession` context. The `ActivitySession` context is passed to any enterprise bean objects or resources that are used by this bean method.

- c. Click **Next**.
- d. Select the methods to which the `ActivitySession` kind policy is to be applied.
- e. Click **Finish**.
- f.

How the container manages the `ActivitySession` boundaries when delegating a method invocation depends on both the **ActivitySession kind** attribute, set here, and the **Transaction attribute** attribute, as described in [Setting transactional attributes in the deployment descriptor](#). For more detail about the relationship between these two properties, see [Combining transaction and ActivitySession container policies](#).

9. Save your changes to the deployment descriptor.
  - a. Close the Deployment Descriptor Editor.
  - b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.
10. Verify the archive files.
11. Generate code for deployment for EJB modules or for enterprise applications that use EJB modules.
12. Optional: Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard. Note that **Run on Server** works on the Windows, Linux/Intel, and AIX operating systems only; you cannot deploy remotely from the Assembly Toolkit to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

#### **Important**

**Important:** Use **Run On Server** for unit testing only. Assembly Server Toolkit controls the WebSphere Application Server installation and, when an application is published remotely, the Toolkit overwrites the server configuration file for that server. Do not use on production servers.

For instructions on remote testing, see the article “Setting Up a Remote WebSphere Application Server in WebSphere Studio V5” at [http://www7b.boulder.ibm.com/wsdd/techjournal/0303\\_yuen/yuen.html](http://www7b.boulder.ibm.com/wsdd/techjournal/0303_yuen/yuen.html).

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that is to run the application; for example, using the administrative console as described in Deploying and managing applications.

---

## Setting Web module ActivitySession deployment attributes with the Assembly Toolkit

Use this task to set the ActivitySession deployment attributes for a Web application to start UserActivitySessions and perform work scoped within ActivitySessions.

You can configure the deployment attributes of an application by using the Deployment Descriptor Editor of WebSphere Studio Application Developer or the Assembly Toolkit.

This topic describes the use of the Assembly Toolkit to configure the deployment attributes. This task description assumes that you have an EAR file, which contains an application enterprise bean that can be deployed in WebSphere Application Server. For more details about using the Assembly Toolkit, see Assembling applications with the Assembly Toolkit.

To set the ActivitySession deployment attributes for a Web application, use the Assembly Toolkit to complete the following steps:

1. Start the Assembly Toolkit.
2. Create or edit the Web module. For example, to change attributes of an existing module, click **File-> Open** then select the archive file for the module. For example, to change attributes of an existing module, use the import wizard to import the EAR or WAR file into the Assembly Toolkit. To start the import wizard:
  - a. Click **File-> Import-> WAR file**
  - b. Click **Next**, then select the WAR file.
  - c. Click **Finish**
3. In the J2EE Hierarchy view, right-click the Web module, then click **Open With > Deployment Descriptor Editor**. A property dialog notebook for the Web module is displayed in the property pane.
4. In the property pane, select the Extended services tab.
5. Select the servlet that you want to change.
6. In the ActivitySession section, set the **ActivitySession control kind** attribute to either Application, Container, or None.

### Application

The Web application is responsible for starting and ending ActivitySessions, as follows:

- If an HttpSession is active when an application begins an ActivitySession, then the container associates the ActivitySession with the HttpSession.
- If an ActivitySession is started in the absence of an HttpSession, then the application must ensure it is completed before the dispatched method completes; otherwise, an exception results.
- If an HttpSession is associated with a request dispatched to an application with this ActivitySession control value, and if that HttpSession has an ActivitySession associated

with it, then the container dispatches the request in the context of that `ActivitySession`. For example, the container resumes the `ActivitySession` context onto the thread before the dispatch.

- A Web application can use both transactions and `ActivitySessions`. Any transactions started within the scope of an `ActivitySession` must be ended by the web component that started them and within the same request dispatch.

#### **Container**

A servlet has no access to `UserActivitySessions`. Any `HttpSession` started by the servlet has an `ActivitySession` automatically associated with it by the container, and this `ActivitySession` is put onto the thread of execution. If such a servlet is dispatched by a request that has an `HttpSession` containing no `ActivitySession`, then the container starts an `ActivitySession` and associates it with the `HttpSession` and the thread.

A Web application can use both transactions and `ActivitySessions`. Any transactions started within the scope of an `ActivitySession` must be ended by the web component that started them and within the same request dispatch.

**None** A servlet has no access to `UserActivitySession`. An `HttpSession` started by the servlet does not have an `ActivitySession` automatically associated with it by the container. If such a servlet is dispatched by a request that has an `HttpSession` containing an `ActivitySession`, then the container dispatches the request in the context of that `ActivitySession`. For example, the container resumes the `ActivitySession` context onto the thread before the dispatch.

7. To apply the changes and close the Assembly Toolkit, click **OK**. Otherwise, to apply the values but keep the property dialog open for additional edits, click **Apply**.
8. Save your changes to the deployment descriptor.
  - a. Close the deployment descriptor editor.
  - b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.
9. Verify the archive files.
10. Generate code for deployment for EJB modules or for enterprise applications that use EJB modules.
11. Optional: Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard. Note that **Run on Server** works on the Windows, Linux/Intel, and AIX operating systems only; you cannot deploy remotely from the Assembly Toolkit to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

#### **Important**

**Important:** Use **Run On Server** for unit testing only. Assembly Server Toolkit controls the WebSphere Application Server installation and, when an application is published remotely, the Toolkit overwrites the server configuration file for that server. Do not use on production servers.

For instructions on remote testing, see the article “Setting Up a Remote WebSphere Application Server in WebSphere Studio V5” at

[http://www7b.boulder.ibm.com/wsdd/techjournal/0303\\_yuen/yuen.html](http://www7b.boulder.ibm.com/wsdd/techjournal/0303_yuen/yuen.html).

After assembling your application, use a systems management tool to deploy the WAR file; for example, using the administrative console as described in *Deploying and managing applications*.

---

## **Disabling or enabling the ActivitySession service**

Use this task to disable or enable the `ActivitySession` service for an application server.

You can use the `ActivitySession Startup` property to specify whether or not the `ActivitySession` service is started automatically for an application server.

To configure the ActivitySession **Startup** property for an application server, use the Administrative console to complete the following steps:

1. Start the Administrative console.
2. In the navigation pane, expand **Servers-> Manage Application Servers** This displays a list of the application servers in the content pane.
3. In the Content pane, select the application server that you want to configure. This displays the properties for the application server in the content pane.
4. In the Additional Properties table, select **ActivitySession service**. This displays the ActivitySession service properties in the content pane.
5. Select or clear the **Startup** property as needed:

**Selected**

[Default] The ActivitySession service is started when the application server is started. This enables applications that specify use of ActivitySessions in their deployment descriptors to run on such an application server.

**Cleared**

The ActivitySession service is not started when the application server is started. Applications that specify use of ActivitySessions in their deployment descriptors cannot start on such an application server.

Any attempt to start an application that uses ActivitySessions is rejected and a message issued:

```
WACS0043E: Error found starting an application.
application_name specified an ActivitySession attribute that is not allowed
when the ActivitySession service is not enabled
```

If this happens during server startup, the server continues to start without the application.

6. Click **OK**.
7. To save your configuration, click **Save** on the task bar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

---

## Configuring the default ActivitySession timeout for an application server

Use this task to configure the default ActivitySession timeout for an application server, after which any started ActivitySessions are completed automatically by the ActivitySession service.

The ActivitySession timeout is used to reset any ActivitySession whose remote client has failed to complete the ActivitySession in a timely fashion. The initial default timeout can be configured separately for each application server, and can be overridden programmatically by the UserActivitySession interface (setSessionTimeout). If an ActivitySession that contains a transaction reaches the timeout, the transaction's timeout is accelerated so that it is timed out (and rolled back) immediately before the ActivitySession is reset.

To configure the default ActivitySession timeout for an application server, use the WebSphere Administrative console to complete the following steps:

1. Start the WebSphere Administrative console.
2. In the navigation pane, expand **Servers-> Manage Application Servers** This displays a list of the application servers in the content pane.
3. In the Content pane, select the application server that you want to configure. This displays the properties for the application server in the content pane.
4. In the Additional Properties table, select **ActivitySession service**. This displays the ActivitySession service properties in the content pane.
5. Set the **ActivitySession timeout** property to the default timeout as an integer number of seconds.

- -1 indicates that ActivitySessions never timeout
- 0 indicates that the default timeout, 300 seconds, applies
- Other values are an integer number of seconds

6. Click **OK**.
7. To save your configuration, click **Save** on the task bar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

## ActivitySession service settings

Use this page to administer the run-time properties of the ActivitySession service.

To view this administrative console page, click **Servers > Application Servers > server\_name > Activity Session Service**.

### Startup

Specifies whether the server will attempt to start the ActivitySession service.

<b>Default</b>	Selected
<b>Range</b>	<p><b>Selected</b></p> <p>When the application server starts, it attempts to start the ActivitySession service automatically.</p> <p><b>Cleared</b></p> <p>The server does not try to start the ActivitySession service. If ActivitySessions are to be used in applications that run on this server, the system administrator must start the service manually or select this property then restart the server.</p>

### Default timeout

The default timeout for an ActivitySession. A server resets an ActivitySession if a remote client has failed to complete the ActivitySession within this time period.

The Default ActivitySession timeout specifies the time after which an ActivitySession is completed automatically by the ActivitySession service, if a remote client has failed to complete the ActivitySession within the specified time. The initial default timeout can be configured separately for each application server, and can be overridden programmatically by the UserActivitySession interface (setSessionTimeout).

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	300 (5 minutes)
<b>Range</b>	<p>-1 through 2147483647 seconds</p> <ul style="list-style-type: none"> <li>• -1 indicates that ActivitySessions never timeout</li> <li>• 0 indicates that the default timeout applies</li> <li>• Other values are an integer number of seconds</li> </ul>

---

## Troubleshooting ActivitySessions

Use this overview task to help resolve a problem that you think is related to the ActivitySession service.

To identify and resolve ActivitySession-related problems, you can use the standard WebSphere Application Server RAS facilities. If you encounter a problem that you think might be related to ActivitySessions, complete the following stages:

1. Check for ActivitySession messages in the admin console. The ActivitySession service produces diagnostic messages prefixed by “WACS”. The error message indicates the nature of the problem and provides some detail. The associated message information provides an explanation and any user actions to resolve the problem.
2. Check for ActivitySession messages in the activity log. Activity log messages produced by the ActivitySession service are accompanied by Log Analyzer descriptions.
3. Check for more messages in the application server’s stdout.log. For more information about a problem, check the stdout.log file for the application server, which should contain more error messages and extra details about the problem.

---

## The ActivitySession service application programming interfaces

The ActivitySession service consists of an application programming interface available to Web applications, session EJBs, and J2EE client applications for application-managed demarcation of ActivitySession context.

Applications use the UserActivitySession interface, which provides demarcation scope methods.

### ActivitySession API

The ActivitySession service provides the UserActivitySession interface for use by EJB Session beans using bean-managed context demarcation, Web application components configured with **ActivitySession control=Web Application**, and J2EE client applications. This UserActivitySession interface defines the set of ActivitySession operations available to an application component. An implementation of this interface is obtained via a JNDI lookup of the URL “java:comp/websphere/UserActivitySession”. It is used to begin and end ActivitySessions and to query various attributes of the active ActivitySession associated with the thread.

For more information about the ActivitySession API, see the ActivitySession API (Javadoc).

The ActivitySession API and the implementation of its interfaces is contained in the com.ibm.websphere.ActivitySession package.

### Programming Examples

The following code extract provides a basic example of using the UserActivitySession interface:

```
// Get initial context
InitialContext ic = new InitialContext();
// Lookup UserActivitySession
UserActivitySession uas = (UserActivitySession)ic.lookup("java:comp/websphere/UserActivitySession");

// Set the ActivitySession timeout to 60 seconds
uas.setSessionTimeout(60);
// Start a new ActivitySession context
uas.beginSession();
// Do some work under this context
MyBeanA beanA.doSomething();
...
MyBeanB beanB.doSomethingElse();
// End the context
uas.endSession(EndModeCheckpoint);
```

---

## Samples: ActivitySessions

This topic describes the ActivitySession samples provided with WebSphere Application Server.

### MasterMind sample

This sample is based on the game MasterMind. It consists of the following components:

- A servlet, configured with Activity session control set to Container, that accesses a stateful session bean.
- A stateful session bean, configured with an activation policy of ActivitySession containing transient state data.

The servlet begins an HttpSession at the start of each new game, and ends it at the end of each game; therefore an ActivitySession lasts for the duration of each game. The ActivitySession activation policy stops the bean from being passivated and therefore the transient data remains in memory. This is to demonstrate HttpSession/ActivationSession association in the web container, and an ActivitySession-scoped activation policy.

#### **J2EE client container application and a CMP entity bean backed by a one-phase commit datasource**

In this sample, the entity bean is configured with the following properties:

- TX\_NOT\_SUPPORTED
- An ActivitySession container managed policy of REQUIRES
- An LTC boundary of ActivitySession
- An LTC Resolution Control of ContainerAtBoundary

The client accesses the UserActivitySession, begins an ActivitySession, updates two instances of the bean, then ends the ActivitySession. It does this twice using EndModeReset then EndModeCheckpoint. This sample demonstrates the following functionality:

- Client access to the UserActivitySession interface
- Multiple RMLTs being scoped to the ActivitySession and automatically taking their completion direction from that of the ActivitySession

The entity bean also holds a transient variable incremented by each method call (gets and sets for the persistent data). This value is checked before the end of the ActivitySession to show that the same bean instance is used. The client checks for the correct results.

#### **A J2EE client container application and two session beans with different ActivitySession types**

This sample consists of a J2EE client container application and the following session beans:

- SLB1, a stateless session bean configured with an ActivitySession Type of Bean.
- SFB2, a stateful session bean configured with ActivitySession Type of Requires, an LTC boundary of ActivitySession, LTC Resolution Control of APPLICATION, and an LTC Unresolved Action of ROLLBACK.

Both beans are configured with TX\_NOTSUPPORTED.

This sample performs the following steps:

1. The client starts SLB1
2. SLB1 accesses the UserActivitySession interface, begins an ActivitySession, then calls a method on SFB2
3. SFB2 accesses the UserActivitySession interface, begins an ActivitySession, calls a method on SFB2
4. SFB2 gets a connection (setAutoCommit false) then uses JDBC to update a single-phase datasource.
5. SLB1 then optionally calls a separate method on SFB2 to finish the work either committing or rolling-back the RMLT.
6. SLB1 then ends the ActivitySession with an EndModeCheckpoint.

This demonstrates that the ActivitySession completion direction is unconnected to the direction of the RMLTs, although their containment is bound to the ActivitySession, and the use of the container using the unresolved action when the RMLT is not completed. It also shows a bean-managed ActivitySessions bean using the UserActivitySession interface. The sample checks for correct results and reports them back to the client.

---

## ActivitySession service: Resources for learning

Use the links in this topic to find relevant supplemental information about ActivitySessions. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

## Chapter 26. Using naming

Naming is used by clients of WebSphere Application Server applications most commonly to obtain references to objects related to those applications, such as Enterprise JavaBeans (EJB) homes. The following steps outline the context of Naming in the overall application development and deployment process. Steps for this task follow:

1. Develop your application using either JNDI or CosNaming (CORBA) interfaces.  
Use these interfaces to look up server application objects that are bound into the name space and obtain references to them. Most Java developers use the JNDI interface. However, the CORBA CosNaming interface is also available for performing Naming operations on WebSphere Application Server name servers or other CosNaming name servers.
2. Assemble your application using the Assembly Toolkit. Application assembly is a packaging and configuration step that is a prerequisite to application deployment. If the application you are assembling is a client to an application running in another process, you should qualify the `jndiName` values in the deployment descriptors for the objects related to the other application. Otherwise, you may need to override the names with qualified names during application deployment. If the objects have fixed qualified names configured for them, you should use them so that the `jndiName` values do not depend on the other application's location within the topology of the cell.
3. Deploy your application  
Put your assembled application onto the application server. If the application you are assembling is a client to an application running in another server process, be sure to qualify the `jndiName` values for the other application's server objects if they are not already qualified.  
For more information on qualified names, see "Lookup names support in deployment descriptors and thin clients."
4. Configure name space bindings. This step is necessary in these cases:
  - Your deployed application is to be accessed by legacy client applications running on previous versions of WebSphere Application Server. In this case, you must configure additional name bindings for application objects relative to the default initial context for legacy clients. (Version 5 clients have a different initial context from legacy clients.)
  - The application requires qualified name bindings for such reasons as:
    - It will be accessed by J2EE client applications or server applications running in another server process.
    - It will be accessed by thin client applications.In this case, you can configure name bindings as additional bindings for application objects. The qualified names for the configured bindings are *fixed*, meaning they do not contain elements of the cell topology that can change if the application is moved to another server. Objects as bound into the name space by the system can always be qualified with a topology-based name. You must explicitly configure a name binding to use as a fixed qualified name.  
For more information on qualified names, see "Lookup names support in deployment descriptors and thin clients." For more information on configured name bindings, see "Configured name bindings."
5. Troubleshoot any problems that develop.  
If a Naming operation is failing and you need to verify whether certain name bindings exist, use the `dumpNameSpace` tool to generate a dump of the name space.

---

### Naming

Naming is used by clients of WebSphere Application Server applications to obtain references to objects related to those applications, such as Enterprise JavaBeans (EJB) homes.

These objects are bound into a mostly hierarchical structure, referred to as a *name space*. In this structure, all non-leaf objects are called *contexts*. Leaf objects can be contexts and other types of objects.

Naming operations, such as lookups and binds, are performed on contexts. All naming operations begin with obtaining an *initial context*. You can view the initial context as a starting point in the name space.

The name space structure consists of a set of *name bindings*, each consisting of a name relative to a specific context and the object bound with that name. For example, the name `myApp/myEJB` consists of one non-leaf binding with the name `myApp`, which is a context. The name also includes one leaf binding with the name `myEJB`, relative to `myApp`. The object bound with the name `myEJB` in this example happens to be an EJB home reference. The whole name `myApp/myEJB` is relative to the initial context, which you can view as a starting place when performing naming operations.

You can access and manipulate the name space through a *name server*. Users of a name server are referred to as *naming clients*. Naming clients typically use the Java Naming and Directory Interface (JNDI) to perform naming operations. Naming clients can also use the Common Object Request Broker Architecture (CORBA) CosNaming interface.

Typically, objects bound to the name space are resources and objects associated with installed applications. These objects are bound by the system, and client applications perform lookup operations to obtain references to them. Occasionally, server and client applications bind objects to the name space. An application can bind objects to transient or persistent partitions, depending on requirements.

In J2EE environments, some JNDI operations are performed with `java:` URL names. Names bound under these names are bound to a completely different name space which is local to the calling process. However, some lookups on the `java:` name space may trigger indirect lookups to the name server.

---

## Version 5 features for name space support

The following are features of the WebSphere Application Server new to naming implementation as of Version 5:

- **Name space is distributed.**

For additional scalability, the name space for a cell is distributed among various servers. Every server has a name server. In previous releases, there was only one name server for an entire administrative domain.

In WebSphere Application Server versions prior to V5, all servers shared the same default initial context, and everything was bound relative to that same initial context. In WebSphere Application Server V5, the default initial context for a server is its server root. System artifacts, such as EJB homes and resources, are bound to the server root of the server with which they are associated.

- **Transient and persistent partitions.**

The name space is partitioned into transient areas and persistent areas. Server roots are transient. System-bound artifacts such as EJB homes and resources are bound under server roots. There is a cell persistent root, which you can use for cell-scoped persistent bindings, and a node persistent root, which you can use to bind objects with a node scope.

- **System name space structure.**

The name space for the entire cell is federated among all servers in the cell. Every server process contains a name server. All name servers provide the same logical view of the cell name space. The various server roots and persistent partitions of the name space are interconnected by means of a system name space. You can use the system name space structure to traverse to any context in the cell name space.

- **Configured bindings.**

You can use the configuration graphical interface and script interfaces to configure bindings in various root contexts within the name space. These bindings are read-only and are bound by the system at server startup.

- **Support for CORBA Interoperable Naming Service (INS) object URLs.**

WebSphere Application Server V5 contains support for Common Object Request Broker Architecture (CORBA) object URLs (corbaloc and corbname) as Java Naming and Directory Interface (JNDI) provider URLs and lookup names.

## Name space logical view

The name space for the entire cell is federated among all servers in the cell. Every server process contains a name server. All name servers provide the same logical view of the cell name space. The various server roots and persistent partitions of the name space are interconnected by a system name space. You can use the system name space structure to traverse to any context in a the cell's name space. A logical view of the name space is shown in the following diagram.

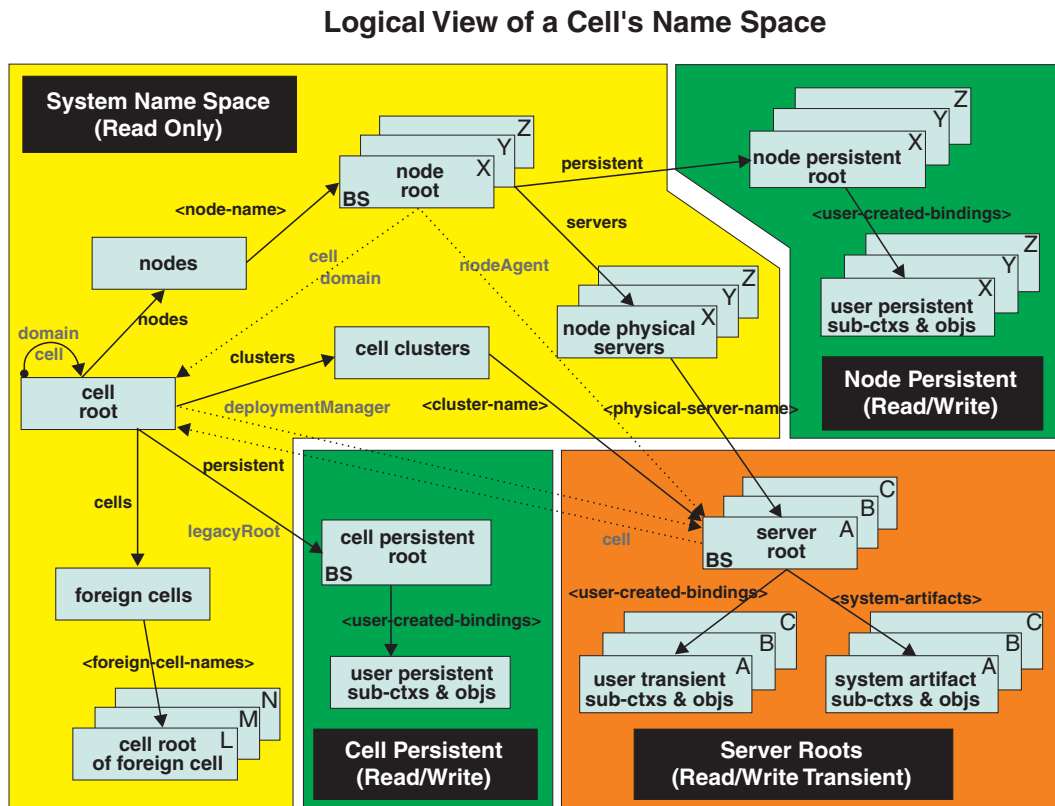

Figure 34. Name Space Logical View

The bindings in the preceding diagram appear with solid arrows, labeled in bold, and dashed arrows, labeled in gray. Solid arrows represent *primary bindings*. A primary binding is formed when the associated subcontext is created. Dashed arrows show *linked bindings*. A linked binding is formed when an existing context is bound under an additional name. Linked bindings are added for convenience or interoperability with previous WebSphere Application Server versions.

A cell name space is composed of contexts which reside in servers throughout the cell. All name servers in the cell provide the same logical view of the cell name space. A name server constructs this view at startup by reading configuration information. Each name server has its own local in-memory copy of the name space and does not require another running server to function. There are, however, a few exceptions. Server roots for other servers are not replicated among all the servers. The respective server for a server root must be running to access that server root context.

In WebSphere Application Server Network Deployment cells, the cell and node persistent areas can be read even if the deployment manager and respective node agent are not running. However, the

deployment manager must be running to update the cell persistent segment, and a node agent must be running to update its respective node persistent segment.

## **Name space partitions**

There are four major partitions in a cell name space:

- System name space partition
- Server roots partition
- Cell persistent partition
- Node persistent partition

### **System name space partition**

The system name space contains a structure of contexts based on the cell topology. The system structure supports traversal to all parts of a cell name space and to the cell root of other cells, which are configured as foreign cells. The root of this structure is the cell root. In addition to the cell root, the system structure contains a node root for each node in the cell. You can access other contexts of interest specific to a node from the node root, such as the node persistent root and server roots for servers configured in that node.

All contexts in the system name space are read-only. You cannot add, update, or remove any bindings.

### **Server roots partition**

Each server in a cell has a server root context. A server root is specific to a particular server. You can view the server roots for all servers in a cell as being in a transient read/write partition of the cell name space. System artifacts, such as EJB homes for server applications and resources, are bound under the server root context of the associated server. A server application can also add bindings under its server root. These bindings are transient. Therefore, the server application creates all required bindings at application startup, so they exist anytime the application is running.

A server cluster is composed of many servers that are logically equivalent. Each member of the cluster has its own server root. These server roots are not replicated across the cluster. In other words, adding a binding to the server root of one member does not propagate it to the server roots of the other cluster members. To maintain the same view across the cluster, you should create all user bindings under the server root by the server application at application startup so that the bindings are present under the server root of each cluster member. Because of Workload Management (WLM) behavior, a JNDI client outside a cluster has no control over which cluster member's server root context becomes the target of the JNDI operation. Therefore, you should execute bind operations to the server root of a cluster member from within that cluster member process only.

Distributing application objects among many server roots is a departure from previous WebSphere Application Server releases, where all system artifacts were bound under a single root. This change can affect the names that clients use to look up these objects.

Server-scoped bindings are relative to a server's server root.

### **Cell persistent partition**

The root context of the cell persistent partition is the cell persistent root. A binding created under the cell persistent root is saved as part of the cell configuration and continues to exist until it is explicitly removed. Applications that need to create additional persistent bindings of objects generally associated with the cell can bind these objects under the cell persistent root.

It is important to note that the cell persistent area is not designed for transient, rapidly changing bindings. The bindings are more static in nature, such as part of an application setup or configuration, and are not created at run time.

An important role of the cell persistent root is as the initial context for clients running in previous WebSphere Application Server versions. If you want to access an enterprise bean by WebSphere

Application Server v4.0.x and 3.5.x clients, you must ensure that a binding for it has been added to the cell persistent root. You can configure these additional bindings as cell-scoped bindings.

### Node persistent partition

The node persistent partition is similar to the cell partition except that each node has its own node persistent root. A binding created under a node persistent root is saved as part of that node configuration and continues to exist until it is explicitly removed.

Applications that need to create additional persistent bindings of objects associated with a specific node can bind those objects under that particular node's node persistent root. As with the cell persistent area, it is important to note that the node persistent area is not designed for transient, rapidly changing bindings. These bindings are more static in nature, such as part of an application setup or configuration, and are not created at run time.

Unlike the cell persistent root, the node persistent root plays no special role in interoperability with WebSphere Application Server clients of previous releases. Node-scoped bindings are relative to a node's node persistent root.

---

## Initial context support

All naming operations begin with obtaining an initial context. You can view the initial context as a starting point in the name space. Use the initial context to perform naming operations, such as looking up and binding objects in the name space.

### Initial contexts registered with the ORB as initial references

The server root, cell persistent root, cell root, and node root are registered with the name server's ORB and can be used as an initial context. An initial context is used by CORBA and enterprise bean applications as a starting point for name space lookups. The keys for these roots as recognized by the ORB are shown in the following table:

Root Context	Initial Reference Key
Server Root	NameServiceServerRoot
Cell Persistent Root	NameServiceCellPersistentRoot
Cell Root	NameServiceCellRoot, NameService
Node Root	NameServiceNodeRoot

A server root initial context is the server root context for the specific server you are accessing. Similarly, a node root initial context is the node root for the server being accessed.

You can use the previously mentioned keys in CORBA INS object URLs (corbaloc and corbaname) and as an argument to an ORB `resolve_initial_references` call. For examples, see CORBA and JNDI programming examples, which show how to get an initial context.

### Default initial contexts

The default initial context depends on the type of client. Different categories of clients and the corresponding default initial context follow.

- **WebSphere Application Server V5 JNDI interface implementation**

The JNDI interface is used by EJB applications to perform name space lookups. WebSphere Application Server clients by default use the WebSphere Application Server CosNaming JNDI plug-in implementation. The default initial context for clients of this type is the server root of the server specified by the provider URL. For more details, refer to the JNDI programming examples on getting initial contexts.

- **WebSphere Application Server JNDI interface implementation prior to V5**

WebSphere Application Server clients running in releases prior to WebSphere Application Server V5 by default use WebSphere Application Server's v4.0 CosNaming JNDI plug-in implementation. The default initial context for clients of this type is the cell persistent root, also known as the *legacy root*.

- **Other JNDI implementation**

Some applications can perform name space lookups with a non-WebSphere Application Server CosNaming JNDI plug-in implementation. Assuming the key **NamingContext** is used to obtain the initial context, the default initial context for clients of this type is the cell root.

- **CORBA**

The standard CORBA client obtains an initial `org.omg.CosNaming.NamingContext` reference with the key **NamingContext**. The initial context in this case is the cell root.

---

## Lookup names support in deployment descriptors and thin clients

Server objects, such as EJB homes, are bound relative to the server root context for the server in which the application is installed. Other objects, such as resources, can also be bound to a specific server root. The names used to look up these objects must be qualified so as to select the correct server root. This is a departure from previous versions of WebSphere Application Server, where these objects were all bound under a single root context. This section discusses what relative and qualified names are, when they can be used, and how you can construct them.

### Relative names

All names are relative to a context. Therefore, a name that can be resolved from one context in the name space cannot necessarily be resolved from another context in the name space. This point is significant because the system binds objects with names relative to the server root context of the server in which the application is installed. Each server has its own server root context. The initial JNDI context is by default the server root context for the server identified by the provider URL used to obtain the initial context. (Typically, the URL consists of a host and port.) For applications running in a server process, the default initial JNDI context is the server root for that server. A relative name will resolve successfully when the initial context is obtained from the server which contains the target object, but it will not resolve successfully from an initial context obtained from another server.

If all clients of a server application run in the same server process as the application, all objects associated with that application are bound to the same initial context as the clients' initial context. In this case, only names relative to the server's server root context are required to access these server objects. Frequently, however, a server application has clients that run outside the application's server process. The initial context for these clients can be different from the server application's initial context, and lookups on the relative names for server objects may fail. These clients need to use the qualified name for the server objects. This point must be considered when setting up the `jndiName` values in a J2EE client application deployment descriptors and when constructing lookup names in thin clients. Qualified names resolve successfully from any initial context in the cell.

### Qualified names

All names are relative to a context. Here, the term *qualified name* refers to names that can be resolved from any initial context in a cell. This action is accomplished by using names that navigate to the same context, the cell root. The rest of the qualified name is then relative to the cell root and uniquely identifies an object throughout the cell. All initial contexts in a server (that is, all naming contexts in a server registered with the ORB as an initial reference) contain a binding with the name **cell**, which links back to the cell root context. All qualified names begin with the string **cell/** to navigate from the current initial context back to the cell root context.

A qualified name for an object is the same throughout the cell. The name can be topology-based, or some fixed name bound under the cell persistent root. Topology-based names, described in more detail below, navigate through the system name space to reach the target object. A fixed name bound under the cell

persistent root has the same qualified name throughout the cell and is independent of the topology. Creating a fixed name under the cell persistent root for a server application object requires an extra step when the server application is installed, but this step eliminates impacts to clients when the application is moved to a different location in the cell topology. The process for creating a fixed name is described later in this section.

Generally speaking, you **must** use qualified names for EJB `jndiName` values in a J2EE client application deployment descriptors and for EJB lookup names in thin clients. The only exception is when the initial context is obtained from the server in which the target object resides. For example, a session bean which is a client to an entity bean can use a relative name if the two beans run in the same server. If the session bean and entity beans run in different servers, the `jndiName` for the entity bean must be qualified in the session bean's deployment descriptors. The same requirement may be true for resources as well, depending on the scope of the resource.

- **Topology-based names**

The system name space partition in a cell's name space reflects the cell's topology. This structure can be navigated to reach any object bound into the cell's name space. Topology-based qualified names include elements from the topology which reflect the object's location within the cell. For a system-bound object, such as an EJB home, the form for a topology-based qualified name depends on whether the object is bound to a single server or cluster. Both forms are described below.

**Single Server**

An object bound in a single server has a topology-based qualified name of the following form:

```
cell/nodes/nodeName/servers/serverName/relativeJndiName
```

where *nodeName* and *serverName* are the node name and server name for the server where the object is bound, and *relativeJndiName* is the unqualified name of the object; that is, the object's name relative to its server's server root context.

**Server Cluster**

An object bound in a server cluster has a topology-based qualified name of the following form:

```
cell/clusters/clusterName/relativeJndiName
```

where *clusterName* is the name of the server cluster where the object is bound, and *relativeJndiName* is the unqualified name of the object; that is, the object's name relative to a cluster member's server root context.

- **Fixed names**

It is possible to create a fixed name for a server object so that the qualified name is independent of the cell topology. This quality is desirable when clients of the application run in other server processes or as pure clients. Fixed names have the advantage of not changing if the object is moved to another server. The `jndiName` values in deployment descriptors for a J2EE client application can reference the qualified fixed name for a server object regardless of the cell topology on which the client or server application is being installed.

Defining a cell-wide fixed name for a server application object requires an extra step after the server application is installed. That is, a binding for the object must be created under the cell persistent root. A fixed name bound under the cell persistent root can be any name, but all names under the cell persistent root must be unique within the cell because the cell persistent root is global to the entire cell.

A qualified fixed name has the form:

```
cell/persistent/fixedName
```

where *fixedName* is an arbitrary fixed name.

The binding can be created programmatically (for example, using JNDI). However, it is probably more convenient to configure a cell-scoped binding for the server object.

You must keep the programmatic or configured binding up-to-date. Configured EJB bindings are based on the location of the enterprise bean within the cell topology, and moving the EJB application to another single server or to a server cluster, for example, requires the configured binding to be updated. Similar changes affect an EJB home reference programmatically bound so that the fixed name would

need to be rebound with a current reference. However, for J2EE clients, the `jndiName` value for the object, and for thin clients, the lookup name for the object, remains the same. In other words, clients that access objects by fixed names are not affected by changes to the configuration of server applications they access.

---

## JNDI support in WebSphere Application Server

IBM WebSphere Application Server includes a name server to provide shared access to Java components, and an implementation of the `javax.naming` JNDI package which supports user access to the WebSphere Application Server name server through the JNDI naming interface.

WebSphere Application Server does **not** provide implementations for:

- `javax.naming.directory` or
- `javax.naming.ldap` packages

Also, WebSphere Application Server does **not** support interfaces defined in the `javax.naming.event` package.

However, to provide access to LDAP servers, the development kit shipped with WebSphere Application Server supports Sun's implementation of:

- `javax.naming.ldap` and
- `com.sun.jndi.ldap.LdapCtxFactory`

WebSphere Application Server's JNDI implementation is based on version 1.2 of the JNDI interface, and was tested with Version 1.2.1 of Sun's JNDI Service Provider Interface (SPI).

The default behavior of this JNDI implementation is adequate for most users. However, users with specific requirements can control certain aspects of JNDI behavior.

---

## Developing applications that use JNDI

References to EJB homes and other artifacts such as data sources are bound to the WebSphere name space. These objects can be obtained through the JNDI interface. Before you can perform any JNDI operations, you need to get an initial context. You can use the initial context to look up objects bound to the WebSphere name space.

These examples describe how to get an initial context and how to perform lookup operations.

- Getting the default initial context
- Getting an initial context by setting the provider URL property
- Setting the provider URL property to select a different root context as the initial context
- Looking up an EJB home with JNDI
- Looking up a JavaMail session with JNDI

In these examples, the default behavior of features specific to WebSphere's JNDI Context implementation is used.

WebSphere Application Server's JNDI context implementation includes special features. JNDI caching enhances performance of repeated lookup operations on the same objects. Name syntax options offer a choice of a name syntaxes, one optimized for typical JNDI clients, and one optimized for interoperability with CosNaming applications. Most of the time, the default behavior of these features is the preferred behavior. However, sometimes you should modify the behavior for specific situations.

JNDI caching and name syntax options are associated with a `javax.naming.InitialContext` instance. To select options for these features, set properties that are recognized by the WebSphere Application Server's

initial context factory. To set JNDI caching or name syntax properties which will be visible to WebSphere Application Server's initial context factory, follow the following steps.

## 1. Optional: Configure JNDI caches

JNDI caching can greatly increase performance of JNDI lookup operations. By default, JNDI caching is enabled. In most situations, this default is the desired behavior. However, in specific situations, use the other JNDI cache options.

Objects are cached locally as they are looked up. Subsequent lookups on cached objects are resolved locally. However, cache contents can become stale. This situation is not usually a problem, since most objects you look up do not change frequently. If you need to look up objects which change relatively frequently, change your JNDI cache options.

JNDI clients can use several properties to control cache behavior.

You can set properties:

- From the command line by entering the actual string value. For example:

```
java -Dcom.ibm.websphere.naming.jndicache.maxentrylife=1440
```

- In a `jndi.properties` file by creating a file named `jndi.properties` as a text file with the desired properties settings. For example:

```
...
com.ibm.websphere.naming.jndicache.cacheobject=none
...
```

Include the file as the beginning of the classpath, so that the class loader loads your copy of `jndi.properties` before any other copies.

- Within a Java program by using the **PROPS.JNDI\_CACHE\*** Java constants, defined in the ***com.ibm.websphere.naming.PROPS*** file. The constant definitions follow:

```
public static final String JNDI_CACHE_OBJECT =
 "com.ibm.websphere.naming.jndicache.cacheobject";
public static final String JNDI_CACHE_OBJECT_NONE = "none";
public static final String JNDI_CACHE_OBJECT_POPULATED = "populated";
public static final String JNDI_CACHE_OBJECT_CLEARED = "cleared";
public static final String JNDI_CACHE_OBJECT_DEFAULT =
 JNDI_CACHE_OBJECT_POPULATED;
```

```
public static final String JNDI_CACHE_NAME =
 "com.ibm.websphere.naming.jndicache.cachename";
public static final String JNDI_CACHE_NAME_DEFAULT = "providerURL";
```

```
public static final String JNDI_CACHE_MAX_LIFE =
 "com.ibm.websphere.naming.jndicache.maxcachelife";
public static final int JNDI_CACHE_MAX_LIFE_DEFAULT = 0;
```

```
public static final String JNDI_CACHE_MAX_ENTRY_LIFE =
 "com.ibm.websphere.naming.jndicache.maxentrylife";
public static final int JNDI_CACHE_MAX_ENTRY_LIFE_DEFAULT = 0;
```

To use the previous properties in a Java program, add the property setting to a hashtable and pass it to the `InitialContext` constructor as follows:

```
java.util.Hashtable env = new java.util.Hashtable();
...

// Disable caching
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_NONE); ...
javax.naming.Context initialContext = new javax.naming.InitialContext(env);
```

## 2. Optional: Specify the name syntax

Most WebSphere applications use JNDI to look up EJB objects and do not need to look up objects bound by CORBA applications. Therefore, the default name syntax used for JNDI names is the most convenient. If your application needs to look up objects bound by CORBA applications, you may need to change your name syntax so that all CORBA CosNaming names can be represented.

JNDI clients can set the name syntax by setting a property. The property setting is applied by the initial context factory when you instantiate a new `java.naming.InitialContext` object. Names specified in JNDI operations on the initial context are parsed according to the specified name syntax.

You can set the property:

- From the command line by entering the actual string value. For example:

```
java -Dcom.ibm.websphere.naming.name.syntax=ins
```

- In a `jndi.properties` file by creating a file named `jndi.properties` as a text file with the desired properties settings. For example:

```
...
com.ibm.websphere.naming.name.syntax=ins
...
```

Include the file as the beginning of the classpath, so that the class loader loads your copy of `jndi.properties` before any other copies.

- Within a Java program by using the `PROPS.NAME_SYNTAX*` Java constants, defined in the `com.ibm.websphere.naming.PROPS` file. The constant definitions follow:

```
public static final String NAME_SYNTAX =
 "com.ibm.websphere.naming.name.syntax";
public static final String NAME_SYNTAX_JNDI = "jndi";
public static final String NAME_SYNTAX_INS = "ins";
```

To use the previous properties in a Java program, add the property setting to a hashtable and pass it to the `InitialContext` constructor as follows:

```
java.util.Hashtable env = new java.util.Hashtable();
...
env.put(PROPS.NAME_SYNTAX, PROPS.NAME_SYNTAX_INS); // Set name syntax to INS
...
javax.naming.Context initialContext = new javax.naming.InitialContext(env);
```

## Example: Getting the default initial context

This example below gets the default initial context. That is, no provider URL is passed to the `javax.naming.InitialContext` constructor. The following section explains the process of determining the address of the bootstrap server to use to obtain the initial context.

```
...
import javax.naming.Context;
import javax.naming.InitialContext;
...
Context initialContext = new InitialContext();
...
```

The default initial context returned depends the runtime environment of the JNDI client. The initial context returned in the various environments are listed below:

- Thin client: The server root context of the server running on the local host at port 2809.
- Pure client:
  - The context specified by the `java.naming.provider.url` property passed to `launchClient` command with the `-CCD` command line parameter. The context usually will be the server root context of the server at the address specified in the URL, although it is possible to construct a `corbaname` or `corbaloc` URL which resolves to some other context.
  - If no provider URL was specified, the server root context of the server running on the host and port specified by the `-CCBootstrapHost` `-CCBootstrapPort` command line parameters. The default host is the local host, and the default port is 2809.
- Server process: The server root context for that process.

Even though no provider URL is explicitly specified in the above example, the `InitialContext` may find a provider URL defined in other places that it searches for property settings.

Users of properties which affect ORB initialization should read the rest of this section for a deeper understanding of exactly how initial contexts are obtained, which has changed from previous releases.

### **Determining which server is used to obtain the initial context**

WebSphere Application Server name servers are CORBA CosNaming name servers, and WebSphere Application Server provides a CosNaming JNDI plug-in implementation for JNDI clients to perform naming operations on WebSphere Application Server name spaces. The WebSphere Application Server CosNaming plug-in implementation is selected through a JNDI property that is passed to the InitialContext constructor. This property is `java.naming.factory.initial`, and it specifies the initial context factory implementation to use to obtain an initial context. The factory returns a `javax.naming.Context` instance, which is part of its implementation.

The WebSphere Application Server initial context factory, `com.ibm.websphere.naming.WsnInitialContextFactory`, is typically used by WebSphere Application Server applications to perform JNDI operations. The WebSphere Application Server run-time environment is set up to use this WebSphere Application Server initial context factory if one is not specified explicitly by the JNDI client. When the initial context factory is invoked, an *initial context* is obtained. The following paragraphs explain how the WebSphere Application Server initial context factory obtains the initial context in client and server environments.

- **Understanding the registration of initial references in server processes**

Every WebSphere Application Server has an ORB used to receive and dispatch invocations on objects running in that server. Services running in the server process can register initial references with the ORB. Each initial reference is registered under a key, which is a string value. An initial reference can be any CORBA object. WebSphere Application Server name servers register several initial contexts as initial references under predefined keys. Each name server initial reference is an instance of the interface `org.omg.CosNaming.NamingContext`.

- **Obtaining initial references in pure client processes**

Pure JNDI clients, that is, JNDI clients which are not running in a WebSphere Application Server process, also have an ORB instance. This client ORB instance can be passed to the InitialContext constructor, but typically the initial context factory creates and initializes the client ORB instance transparently. A client ORB can be initialized with initial references, but the initial references most likely resolve to objects running in some server. The initial context factory does not define any default initial references when it initializes an ORB. If the `resolve_initial_references` method is invoked on the client ORB when no initial references have been configured, the method invocation fails. This condition is typical for pure client processes. To obtain an initial NamingContext reference, the initial context factory must invoke `string_to_object` with an IIOP type CORBA object URL, such as `corbaloc:iiop:myhost:2809`. The URL specifies the address of the server from which to obtain the initial context. The host and port information is extracted from the provider URL passed to the InitialContext constructor. If no provider URL is defined, the WebSphere Application Server initial context factory uses the default provider URL of `corbaloc:iiop:localhost:2809`. The `string_to_object` ORB method resolves the URL and communicates with the target server ORB to obtain the initial reference.

- **Obtaining initial references in server processes**

If the JNDI client is running in a WebSphere Application Server process, the initial context factory obtains a reference to the server ORB instance if the JNDI client does not provide an ORB instance. Typically, JNDI clients running in server processes use the server ORB instance; that is, they do not pass an ORB instance to the InitialContext constructor. The name server which is running in the server process sets a provider URL as a `java.lang.System` property to serve as the default provider URL for all JNDI clients in the process. This default provider URL is `corbaloc:rir:/NameServiceServerRoot`. This URL resolves to the server root context for that server. (The URL is equivalent to invoking `resolve_initial_references` on the ORB with a key of `NameServiceServerRoot`. The name server registers the server root context as an initial reference under that key.)

- **Understanding the legacy ORB protocol**

Previous versions of WebSphere Application Server used a different ORB implementation, which used a legacy protocol in contrast with the Interoperable Name Service (INS) protocol now used. This change has affected the implementation of the WebSphere Application Server initial context factory. **Certain types of pure clients can experience different behavior when getting initial JNDI contexts as compared to previous releases of WebSphere Application Server.** This behavior is discussed in more detail below.

The following ORB properties are used with the legacy ORB protocol for ORB initialization and are now deprecated:

- com.ibm.CORBA.BootstrapHost
- com.ibm.CORBA.BootstrapPort

The new INS ORB is different in a major respect, in that it exhibits no default behavior if no initial references are defined. In the legacy ORB, the bootstrap host and port values defaulted to localhost and 900. All initial references were obtained from the server running on the bootstrap host and port. So, if the ORB user provided no bootstrap host and port, all initial references are resolved from the server running on the local host at port 900. The INS ORB has no concept of bootstrap host or bootstrap port. All initial references are defined independently. That is, different initial references could resolve to different servers. If ORB.resolve\_initial\_references is invoked with a key such that the ORB is not initialized with an initial reference having that key, the call fails.

In previous releases of WebSphere Application Server, the initial context factory invoked resolve\_initial\_references on the ORB in the absence of any provider URL. This action succeeded if a name server at the default bootstrap host and port was running. Today, with the INS ORB, this would fail. (Actually, the ORB would fall back to the legacy protocol during the deprecation period, but when the legacy protocol is no longer supported, the operation would fail.) The initial context factory now uses a default provider URL of corbaloc:iiop:localhost:2809, and invokes string\_to\_object with the provider URL. This operation preserves the behavior that pure clients in previous releases experienced when they set no ORB bootstrap properties or provider URL. **However, this different initial context factory implementation changes the behavior experienced by certain legacy pure clients, which do not specify a provider URL:**

- Clients which set the ORB bootstrap properties listed above when getting an initial context.
- Clients which supply their own ORB instance to the InitialContext constructor.

There are two ways to circumvent this change of behavior:

- Always specify an IIOP type provider URL. This approach does not depend on the bootstrap host and port properties and continues to work when support for the bootstrap host and port properties is removed. For example, you can express bootstrap host and port property values of myHost and 2809, respectively, as corbaloc:iiop:myHost:2809.
- Use an rir type provider URL:
  - Specify corbaloc:rir:/NameServiceServerRoot if the ORB is initialized to use a WebSphere Application Server 5 server as the bootstrap server.
  - Specify corbaname:rir:/NameService#domain/legacyRoot if the ORB is initialized to use a WebSphere Application Server 4.0.x server as the bootstrap server.
  - Specify corbaloc:rir:/NameService if the ORB is initialized to use a server other than a WebSphere Application Server 5 or 4.0.x server as the bootstrap server.

URLs of this type are equivalent to invoking resolve\_initial\_references on the ORB with the specified key. If the bootstrap host and port properties are being used to initialize the ORB, this approach will not work when the bootstrap and host properties are no longer supported.

- **The InitialContext constructor search order for JNDI properties**

If the code snippet shown at the beginning of this section is executed by an application, the bootstrap server depends on the value of the property, java.naming.provider.url. If the property is not set (in server processes the default value is set as a system property), the default host of localhost and default port of 2809 are used as the address of the server from which to obtain the initial context. The JNDI specification describes where the InitialContext constructor looks for java.naming.provider.url property settings, but briefly, the property is picked up from the following places in the order shown:

1. The InitialContext constructor. This does not apply to the above example since the example uses the empty InitialContext constructor.

2. System environment. You can add JNDI properties to the system environment as an option on the Java command invocation and by program code. The recommended way to set the provider URL in the system environment is as an option supplied to the Java command invocation. Setting the provider URL in this manner is not temporal, so that getting a default initial context will always yield the same result. It is generally recommended that program code not set the provider URL property in the system environment because as a side-effect, this could adversely affect other, possibly unrelated, code running elsewhere in the same process.
3. `jndi.properties` file. There may be many `jndi.properties` files that are within the scope of the class loader in effect. All `jndi.properties` files are used for setting JNDI properties, but the provider URL setting is determined by the first `jndi.properties` file returned by the class loader.

## Example: Getting an initial context by setting the provider URL property

In general, JNDI clients should assume the correct environment is already configured so there is no need to explicitly set property values and pass them to the `InitialContext` constructor. However, a JNDI client may need to access a name space other than the one identified in its environment. In this case, it is necessary to explicitly set the `java.naming.provider.url` (provider URL) property used by the `InitialContext` constructor. A provider URL contains bootstrap server information that the initial context factory can use to obtain an initial context. Any property values passed in directly to the `InitialContext` constructor take precedence over settings of those same properties found elsewhere in the environment.

You can use two different provider URL forms with WebSphere Application Server's initial context factory:

- A CORBA object URL (new for J2EE 1.3)
- An IIOP URL

CORBA object URLs are more flexible than IIOP URLs and are the recommended URL format to use. CORBA object URLs are part of the OMG CosNaming Interoperable Naming Specification. A corbaname URL, for example, can include initial context and lookup name information and can be used as a lookup name without the need to explicitly obtain another initial context. The IIOP URLs are the legacy JNDI format, but are still supported by the WebSphere Application Server initial context factory.

The following examples illustrate the use of these URLs.

### Using a CORBA object URL

This example shows a CORBA object URL.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
 "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, "corbaloc:iiop:myhost.mycompany.com:2809");
Context initialContext = new InitialContext(env);
...
```

### Using a CORBA object URL with multiple name server addresses

CORBA object URLs can contain more than one bootstrap address. You can use this feature when attempting to obtain an initial context from a server cluster. You can specify the bootstrap addresses for all servers in the cluster in the URL. The operation succeeds if at least one of the servers is running, eliminating a single point of failure. There is no guarantee of any particular order in which the address list will be processed. For example, the second bootstrap address may be used to obtain the initial context even though the server at the first bootstrap address in the list is available.

Multiple-address provider URLs should only contain the bootstrap addresses of members of the same cluster. Otherwise, incorrect behavior may occur.

An example of a corbaloc URL with multiple addresses follows.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
 "com.ibm.websphere.naming.WsnInitialContextFactory");
// All of the servers in the provider URL below are members of
// the same cluster.
env.put(Context.PROVIDER_URL,
 "corbaloc:myhost1:9810,myhost1:9811,myhost2:9810");
Context initialContext = new InitialContext(env);
...
```

## Using a CORBA object URL from a non-WebSphere Application Server JNDI implementation

Initial context factories for CosNaming JNDI plug-in implementations other than the WebSphere Application Server initial context factory most likely obtain an initial context using the object key, `NameService`. When you use such a context factory to obtain an initial context from a WebSphere Application Server name server, the initial context is the cell root context. Since system artifacts such as EJB homes associated with a server are bound under the server's server root context, names used in JNDI operations must be qualified. If you want to use relative names, ensure your initial context is the server root context under which the target object is bound. In order to make the server root context the initial context, specify a corbaloc provider URL with an object key of `NameServiceServerRoot`.

This example shows a CORBA object type URL from a non-WebSphere Application Server JNDI implementation. This example assumes full CORBA object URL support by the non-WebSphere Application Server JNDI implementation. The object key of `NameServiceServerRoot` is specified so that the initial context will be the specified server's server root context.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
 "com.somecompany.naming.TheirInitialContextFactory");
env.put(Context.PROVIDER_URL,
 "corbaname:iiop:myhost.mycompany.com:9810/NameServiceServerRoot");
Context initialContext = new InitialContext(env);
...
```

If qualified names are used, you can use the default key of `NameService`.

## Using an IIOP URL

The IIOP type of URL is a legacy format which is not as flexible as CORBA object URLs. However, URLs of this type are still supported. The following example shows an IIOP type URL as the provider URL.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
 "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, "iiop://myhost.mycompany.com:2809");
Context initialContext = new InitialContext(env);
...
```

## Example: Setting the provider URL property to select a different root context as the initial context

Each server contains its own server root context, and, when bootstrapping to a server, the server root is the default initial JNDI context. Most of the time, this default is the desired initial context, since system artifacts such as EJB homes are bound there. However, other root contexts exist, which can contain bindings of interest. It is possible to specify a provider URL to select other root contexts.

### Selecting the initial root context with a CORBA object URL

There are several object keys registered with the bootstrap server that you can use to select the root context for the initial context. To select a particular root context with a CORBA object URL object key, set the object key to the corresponding value. The default object key is NameService. Using JNDI yields the server root context. A table that lists the different root contexts and their corresponding object key follows:

Root Context	CORBA Object URL Object Key
Server Root	NameServiceServerRoot
Cell Persistent Root	NameServiceCellPersistentRoot
Cell Root	NameServiceCellRoot
Node Root	NameServiceNodeRoot

The following example shows the use of a corbaloc URL with the object key set to select the cell persistent root context as the initial context.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
 "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL,
 "corbaloc:iiop:myhost.mycompany.com:2809/NameServiceCellPersistentRoot");
Context initialContext = new InitialContext(env);
...
```

### Selecting the initial root context with the name space root property

You can also select the initial root context by passing a name space root property setting to the InitialContext constructor. Generally, the object key setting described above is sufficient. Sometimes a property setting is preferable. For example, you can set the root context property on the Java invocation to make which server root is being used as the initial context transparent to the application. The default server root property setting is defaultroot, which yields the server root context.

Root Context	Name Space Root Property Value
Server Root	bootstrapserverroot
Cell Persistent Root	cellpersistentroot
Cell Root	cellroot
Node Root	bootstrapnoderoot

The initial context factory ignores the name space root property if the provider URL contains an object key other than NameService.

The following example shows use of the name space root property to select the cell persistent root context as the initial context. Note that available constants are used instead of hard-coding the property name and value.

```

...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
import com.ibm.websphere.naming.PROPS;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
 "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, "corbaloc:iiop:myhost.mycompany.com:2809");
env.put(PROPS.NAME_SPACE_ROOT, PROPS.NAME_SPACE_ROOT_CELL_PERSISTENT);
Context initialContext = new InitialContext(env);
...

```

## Example: Looking up an EJB home with JNDI

Most applications which use JNDI run in a container. Some do not. The name used to look up an object depends on whether or not the application is running in a container. The examples below show lookups from each type of application. Sometimes it is more convenient for an application to use a corbaname URL as the lookup name. Container-based JNDI clients and thin Java clients can use a corbaname URL. An example of a lookup with a corbaname URL is also included in this section.

### JNDI lookup from an application running in a container

Applications that run in a container can use `java:` lookup names. Lookup names of this form provide a level of indirection such that the lookup name used to look up an object is not dependent on the object's name as it is bound in the name server's name space. The deployment descriptors for the application provide the mapping from the `java:` name and the name server lookup name. The container sets up the `java:` name space based on the deployment descriptor information so that the `java:` name is correctly mapped to the corresponding object.

The following example shows a lookup of an EJB home. The actual home lookup name is determined by the application's deployment descriptors.

```

// Get the initial context as shown in a previous example
...
// Look up the home interface using the JNDI name
try {
 java.lang.Object ejbHome =
 initialContext.lookup(
 "java:comp/env/com/mycompany/accounting/AccountEJB");
 accountHome = (AccountHome)javax.rmi.PortableRemoteObject.narrow(
 (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
catch (NamingException e) { // Error getting the home interface
 ...
}

```

### JNDI lookup from an application that does not run in a container

Applications that do not run in a container cannot use `java:` lookup names because it is the container which sets the `java:` name space up for the application. Instead, an application of this type must look the object up directly from the name server. Each application server contains a name server. System artifacts such as EJB homes are bound relative to the server root context in that name server. The various name servers are federated by means of a system name space structure. The recommended way to look up objects on different servers is to qualify the name so that the name resolves from any initial context in the cell. If a relative name is used, the initial context must be the same server root context as the one under which the object is bound. The form of the qualified name depends on whether the qualified name is a topology-based name or a fixed name. A topology based name depends on whether the object resides in a single server or a server cluster. Examples of each form of qualified name follow.

- **Topology-based qualified names**

Topology-based qualified names traverse through the system name space to the server root context context under which the target object is bound. A topology-based qualified name resolves from any initial context in the cell. The topology-based qualified name depends on whether the object resides on a single server or server cluster. Examples of each lookup follow.

### Single server

The following example shows a lookup of an EJB home that is running in the single server, MyServer, configured in the node, Node1.

```
// Get the initial context as shown in a previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
// Look up the home interface using the JNDI name
try {
 java.lang.Object ejbHome = initialContext.lookup(
 "cell/nodes/Node1/servers/MyServer/com/mycompany/accounting/AccountEJB");
 accountHome = (AccountHome)javadoc.rmi.PortableRemoteObject.narrow(
 (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
catch (NamingException e) { // Error getting the home interface
 ...
}
```

### Server cluster

The example below shows a lookup of an EJB home which is running in the cluster, MyCluster. The name can be resolved if any of the cluster members is running.

```
// Get the initial context as shown in a previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
// Look up the home interface using the JNDI name
try {
 java.lang.Object ejbHome = initialContext.lookup(
 "cell/clusters/MyCluster/com/mycompany/accounting/AccountEJB");
 accountHome = (AccountHome)javadoc.rmi.PortableRemoteObject.narrow(
 (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
catch (NamingException e) { // Error getting the home interface
 ...
}
```

- **Fixed qualified names**

If the target object has a cell-scoped fixed name defined for it, you can use its qualified form instead of the topology-based qualified name. Even though the topology-based name works, the fixed name does not change with the specific cell topology or with the movement of the target object to a different server. An example lookup with a qualified fixed name is shown below.

```
// Get the initial context as shown in a previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
// Look up the home interface using the JNDI name
try {
 java.lang.Object ejbHome = initialContext.lookup(
 "cell/persistent/com/mycompany/accounting/AccountEJB");
 accountHome = (AccountHome)javadoc.rmi.PortableRemoteObject.narrow(
 (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
catch (NamingException e) { // Error getting the home interface
 ...
}
```

## JNDI lookup with a corbaname URL

A corbaname can be useful at times as a lookup name. If, for example, the target object is not a member of the federated name space and cannot be located with a qualified name, a corbaname can be a convenient way to look up the object. A lookup with a corbaname URL follows.

```
// Get the initial context as shown in a previous example
...
// Look up the home interface using a corbaname URL
try {
 java.lang.Object ejbHome = initialContext.lookup(
 "corbaname:iiop:someHost:2809#com/mycompany/accounting/AccountEJB");
 accountHome = (AccountHome)javax.rmi.PortableRemoteObject.narrow(
 (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
catch (NamingException e) { // Error getting the home interface
 ...
}
```

## Example: Looking up a JavaMail session with JNDI

The example below shows a lookup of a JavaMail resource. The actual lookup name is determined by the application's deployment descriptors.

```
// Get the initial context as shown above
...
Session session =
 (Session) initialContext.lookup("java:comp/env/mail/MailSession");
```

## JNDI interoperability considerations

This section explains considerations to take into account when interoperating with previous releases of WebSphere Application Server and with non-WebSphere Application Server JNDI clients. Also, the way resources from MQSeries must be bound to the name space has changed and is described below.

### Interoperability with previous WebSphere Application Server Releases

- **EJB clients running on WebSphere Application Server V3.5 or V4.0 accessing EJB applications running on WebSphere Application Server V5**

Applications migrated from previous versions of WebSphere Application Server may still have clients still running in a previous release. The default initial JNDI context for EJB clients running on previous versions of WebSphere Application Server is the cell persistent root (legacy root). The home for an enterprise bean deployed in version 5 is bound to its server's server root context. In order for the EJB lookup name for down-level clients to remain unchanged, configure a binding for the EJB home under the cell persistent root.

**Note:** EJB clients running in version 3.5 must be running in version 3.5.5 or above, or in version 3.5.3 or 3.5.4 with e-fix PQ51387 installed.

- **EJB clients running on WebSphere Application Server V5 accessing EJB applications running on WebSphere Application Server V3.5 or V4.0 servers**

The default initial context for a WebSphere Application Server v3.5 or v4.0 server is the correct initial context. Simply look up the JNDI name under which the EJB home is bound.

**Note:** To enable WebSphere Application Server V5 clients to access version 3.5.x and 4.0.x servers, the down-level installations must have e-fix PQ60074 installed.

### EJB clients running in an environment other than WebSphere Application Server accessing EJB applications running on WebSphere Application Server V5 servers

When an EJB application running in WebSphere Application Server V5 is accessed by a non-WebSphere Application Server EJB client, the JNDI initial context factory is presumed to be a non-WebSphere

Application Server implementation. In this case, the default initial context will be the cell root. If the JNDI service provider being used supports CORBA object URLs, the corbaname format can be used to look up the EJB home. The construction of the stringified name depends on whether the object is installed on a single server or cluster, as shown below.

- **Single server**

```
initialContext.lookup(
 "corbaname:iiop:myHost:2809#cell/nodes/node1/servers/server1/myEJB");
```

According to the URL above, the bootstrap host and port are myHost and 2809, and the enterprise bean is installed in a server **server1** in node **node1** and bound in that server under the name **myEJB**.

- **Server cluster**

```
initialContext.lookup(
 "corbaname:iiop:myHost:2809#cell/clusters/myCluster/myEJB");
```

According to the URL above, the bootstrap host and port are **myHost** and **2809**, and the enterprise bean is installed in a server cluster named **myCluster** and bound in that cluster under the name **myEJB**.

The above lookup will work with any name server bootstrap host and port configured in the same cell.

The above lookup will also work if the bootstrap host and port belongs to a member of the cluster itself.

To avoid a single point of failure, the bootstrap server host and port for each cluster member could be listed in the URL as follows:

```
initialContext.lookup(
 "corbaname:iiop:host1:9810,host2:9810#cell/clusters/myCluster/myEJB");
```

The name prefix **cell/clusters/myCluster/** is not necessary if bootstrapping to the cluster itself, but it will work. The prefix is needed, however, when looking up enterprise beans in other clusters. Name bindings under the **clusters** context are implemented on the name server to resolve to the server root of a running cluster member during a lookup; thus avoiding a single point of failure.

- **Without CORBA object URL support**

If the JNDI initial context factory being used does not support CORBA object URLs, the initial context can be obtained from the server, and the lookup can be performed on the initial context as follows:

```
Hashtable env = new Hashtable();
env.put(CONTEXT.PROVIDER_URL, "iiop://myHost:2809");
Context ic = new InitialContext(env);
Object o = ic.lookup("cell/clusters/myCluster/myEJB");
```

## Binding resources from MQSeries 5.2

In previous releases of WebSphere Application Server, the MQSeries jmsadmin tool could be used bind resources to the name space. When used with a WebSphere Application Server V5 name space, the resource will be bound within a transient partition in the name space and will not persist past the life of the server process. Instead of binding the MQSeries resources with the jmsadmin tool, bind them from the WebSphere Application Server administrative console, under Resources in the left panel on the console

## JNDI caching

To increase the performance of JNDI operations, the WebSphere Application Server JNDI implementation employs caching to reduce the number of remote calls to the name server for lookup operations. For most cases, use the default cache setting.

When an InitialContext object is instantiated, an association is established between the InitialContext instance and a cache. The initial context and any contexts returned directly or indirectly from a lookup on the initial context are all associated with that same cache instance. By default, the association is based on the provider URL, in particular, the host name and port. The caller can specify the cache name to override this default behavior. A cache instance of a given name is shared by all instances of InitialContext configured to use a cache of that name which were created with the same context class loader in effect. Two EJB applications running in the same server will use their own cache instances, if they are using different context class loaders, even if the cache names are the same.

After an association between an InitialContext instance and cache is established, the association does not change. A `javax.naming.Context` object returned from a lookup operation inherits the cache association of the Context object on which the lookup was performed. Changing cache property values with the `Context.addToEnvironment()` or `Context.removeFromEnvironment()` method does not affect cache behavior. You can change properties affecting a given cache instance with each InitialContext instantiation.

A cache is restricted to a process and does not persist past the life of that process. A cached object is returned from lookup operations until either the max cache life for the cache is reached, or the max entry life for the object's cache entry is reached.

After this time, a lookup on the object causes the cache entry for the object to be refreshed. If a bind or rebind operation is executed on an object, the change is not reflected in any caches other than the one associated with the context from which the bind or rebind was issued. This scenario is most likely to happen when multiple processes are involved, since different processes do not share the same cache, and context objects in all threads in a process typically share the same cache instance for a given name service provider.

Usually, cached objects are relatively static entities, and objects becoming stale are not a problem. However, you can set timeout values on cache entries or on a cache so that cache contents are periodically refreshed.

## JNDI cache settings

Various cache property settings follow. Ensure that all property values are string values.

### **com.ibm.websphere.naming.jndicache.cachename**

The name of the cache to associate with an initial context instance can be specified with this property.

It is possible to create multiple InitialContext instances, each operating on the name space of a different name server. By default, objects from each bootstrap address are cached separately, since they each involve independent name spaces and name collisions could occur if they used the same cache. The provider URL specified when the initial context is created by default serves as the basis for the cache name. With this property, a JNDI client can specify a cache name. Valid options for cache names follow:

Valid options	Resulting cache behavior
<b>providerURL (default)</b>	Use the value for <code>java.naming.provider.url</code> property as the basis for the cache name. Cache names are based on the bootstrap host and port specified in the URL. The bootstrap host is normalized to a fully qualified name, if possible. For example, <code>"corbaname:iiop:server1:2809#some/starting/context"</code> and <code>"corbaloc:iiop://server1"</code> are normalized to the same cache name. If no provider URL is specified, a default cache name is used.
<b>Any string</b>	Use the specified string as the cache name. You can use any arbitrary string with a value other than <code>"providerURL"</code> as a cache name.

### **com.ibm.websphere.naming.jndicache.cacheobject**

Turn caching on or off and clear an existing cache with this property.

By default, when an InitialContext is instantiated, it is associated with an existing cache or, if one does not exist, a new one is created. An existing cache is used with its existing contents. In some circumstances, this behavior is not desirable. For example, when objects that are looked up change frequently, they can become stale in the cache. Other options are available. The following table lists these other options along with the corresponding property value.

Valid values	Resulting cache behavior
--------------	--------------------------

<b>populated (default)</b>	Use a cache with the specified name. If the cache already exists, leave existing cache entries in the cache; otherwise, create a new cache.
<b>cleared</b>	Use a cache with the specified name. If the cache already exists, clear all cache entries from the cache; otherwise, create a new cache.
<b>none</b>	Do not cache. If this option is specified, the cache name is irrelevant. Therefore, this option will not disable a cache that is already associated with other InitialContext instances. The InitialContext that is instantiated is not associated with any cache.

### **com.ibm.websphere.naming.jndicache.maxcachelife**

Impose a limit to the age of a cache with this property.

By default, cached objects remain in the cache for the life of the process or until cleared with the `com.ibm.websphere.naming.jndicache.cacheobject` property set to "cleared". This property enables a JNDI client to set the maximum life of a cache. This property differs from the `maxentrylife` property (below) in that the entire cache is cleared when the cache lifetime is reached. The table below lists the various `maxcachelife` values and their affect on cache behavior:

<b>Valid options</b>	<b>Resulting cache behavior</b>
<b>0 (default)</b>	Make the cache lifetime unlimited.
<b>Positive integer</b>	Set the maximum lifetime of the entire cache, in minutes, to the specified value. When the maximum lifetime for the cache is reached, the next attempt to read any entry from the cache causes the cache to be cleared

### **com.ibm.websphere.naming.jndicache.maxentrylife**

Impose a limit to the age of individual cache entries with this property.

By default, cached objects remain in the cache for the life of the process or until cleared with the `com.ibm.websphere.naming.jndicache.cacheobject` property set to `cleared`. This property enables a JNDI client to set the maximum lifetime of individual cache entries. This property differs from the `maxcachelife` property in that individual entries are refreshed individually as their maximum lifetime reached. This might avoid any noticeable change in performance that might occur if the whole cache is cleared at once. The table below lists the various `maxentrylife` values and their effect on cache behavior:

<b>Valid options</b>	<b>Resulting cache behavior</b>
<b>0 (default)</b>	Lifetime of cache entries is unlimited.
<b>Positive integer</b>	Set the maximum lifetime of individual cache entries, in minutes, to the specified value. When the maximum lifetime for an entry is reached, the next attempt to read the entry from the cache causes the individual cache entry to refresh.

## **Example: Controlling JNDI cache behavior from a program**

Following are examples that illustrate how you can use JNDI cache properties to achieve the desired cache behavior. Cache properties take effect when an InitialContext object is constructed.

```
import java.util.Hashtable;
import javax.naming.InitialContext;
import javax.naming.Context;
import com.ibm.websphere.naming.PROPS;
```

```
/*****
```

```
Caching discussed in this section pertains to the WebSphere Application
Server initial context factory. Assume the property,
java.naming.factory.initial, is set to
"com.ibm.websphere.naming.WsnInitialContextFactory" as a
java.lang.System property.
```

```

*****/

Hashtable env;
Context ctx;

// To clear a cache:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_CLEARED);
ctx = new InitialContext(env);

// To set a cache's maximum cache lifetime to 60 minutes:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_MAX_LIFE, "60");
ctx = new InitialContext(env);

// To turn caching off:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_NONE);
ctx = new InitialContext(env);

// To use caching and no caching:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_POPULATED);
ctx = new InitialContext(env);
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_NONE);
Context noCacheCtx = new InitialContext(env);

Object o;

// Use caching to look up home, since the home should rarely change.
o = ctx.lookup("com/mycom/MyEJBHome");
// Narrow, etc. ...

// Do not use cache if data is volatile.
o = noCacheCtx.lookup("com/mycom/VolatileObject");
// ...

```

## JNDI name syntax

JNDI name syntax is the default syntax and is suitable for typical JNDI clients.

This syntax includes the following special characters: forward slash (/) and backslash (\). Components in a name are delimited by a forward slash. The backslash is used as the escape character. A forward slash is interpreted literally if it is escaped, that is, preceded by a backslash. Similarly, a backslash is interpreted literally if it is escaped.

## INS name syntax

INS syntax is designed for JNDI clients that need to interoperate with CORBA applications.

The INS syntax allows a JNDI client to make the proper mapping to and from a CORBA name. INS syntax is very similar to the JNDI syntax with the additional special character, dot (.). Dots are used to delimit the `id` and `kind` fields in a name component. A dot is interpreted literally when it is escaped. Only one unescaped dot is allowed in a name component. A name component with a non-empty `id` field and empty `kind` field is represented with only the `id` field value and must not end with an unescaped dot. An empty name component (empty `id` and empty `kind` field) is represented with a single unescaped dot. An empty string is not a valid name component representation.

## JNDI to CORBA name mapping considerations

WebSphere Application Server name servers are an implementation of the CORBA CosNaming interface. WebSphere Application Server provides a JNDI implementation which you can use to access CosNaming name servers through the JNDI interface. Issues can exist when mapping JNDI name strings to and from CORBA names.

Each component in a CORBA name consists of an `id` and `kind` field, but a JNDI name component consists of no such fields. Each component in a JNDI name is atomic. Typical JNDI clients do not need to make a distinction between the `id` and `kind` fields of a name component, or know how JNDI name strings map to CORBA names. JNDI clients of this sort can use the JNDI syntax described below. When a name is parsed according to JNDI syntax, each name component is mapped to the `id` field of the corresponding CORBA name component. The `kind` field always has an empty value. This basic syntax is the least obtrusive to the JNDI client in that it has the fewest special characters. However, you cannot represent with this syntax a CORBA name with a non-empty `kind` field. This restriction can prevent EJB applications from interoperating with CORBA applications.

Some clients, however must interoperate with CORBA applications which use CORBA names with non-empty `kind` fields. These JNDI clients must make a distinction between `id` and `kind` so that JNDI names are correctly mapped to CORBA names, particularly when the CORBA names contain components with non-null `kind` fields. Such JNDI clients can use the INS name syntax. With its additional special character, you can use INS to represent any CORBA name. Use of this syntax is not recommended unless it is necessary, because this syntax is more restrictive from the JNDI client's perspective in that the JNDI client must be aware that name components with multiple unescaped dots are syntactically invalid. INS name syntax is part of the OMG CosNaming Interoperable Naming Specification.

### Example: Setting the syntax used to parse name strings

JNDI clients which must interoperate with CORBA applications may need to use INS name syntax to represent names in string format. The name syntax property may be passed to the `InitialContext` constructor through its parameter, in the System properties, or in a `jndi.properties` file. The initial context and any contexts looked up from that initial context will parse name strings based on the specified syntax.

The following example shows how to set the name syntax to make the initial context parse name strings according to INS syntax.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
import com.ibm.websphere.naming.PROPS; // WebSphere naming constants
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
 "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, ...);
env.put(PROPS.NAME_SYNTAX, PROPS.NAME_SYNTAX_INS);
Context initialContext = new InitialContext(env);
// The following name maps to a CORBA name component as follows:
// id = "a.name", kind = "in.INS.format"
// The unescaped dot is used as the delimiter.
// Escaped dots are interpreted literally.
java.lang.Object o = initialContext.lookup("a\\.name.in\\.INS\\.format");
...
```

---

## Developing applications that use CosNaming (CORBA Naming interface)

CORBA clients can perform naming operations on WebSphere name servers through the CosNaming interface. The following examples show how to obtain an ORB instance and an initial context as well as how to look up an EJB home.

**Note:** To enable WebSphere Application Server V5 clients to access Versions 3.5.x and 4.0.x servers, the earlier installations must have e-fix PQ60074 installed.

1. Get an initial context
2. Perform desired CosNaming operations

### Example: Getting an initial context with CosNaming

In the WebSphere Application Server, an initial context is obtained from a bootstrap server. The address for the bootstrap server consists of a host and port. To get an initial context, you must know the host and port for the server that is used as the bootstrap server.

Obtaining an initial context consists of two basic steps:

1. Obtain an ORB reference
2. Invoke a method on the ORB to obtain the initial reference

These steps are now explained in more detail.

### Obtaining an ORB reference

Pure CosNaming clients, that is clients that are not running in a server process, must create and initialize an ORB instance with which to obtain the initial context. CosNaming clients which run in server processes can obtain a reference to the server ORB with a JNDI lookup. The following examples illustrate how to create and initialize a client ORB and how to obtain a server ORB reference.

### Creating a client ORB instance

To create an ORB instance, invoke the static method, `org.omg.CORBA.ORB.init`. The `init` method requires a property set to the name of the ORB class you want to instantiate. An ORB implementation with the class name `com.ibm.CORBA.iop.ORB` is included with the WebSphere Application Server. The WebSphere Application Server ORB recognizes additional properties with which you can specify initial references.

The basic steps for creating an ORB are as follows:

1. Create a Properties object.
2. Set the ORB class property to WebSphere Application Server's ORB class.
3. If the bootstrap server is INS-compliant, set the initial reference properties. If the bootstrap server is not INS-compliant (meaning, WebSphere Application Server v4.0.x or earlier), set bootstrap host and port for bootstrap server.
4. Invoke `ORB.init`, passing in the Properties object.

### Usage scenario

```
...
import java.util.Properties;
import org.omg.CORBA.ORB;
...
Properties props = new Properties();
props.put("org.omg.CORBA.ORBClass", "com.ibm.CORBA.iop.ORB");
props.put("com.ibm.CORBA.ORBInitRef.NameService",
 "corbaloc:iiop:myhost.mycompany.com:2809/NameService");
```

```

props.put("com.ibm.CORBA.ORBInitRef.NameServiceServerRoot",
"corbaloc:iiop:myhost.mycompany.com:2809/NameServiceServerRoot");
ORB _orb = ORB.init((String[])null, props);
...

```

Notice the initial reference definitions for NameService and NameServiceServerRoot. The initial context returned for NameService depends on the type of bootstrap server. The key NameServiceServerRoot is a key introduced in WebSphere Application Server V5. For more information on initial contexts, see the section Initial Contexts.

**Note:** The properties com.ibm.CORBA.BootstrapHost and com.ibm.CORBA.BootstrapPort are deprecated. They are needed, however, to connect to WebSphere Application Servers of Version 4.0.x or earlier. The default bootstrap host is the local host and the default port is 2809.

### Obtaining a reference to the server ORB

CosNaming clients which run in a server process can obtain a reference to the server ORB with a JNDI lookup on a java: name, shown as follows:

#### Usage scenario

```

...
import javax.naming.Context;
import javax.naming.InitialContext;
import org.omg.CORBA.ORB;
...
Context initialContext = new InitialContext();
ORB orb = (ORB) initialContext.lookup("java:comp/ORB");
...

```

### Using an ORB reference to get an initial naming reference

There are two basic ways to get an initial CosNaming context. Both ways involve an ORB method invocation. The first way is to invoke the resolve\_initial\_references method on the ORB with an initial reference key. For this call to work, the ORB must be initialized with an initial reference for that key. The other way is to invoke the string\_to\_object method on the ORB, passing in a CORBA object URL with the host and port of the bootstrap server. The following examples illustrate both approaches.

#### Invoking resolve\_initial\_references

Once an ORB reference is obtained, invoke the resolve\_initial\_references method on the ORB to obtain a reference to the initial context. The following code example invokes resolve\_initial\_reference on an ORB reference.

#### Usage scenario

```

...
import org.omg.CORBA.ORB;
import org.omg.CosNaming.NamingContextExt;
import org.omg.CosNaming.NamingContextExtHelper;
...
// Obtain ORB reference as shown in examples earlier in this section
...
org.omg.CORBA.Object obj = _orb.resolve_initial_references("NameService");
NamingContextExt initCtx = NamingContextExtHelper.narrow(obj);
...

```

Note that the key NameService is passed to the resolve\_initial\_references method. Other initial context keys are registered in WebSphere Application Servers. For example, NameServiceServerRoot can be used to obtain a reference to the server root context in the bootstrap name server. For more information on the initial contexts registered in server ORBs, please see the section Initial Contexts.

## Invoking string\_to\_object with a CORBA object URL

You can use an INS-compliant ORB to obtain an initial context even if the ORB is not initialized with any initial references or bootstrap properties, or if those property settings are for a different server than the name server from which you want to obtain the initial context. To obtain an initial context by explicitly specifying the bootstrap name server, invoke the `string_to_object` method on the ORB, passing in a CORBA object URL which contains the bootstrap server host and port.

The code in the example below invokes the `string_to_object` method on an existing ORB reference, passing in a CORBA object URL which identifies the desired initial context.

### Usage scenario

```
...
import org.omg.CORBA.ORB;
import org.omg.CosNaming.NamingContextExt;
import org.omg.CosNaming.NamingContextExtHelper;
...
// Obtain ORB reference as shown in examples earlier in this section
...
org.omg.CORBA.Object obj =
 orb.string_to_object("corbaloc:iiop:myhost.mycompany.com:2809/NameService");
NamingContextExt initCtx = NamingContextExtHelper.narrow(obj);
...
```

Note that the key `NameService` is used in the `corbaloc` URL. Other initial context keys are registered in WebSphere Application Servers. For example, you can use `NameServiceServerRoot` to obtain a reference to the server root context in the bootstrap name server.

## Using an existing ORB and invoking string\_to\_object with a CORBA object URL with multiple name server addresses to get an initial context

CORBA object URLs can contain more than one bootstrap server address. Use this feature when attempting to obtain an initial context from a server cluster. You can specify the bootstrap server addresses for all servers in the cluster in the URL. The operation will succeed if at least one of the servers is running, eliminating a single point of failure. There is no guarantee of any particular order in which the address list will be processed. For example, the second bootstrap server address may be used to obtain the initial context even though the first bootstrap server in the list is available. An example of a `corbaloc` URL with multiple addresses follows.

```
...
import org.omg.CORBA.ORB;
import org.omg.CosNaming.NamingContextExt;
import org.omg.CosNaming.NamingContextExtHelper;
...
// Assume orb is an existing ORB instance
org.omg.CORBA.Object obj = orb.string_to_object(
 "corbaloc::myhost1:9810,:myhost1:9811,:myhost2:9810/NameService");
NamingContextExt initCtx = NamingContextExtHelper.narrow(obj);
...
```

## Example: Looking up an EJB home with CosNaming

You can look up an EJB home or other CORBA object from a WebSphere Application Server name server through the CORBA `CosNaming` interface. You can invoke `resolve` or `resolve_str` on the initial context, or you can invoke `string_to_object` on the ORB. You can use a qualified name so that the name resolves regardless of which name server the lookup is executed on, or use an unqualified name that only resolves from the server root context on the name server that actually contains the object binding. (The qualified name traverses the federated system name space to the specified server root context.)

## Qualified and unqualified names

Each application server contains a name server. System artifacts such as EJB homes are bound in that name server. The various name servers are federated by means of a system name space structure. The recommended way to look up objects on different servers is to use a qualified name. A qualified name can be a topology-based name, based on the name of the cluster or single server and node that contains the object. You can define fixed qualified names for objects. With qualified names, you can look up objects residing on different servers from the same initial context by traversing the system name space structure. Alternatively, you can use an unqualified name, but an unqualified name will only resolve using the name server associated with the object's application server.

## CosNaming.resolve (and resolve\_str) vs. ORB.string\_to\_object

If you have an initial context from any name server in a WebSphere Application Server cell, you can look up any CORBA object with a qualified name. You do not need additional host and port information for the target object's name server.

Alternatively, you can look up an object by invoking `string_to_object` on the ORB, passing in a corbaname URL. Typically, an IIO type URL is specified, so the bootstrap address information required for an initial context must be contained in the URL. You can use a qualified or unqualified stringified name, but an unqualified name resolves only if the initial context is from the name server in which the object is bound.

The following examples show CosNaming resolve operations using qualified topology-based lookup names and an unqualified lookup name.

## CosNaming resolve operation using a qualified name

The topology-based qualified name for an object depends on whether the object is bound in a single server or a server cluster. Examples of each follow.

### Single Server

The following example shows the lookup of an EJB home that is running in a single server. The enterprise bean that is being looked up is running in the server, `MyServer`, on the node, `Node1`.

```
// Get the initial context as shown in the previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
// Look up the home interface using the name under which the EJB home is bound
org.omg.CORBA.Object ejbHome = initialContext.resolve_str(
 "cell/nodes/Node1/servers/MyServer/mycompany/accounting/AccountEJB");
accountHome =
 (AccountHome)javax.rmi.PortableRemoteObject.narrow(ejbHome, AccountHome.class);
```

### Server Cluster

The following example shows a lookup of an EJB home that is running in a cluster. The enterprise bean being that is looked up is running in the cluster, `Cluster1`. The name can be resolved if any of the cluster members is running.

### Usage scenario

```
// Get the initial context as shown in the previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
// Look up the home interface using the name under which the EJB home is bound
org.omg.CORBA.Object ejbHome = initialContext.resolve_str(
```

```

 "cell/clusters/Cluster1/mycompany/accounting/AccountEJB");
accountHome =
 (AccountHome)javax.rmi.PortableRemoteObject.narrow(ejbHome, AccountHome.class);

```

## ORB string\_to\_object operation using an unqualified stringified name

If the resolve operation is being performed on the name server that contains the object, the system name space does not need to be traversed, and you can use an unqualified lookup name. Note that this name does not resolve on other name servers. If an unqualified name is provided, the object key must be `NameServiceServerRoot` so that the correct initial context is selected. If a qualified name is provided, you can use the default key of `NameService`.

The following example shows a lookup of an EJB home. The enterprise bean that is being looked up is bound on the name server running on the host `myHost` on port `2809`. Note the object key of `NameServiceServerRoot`.

```

// Assume orb is an existing ORB instance
...
// Look up the home interface using the name under which the EJB home is bound
org.omg.CORBA.Object ejbHome = orb.string_to_object(
 "corbaname:iiop:myHost:2809/NameServiceServerRoot#mycompany/accounting");
accountHome =
 (AccountHome)javax.rmi.PortableRemoteObject.narrow(ejbHome, AccountHome.class);

```

---

## Configured name bindings

Administrators can configure bindings into the name space. A configured binding is different from a programmatic binding in that the system creates the binding every time a server is started, even if the target context is in a transient partition.

Administrators can add name bindings to the name space through the configuration. Name servers add these configured bindings to the name space view, by reading the configuration data for the bindings. Configuring bindings is an alternative to creating the bindings from a program. Configured bindings have the advantage of being created each time a server starts, even when the binding is created in a transient partition of the name space. Cell-scoped configured bindings provide interoperability with JNDI clients running on previous versions of WebSphere Application Server. Additionally, you can configure cell-scoped bindings to create a fixed qualified name for server objects.

### Scope

You can configure a binding at one of the following three scopes: cell, node, or server. Cell-scoped bindings are created under the cell persistent root context. Node-scoped bindings are created under the node persistent root context for the specified node. Server-scoped bindings are created under the server root context for the selected server. If the target server of a server-scoped binding is a cluster, the binding is created under the server root context of each cluster member.

**Note:** The term *server* includes clusters and can be used interchangeably with the term *cluster* with respect to configured bindings. When applied to a cluster, a server-scoped binding is created in the server root for all member servers.

The scope you select for new bindings depends on how the binding is to be used. For example, if the binding is not specific to any particular node or server, or if you do not want the binding to be associated with any specific node or server, a cell-scoped binding is a suitable scope. Defining fixed names for enterprise beans to create fixed qualified names is just such an application. If a binding is to be used only by clients of an application running on a particular server, or if you want to configure a binding with the same name on different servers which resolve to different objects, a server-scoped binding would be appropriate. Note that two servers can have configured bindings with the same name but resolve to different objects. At the cell scope, only one binding with a given name can exist.

## Intermediate Contexts

Intermediate contexts created with configured bindings are read-only. For example, if an EJB home binding is configured with the name `some/compound/name/ejbHome`, the intermediate contexts `some`, `some/compound`, and `some/compound/name` will be created as read-only contexts. You cannot add, update, or remove any read-only bindings.

The configured binding name cannot conflict with existing bindings. However, configured bindings can use the same intermediate context names. Therefore, a configured binding with the name `some/compound/name2/ejbHome2` does not conflict with the previous example name.

## Configured binding types

Types of objects that you can bind follow:

### **EJB: EJB home installed in some server in the cell**

The following data is required to configure an EJB home binding:

- JNDI name of the EJB server or server cluster where the enterprise bean is deployed
- Target root for the configured binding (scope)
- The name of the configured binding, relative to the target root.

This type of binding is of special significance because you can use it to provide interoperability with WebSphere Application Server v3.5.x and v4.0.x JNDI clients. The default initial context for these earlier clients is the cell persistent root, which is different from the initial context of the server root for WebSphere Application Server V5 JNDI clients. If you migrate an application to the current release, you can configure an EJB binding at the cell scope so that the lookup names for the enterprise bean do not change for clients still running in a earlier WebSphere Application Server version.

A cell-scoped EJB binding is also useful for creating a fixed lookup name for an enterprise bean so that the qualified name is not dependent on the topology.

### **CORBA: CORBA object available from some CosNaming name server**

You can identify any CORBA object bound into some INS compliant CosNaming server with a `corbaname` URL. The referenced object does not have to be available until the binding is actually referenced by some application.

The following data is required in order to configure a CORBA object binding:

- The `corbaname` URL of the CORBA object
- An indicator if the bound object is a context or leaf node object (to set the correct CORBA binding type of context or object).
- Target root for the configured binding
- The name of the configured binding, relative to the target root.

### **Indirect: Any object bound in WebSphere Application Server name space accessible with JNDI**

Besides CORBA objects, this includes `javax.naming.Referenceable`, `javax.naming.Reference`, and `java.io.Serializable` objects. The target object itself is not bound to the name space. Only the information required to look up the object is bound. Therefore, the referenced name server does not have to be running until the binding is actually referenced by some application. The following data is required in order to configure an indirect JNDI lookup binding:

- JNDI provider URL of name server where object resides
- JNDI lookup name of object
- Target root for the configured binding (scope)
- The name of the configured binding, relative to the target root.

A cell-scoped indirect binding is useful when creating a fixed lookup name for a resource so that the qualified name is not dependent on the topology. You can also achieve this topology by widening the scope of the resource definition.

**Note:** WebSphere Application Server v3.5.x clients cannot access this type of binding .

**String: String constant**

You can configure a binding of a string constant. The following data is required to configure a string constant binding:

- String constant value
- Target root for the configured binding (scope)
- The name of the configured binding, relative to the target root.

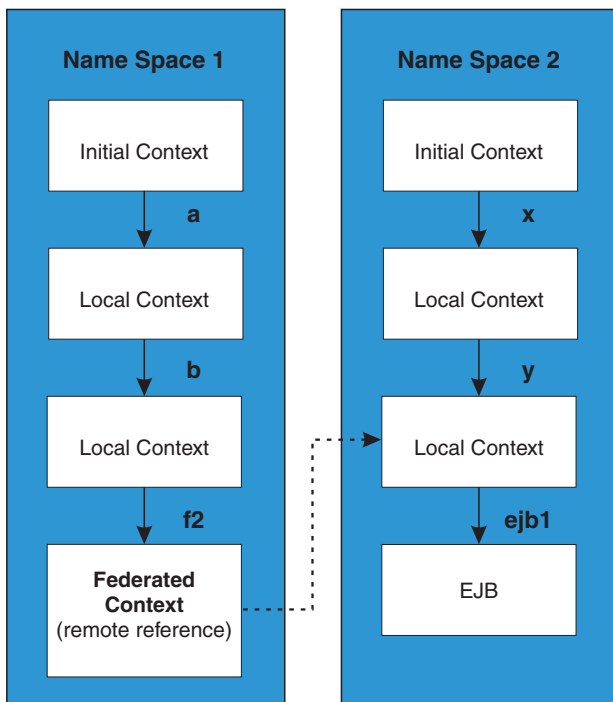

---

## Name space federation

Federating name spaces involves binding contexts from one name space into another name space.

For example, assume that a name space, Name Space 1, contains a context under the name a/b. Also assume that a second name space, Name Space 2, contains a context under the name x/y. (See the following illustration.) If context x/y in Name Space 2 is bound into context a/b in Name Space 1 under the name f2, the two name spaces are federated. Binding f2 is a federated binding because the context associated with that binding comes from another name space. From Name Space 1, a lookup of the name a/b/f2 returns the context bound under the name x/y in Name Space 2. Furthermore, if context x/y contains an Enterprise JavaBeans (EJB) home bound under the name ejb1, the EJB home could be looked up from Name Space 1 with the lookup name a/b/f2/ejb1. Notice that the name crosses name spaces. This fact is transparent to the naming client.

### Federated Name Spaces

In a WebSphere Application Server name space, you can create federated bindings with the following restrictions:

- Federation is limited to CosNaming name servers. A WebSphere Application Server name server is a Common Object Request Broker Architecture (CORBA) CosNaming implementation. You can create federated bindings to other CosNaming contexts. You cannot, for example, bind contexts from an LDAP name server implementation.

- If you use JNDI to federate the name space, you must use WebSphere Application Server's initial context factory to obtain the reference to the federated context. If you use some other initial context factory implementation, you either may not be able to create the binding, or the level of transparency may be reduced.
- A federated binding to a non-WebSphere Application Server naming context has the following functional limitations:
  - JNDI operations are restricted to the use of CORBA objects. For example, you can look up EJB homes, but you cannot look up non-CORBA objects such as data sources.
  - JNDI caching is not supported for non-WebSphere Application Server name spaces. This restriction affects the performance of lookup operations only.
- Do not federate two WebSphere Application Server stand-alone server name spaces. Incorrect behavior may result. If you want to federate WebSphere Application Server name spaces, you should use servers running under the Network Deployment or Enterprise packages of WebSphere Application Server.

---

## Name space bindings

Administrators can add name bindings to the name space through the configuration. Name servers add these configured bindings to the name space view by reading the configuration data for the bindings. Configuring bindings is an alternative to creating the bindings from a program.

Configured bindings are created each time a server starts, even when the binding is created in a transient partition of the name space. One major use of configured bindings is to provide interoperability with JNDI clients running on previous versions of the WebSphere Application Server.

There are four different kinds of bindings that you can configure:

- Enterprise JavaBeans (EJB)
- CORBA object
- Indirect Lookup
- String

---

## Configuring and viewing name space bindings

To view or configure an EJB, CORBA, Indirect lookup or string name space binding, complete the following:

1. Open the Administrative console.
2. Click **Environment**.
3. Click **Manage Name Space Bindings**.
4. Select the desired scope by entering in a node name for node-scoped bindings, or a node name and server name for server-scoped bindings, and click **Apply**.
5. To create a new binding, click **New** and follow the instructions. To edit a previously created binding, click the binding you want to edit and proceed to the next step.
6. Edit the Binding identifier, the Name in name space, and the String value fields as desired.

**Note:** All of these fields are required.

7. Click **Finish** to register the changes.

## String binding settings

Use this page to configure a new string binding or to view or edit an existing string binding.

To view this administrative console page, click **Environment** > **Naming** > **Name Space Bindings** > *string\_namespace\_binding*.

## Scope

Shows the scope of the configured binding. This value indicates the configuration location for the `namebindings.xml` file. This field is for information purposes only and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped, the starting context is the server's server root context.

## Binding Type

Shows the type of binding configured. Possible choices are String, EJB, CORBA, and Indirect. This field is for information purposes only and cannot be updated.

## Binding Identifier

Specifies the name that uniquely identifies this configured binding.

## Name in Name Space

Specifies the name used for this binding in the name space. This name can be a simple or compound name depending on the portion of the name space where this binding is configured.

## String Value

Specifies the string to be bound into the name space.

## CORBA object binding settings

Use this page to configure a new name binding of a CORBA object binding, or to view or edit an existing CORBA object binding.

To view this administrative console page, click **Environment > Naming > Name Space Bindings > CORBA\_namespace\_binding**.

## Scope

Shows the scope of the configured binding. This value indicates the configuration location for the `namebindings.xml` file. This field is for information purposes only and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped, the starting context is the server's server root context.

## Binding Type

Shows the type of binding configured. Possible choices are String, EJB, CORBA, and Indirect. This field is for information purposes only and cannot be updated.

## Binding Identifier

Specifies the name that uniquely identifies this configured binding.

## Name in Name Space

Specifies the name used for this binding in the name space. This name can be a simple or compound name depending on the portion of the name space where this binding is configured.

## Corbaname URL

Specifies the CORBA name URL string identifying where the object is bound in a CosNaming server.

## Federated Context

Specifies whether the target is a CosNaming context (true) or a leaf node object (false).

Value

Result

<b>true</b>	The target object is bound with a context CORBA binding type. If the corbaname URL does not resolve to a NamingContext, an error occurs when the binding is first used (which is when the URL is first resolved).
<b>false</b>	The target object is bound with an object CORBA binding type.

## Indirect lookup binding settings

Use this page to configure a new indirect lookup name binding, or to view or edit an existing indirect lookup binding.

To view this administrative console page, click **Environment > Naming > Name Space Bindings > indirect\_lookup\_namespace\_binding**.

### Scope

Shows the scope of the configured binding. This value indicates the configuration location for the namebindings.xml file. This field is for information purposes only and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped, the starting context is the server's server root context.

### Binding Type

Shows the type of binding configured. Possible choices are String, EJB, CORBA, and Indirect. This field is for information purposes only and cannot be updated.

### Binding Identifier

Specifies the name that uniquely identifies this configured binding.

### Name in Name Space

Specifies the name used for this binding in the name space. This name can be a simple or compound name depending on the portion of the name space where this binding is configured.

### Provider URL

Specifies the provider URL string needed to obtain a JNDI initial context.

### JNDI Name

Specifies the name used to look up the target object from the initial context.

## EJB binding settings

Use this page to configure a new EJB binding, or to view or edit an existing EJB binding.

To view this administrative console page, click **Environment > Naming > Name Space Bindings > EJB\_namespace\_binding**.

### Scope

Shows the scope of the configured binding. This value indicates the configuration location for the namebindings.xml file. This field is for information purposes only and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped, the starting context is the server's server root context.

## Binding Type

Shows the type of binding configured. Possible choices are String, EJB, CORBA, and Indirect. This field is for information purposes only and cannot be updated.

## Binding Identifier

Specifies the name that uniquely identifies this configured binding.

## Name in Name Space

Specifies the name used for this binding in the name space. This name can be a simple or compound name depending on the portion of the name space where this binding is configured.

## Enterprise Bean Location

Specifies whether the enterprise bean is running in a server cluster or a single server. If Single Server is specified, type the node name.

## Server

Specifies the name of the cluster or non-clustered server in which the enterprise bean is configured.

## JNDI Name

Specifies the JNDI name of the deployed enterprise bean (the bean's JNDI name that is in the enterprise bean bindings--not the java:comp name)

## Name space binding collection

Use this page to configure a name binding of an EJB, a CORBA CosNaming NamingContext, a CORBA leaf node object, an object that you can look up using JNDI, or a constant string value.

Binding information for configured bindings is stored in the configuration and applied upon startup of the name server for each server within the scope of the binding.

To view the Manage Name Space Bindings Settings page, click **Environment > Naming > Name Space Bindings**.

Click the check boxes to select one or more of the users in your collection. Use the buttons to control the selected users.

## Name

Shows the names given to uniquely identify these configured bindings.

## Scope

Shows the scope of the configured binding. This value indicates the configuration location for the namebindings.xml file. This field is for information purposes only and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped, the starting context is the server's server root context.

## Binding Type

Shows the type of binding configured. Valid values are String, EJB, CORBA, and Indirect. This field is for information purposes only and cannot be updated.

---

## Configuring name servers

To configure a name server, complete the following:

1. Open the administrative console.
2. Click **Servers**.
3. Click **Application Servers**.
4. Click the application server you want to configure.
5. Click **Server Components**.
6. Click **Name Server**.
7. Edit the fields as desired.

**Note:** All of these fields are mandatory.

8. To make other changes, click **Custom Properties**.
9. Click **OK** to register your changes.

### Name server settings

Use this page to configure Naming Service Provider settings for the application server.

To view this administrative console page, click one of the following paths:

- **Servers > Application Servers > *server\_name* > Server Components > Name Server**
- **Servers > JMS Servers > *server\_name* > Server Components > Name Server**

#### Name

Specifies the display name for the server.

<b>Data type</b>	String
------------------	--------

#### Initial State

Specifies the execution state. The options are: *Started* and *Stopped*.

<b>Data type</b>	String
<b>Default</b>	Started

---

## Troubleshooting name space problems

Many naming problems can be avoided by fully understanding the key underlying concepts of WebSphere Application Server naming.

1. Review the key concepts of WebSphere Application Server naming, especially Name space logical view and Lookup names support in deployment descriptors and thin clients.
2. Review the programming examples that are included in the sections explaining the JNDI and CosNaming interfaces.
3. Read "Naming services component troubleshooting tips" in the Information Center for additional general information.
4. Read "Cannot look up an object hosted by WebSphere Application Server from a servlet, JSP file, or other client" in the Information Center if you encounter the described problem.

## dumpNameSpace tool

You can use the dumpNameSpace tool to dump the contents of a name space accessed through a name server. When you invoke the dumpNameSpace tool, the naming service must be active. The dumpNameSpace tool cannot dump name spaces local to the server process, such as those with java: and local: URL schemes. The local: name space contains references to enterprise beans with local interfaces. Use the name space dump utility for java:, local: and server name spaces to dump java: and local: name spaces.

Note that the server root context for the server at the specified host and port is dumped (unless a non-default starting context which precludes it is specified). The server root contexts for other servers are not dumped.

If you run the dumpNameSpace tool, a login prompt is displayed. If you cancel the login prompt, the dumpNameSpace tool continues outbound with an "UNAUTHENTICATED" credential. Thus, by default, an "UNAUTHENTICATED" credential is used that is equivalent to the "Everyone" access authorization policy. You can modify this default setting by changing the value for the com.ibm.CSI.performClientAuthenticationRequired property to true in the install\_dir/properties/sas.client.props file. When you change this property to true, rerun the dumpNameSpace tool, and cancel the login prompt, the authorization fails and the command will not continue outbound.

Command line invocation descriptions of the dumpNameSpace tool follow. This section includes sample output.

You can also access this tool through its program interface. Refer to the class com.ibm.websphere.naming.DumpNameSpace in the WebSphere Application Server API documentation. To invoke the tool through the command line, enter the following command from the WebSphere/AppServer/bin directory:

Platform	Command
UNIX	dumpNameSpace.sh <i>[-keyword value]...</i>
Windows NT	dumpNameSpace <i>[-keyword value]...</i>

### Parameters

The keywords and associated values for the dumpNameSpace utility follow:

**-host** *myhost.austin.ibm.com*

Indicates the bootstrap host or the WebSphere Application Server host whose name space you want to dump. The value defaults to **localhost**.

**-port** *nnn*

Indicates the bootstrap port which, if not specified, defaults to **2809**.

**-root** {*cell | server | node | host | legacy | tree | default*}

Indicates the root context to use as the initial context for the dump. The applicable root options and default root context depend on the type of name server from which the dump is being obtained. This information is provided in the following tables.

For WebSphere Application Servers V5 or later:

cell	DumpNameSpace default. Dump the tree starting at the cell root context.
server	Dump the tree starting at the server root context.
node	Dump the tree starting at the node root context. (Synonymous with host.)

For WebSphere Application Servers v4.0 or later:

legacy	DumpNameSpace default. Dump the tree starting at the legacy root context.
host	Dump the tree starting at the bootstrap host root context. (Synonymous with node.)
tree	Dump the tree starting at the tree root context.

For all WebSphere Application Servers and other name servers:

default	Dump the tree starting at the initial context which JNDI returns by default for that server type. This is the only -root choice that is compatible with WebSphere Application Servers prior to v4.0 and with non-WebSphere Application Server name servers.
---------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**-url** *some provider URL*

Indicates the value for the java.naming.provider.url property used to get the initial JNDI context. This option can be used in place of the -host, -port, and -root options. If the -url option is specified, the -host, -port, and -root options are ignored.

**-factory** *com.ibm.websphere.naming.WsnInitialContextFactory*

Indicates the initial context factory to be used to get the JNDI initial context. The value defaults to: *com.ibm.websphere.naming.WsnInitialContextFactory* The default value generally does not need to be changed.

**-startAt** *some/subcontext/in/the/tree*

Indicates the path from the bootstrap host's root context to the top level context where the dump should begin. The utility recursively dumps subcontexts below this point. It defaults to an empty string, that is, the bootstrap host root context.

**-format{jndi | ins}**

Option	Description
jndi	The default. Displays name components as atomic strings.
ins	Shows name components parsed per INS rules (id.kind).

**-report {short | long}**

Option	Description
short	The default. Dumps the binding name and bound object type. This output is also provided by JNDI Context.list().
long	<p>Dumps the binding name, bound object type, local object type, and string representation of the local object (that is, the IORs, string values, and other values that are printed).</p> <p>For objects of user-defined classes to display correctly with the long report option, it may be necessary to add their containing directories to the list of directories searched. Set the environment variable <b>WAS_USER_DIRS</b>. The value can include one or more directories, as for example:</p> <p><b>Platform</b></p> <p><b>Command</b></p> <p><b>UNIX</b> WAS_USER_DIRS=/usr/classdir1:/usr/classdir2 export WAS_USER_DIRS</p> <p><b>Windows NT</b> set WAS_USER_DIRS=c:\classdir1;d:\classdir2</p> <p>All zip, jar, and class files in the specified directories can then be resolved by the class loader when running <b>dumpNameSpace</b>.</p>

**-traceString** *"some.package.name.to.trace.\*=all=enabled"*

Represents the trace string with the same format as that generated by the servers. The output is sent to the file, DumpNameSpaceTrace.out.

## Example: Invoking the name space dump utility

It is often helpful to view a dump of the name space to understand why a naming operation is failing. You can invoke the name space dump utility from the command line or from a program. Examples of each option follow.

### Invoking name space dump utility from a command line

Invoke the name space dump utility from the command line by entering the following command:

```
dumpNameSpace -host myhost.mycompany.com -port 901
```

**OR**

```
dumpNameSpace -url corbaloc:iiop:myhost.mycompany.com:901
```

There are several command line options to choose from. For detailed help, enter the following command:

```
dumpNameSpace -help
```

### Invoking name space dump utility from a Java program

You can dump name spaces from a program with the `com.ibm.websphere.naming.DumpNameSpace` API. Refer to the WebSphere Application Server API documentation for details on the `DumpNameSpace` program interface

The following example illustrates how to invoke the name space dump utility from a Java program:

```
{
 ...
 import javax.naming.Context;
 import javax.naming.InitialContext;
 import com.ibm.websphere.naming.DumpNameSpace;
 ...
 java.io.PrintStream filePrintStream = ...
 Context ctx = new InitialContext();
 // Starting context for dump
 ctx = (Context) ctx.lookup("cell/nodes/node1/servers/server1");
 DumpNameSpace dumpUtil =
 new DumpNameSpace(filePrintStream, DumpNameSpace.SHORT);
 dumpUtil.generateDump(ctx);
 ...
}
```

## Name space dump utility for java:, local: and server name spaces

Sometimes it is helpful to dump the `java:` name space for a J2EE application. You cannot use the `dumpNameSpace` command line utility for this purpose because the application's `java:` name space is accessible only by that J2EE application. From the WebSphere Application Server scripting tool, you can invoke a `NameServer` MBean to dump the `java:` name space for any J2EE application running in that same server process.

There is another name space local to server process which you cannot dump with the `dumpNameSpace` command line utility. This name space has the URL scheme of `local:` and is used by the container to bind objects locally instead of through the name server. The `local:` name space contains references to enterprise beans with local interfaces. There is only one `local:` name space in a server process. You can dump the `local:` name space by invoking the `NameServer` MBean associated with that server process.

## Name space dump options

Name space dump options are specified in the MBean invocation as a parameter in character string format. The option descriptions follow.

### **-startAt** *some/subcontext/in/the/tree*

Indicates the path from the name space root context to the top level context where the dump should begin. The utility recursively dumps subcontexts below this point. It defaults to an empty string, that is, the root context.

### **-report {short | long}**

Option	Description
short	The default. Dumps the binding name and bound object type. This output is also provided by JNDI Context.list().
long	Dumps the binding name, bound object type, local object type, and string representation of the local object (that is, the IORs, string values, and other values that are printed).

### **-root {tree | host | legacy | cell | node | server | default}**

Specify the root context of where the dump should start. The default value for `-root` is `cell`. This option is only valid for server name space dumps.

Option	Description
tree	Dump the tree starting at the tree root context.
host	Dump the tree starting at the server host root context (synonymous with "node").
legacy	Dump the tree starting at the legacy root context.
cell	Dump the tree starting at the cell root context. This is the default option.
node	Dump the tree starting at the node root context (synonymous with "host").
server	Dump the tree starting at the server root context. This is <code>-root</code> default.
default	Dump the tree starting at the initial context which JNDI returns by default for that server type.

### **-format {jndi | ins}**

Specify the format to display name component as atomic strings or parsed according to INS rules (id.kind). This option is only valid for server name space dumps.

Option	Description
jndi	Display name components as atomic strings. This is <code>-format</code> default.
ins	Display name components parsed according to INS rules (id.kind).

## NameServer MBean invocation

1. Enter the WebSphere Application Server scripting command prompt.

Invoke a method on a NameServer MBean by using the WebSphere Application Server scripting tool. Enter the scripting command prompt by typing the following command:

Platform	Command
UNIX	wsadmin.sh
Windows NT	wsadmin

Use the `-help` option for help on using the `wsadmin` command.

2. Select the NameServer MBean instance to invoke.

Execute the following script commands to select the NameServer instance you want to invoke. For example,

```
set mbean [$AdminControl completeObjectName WebSphere:*,type=NameServer,cell=
 cellName,node=nodeName,process=serverName]
```

where *cellName*, *nodeName*, and *serverName* are the names of the cell, node, and server for the MBean you want to invoke. The specified server must be running before you can invoke a method on the MBean.

You can see a list of all NameServer MBeans current running by issuing the following query:

```
$AdminControl queryNames {*:*,type=NameServer}
```

3. Invoke the NameServer MBean.

#### **java: name space**

Dump a java: name space by invoking the `dumpJavaNameSpace` method on the NameServer MBean. Since each server application has its own java: name space, the application must be specified on the method invocation. An application is identified by the application name, module name, and component name. The method syntax follows:

```
$AdminControl invoke $mbean dumpJavaNameSpace {{appName}{modName}{compName}{opts}}
```

where *appName* is the application name, *modName* is the module name, and *compName* is the component name of the java: name space you want to dump. The value for *opts* is the list of name space dump options described earlier in this section. The list can be empty.

#### **local: name space**

Dump a java: name space by invoking the `dumpLocalNameSpace` method on the NameServer MBean. Since there is only one local: name space in a server process, you have to specify the name space dump options only.

```
$AdminControl invoke $mbean dumpLocalNameSpace {{opts}}
```

where *opts* is the list of name space dump options described earlier in this section. The list can be empty.

#### **Server name space**

Dump a server name space by invoking the `dumpServerNameSpace` method on an application server's NameServer MBean. This provides an alternative way to dump the name space on an application server, much like the `dumpNameSpace` command line utility.

```
$AdminControl invoke $mbean dumpServerNameSpace {{opts}}
```

where *opts* is the list of name space dump options described earlier in this section. The list can be empty.

### **Name space dump output**

Name space dump output is sent to the console. It is also written to the file `DumpNameSpace.log`, in the server's log directory.

## **Example: Invoking the name space dump utility for java: and local: name spaces**

It is often helpful to view the dump of a java: or local: name space to understand why a naming operation is failing. The NameServer MBean running in the application's server process can be invoked from the WebSphere Application Server scripting tool to generate a dump of these name spaces. Examples of NameServer MBean calls to generate dumps of java: and local: name spaces follow.

## Dumping a java: name space

Assume you want to dump the java: name space of an application component running in server server1 on node node1 of the cell MyCell. The application name is AcctApp in module AcctApp.war, and the component name is Acct Servlet. The following script commands generate a long format dump of the application's java: name space of that application:

```
set mbean [$AdminControl completeObjectName WebSphere:*,type=NameServer,cell=MyCell,node=node1,process=server1]
$AdminControl invoke $mbean dumpJavaNameSpace {{AcctApp}{AcctApp.war}{Acct Servlet}{-report long}}
```

## Dumping a local: name space

Assume you want to dump the local: name space for the server server1 on node node1 of cell MyCell. The following script commands will generate a short format dump of that server's local name space:

```
set mbean [$AdminControl completeObjectName WebSphere:*type=NameServer,cell=MyCell,node=node1,process=server1]
$AdminControl invoke $mbean dumpLocalNameSpace {{-report short}}
```

## Name space dump sample output

Name space dump output looks like the following example, which is the **SHORT** dump format:

```
Getting the initial context
Getting the starting context
```

```

## Naming and directories: Resources for learning

Use the following links to find relevant supplemental information about naming and directories. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

### Programming instructions and examples

## Chapter 27. Using the dynamic cache service to improve performance

The dynamic cache service works within an application server Java virtual machine (JVM), intercepting calls to cacheable objects. For example, it intercepts calls through a servlet service() method or a command execute() method, and either stores the output of the object to, or serves the content of the object from the dynamic cache.

WebSphere Application Server, Version 4.0, supported the configuration of dynamic servlet caching through the servletcache.xml file. To utilize the new and improved functionality of the dynamic cache service, configure your cache policy using the cachespec.xml format. See “Configuring cacheable objects with the cachespec.xml file” on page 1354 for more information.

The dynamic caching documentation provides you with the following tasks to enable and configure the dynamic cache service, as well as advanced features, such as controlling external caches and building user-defined drop-in components to customize the cache operation.

1. Enable the dynamic cache service globally.
2. Configure servlet caching.
3. Configure Edge Side Include (ESI) caching.
4. Configure command caching.
5. Configure Web services caching.
6. Troubleshoot any problems with the dynamic cache service.

To use the DistributedMap interface for the dynamic cache, see Using the DistributedMap interface for the dynamic cache.

---

### Dynamic cache

Caching the output of servlets, commands and JavaServer Pages (JSP) files, improves application performance. WebSphere Application Server consolidates several caching activities, including servlets, Web services, and WebSphere commands into one service called the *dynamic cache*. These caching activities work together to improve application performance, and share many configuration parameters, which are set in the dynamic cache service of an application server.

You can use the dynamic cache to improve the performance of servlet and JSP files by serving requests from an in-memory cache. Cache entries contain servlet output, results of servlet execution, and metadata.

---

### Configuring cache replication

Cache replication leverages the WebSphere internal replication service that is also leveraged for HttpSession memory-to-memory replication for failover purposes. Hence, a replication domain with at least one replicator entry needs to exist in order to replicate the data. The dynamic cache service, in essence, connects to the replicator. See more information in the topic referring to managing internal replication, “Replicating data,” in the Information Center.

To configure cache replication and its features:

1. Click **Servers > Application Servers** in the administrative console navigation tree.
2. Click *server*.
3. Click **Dynamic Cache Service**.
4. Select the **Enable cache replication** check box in the **Cache replication** field.

To manage **batch update** or **PUSH-PULL - PUSH/PULL**, repeat steps 1-4, then click the **Enable cache replication** link to the right of the **Enable cache replication** check box. Batch update interval is set under **push frequency**. PUSH-PULL-PUSH/PULL is set through the **runtime mode**.

You can also select which replication domain and initial replicator entry the dynamic cache will utilize (either those managed within the cell or across the cell).

## Cache replication

Data is generated one time and copied or replicated to other servers in the cluster, saving execution time and resources. Caching in a cluster has additional concerns. In particular, the same data can be required and generated in multiple places. Also, the permission the resources need to generate the cached data can be restricted, preventing access to the data.

Cache replication addresses these concerns by generating the data one time and copying or replicating it to the other servers in the cluster. It also aids in cache consistency, in that cache entries that are not needed are removed or replaced.

The data replication configuration can exist as part of the Web container dynamic cache configuration accessible through the administrative console, or on a per cache entry basis through the `cachespec.xml` file. With the `cachespec.xml` file, you can configure cache replication at the Web container level, but disable it for a specific cache entry.

Cache replication can take on three forms:

- **PUSH** - Send out new entries, both ID and data, and updates to those entries.
- **PULL** - Requests data from other servers in the cluster when that data is not locally present. This mode of replication is not recommended.
- **PUSH/PULL** - Sends out IDs for new entries, then, only requests from other servers in the cluster entries for IDs previously broadcast. The dynamic cache always sends out cache entry invalidations.

The dynamic cache provides a batch update option. Specifically, for PUSH or PUSH/PULL, the dynamic cache broadcasts the update asynchronously, based on a timed interval rather than sending them immediately upon inception. Invalidators are sent immediately. Distribution of invalidations prevents stale data from residing in a cluster.

## Internal messaging configuration settings

Use this page to set advanced configurations for Memory to Memory session replication.

To view this administrative console page, click **Servers > Application Servers > server > Dynamic Cache Service > Cache replication > Enable cache replication** .

The advanced replication settings include fields for choosing the initial replicator entry that connects to the replicator domains. As an alternative, you can specify the IP addresses and ports (of the form `address:port`) for connection to replicators outside of the cell that the server is administered under. By default, if a replicator is defined on the server you are configuring, that server is the one chosen for cache replication. Select the advanced properties only if you want to deviate from the default setting.

### Internal messaging server

Specifies a domain from which your data will be replicated. Depending on the domain you choose to replicate the data, you can choose any of the replicators defined under that domain. You can use the default domain or choose one from the drop down window.

### Runtime mode

Specifies the global sharing policy for this server.

The following settings are available:

- **Both push and pull** sends the cache ID of newly updated content to other servers in the replication domain. Then, if one of the other servers requests the content, and that server has the ID of the cache entry for the previously updated content, it will retrieve the content from the publishing server. On the other hand, if a request is made for an ID which has not been previously published, the server assumes it does not exist in the cluster and creates a new entry.
- **Push only** sends the cache ID and cache content of new content to all other servers in the replication domain.
- The sharing policy of **Not Shared** results in the cache ID and cache content not being shared with other servers in the replication domain.

The default setting for a non-clustered environment is **Not Shared**. When enabling replication, the default value is **Push only**.

### Push frequency

Specifies the time in seconds to wait before pushing new or modified cache entries to other servers. A value of 0 (zero) means send immediately.

Setting this property to a value greater than 0 (zero) causes a "batch" push of all cache entries that are created or modified during the time period.

Default	0 (equivalent to immediate)
---------	-----------------------------

---

## Enabling the dynamic cache service

In order to use the dynamic cache service, you must first enable it.

1. Open the administrative console.
2. Click **Servers > Application Servers** in the administrative console navigation tree.
3. Click a server.
4. Click **Dynamic Cache Service** under Additional Properties.
5. Select **Enable service at server startup** in the **Startup state** field.
6. Click **Apply** or **OK**.
7. Restart WebSphere Application Server.

The dynamic cache service will now cache content for requests that have cache policies configured.

## Dynamic cache service settings

Use this page to configure and manage the dynamic cache service settings.

To view this administrative console page, click **Servers > Application Servers > server > Dynamic Cache Service**.

### Startup state

Specifies whether the dynamic cache is enabled.

### Cache size

Specifies a positive integer as the value for the maximum number of entries the cache holds.

Enter the cache size value in this field between the range of 100 through 200,000.

### Default priority

Specifies the default priority for cache entries, determining how long an entry stays in a full cache.

Default	1
---------	---

Range	1 to 255
-------	----------

## Disk offload

Specifies whether disk offload is enabled.

By default, the dynamic cache maintains the number of entries configured in memory. If new entries are created while the cache is full, the priorities configured for each cache entry and a least recently used algorithm, are used to remove entries from the cache. In addition to having a cache entry removed from memory when the cache is full, you can enable disk offload to have a cache entry copied to the file system (the location is configurable). Later, if that cache entry is needed, it is moved back to memory from the file system.

## Cache replication

Specifies whether cache replication is enabled.

You can also configure advanced cache replication settings.

## Configuring servlet caching

To enable servlet caching, you must complete “Enabling the dynamic cache service” on page 1345.

1. Open the administrative console.
2. Click **Servers > Application Servers** in the console navigation tree.
3. Click a server.
4. Click **Web Container**.
5. Select **Enable servlet caching** under the Configuration tab.
6. Click **Apply** or **OK**.

Define the cache policy for your servlets by “Configuring cacheable objects with the cachespec.xml file” on page 1354.

## Servlet caching

After a servlet is invoked and generating the output to cache, a cache entry is created containing the output and the side effects of the invocation. For example, these side effects can include calls to other servlets or JavaServer Pages (JSP) files, as well as metadata about the entry, including timeout and entry priority information.

Unique entries are distinguished by an ID string generated from the `HttpServletRequest` object for each invocation of the servlet. You can then base servlet caching on:

- Request parameters and attributes the URI used to invoke the servlet
- Session information
- Other options, including cookies

Since JSP files are compiled by WebSphere Application Server into servlets, the dynamic cache function treats them the same, except in specifically documented situations.

## Configuring the dynamic cache disk offload

By default, when the number of cache entries reaches the configured limit for a given WebSphere server, eviction of cache entries occurs, allowing new entries to enter the cache service. The dynamic cache includes an alternative feature named disk offload, that copies the evicted cache entries to disk for potential future access.

To configure disk offload:

1. Open the administrative server.
2. Click **Server > Application Server** in the administrative console navigation tree.
3. Click *server*.
4. Click **Dynamic Cache Service**.
5. Click the **Enable disk offload** check box in the **Disk offload** field. You can also set the disk offload location in this field.
6. Click **Apply** or **OK**.

### Application servers must have different disk offload locations

When you have two or more application servers with servlet caching enabled and the application servers specify the same disk offload location for their caches through the dynamic cache service, the following exceptions might occur:

```
java.lang.NullPointerException
 at com.ibm.ws.cache.CacheOnDisk.readTemplate(CacheOnDisk.java:686)
 at com.ibm.ws.cache.Cache.internalInvalidateByTemplate(Cache.java:828)
```

or:

```
java.lang.NullPointerException
 at com.ibm.ws.cache.CacheOnDisk.readCacheEntry(CacheOnDisk.java:600)
 at com.ibm.ws.cache.Cache.getCacheEntry(Cache.java:341)
```

If one server is run as root and the other servers are run as nonroot, this problem could occur. For example, if server1 runs as root and server2 runs as wasuser or wasgroup, the cache files in the disk offload location might be created with root permissions. This situation causes the applications running on the nonroot servers to crash when they try to read or write to the cache.

The disk offload location must be unique for servers defined on the same node. If you have multiple servers defined on the same node, make sure the disk offload location is different for each server as defined on the **Dynamic Cache Service** panel, **Offload location** field.

## Configuring Edge Side Include caching

Edge Side Include (ESI) is configured through the `plugin-cfg.xml` file.

The Web server plug-in contains a built-in ESI processor. The ESI processor has the ability to cache whole pages, as well as fragments, providing a higher cache hit ratio. The cache implemented by the ESI processor is an in-memory cache, not a disk cache, therefore, the cache entries are not saved when the Web server is restarted.

The basic operation of the ESI processor is as follows: When a request is received by the Web server plug-in, it is sent to the ESI processor, unless the ESI processor is disabled. It is enabled by default. If a cache miss occurs, a `Surrogate-Capabilities` header is added to the request and the request is forwarded to the WebSphere Application Server. If the dynamic servlet cache is enabled in the application server, and the response is edge cacheable, the application server returns a `Surrogate-Control` header in response to the WebSphere Application Server plug-in.

The value of the `Surrogate-Control` response header contains the list of rules which are used by the ESI processor in order to generate the cache ID. The response is then stored in the ESI cache, using the cache ID as the key. For each ESI include tag in the body of the response, a new request is processed such that each nested include results in either a cache hit or another request forwarded to the application server. When all nested includes have been processed, the page is assembled and returned to the client.

The ESI processor is configurable through the WebSphere Web server plug-in configuration file `plugin-cfg.xml`. The following is an example of the beginning of this file, which illustrates the ESI configuration options.

```
<?xml version="1.0"?>
<Config>
 <Property Name="esiEnable" Value="true"/>
 <Property Name="esiMaxCacheSize" Value="1024"/>
 <Property Name="esiInvalidationMonitor" Value="false"/>
</Config>
```

The first option, `esiEnable`, can be used to disable the ESI processor by setting the value to false. ESI is enabled by default. If ESI is disabled, then the other ESI options are ignored.

The second option, `esiMaxCacheSize`, is the maximum size of the cache in 1K byte units. The default maximum size of the cache is 1 megabyte. If the cache is full, the first entry to be evicted from the cache is the entry that is closest to expiration.

The third option, `esiInvalidationMonitor`, specifies whether or not the ESI processor should receive invalidations from the application server. ESI works well when the Web servers following a threading model is used, and only one process is started. When multiple processes are started, each process caches the responses independently and the cache is not shared. This could lead to a situation where, the system's memory is fully used up by ESI processor. There are three methods by which entries are removed from the ESI cache: first, an entry's expiration timeout could fire; second, an entry may be purged to make room for newer entries; or third, the application server could send an explicit invalidation for a group of entries. In order for the third mechanism to be enabled, the `esiInvalidationMonitor` property must be set to true and the `DynaCacheEsi` application must be installed on the application server. The `DynaCacheEsi` application is located in the `installableApps` directory and is named `DynaCacheEsi.ear`. If the `ESIInvalidationMonitor` property is set to true but the `DynaCacheEsi` application is not installed, then errors will occur in the webserver plugin and the request will fail.

The ESI processor's cache can be monitored through the `CacheMonitor` application. In order for ESI processor's cache to be visible in the `CacheMonitor`, the `DynaCacheEsi` application must be installed as described above and the `ESIInvalidationMonitor` property must be set to true in the `plugin-cfg.xml` file.

When WebSphere Application Server is used to serve static data, such as images and HTML on the application server, the URLs are also cached in the ESI processor. This data has a default timeout of 300 seconds. You can change the timeout value by adding the property `com.ibm.servlet.file.esi.timeOut` to your JVM's command line parameters. The following example shows how to set a one minute timeout on static data cached in the plug-in:

```
-Dcom.ibm.servlet.file.esi.timeOut=60
```

For more information about the `plugin-cfg.xml` file see "Manually editing the plug-in configuration" in the Information Center.

For information about configuring alternate URL, see "Configuring alternate URL."

## Configuring alternate URL

Alternate URL is a method for edge caching JavaServer Pages (JSP) files and servlet responses that you can not request externally. Dynamic cache provides support to recognize the presence of an Edge Side Include (ESI) processor and to generate ESI include tags and appropriate cache policies for edge cacheable fragments. However, for a fragment to be edge cacheable, you must be able to externally request it from the application server. In other words, if a user types the URL in their browser with the appropriate parameters and cookies for the fragment, WebSphere Application Server must return the content for that fragment.

One of the standard J2EE programming architectures is the model-view-controller (MVC) architecture, where a call to a controller servlet might include one or more child JSP files to construct the view. When

using the MVC programming model, the child JSP files are edge cacheable only if you can request these JSP files externally, which is not usually the case. For example, if a child JSP file uses one or more request attributes that are determined and set by the controller servlet, you cannot cache that JSP file on the edge. You can use alternate URL support to overcome this limitation by providing an alternate controller servlet URL used to invoke the JSP file.

The alternate URL for a JSP file or a servlet is set in the `cachespec.xml` file as a property with the name `alternate_url`. You can set the alternate URL either on a per cache-entry basis or on a per cache-id basis. It is valid only if the `EdgeCacheable` property is also set for that entry. If the `EdgeCacheable` property is not set, the `alternate_url` property is ignored. The following is a sample cache policy using the `alternate_url` property:

```
<cache-entry>
 <class>servlet</class>
 <name>/AltUrlTest2.jsp</name>
 <property name="EdgeCacheable">true</property>
 <property name="alternate_url">/alturlcontroller2</property>
 <cache-id>
 <timeout>600</timeout>
 <priority>2</priority>
 </cache-id>
</cache-entry>
```

For more information on the `cachespec.xml` file, see `Cachespec.xml` file.

## Configuring external cache groups

The dynamic cache can control caches outside of the application server, such as IBM Edge Server, an IBM HTTP Server for distributed platforms' Fast Response Cache Accelerator (FRCA) cache, and a WebSphere HTTP Server for distributed platforms plug-in ESI Fragment Processor. When external cache groups are defined, the dynamic cache matches externally cacheable cache entries with those groups, and pushes cache entries and invalidations out to those groups. This allows WebSphere Application Server to manage dynamic content beyond the application server. The content can then be served from the external cache, instead of the application server, improving savings in performance.

1. Open the administrative console.
2. Enable the dynamic cache.
  - a. Click **Servers > Application Servers** in the administrative console navigation tree.
  - b. Click a *server*.
  - c. Click **Dynamic Cache Service**.
  - d. Select the check box in the **Startup state** field to enable the dynamic cache.
3. Define the external cache group in which WebSphere Application Server should control.
  - a. Click **External Caching Groups** from the Dynamic Cache administrative console page.
  - b. Click **New** or choose an external cache group from the list.
4. Configure cache group members.
  - a. Click **External cache groups** from the Dynamic Cache administrative console page. Then click **New** or choose an external cache group from the list.
  - b. Click **External cache group members > New** or choose an external cache group member from the list.
  - c. Type the configuration string in the **Address** field.
  - d. Type the adapter bean name in the **Adapter Bean Name** field.
  - e. **Save** the configuration.
  - f. Click **Apply** or **OK**.

## External cache group collection

Use this page to define sets of external caches controlled by WebSphere Application Server on Web servers, such as IBM Edge Server and IBM HTTP Server.

To view this administrative console page, click **Servers > Application Servers > server > Dynamic Cache Service > External Cache Groups**.

### **Name:**

Specifies the external cache group name.

The external cache group name needs to match the **ExternalCache** property as defined in the servlet or JSP `cachespec.xml` file.

When external caching is enabled, the cache matches pages with its URIs and pushes matching pages to the external cache. The entries can then be served from the external cache, instead of the application server.

### **Type:**

Specifies the external cache group type.

## External cache group settings

Use this page to configure sets of external caches controlled by WebSphere Application Server on Web servers, such as IBM Edge Server and IBM HTTP Server.

To view this administrative console page, click **Servers > Application Server > server > Dynamic Cache Service > External Cache groups > external\_cache\_group**.

### **Name:**

Specifies the external cache group name.

The external cache group name needs to match the **ExternalCache** property as defined in the servlet or JavaServer Pages (JSP) `cachespec.xml` file.

When external caching is enabled, the cache matches pages with its URIs and pushes matching pages to the external cache. The entries can then be served from the external cache, instead of the application server. This ability creates a significant savings in performance.

### **Type:**

Specifies the external cache group type.

## External cache group member collection

Use this page to define specific caches that are members of a cache group.

To view this administrative console page, click **Servers > Application Servers > server > Dynamic Cache Service > External Cache groups > external\_cache\_group > External cache group members**.

### **Address:**

Specifies a configuration string used by external cache adapter bean to connect to the external cache.

### **AdapterBeanName:**

Specifies the adapter bean name.

Example adapter bean names supported in WebSphere Application Server are:

Cache type	AdapterBeanName	Address
Fast Response Cache Accelerator (FRCA) cache - AFPA	com.ibm.ws.cache.servlet.Afpa	Port on which afpa listens
ESI Fragment Processor plug-in for WebSphere HTTP server	com.ibm.websphere.servlet.cache.ESIInvalidatorServlet	local host
IBM Edge Server - WTE	com.ibm.websphere.edge.dynacache.WteAdapter	hostname:port (host name and port on which WTE is listening)

## External cache group member settings

Use this page to configure specific caches that are members of a cache group.

To view this administrative console page, click **Servers > Application Servers > server > Dynamic Cache Service > External Cache groups > external\_cache\_group > External cache group members > external\_cache\_group\_member**.

### **Address:**

Specifies a configuration string used by external cache adapter bean to connect to the external cache.

### **AdapterBeanName:**

Specifies the adapter bean name.

Example adapter bean names supported in WebSphere Application Server are:

<b>AFPA</b>
AdapterBeanName: com.ibm.ws.cache.servlet.Afpa
Address: Port on which afpa listens
<b>ESI</b>
AdapterBeanName: com.ibm.websphere.servlet.cache.ESIInvalidatorServlet
Address: local host
<b>WTE</b>
AdapterBeanName: com.ibm.websphere.edge.dynacache.WteAdapter
Address: hostname:port (host name and port on which WTE is listening)

## Configuring high-speed external caching through the Web server

IBM HTTP Server for Windows NT and Windows 2000 operating systems contains a high-speed cache referred to as the *Fast Response Cache Accelerator*, or *cache accelerator*.

The Fast Response Cache Accelerator is available on Windows NT and Windows 2000 operating systems and AIX platforms. However, support to cache dynamic content is only available on Windows NT and Windows 2000 operating systems.

You can enable cache accelerator to cache static and dynamic content. To enable cache accelerator for caching static content, add the following directives to the `http.conf` configuration file, in the IBM HTTP Server conf directory:

- `AfpaEnable`
- `AfpaCache on`
- `AfpaLogFile "install_root\IBMHttpServer\logs\afpalog" V-ECLF`

To enable cache accelerator for caching dynamic content, such as servlets and Java Server Pages (JSP) files, configure the WebSphere Application Server and the IBM HTTP Server for distributed platforms:

1. Configure WebSphere Application Server to enable Fast Response Cache Accelerator. It is important to follow all the steps for every application server in the cluster.
  - a. Turn on servlet caching for each application server that uses the cache accelerator.
  - b. Configure an external cache group on the application server:
    - 1) Click **Servers > Application Servers > server1 > Dynamic Cache Service > External Cache Groups**.
    - 2) Click **New** on the External cache group administrative console page to define an external cache group named `afpa` for each application server that uses the cache accelerator.
    - 3) In the **External cache group** field, type `afpa` and apply the changes.
  - c. Add a member to the group with an adapter bean name of `com.ibm.ws.cache.servlet.Afpa`.
    - 1) Click **Afpa > External cache group members**.
    - 2) Click **New** on the External cache group members administrative console page.
    - 3) In the **AdapterBean name** field, type `com.ibm.ws.cache.servlet.Afpa`.
    - 4) In the **Address** field, enter an unused port number.
  - d. Add a cache policy in the `cachespec.xml` file for the servlet or JSP file you want to cache. Add the following property to the cache policy:

```
<property name="ExternalCache">afpa</property>
```
2. Enable cache accelerator on the IBM HTTP Server for distributed platforms:
  - a. Add the following directives to the end of the `httpd.conf` file:
    - `AfpaEnable`
    - `AfpaCache on`
    - `AfpaLogFile "install_root\IBMHttpServer\logs\afpalog" V-ECLF`
    - `LoadModule afpaplugin_module install_root/bin/afpaplugin.dll`
    - `AfpaPluginHost WAS_Hostname:port`, where `WAS_Hostname` is the host name of the application server and `port` is the port you specified in the **Address** field while configuring the external cache group member

The `LoadModule` directive loads the IBM HTTP Server plug-in that connects the Fast Response Cache Accelerator to the WebSphere Application Server fragment cache. If multiple IBM HTTP Servers are routing requests to a single application server, add the directives above to the `http.conf` file of each of these IBM HTTP Servers for distributed platforms. If one IBM HTTP Server is routing requests to a cluster of application servers, add the `AfpaPluginHost WAS_Hostname:port` directive to the `http.conf` file for each application server in the cluster. For example, if there are three application servers in the cluster, add the following directives to the `http.conf` file:

- `LoadModule afpaplugin_module install_root/bin/afpaplugin.dll`
- `AfpaPluginHost WAS1_Hostname:port1`
- `AfpaPluginHost WAS2_Hostname:port2`
- `AfpaPluginHost WAS3_Hostname:port3`

### **Configuring Fast Response Cache Accelerator cache size through a distributed platforms Web server:**

In the default IBM HTTP Server for distributed platforms configuration, the maximum Fast Cache Accelerator dynamic cache size is calculated as 1/8 of physical pin-able memory. On a machine with 384

megabytes of RAM, it allows a maximum of approximately 50 megabytes for the Fast Cache Accelerator dynamic cache. When this limit is reached, the Cache Accelerator then deletes older entries to cache new ones.

Follow these steps to configure the Cache Accelerator:

Using the IBM HTTP Server for distributed platforms' `AfpaDynaCacheMax` directive, tune the maximum allowed cache size:

1. Place the directive in the global server configuration scope, along with the other default Fast Cache Accelerator directives.
2. Enable Fast Cache Accelerator. To enable the Fast Cache Accelerator, update the following directives in this IBM HTTP Server's `http.conf` file:

```
AfpaEnable
AfpaCache on
AfpaLogFile "c:/Program Files/IBM HTTP Server/logs/afpalog" V-ECLF
AfpaDynaCacheMax 10
```

These above settings limit the dynamic cache size to 10 megabytes. If you use these directives to increase cache size, do not make the cache so large that all the physical memory is consumed. Determine how much memory is available when all applications are running, by using the Windows Task Manager.

Assign no more than 50% of available physical memory to the dynamic cache. Specifying too large a cache not only decreases the performance of other applications, but also puts you at a risk for completely running out of memory.

The default configuration does not include the `AfpaDynaCacheMax` directive where the cache size is automatically calculated as 1/8 of physical memory.

---

## Displaying cache information

The dynamic cache monitor is an installable Web application that displays simple cache statistics, cache entries, and cache policy information.

1. Use the administrative console to install the cache monitor application from the `install_root/installableApps` directory. The application is named `CacheMonitor.ear`. Install the cache monitor onto the application server you are trying to monitor. Installing the cache monitor on the `admin_host` (port 909x) is more secure than installing it on the `default_host` (908x), and so it is preferable to install it onto the `admin_host`.
2. Configure the HTTP transport and host alias for the server with cache monitor installed.
  - a. If you installed the cache monitor on the `admin_host` (port 909x), check if an HTTP transport has been created. Click **Application Servers > server > Web Container > HTTP Transports**. If an HTTP transport (port 909x) does not exist you must create an HTTP transport in the `admin_host` for this server. If you are using `server1`, an HTTP transport is installed by default for admin port 9090.
  - b. Add a host alias for the port your server is using. Click **Environment > Virtual Hosts > host\_type > Host Aliases** and create a new **Host Name** and **Port** to add to the list.
  - c. You can then access the cache monitor using `http://your_host_name:your_port_number/cachemonitor`.

**Tip:** You can find the port number in the `SystemOut.log` file. Look for message SRVE0171I.

3. Access the Web application using a Web browser and the URL `http://your_host_name:your_port_number/cachemonitor`, where `your_port_number` is the port associated with the host on which you installed the cache monitor application.
4. Verify that the cache monitor is working properly.
  - a. View the Statistics page and verify the cache configuration and cache data. Click **Reset Statistics** to reset the counters

- b. View the Cache Policies page to see which cache policies are currently loaded in the dynamic cache. Click on a template to view the cache ID rules for the template.
- c. View the Cache Contents page to examine the contents currently cached in memory.
- d. View the ESI Statistics page to view data about the current ESI processors configured for caching. Click **Refresh Statistics** to see the latest statistics or content from the ESI processors. Click **Reset Statistics** to reset the counters.
- e. View the Disk Offload page to view content currently off-loaded from memory to disk.

When viewing contents on memory or disk, click on a template to view all entries for that template, click on a dependency ID to view all entries for the ID, or click on the cache ID to view the entire data cached for that entry.

5. Use the cache monitor to perform basic operations on data in a cache.

**Remove an entry from cache**

Click **Invalidate** when viewing a cache entry.

**Remove all entries for a certain dependency ID**

Click **Invalidate** when viewing entries for a dependency ID.

**Remove all entries for a certain template**

Click **Invalidate** when viewing entries for a template.

**Move an entry to the front of the Least Recently Used queue to avoid eviction**

Click **Refresh** when viewing a cache entry.

**Move an entry from disk to cache**

Click **Send to Memory** when viewing a cache entry on disk.

**Clear the entire contents of the cache**

Click **Clear Cache** while viewing statistics or contents.

**Clear the contents on the ESI processors**

Click **Clear Cache** while viewing ESI statistics or contents.

**Clear the contents of the disk cache**

Click **Clear Disk** while viewing disk contents.

---

## Configuring cacheable objects with the cachespec.xml file

Define cacheable objects inside the `cachespec.xml`, found inside the Web module `WEB-INF` or enterprise bean `META-INF` directory.

You can place a global `cachespec.xml` in the application server properties directory, but the recommended method is to place the cache configuration file with the deployment module. The root element of the `cachespec.xml` file is `<cache>`, which contains `<cache-entry>` elements.

Within a `<cache-entry>...</cache-entry>` element are parameters that allow you to complete the following tasks to enable the dynamic cache with the `cachespec.xml` file:

1. Develop a `cachespec.xml` file.
  - a. Create a caching configuration file.
 

In the `<install_root>/properties` directory, locate the `cachespec.sample.xml` file.
  - b. Copy the `cachespec.sample.xml` file to `cachespec.xml` in Web module `WEB-INF` or enterprise bean `META-INF` directory.
2. Define the cache-entry elements necessary to identify the cacheable objects. See the topic “Cachespec.xml file” on page 1356 for a list of elements.
3. Develop cache-ID rules.

To cache an object, WebSphere Application Server must know how to generate unique IDs for different invocations of that object. The `<cache-id>` element performs that task. Each cache entry can have multiple cache-ID rules that execute in order until either a rule returns non-empty cache-ID or no more rules remain to execute. If none of the cache-ID generation rules produce a valid cache ID, then the object is not cached. Develop these IDs in one of two ways:

- Use the `<component>` element defined in the cache policy of a cache entry (recommended)
- Write custom Java code to build the ID from input variables and system state

To configure the cache entry to use the `IdGenerator`, specify your `IdGenerator` in the XML file by using the `<idgenerator>` tag, for example:

```
<cache-entry>
 <class>servlet</class>
 <name>/servlet/CommandProcessor</name>
<cache-id>
 <idgenerator>com.mycompany.SampleIdGeneratorImpl</idgenerator>
 <timeout>60</timeout>
</cache-id>
</cache-entry>
```

4. Specify dependency ID rules. Use dependency ID elements to specify additional cache group identifiers that associate multiple cache entries to the same group identifier.

The dependency ID is generated by concatenating the dependency ID base string with the values returned by its component elements. If a required component returns a null value, then the entire dependency ID does not generate and is not used. You can validate the dependency IDs explicitly through the WebSphere Dynamic Cache API, or use another cache-entry `<invalidation>` element. Multiple dependency ID rules can exist per cache-entry. All dependency ID rules separately execute. See the topic “Cachespec.xml file” on page 1356 for a list of `<component>` elements.

5. Invalidate other cache entries as a side effect of this object execution, if relevant. You can define invalidation rules in exactly the same manner as dependency IDs. However, the IDs that generate by invalidation rules are used to invalidate cache entries that have those same dependency IDs.

The invalidation ID is generated by concatenating the invalidation ID base string with the values returned by its component element. If a required component returns a null value, then the entire invalidation ID is not generated and no invalidation occurs. Multiple invalidation rules can exist per cache-entry. All invalidation rules separately execute.

6. Verify the cacheable page.

Typically you declare several `<cache-entry>...</cache-entry>` elements inside a `cachespec.xml` file.

The dynamic cache responds to changes in this file. When new versions of the `cachespec.xml` are detected, the old policies are replaced. Objects cached through the old policy file are not automatically invalidated from the cache; they are either reused with the new policy or eliminated from the cache through its replacement algorithm.

For each of the three IDs (cache, dependency, invalidation) generated by cache entries, a `<cache-entry>` can contain multiple elements. The dynamic cache will execute the `<cache-id>` rules in order, and the first one that successfully generates an ID will be used to cache that output. If the object is to be cached, each one of the `<dependency-id>` elements will be executed to build a set of dependency IDs for that cache entry. Finally, each of the `<invalidation>` elements will be executed, building a list of IDs that the dynamic cache will invalidate, whether or not this object is cached.

## Verifying the cacheable page

Verify the cacheable page by following these steps:

1. View the snoop servlet in the default application by accessing the URI: `/snoop`
2. Invoke and reload the URI several times using a different Web browser or using different parameters. This action returns the same output for the snoop servlet. The snoop servlet is now operating incorrectly, because it displays the request information from its first invocation rather than from the current request.
3. Inspect the entry in the cache with the dynamic cache monitor.

## Cachespec.xml file

The cache parses the `cachespec.xml` file on startup, and extracts from each `<cache-entry>` element a set of configuration parameters. Every time a new servlet or other cacheable object initializes, the cache attempts to match each of the different cache-entry elements, to find the configuration information for that object. Different cacheable objects have different `<class>` elements. You can define the specific object a cache policy refers to using the `<name>` element.

### Location

The `cachespec.xml` file is found inside the `WEB-INF` directory of a Web module.

You can place a global `cachespec.xml` file in the application server properties directory, but the recommended method is to place the cache configuration file with the deployment module. (To place the cache configuration file with the deployment module, use the Assembly ToolkitApplication Assembly Tool (AAT) to define the cacheable objects.

The root element of the `cachespec.xml` file is `cache`, which contains `cache-entry` elements.

The `cachespec.dtd` file is available in the application server properties directory.

### Usage notes

#### Cachespec.xml elements

Each cache entry must specify certain basic information that the dynamic cache uses to process that entry. This section explains the function of each cache entry element of the `cachespec.xml` file including:

- `class`
- `name`
- `sharing-policy`
- `property`
- `cache-id`

#### class

```
<class>command | servlet | webservice</class>
```

This element is required and governs how the application server interprets the remaining cache policy definition. The value `servlet` refers to servlets and JavaServer Pages (JSP) files deployed in the WebSphere Application Server servlet engine. The `webservice` class extends the `servlet` with special component types for Web services requests. Finally, the value `command` refers to classes using the WebSphere command programming model. The following examples illustrate the `class` element:

```
<class>command</class>
<class>servlet</class>
<class>webservice</class>
```

#### name

```
<name>name</name>
```

where *name* is the fully qualified class name of the command, servlet, or Web service.

There are two ways to use `<name>` to specify a cacheable object:

- For commands and Web services, this required element must include the package name, if any, and class name, including a trailing `.class`, of the configured object.
- For Web Services, include the URI of the SOAP router associated with the Web service that you want to cache.

- For servlets and JSP files, if the cachespec.xml file is in the WebSphere Application Server properties directory, this required element must include the full URI of the JSP file or servlet to cache. For servlets and JSP files, if the cachespec.xml file is in the Web application, this required element can be relative to the specific Web application context root.

**Note:** The preferred location of the cachespec.xml file is in the Web application, not the properties directory.

You can specify multiple <name> elements within a <cache-entry> if you have different mappings that refer to the same servlet.

The following examples illustrate the name element:

```
<name>com.mycompany.MyCommand.class</name>
<name>default_host:/servlet/snoop</name>
<name>com.mycompany.beans.MyJavaBean</name>
<name>mywebapp/myjsp.jsp</name>
```

### sharing-policy

```
<sharing-policy> not-shared | shared-push | shared-pull | shared-push-pull</sharing-policy>
```

When working within a cluster with a distributed cache, these values determine the sharing characteristics of entries created from this object. If this element is not present, a not-shared value is assumed. Also, in non-distributed environments, not-shared is the only valid value. When enabling replication, the default value is shared-push only. This property does not affect distribution to Edge Side Include processors through the Edge fragment caching property.

Value	Description
not-shared	Cache entries for this object are not shared among different application servers. These entries can contain non-serializable data. For example, a cached servlet can place non-serializable objects into the request attributes, if the <class> type supports it.
shared-push	Cache entries for this object are automatically distributed to the dynamic caches in other application servers or cooperating Java virtual machines (JVMs). Each cache has a copy of the entry at the time it is created. These entries cannot store non-serializable data.
shared-pull	Cache entries for this object are shared between application servers on demand. If an application server gets a cache miss for this object, it queries the cooperating application servers to see if they have the object. If no application server has a cached copy of the object, the original application server executes the request and generates the object. These entries cannot store non-serializable data. This mode of sharing is not recommended.
shared-push-pull	Cache entries for this object are shared between application servers on demand. When an application server generates a cache entry, it broadcasts the cache ID of the created entry to all cooperating application servers. Each server then knows whether an entry exists for any given cache ID. On a given request for that entry, the application server knows whether to generate the entry or pull it from somewhere else. These entries cannot store non-serializable data.

The following example shows a sharing policy:

```
<sharing-policy>not-shared</sharing-policy>
```

### property

```
<property name="key">value</property>
```

where *key* is the name of the property defined for this cache entry element, and *value* is the corresponding value.

You can set optional properties on a cacheable object, such as a description of the configured servlet. The class determines valid properties of the cache entry. At this time, the following properties are defined:

Property	Valid classes	Value
ApplicationName	All	Overrides the J2EENAME application ID so that multiple applications can share a common cache ID namespace.
EdgeCacheable	Servlet	True or false. Default is false. If the property is true, then the given servlet or JSP file is externally requested from an Edge Side Include processor. Whether or not the servlet or JSP file is cacheable depends on the rest of the cache specification.
ExternalCache	Servlet	Specifies the external cache name. The external cache name needs to match the external cache group name.
consume-subfragments	Servlet or Web service	True or false. Default is false. When a servlet is cached, only the content of that servlet is stored, and includes placeholders for any other fragments to which it includes or forwards. Consume-subfragments (CSF) tells the cache not to stop saving content when it includes a child servlet. The parent entry, the one marked CSF, includes all the content from all fragments in its cache entry, resulting in one big cache entry that has no includes or forwards, but the content from the whole tree of entries. This can save a significant amount of application server processing, but is typically only useful when the external HTTP request contains all the information needed to determine the entire tree of included fragments.
alternate_url	Servlet	Specifies the alternate URL used to invoke the servlet or JSP file. The property is valid only if the EdgeCacheable property also is set for the cache entry.

persist-to-disk	All	True or false. Default is true. When this property is set to false, the cache entry is not written to the disk when overflow or server stopping occurs.
save-attributes	Servlet	True or false. Default is true. When this property is set to false, the request attributes are not saved with the cache entry.

## cache-id

To cache an object, the application server must know how to generate a unique ID for different invocations of that object. These IDs are built either from user-written custom Java code or from rules defined in the cache policy of each cache entry. Each cache entry can have multiple cache ID rules that are executed in order until either:

- A rule returns a non-empty cache ID, or
- No more rules are left to execute.

If none of the cache ID generation rules produce a valid cache ID, the object is not cached.

Each `cache-id` element defines a rule for caching an object and is composed of the sub-elements `component`, `timeout`, `priority`, and `property`. The following example illustrates a `cache-id`:

```
<cache-id>component*| timeout? | priority? | property* </cache-id>
```

## component sub-element

Use the `component` sub-element to generate a portion of the cache ID. Each `component` sub-element consists of the attributes `id`, `type`, and `ignore-value`, and the elements `method`, `field`, `required`, `value`, and `not-value`.

- Use the `id` attribute to identify the component.
- Use the `type` attribute to identify the type of component. The following table lists the values for the `type`.

Type	Valid classes	Meaning
method	command	Calls the indicated method on the command or object
field	command	Retrieves the named field in the command or object
parameter	servlet	Retrieves the named parameter value from the request object
parameter-list	servlet	Retrieves a list of values for the named parameter
session	servlet	Retrieves the named value from the <code>HTTPSession</code>
cookie	servlet	Retrieves the named cookie value
attribute	servlet	Retrieves the named request attribute
header	servlet and Web service	Retrieves the named request header
pathInfo	servlet	Retrieves the <code>pathInfo</code> from the request
servletpath	servlet	Retrieves the servlet path
locale	servlet	Retrieves the request locale

SOAPEnvelope	Web service	Retrieves the SOAPEnvelope from a Web services request. An ID attribute of Hash uses a Hash of the SOAPEnvelope, while Literal uses the SOAPEnvelope as received.
SOAPAction	Web service	Retrieves the SOAPAction header, (if available), for a Web services request.
serviceOperation	Web service	Retrieves the service operation for a Web services request
serviceOperationParameter	Web service	Retrieves the specified parameter from a Web services request

- Use the `ignore-value` attribute to specify whether or not to use the value returned by this component in cache ID formation. This is an optional attribute with a default value of `false`. If the value is `true`, only the ID of the component is used when creating a cache ID, or no output is used when creating a dependency or invalidation ID.

- Use the **method** element to call a void method on a returned object. You can infinitely nest method and field objects in any combination. The method must be public and is not valid for edge-cacheable components. For example:

```
<component id="getUser" type="method"><method>getUserInfo
<method>getName</method></method></component>
```

This method is equivalent to `getUser().getUserInfo().getName()`

- Use the **field** element to access a field in a returned object. You can infinitely nest method and field objects in any combination. The field must be public. Not valid for edge-cacheable components. For example:

```
<component id="getUser" type="method"><method>getUserInfo
<field>name</field></method></component>
```

This method is equivalent to `getUser().getUserInfo().name`

- Use the **required** element to specify whether or not this component must return a non-null value for this cache ID for it to represent a valid cache. If set to `true`, this component must return a non-null value for this cache ID to represent a valid cache ID. If set to `false`, the default, a non-null value is used in the formation of the cache ID and a null value means that this component is not used at all in the ID formation. For example:

```
<required>true</required>
```

- Use the **value** element to specify values that must match to use this component in cache ID formation. For example:

```
<component id="getUser" type="method"><value>blue</value>
<value>red</value> </component>
```

- Use the **not-value** element to specify values that must not match to use this component in cache ID formation. This method is similar to `<value>`, but instead prescribes the defined values from caching. You can use multiple `<not-value>` elements when there is more than one invalid value. For example:

```
<component id="getUser" type="method">
<required>true</required>
<not-value>blue</not-value>
<not-value>red</not-value></component>
```

The component element can have either a method and a field element, a value element, or a not-value element. The method and field elements apply only to commands. The following example illustrates the attributes of a component element:

```
<component id="isValid" type="method" ignore-value="true"><component>
```

### timeout sub-element

The timeout sub-element is used to specify a time-to-live (TTL) value for the cache entry. For example,

`<timeout>value</timeout>`

where *value* is the amount of time, in seconds, to keep the cache entry. If 0, or a negative value is specified, the cache entry is kept indefinitely.

### priority sub-element

Use the priority sub-element to specify the priority of a cache entry in a cache. The priority weighting is used by the least recently used (LRU) algorithm, of the cache to decide which entries to remove from the cache if the cache runs out of storage space. For example,

`<priority>value</priority>`

where *value* is a positive integer between 1 and 255 inclusive.

### property sub-element

Use the property sub-element to specify generic properties for the cache entry. For example,

`<property name="key">value</property>`

where *key* is the name of the property to define, and *value* is the corresponding value.

For example:

`<property name="description">The Snoop Servlet</property>`

Property	Valid classes	Meaning
sharing-policy/timeout/priority	All	Overrides the settings for the containing cache entry when the request matches this cache ID.
EdgeCacheable	servlet	Overrides the settings for the containing cache entry when the request matches this cache ID.

### idgenerator and metadatagenerator elements

Use the `idgenerator` element to specify the class name loaded for the generation of the cache ID. The `IdGenerator` must implement the `com.ibm.websphere.servlet.cache.IdGenerator` interface. The `IdGenerator` must build and set cache IDs, group IDs and invalidation IDs. An example of the `idgenerator` element follows:

`<idgenerator> classname classname </idgenerator>`

(where *classname*= Fully qualified name of the class to use)

Use the `metadatagenerator` element to specify the class name loaded for the metadata generation cache ID. The `MetadataGenerator` class must implement the `com.ibm.websphere.servlet.cache.MetadataGenerator` interface. The `MetadataGenerator` defines properties like timeout, external caching or generic properties. An example of the `metadatagenerator` element follows:

`<metadatagenerator> classname classname </metadatagenerator>`

(where *classname*= Fully qualified name of the class to use)

---

## Configuring command caching

Cacheable commands are stored in the cache for re-use with a similar mechanism for servlets and Java Server Pages (JSP) files. However, in this case, the unique cache IDs are generated based on methods and fields present in the command as input parameters. For example, a **GetStockQuote** command can have a symbol as its input parameter.

A unique cache ID can generate from the name of the command, plus the value of the symbol.

To use command caching you must:  
Create a command.

1. Define an interface. The Command interface specifies the most basic aspects of a command. You must define the interface that extends one or more of the interfaces in the command package. The command package consists of three interfaces:
  - TargetableCommand
  - CompensableCommand
  - CacheableCommand

In practice, most commands implement the TargetableCommand interface, which allows the command to execute remotely. The code structure of a command interface for a targetable command follows:

```
...
import com.ibm.websphere.command.*;
public interface MyCommand extends TargetableCommand {
 // Declare application methods here
}
```

2. Provide an implementation class for the interface. Write an interface that extends the CacheableCommandImpl class and implements your command interface. This class contains the code for the methods in your interface, the methods inherited from extended interfaces like the CacheableCommand interface, and the required or abstract methods in the CacheableCommandImpl class. You can also override the default implementations of other methods provided in the CacheableCommandImpl class.

## Command class

To write a command interface, extend one or more of the three interfaces included in the command package. The base interface for all commands is the Command interface. This interface provides only the client-side interface for generic commands and declares three basic methods:

- **isReadyToCallExecute**. This method is called on the client side before the command passes to the server for execution.
- **execute**. This method passes the command to the target and returns any data.
- **reset**. This method reverts any output properties to the values they had before the execute method was called so that you can reuse the object.

The implementation class for your interface must contain implementations for the isReadyToCallExecute and reset methods.

## CacheableCommandImpl class

Commands are implemented by extending the class CacheableCommandImpl, which implements the CacheableCommand interface.

The CacheableCommandImpl class is an abstract class that provides implementations for some of the methods in the CacheableCommand interface, for example, setting return values. This class declares additional methods that the application must implement, for example, how to execute the command.

The code structure of an implementation class for the CacheableCommand interface follows:

```
...
import com.ibm.websphere.command.*;
public class MyCommandImpl extends CacheableCommandImpl
implements MyCommand {
 // Set instance variables here ...
 // Implement methods in the MyCommand interface ...
 // Implement abstract methods in the CacheableCommandImpl class
 ...
}
```

## Example: Caching a command object

This example of command caching is a simple stock quote command.

The following is a stock quote command bean. It accepts a ticker as an input parameter and produces a price as its output parameter.

```
public class QuoteCommand extends CacheableCommandImpl
{
 private String ticker;
 private double price;
 // called to validate that command input parameters have been set
 public boolean isReadyToCallExecute() {
 return (ticker!=null);
 }
 // called by a cache-hit to copy output properties to this object
 public void setOutputProperties(TargetableCommand fromCommand) {
 QuoteCommand f = (QuoteCommand)fromCommand;
 this.price = f.price;
 }

 // business logic method called when the stock price must be retrieved
 public void performExecute()throws Exception {...}

 //input parameters for the command
 public void setTicker(String ticker) { this.ticker=ticker;}
 public String getTicker() { return ticker;}

 //output parameters for the command
 public double getPrice() { return price;};
}
```

To cache the above command object using the stock ticker as the cache key and using a 60 second time-to-live, use the following cache policy:

```
<cache>
<cache-entry>
<class>command</class>
<sharing-policy>not-shared</sharing-policy>
<name>QuoteCommand</name>
<cache-id>
<component type="method" id="getTicker">
<required>true</required>
</component>
<priority>3</priority>
<timeout>60</timeout>
</cache-id>
</cache-entry>
</cache>
```

---

## Using the DistributedMap interface for the dynamic cache

The DistributedMap interface is a simple interface for the dynamic cache. Using the DistributedMap interface, J2EE applications and system components can cache and share Java objects by storing a reference to the object in the cache. The default WebSphere dynamic cache instance is created if dynamic cache service is enabled in the administrative console. This default instance is bound into the global JNDI namespace using the name `services/cache/distributedmap`. For information on how to enable the dynamic cache service globally, see [Enabling the dynamic cache service](#).

Multiple instances of the DistributedMap interface on the same Java virtual machine (JVM) enables applications to separately configure cache instances as needed. Each instance of DistributedMap has its own properties:

- **Cache JNDI name.** The JNDI name is used for calling a particular DistributedMap instance.
- **Cache size (Property name: `cacheSize`, Default: 2000).** Dynamic cache maintains the maximum number of entries in memory.
- **Enable disk offload (Property name: `enableDiskOffload`, Default: `false`).**
  - Disk offload is disabled - If a new entry is created while the cache is full, the priorities configured for each entry, along with at least recently used algorithm are used to remove the entry from the cache in memory.
  - Disk offload is enabled - If a new entry is created while the cache is full, the priorities configured for each entry, along with a recently used algorithm are used to remove the entry from the cache in memory. The entry that is removed is copied to the local file system, specified by the disk offload location.
- **Disk offload location (Property name: `diskOffloadLocation`).** If disk offload location is not specified, the default location, `$install_root/temp/node/servername/_dynacache/cacheJNDIname` will be used. If disk offload location is specified, the node, server name, and cache instance name will be appended. For example, `$install_root/diskoffload` generates the location as `$install_root/diskoffload/node/servername/cacheJNDIname`. This value is ignored if `enableDiskOffload` is `false`.
- **Flush to disk default (Property name: `flushToDiskOnStop`, Default: `false`).** Set this value to `true` to save in-memory cached objects to disk when the server is stopped. This value is ignored if `enableDiskOffload` is `false`.
- **Use listener context (Property name: `useListenerContext`, Default: `false`).** Used for cache invalidation listener. If the user wants to use listener J2EE context for callback, set this to `true`. If the user wants to use the caller thread context for callback, set this to `false`.

There are three methods for configuring and using cache instances.

### Method 1 - Administrative Console

You can create additional cache instances using the Administrative Console. Click **Resources > Cache Instances**. After you create a new cache instance, you can optionally add additional properties, such as `flushToDiskOnStop` and `useListenerContext`, using the custom properties. See “Cache instance settings” on page 1366 for more information.

If you defined two cache instances in the Administrative Console with JNDI names of **`services/cache/instance_one`** and **`services/cache/instance_two`**, you can use the following code to look up the cache instances:

```
InitialContext ic = new InitialContext();
DistributedMap dm1 = (DistributedMap)ic.lookup("services/cache/instance_one");
DistributedMap dm2 = (DistributedMap)ic.lookup("services/cache/instance_two");
```

**Note:** For more information about the DistributedMap interface, see the Javadoc for the `com.ibm.websphere.cache` package.

## Method 2 - Properties file

**Note:** The `distributedmap.properties` file will be deprecated in a future release. Using the Administrative Console is the recommended way to configure cache instances.

You can create additional cache instances using the `distributedmap.properties` file with the following format :

```
cache.instance.0=/services/cache/instance_one
cache.instance.0.cacheSize=1000
cache.instance.0.enableDiskOffload=true
cache.instance.0.diskOffloadLocation=${WAS_INSTALL_ROOT}/diskOffload
cache.instance.0.flushToDiskOnStop=true
cache.instance.0.useListenerContext=true
cache.instance.1=/services/cache/instance_two
cache.instance.1.cacheSize=1500
cache.instance.1.enableDiskOffload=false
cache.instance.1.flushToDiskOnStop=false
cache.instance.1.useListenerContext=false
```

The preceding example creates two `DistributedMap` instances named `instance_one` and `instance_two`. `instance_one` has a cache entry size of 1,000 and `instance_two` has a cache entry size of 1,500. Disk offload is enabled in `instance_one` and disabled in `instance_two`. Use listener context is enabled in `instance_one` and disabled in `instance_two`. Flush to disk on stop is enabled in `instance_one` and disabled in `instance_two`.

You must place the `distributedmap.properties` file in either your application server or application class path. For example, you can use your application WAR file, `WEB-INF\classes` directory, or `was_root\classes` directory. The first entry in the properties file (`cache.instance.0`) specifies the JNDI name for the cache instance in the global namespace. You can use the following code to look up the cache instance:

```
InitialContext ic = new InitialContext();
DistributedMap dm1 = (DistributedMap)ic.lookup("services/cache/instance_one");
DistributedMap dm2 = (DistributedMap)ic.lookup("services/cache/instance_two");
```

**Note:** For more information about the `DistributedMap` interface, see the Javadoc for the `com.ibm.websphere.cache` package.

## Method 3 - Resource references

**Note:** Method three is an extension to method one or method two, listed above. First use either method one or method two.

Define a `resource-ref` in your module deployment descriptor (`web.xml` and `ibm-web-bnd.xml` files) and look up the cache using the `java:comp` namespace.

### Resource-ref example:

#### File: `web.xml`

```
<resource-ref id="ResourceRef_1">
 <res-ref-name>dmap/LayoutCache</res-ref-name>
 <res-type>com.ibm.websphere.cache.DistributedMap</res-type>
 <res-auth>Container</res-auth>
 <res-sharing-scope>Shareable</res-sharing-scope>
</resource-ref>
<resource-ref id="ResourceRef_2">
 <res-ref-name>dmap/UserCache</res-ref-name>
 <res-type>com.ibm.websphere.cache.DistributedMap</res-type>
 <res-auth>Container</res-auth>
 <res-sharing-scope>Shareable</res-sharing-scope>
</resource-ref>
```

#### File: `ibm-web-bnd.xml`

```
<?xml version="1.0" encoding="UTF-8"?>
```

```

<webappbnd:WebAppBinding xmi:version="2.0" xmlns:xmi="http://www.omg.org/XMI"
xmlns:webappbnd="webappbnd.xmi"
xmlns:webapplication="webapplication.xmi" xmlns:commonbnd="commonbnd.xmi"
xmlns:common="common.xmi"
xmi:id="WebApp_ID_Bnd" virtualHostName="default_host">
 <webapp href="WEB-INF/web.xml#WebApp_ID"/>
 <resRefBindings xmi:id="ResourceRefBinding_1" jndiName="services/cache/instance_one">
 <bindingResourceRef href="WEB-INF/web.xml#ResourceRef_1"/>
 </resRefBindings>
 <resRefBindings xmi:id="ResourceRefBinding_2" jndiName="services/cache/instance_two">
 <bindingResourceRef href="WEB-INF/web.xml#ResourceRef_2"/>
 </resRefBindings>
</webappbnd:WebAppBinding>

```

The following example shows how to look up the resource-ref:

```

InitialContext ic = new InitialContext();
DistributedMap dm1a =(DistributedMap)ic.lookup("java:comp/env/dmap/LayoutCache");
DistributedMap dm2a =(DistributedMap)ic.lookup("java:comp/env/dmap/UserCache");

```

The previous resource-ref example maps `java:comp/env/dmap/LayoutCache` to `/services/cache/instance_one` and `java:comp/env/dmap/UserCache` to `/services/cache/instance_two`. In the examples, `DistributedMap dm1` and `dm1a` are the same map. `DistributedMap dm2` and `dm2a` are the same map.

**Note:** The `DistributedMap` interface does not currently have authorization or access control associated with any of the cache entries.

To learn how to share cached objects in a clustered environment, see [Sharing cached objects in a clustered environment](#).

## Sharing cached objects in a clustered environment

In a clustered environment, the content you place in cache might be shared with other servers in the cluster. The content might also be off-loaded to disk. If you intend to have the cached objects shared or off-loaded to disk, you must make these particular objects serializable. If the objects you place in cache are non-serializable, you must specify that the sharing policy for these objects is "not shared". The `DistributedMap` interface Javadoc contains information about how to specify the sharing policy for a cached object. Specifying a sharing policy other than "not shared" for non-serializable objects can result in poor system performance.

## Cache instance settings

A cache instance is a location, in addition to the default shared dynamic cache, where any Java 2 platform, Enterprise Edition (J2EE) application can store, distribute, and share data. The cache instance gives applications greater flexibility and better tuning of the cache resources. The programming interface to access this cache instance is called `DistributedMap`. See the `DistributedMap` API documentation in the WebSphere Application Server Javadoc for more information.

To view this administrative console page, click **Resources > Cache Instances**.

### Name

Specifies the required display name for the resource.

### JNDI name

Specifies the Java Naming and Directory Interface (JNDI) name for the resource. Use this name when looking up a reference to this cache instance. The returned object has a `DistributedMap` type.

### Description

Specifies a description for the resource. This field is optional.

## Category

Specifies a category string to classify or group the resource. This field is optional.

## Cache Size

Specifies a positive integer for the maximum number of entries that the cache holds.

The range is 100 to 200,000.

## Default Priority

Specifies the default priority for servlets that can be cached. This value determines how long an entry stays in a full cache.

The recommended value is one.

## Enable Disk Offload

Selecting this option will enable disk offloading.

## Disk Offload Location

Specifies the directory used for disk offload.

## Flush to Disk

Specifies if in-memory cached objects are saved to disk when the server is stopped. This value is ignored if the Enable Disk Offload value is false.

## Use Listener Context

Set this value to `true` to have invalidation events sent to registered invalidation listeners using the J2EE context of the listener.

## Additional custom properties (available only when a cache instance is created)

Custom properties are available for the `flushToDiskOnStop` and `useListenerContext` instances.

You can define custom properties after you create a cache instance.

**Name** Specifies the name of the custom property. In this case, the name is either `flushToDiskOnStop` or `useListenerContext`. This field is required.

**Value** Specify `true` or `false` to indicate the value of the custom property. This field is required.

### Description

Describes any bounds or values of the custom property. This field is optional.

## Cache instance collection

Use this page to configure and manage cache instances.

To view this administrative console page, click **Resources > Cache Instances > New**.

## Scope

Use the Scope to limit the availability of the cache instance to a particular cell, node, or server. Select the Cell scope to view and configure cache instances that are available to all servers within the cell. Specify the Node scope to view and configure cache instances that are available to all servers with the particular node. Specify the Server scope to view and configure cache instances that are available only on the specific server.

## Name

Specifies the required display name for the resource.

## JNDI name

Specifies the Java Naming and Directory Interface (JNDI) name for the resource. Use this name when looking up a reference to this cache instance. The returned object is of the DistributedMap type.

## Description

Specifies a description for the resource. This field is optional.

## Category

Specifies a category string to classify or group the resource. This field is optional.

## Cache Size

Specifies a positive integer for the maximum number of entries that the cache holds.

The range is 100 to 200,000.

## Enable Disk Offload

Selecting this option enables disk offloading.

By default, dynamic cache only maintains the number of entries configured in memory. If new entries are created while the cache is full, the priorities configured for each cache entry, along with a least recently used (LRU) algorithm, are used to remove entries from the cache. As an alternative, you can configure disk offload to copy entries onto the file system for access at a later time. The location to copy the entries is configurable.

## Cache instance service settings

The Cache Instance Service enables server-level configuration for Cache Instance resources.

To view this administrative console page, click **Servers > Application Servers > server1 > Cache Instance Service**.

## Startup

Specifies whether the server will attempt to start the specified service when the server starts. Checking the box turns this service on or off.

## Invalidation listeners

Invalidation listener mechanism uses Java events for alerting applications when contents are removed from the cache.

Applications implement the InvalidationListener interface (defined in the `com.ibm.websphere.cache` package) and register it to the cache using the DistributedMap interface. Listeners receive InvalidationEvents (defined in the `com.ibm.websphere.cache` package) when entries from the cache are evicted, due to an explicit user invalidation, timeout, least recently used (LRU) eviction, cache clear, or disk timeout. Applications can immediately recalculate the invalidated data and prime the cache before the next user request.

Enable listener support in DistributedMap before registering listeners. DistributedMap can also be configured to use the invalidation listener J2EE context from registration time during callbacks. Setting the value of the custom property `useListenerContext` to true will enable the invalidation listener J2EE context for callbacks. See Cache instance settings for more information.

The following example shows how to set up an invalidation listener:

```
dmap.enableListener(true); // Enable cache invalidation listener.
InvalidationListener listener = new MyListenerImpl(); //Create invalidation listener object.
dmap.addInvalidationListener(listener); //Add invalidation listener.
:
:
```

```
 :
dmap.removeInvalidationListener(listener); //Remove the invalidation listener.
//This increases performance.
dmap.enableListener(false); // Disable cache invalidation listener.
//This increases performance.
```

For more information about invalidation listeners, see the Javadoc for the `com.ibm.websphere.cache` package.

---

## Example: Caching Web services

The following is an example of building a set of cache policies for a simple Web services application. The application in this example stores stock quotes, and has operations to read, update the price of, and buy a given stock symbol.

Following are two SOAP message examples that the application can receive, with accompanying HTTP Request headers.

The first message sample contains a SOAP message for a `GetQuote` operation, requesting a quote for IBM. This is a read-only operation that gets its data from the back-end, and is very cacheable. In this example the SOAP message is cached and a timeout is placed on its entries to guarantee the quotes it returns are not too out of date.

### Message example 1

```
POST /soap/servlet/soaprouter
HTTP/1.1
Host: www.myhost.com
Content-Type: text/xml; charset="utf-8"
SOAPAction: urn:stockquote-lookup
<SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/"
SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
<SOAP-ENV:Body>
<m:getQuote xmlns:m="urn:stockquote:>
<symbol>IBM</symbol>
</m:getQuote>
</SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

The `SOAPAction` HTTP header in the request is defined in the SOAP specification and is used by HTTP proxy servers to dispatch requests to particular HTTP servers. WebSphere Application Server dynamic cache can use this header in its cache policies to build IDs without having to parse the SOAP message.

Message example 2 illustrates a SOAP message for a `BuyQuote` operation. While message 1 is cacheable, this message is not, because it updates the back-end database.

### Message example 2

```
POST /soap/servlet/soaprouter
HTTP/1.1
Host: www.myhost.com
Content-Type: text/xml; charset="utf-8"
SOAPAction: urn:stockquote-update
<SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/"
SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
<SOAP-ENV:Body>
<m:buyStock xmlns:m="urn:stockquote:>
<symbol>IBM</symbol>
</m:buyStock>
</SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

The graphic illustrates how to invoke methods with the SOAP messages. In Web services terms, especially Web Service Definition Language (WSDL), a service is a collection of operations such as getQuote and buyStock. A body element namespace (urn:stockquote in our example) defines a service, and the name of the first body element indicates the operation.

The following is an example of WSDL for the getQuote operation:

```
<?xml version="1.0"?>
<definitions name="StockQuoteService-interface"
targetNamespace="http://www.getquote.com/StockQuoteService-interface"
xmlns:tns="http://www.getquote.com/StockQuoteService-interface"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
xmlns="http://schemas.xmlsoap.org/wsdl/"
<message name="SymbolRequest">
<part name="return" type="xsd:string"/>
</message>
<portType name="StockQuoteService">
<operation name="getQuote">
<input message="tns:SymbolRequest"/>
<output message="tns:QuoteResponse"/>
</operation>
</portType>
<binding name="StockQuoteServiceBinding"
type="tns:StockQuoteService">
<soap:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/http"/>
<operation name="getQuote">
<soap:operation soapAction="urn:stockquote-lookup"/>
<input>
<soap:body use="encoded" namespace="urn:stockquote"
encodingStyle="http://schemas.xmlsoap.org/soap/encoding"/>
</input>
<output>
<soap:body use="encoded" namespace="urn:stockquotes"
encodingStyle="http://schemas.xmlsoap.org/soap/encoding"/>
</output>
</operation>>
</binding>
</definition>
```

To build a set of cache policies for a Web services application configure WebSphere Application Server dynamic cache to recognize cacheable service operation of the operation.

WebSphere Application Server inspects the HTTP request to determine whether or not an incoming message can be cached based on the cache policies defined for an application. In this example, buyStock and stock-update are not cached, but stockquote-lookup is cached. In the cachespec.xml file for this Web application, the cache policies need defining for these services so that the dynamic cache can handle both SOAPAction and service operation.

WebSphere Application Server uses the operation and the message body in Web services cache IDs, each of which has a component associated with them. Therefore, each Web services <cache-id> rule contains only two components. The first is for the operation. Because you can perform the stockquote-lookup operation by either using a SOAPAction header or a service operation in the body, you must define two different <cache-id> elements, one for each method. The second component is of type "body", and defines how WebSphere Application Server should incorporate the message body into the cache ID. You can use a hash of the body, although it is legal to use the literal incoming message in the ID.

The incoming HTTP request is analyzed by WebSphere Application Server to determine which of the <cache-id> rules match. Then, the rules are applied to form cache or invalidation IDs.

The following is sample code of a cachespec.xml file defining SOAPAction and servicesOperation rules:

```
<cache>
<cache-entry>
<class>webservice</class>
<name>/soap/servlet/soaprouter</name>
<sharing-policy>not-shared</sharing-policy>
<cache-id>
<component id="" type=SOAPAction>
<value>urn:stockquote-lookup</value>
</component>
<component id="Hash" type="SOAPEnvelope"/>
<timeout>3600</timeout>
<priority>1</priority>
</cache-id>
<cache-id>
<component id="" type="serviceOperation">
<value>urn:stockquote:getQuote</value>
</component>
<component id="Hash" type="SOAPEnvelope"/>
<timeout>3600</timeout>
<priority>1</priority>
</cache-id>
</cache-entry>
</cache>
```

---

## Example: Configuring the dynamic cache

This example puts all the steps together for configuring the dynamic cache with the cachespec.xml file, showing the use of the cache ID generation rules, dependency IDs, and invalidation rules.

Suppose we have a servlet which is used to manage a simple news site. This servlet uses the query parameter "action" to determine whether the request is being used to "view" news or "update" news (used by the administrator). Further, another query parameter "category" is used to select the news category. Further, suppose that this site supports an optional customized layout, which is stored in the user's session using the attribute name "layout". Here are example URL requests to this servlet:

<http://yourhost/yourwebapp/newscontroller?action=view&category=sports> (Returns a news page for the sports category )

<http://yourhost/yourwebapp/newscontroller?action=view&category=money> (Returns a news page for the money category)

<http://yourhost/yourwebapp/newscontroller?action=update&category=fashion> (Allows the administrator to update news in the fashion category)

Here are the steps for configuring dynamic cache with cachespec.xml, using the information provided to you:

1. Define the cache-entry elements necessary to identify the servlet. In this case, the servlet's URI is "newscontroller" so this will be our cache-entry's name element. Also, since we are caching a servlet/JavaServer Page (JSP), the cache-entry class is "servlet".

```
<cache-entry>
<name> /newscontroller </name>
<class>servlet </class>
</cache-entry>
```

2. Define cache ID generation rules. For this servlet, we only want to cache when action=view, so one component of the cache ID will be the parameter "action" when the value equals "view". The news category is also an essential part of the cache ID. Finally, the optional session attribute for the user's layout is included in the cache ID. The cache-entry now looks like this:

```
<cache-entry>
<name> /newscontroller </name>
<class>servlet </class>
<cache-id>
<component id="action" type="parameter">
<value>view</value>
<required>true</required>
</component>
<component id="category" type="parameter">
<required>true</required>
</component>
<component id="layout" type="session">
<required>false</required>
</component>
</cache-id>
</cache-entry>
```

3. Define dependency ID rules. For this servlet, a dependency ID will be added for the category. Later, when the category is invalidated due to an update event, all views of that news category will be invalidated. After adding our dependency-id, the cache-entry now looks like this:

```
<cache-entry>
<name>newscontroller </name>
<class>servlet </class>
<cache-id>
<component id="action" type="parameter">
<value>view</value>
<required>true</required>
</component>
<component id="category" type="parameter">
<required>true</required>
</component>
<component id="layout" type="session">
<required>false</required>
</component>
</cache-id>
<dependency-id>category
<component id="category" type="parameter">
<required>true</required>
</component>
</dependency-id>
</cache-entry>
```

4. Define invalidation rules. Since we defined a category dependency ID, we will now define an invalidation rule to invalidate the category when action=update. To incorporate the conditional logic, we will add "ignore-value" components into the invalidation rule. These components will not add to the output of the invalidation ID, but will only determine whether or not the invalidation ID is created and executed. The final cache-entry now looks like this:

```
<cache-entry>
<name>newscontroller </name>
<class>servlet </class>
<cache-id>
<component id="action" type="parameter">
<value>view</value>
<required>true</required>
```

```

 </component>
 <component id="category" type="parameter">
 <required>true</required>
 </component>
 <component id="layout" type="session">
 <required>false</required>
 </component>
 </cache-id>
 <dependency-id>category
 <component id="category" type="parameter">
 <required>true</required>
 </component>
 </dependency-id>
 <invalidation>category
 <component id="action" type="parameter" ignore-value="true">
 <value>update</value>
 <required>true</required>
 </component>
 <component id="category" type="parameter">
 <required>true</required>
 </component>
 </invalidation>
</cache-entry>

```

---

## Cache monitor

Cache monitor is an installable Web application that provides a real-time view of the current state of dynamic cache. You use it to help verify that dynamic cache is operating as expected. The only way to manipulate the data in the cache is by using the cache monitor. It provides a GUI interface to manually change data.

Cache monitor does not provide a view for cache instance resources.

Cache monitor provides a way to:

- **Verify the configuration of dynamic cache**

The WebSphere Application Server administrative console provides ways to enable the dynamic cache service and configure properties, such as maximum size of the cache and disk offload location, as well as advanced features such as controlling external caches. Cache monitor offers a way for dynamic cache users to verify the configuration of the dynamic cache by providing a convenient view of the configured features and properties in the cache monitor.

- **Verify the cache policies**

To cache an object, WebSphere Application Server must know how to generate unique IDs for different invocations of that object. This is performed by providing rules for each cacheable object in the `cachespec.xml` file, found inside the Web module `WEB-INF` or enterprise bean `META-INF` directory. Each cacheable object can have multiple cache ID rules that execute in sequence until either a rule returns a cache ID or no more rules remain to execute. If none of the cache ID generation rules produce a valid cache ID, then the object is not cached. Since there can be multiple `cachespec.xml` files with multiple cache ID rules, cache monitor provides a convenient way to verify the policies of each object. It offers a view of all the cache policies currently loaded in dynamic cache. This view is also convenient to verify that the `cachespec.xml` file was read by the dynamic cache without errors.

- **Monitor cache statistics**

Cache monitor provides a view of the essential cache data, such as number of cache hits, cache misses, and number of entries in cache. This helps to tune the cache configuration optimally to get the best performance improvement out of dynamic cache. For example, if the number of used entries is often high, and entries are being removed and recreated, one might consider increasing the maximum size of the cache or enabling disk offload.

- **Monitor the data flowing through the cache**

Once a cacheable object is invoked, dynamic cache creates a cache entry for it that contains the output of the execution and metadata, such as time to live, sharing policy, etc. Entries are distinguished by a

unique ID string that is based on the rules specified in the `cachespec.xml` file for this objects name. Objects with the same name may generate multiple cache IDs for different invocations, based on request parameters and attributes for each invocation. Cache monitor provides a view of all the cache entries currently in cache, based on the unique ID. It also provides a view of the group of cache entries that share a common name (also known as template). Cache entries can also be grouped together by a dependency ID, which is used to invalidate the entire group of entries dependent on a common entity. Therefore, cache monitor also provides a view of the group of cache entries that share a common dependency ID.

For each entry, cache monitor also displays metadata, such as time to live, priority and sharing-policy, and provides a view of the output that has been cached. This helps the customer to verify which pages have been cached, that the pages have been cached with the right attributes such as time to live, priority, etc., and that the pages have the right content.

- **Monitor the data in the edge cache**

Dynamic cache provides support to recognize the presence of an Edge Side Include (ESI) processor and to generate ESI include tags and appropriate cache policies for edge cacheable fragments. The ESI processor has the ability to cache whole pages, as well as fragments, providing a higher cache hit ratio. There can be multiple ESI processors running on multiple hosts configured for caching.

Cache monitor provides a list of all ESI processes and their hosts that are enabled for caching. It also provides a way to select a host or a processor, and view its edge cache statistics as well as current cache entries.

- **View the data offloaded to the disk**

By default, when the number of cache entries reaches the configured limit for a given server, eviction of cache entries occurs, allowing new entries to enter the cache service. The dynamic cache includes the disk offload feature that copies the evicted cache entries to disk for future access. Cache monitor offers a view of the content offloaded to disk that corresponds to the view of contents cached in memory.

- **Manage the data in the cache**

Besides displaying cache content, cache monitor also provides some basic operations on the data in the cache:

- Removing an entry from the cache
- Removing all entries for a certain dependency ID
- Removing all entries for a certain name (template)
- Moving an entry to the front of the least recently used queue to avoid eviction
- Moving an entry from the disk to the cache
- Clearing the entire contents of the cache
- Clearing the contents of the disk cache

These functions are useful for dynamic cache customers, as they provide a way to manually change the state of the cache without having to restart the server.

## Edge cache statistics

Cache monitor provides a view of the edge cache statistics.

The following statistics are available:

- **ESI Processors.** Number of processes configured as edge caches.
- **Number of Edge Cached Entries.** Number of entries currently cached on all edge servers and processes.
- **Cache Hits.** Number of requests that match entries on edge servers.
- **Cache Misses By URL.** A cache policy does not exist on the edge server, for the requested template.

**Note:**

- The initial ESI request for a template that has a cache policy on WebSphere Application Server will result in a miss.
- Every request for a template that does not have a cache policy on WebSphere Application Server will result in a miss by URL on the edge server.

- **Cache Misses By Cache ID.** The policy for the requested template exists on the edge server, and a cache ID is created, based on the ID rules and the request attributes, but the cache entry for this ID does not exist.

**Note:** If the policy exists on the edge server for the requested template, but a cache ID match is not found, based on the ID rules and the request attributes, it is not treated as a cache miss.

- **Cache Timeouts.** Number of entries removed from the edge cache, based on the timeout value.
- **Evictions.** Number of entries removed from the edge cache, due to invalidations received from WebSphere Application Server.

---

## Troubleshooting the dynamic cache service

Complete the steps below to resolve problems that you think are related to the dynamic cache service.

1. Review the JVM logs for your application server. Messages prefaced with *DYNA* result from dynamic cache service operations.
  - a. View the JVM logs for your application server. Each server has its own JVM log file. For example, if your server is named *Member\_1*, the JVM log is located in the subdirectory *install\_root/logs/Member\_1*. To use the administration console to review the JVM logs, click **Troubleshooting > Logs and Trace > server\_name > JVM Logs > Runtime > View**.
  - b. Find any messages prefaced with *DYNA* in the JVM logs, and write down the message IDs. A sample message having the message ID *DYNA0030E* follows:  
 DYNA0030E: "property" element is missing required attribute "name".
  - c. Find the message for each message ID in the information center for WebSphere Application Server. In the information center navigation tree, click **product\_name > Reference > Messages > DYNA** to view dynamic cache service messages.
  - d. Read the message **Explanation** and **User Action** statements. A search for the message ID *DYNA0030E* displays a page having the following message:  
**DYNA0030E: "property" element is missing required attribute "name".**  
**Explanation:** A required attribute was missing in the cache configuration.  
**User Action:** Add the required attribute to your cache configuration file.  
 This explanation and user action suggests that you can fix the problem by adding or correcting a required attribute in the cache configuration file.
  - e. Try the solutions stated under **User Action** in the *DYNA* messages.
2. Use the cache monitor to determine whether the dynamic cache service is functioning as expected. The cache monitor is an installable Web application that displays simple cache statistics, cache entries, and cache policy information.
3. If you have completed the preceding steps and still cannot resolve the problem, contact your IBM software support representative. Use the collector tool (*collector.bat* or *collector.sh* located in the *bin* directory) to gather trace information and other configuration information for the support team to diagnose the problem. The collector tool gathers dynamic cache service files and packages them into a JAR file. The IBM representative can specify when and where to send the JAR file. The IBM representative might ask you to complete a diagnostic trace. To enable tracing in the administrative console, click **Troubleshooting > Logs and Trace > server\_name > Diagnostic Trace** and specify **Enable trace with the following specification**. The IBM representative can tell you what trace specification to enter. Note that dynamic cache trace files can become large in a short period of time; you can limit the size of the trace file by starting the trace, immediately recreating the problem, and immediately stopping the trace.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

For technical support on dynamic cache service, see the IBM Support page.

## Troubleshooting tips for the dynamic cache service

The dynamic cache service works within an application server Java virtual machine (JVM), intercepting calls to cacheable objects. This article describes some common run-time and configuration problems and remedies.

### Servlets are not cached

**Recommended response** Enable servlet caching. On the Web container page of the administrative console, select the **Enable servlet caching** check box.

### Cache entries are not written to disk

**Explanation** Cache entries are written to disk when the cache is full and new entries are added to the memory cache. Cache entries also are written to disk when the `flushToDiskOnStop` system property is set and the server is stopped.

**Recommended response** Verify that **Disk offload** is enabled on the Dynamic Cache Service page of the administrative console. Also verify that cache entries written to disk are serializable and do not have the `PersistToDisk` configuration set to `false`.

### Some servlets are not replicated or written to disk

**Recommended response** Ensure that the attributes and response are serializable. If you do not want to store the attributes, use the following property in your cache policy:  
`<property name="save-attributes">false</property>`

### Dynamic cache service does not cache fragments on the Edge

**Recommended response** Set the `EdgeCacheable` property to `true` in the cache policy for those entries that are to be cached on the Edge.  
`<property name="EdgeCacheable">true</property>`

### Dynamic cache invalidations are not sent to the IBM HTTP Server (IHS) plug-in

**Explanation** The `DynaCacheEsi`.ear file is required to send invalidations to external caches.  
**Recommended response** Install `DynaCacheEsi`.ear using the administrative console.

### Cache entries are evicted often

**Problem** The cache is full and new entries are added to the cache.  
**Explanation** Cache entries are evicted when the cache is full and new entries are added to the cache. A LRU eviction mechanism removes the least recently used entry to make space for the new entries.  
**Recommended response** Either enable **Disk offload** on the Dynamic Cache Service page of the administrative console so the entries are written to disk. Or, increase the cache size to accommodate more entries in the cache.

### Cache entries in disk with timeout set to 0 expire after one day

<b>Explanation</b>	The maximum lifetime of an entry in disk cache is 24 hours. A timeout of 0 in the cache policy configures these entries to stay in disk cache for one whole day, unless they are evicted earlier.
<b>Recommended response</b>	Set the timeout for the cache policy to a number greater than 0.

### I cannot monitor cache entries on the Edge

<b>Explanation</b>	Use the cache monitor for monitoring contents in memory cache, disk cache and external caches (Edge cache). For the ESI processor's cache to be visible in the cache monitor, the DynaCacheEsi.ear application must be installed and the esiInvalidationMonitor property must be set to true in the plugin-cfg.xml file.
<b>Recommended response</b>	Install the DynaCacheEsi.ear application and set the esiInvalidationMonitor property to true in the plugin-cfg.xml file.

### I want to cache static contents using the dynamic cache service

<b>Explanation</b>	You can cache static contents using the dynamic cache service. Static contents in WebSphere application server are served by the SimpleFileServlet file.
<b>Recommended response</b>	Create a cache policy for the class <code>com.ibm.ws.webcontainer.servlet.SimpleFileServlet.class</code> to cache static contents. It is advisable to use the dynamic cache service for caching more expensive dynamic contents than static contents.

### I want to tune cache for my environment

<b>Recommended response</b>	Use the Tivoli Performance viewer to study the caching behavior for your applications. Also, do the following: <ul style="list-style-type: none"><li>• Increase the priority of cache entries that are expensive to regenerate.</li><li>• Modify timeout of entries so that they stay in memory as long as they are valid.</li><li>• Enable disk offload to store LRU evicted entries.</li><li>• Increase the cache size.</li></ul>

## Chapter 28. Using user profiles

**Note:** User Profile Manager API is deprecated in the current release, and there is no replacement available.

IBM WebSphere Application Server provides a service for processing user profiles, called the *User Profile Manager*. The service is provided in the form of an EJB entity bean that servlets can call whenever they are required to access a user profile.

The key activities for implementing user profiles are summarized.

1. Customize the user profile support as necessary. Options include:
  - Using the data representation class with the name-value pairs it currently supports (no action required)
  - Extending the data representation class to support additional, arbitrary name-value pairs
  - Adding columns to the base user profile representation
  - Extending the User Profile enterprise bean to import existing databases

Evaluate whether the user profile representation provided by IBM represents the kind of data you want to keep about your users. You might find it desirable to customize the IBM user profile support.

2. Create or modify servlets to use the User Profile Manager and related user profile support classes to maintain user profiles on behalf of Web applications.
3. Assemble your application.
4. Deploy your application.
5. Ensure the administrator appropriately configures User Profile Managers using `userprofile.xml` file. If the programmer and administrator are not the same person, the programmer might need to provide settings information to the administrator, based on how the programmer implemented user profiles.

---

### User profile

Some applications collect data about the users with which they interact. The data is stored in a database. The next time the user interacts with the application, the application recalls the data.

Because the application already knows something about the user, it can provide the user with a more personalized experience.

User profiles provide a means by which a company can maintain and manage database tables containing fields for demographic data and use those tables to interact with a database of individual customers or other users on the company system.

For example, when a repeat user logs onto a Web site that supports user profiles, the Web site can display headlines and advertising tailored to the shopping preferences of that user. The site can address the user by logon name.

An application implementing user profiles requires database access for storing the user profile data it gathers.

---

### UserProfileManager class

Servlets and other application building blocks requiring user profile support should make calls to the class:  
`com.ibm.websphere.userprofile.UserProfileManager`

The class supports the following functions:

- Creating and deleting user profiles
- Getting and updating (cached and immediate) to and from the database

- Getting user profiles for read-only tasks
- Performing queries on database columns

---

## User profile development options

The application developer has a few options for customizing the user profile support provided by IBM WebSphere Application Server. The Related information provides instructions and additional details about each option.

### Extending the data represented in user profiles

Web applications can maintain several pieces of data about users. You can extend the data representation to allow the collection of arbitrary name-value pairs.

Use the following interface with the `com.ibm.websphere.userprofile.UserProfileExtender` class to extend a user profile hash table:

```
com.ibm.websphere.userprofile.UserProfileProperties
```

This action enables you to place arbitrary name-value pairs in the user profile. Extending the hash table is similar to using the `java.util.Dictionary` class in the base JDK 1.x, or any of the classes that extend it.

### Adding columns to the base user profile implementation

Application developers can customize user profiles by adding columns to the base user profile implementation. Adding new columns is accomplished by implementing the interface:

```
com.ibm.websphere.userprofile.UserProfileExtender
```

and extending the base class:

```
com.ibm.servlet.personalization.userprofile.UserProfile
```

The application developer can add columns to but not delete columns from the base implementation.

Adding columns is a two-step process, as follows:

1. Extend the `UserProfile` class.
2. Modify your existing servlets to use the new columns.

Several examples are available to demonstrate how to extend the base user profile implementation and utilize the extension with a servlet.

Example	Description
<code>UPServletExample.java</code>	Demonstrates how a servlet opens a user profile and prints the fields contained within.
<code>UserProfileExtendedSample.java</code>	Shows how to extend the <code>UserProfile</code> class to add a column to the user profile for a cellular phone number.  The WebSphere Application Server administrator configures the User Profile Manager to point to the extended class.
<code>UPServletExampleExtended.java</code>	Shows how to modify the <code>UPServletExample</code> servlet to include the cellular phone number in the output.
<code>UserProfileExtended.java</code>	Shows how to extend a hash table to place arbitrary name-value pairs into the user profile.
<code>UPServletExtended.java</code>	Shows how to extend the servlet. When any of the newly added columns are removed or replaced, look for the table named "USERPROFILE" in the database to which the user profile is configured and drop that table.

The examples are encoded in HTML for viewing in a browser. The documentation directory also contains nonHTML versions (.java files) that are ready for use.

## Extending the User Profile enterprise bean and importing legacy databases

Application developers can extend the User Profile enterprise bean itself and import legacy databases into the user profile. The main advantage in extending the User Profile enterprise bean is to gain the ability to import existing databases into the user profile. You can also extend this enterprise bean to add columns to the base user profile implementation.

### Example: UPServletExample.java

```
import java.io.*;
import java.util.*;

import javax.servlet.*;
import javax.servlet.http.*;

import com.ibm.websphere.userprofile.UserProfile;
import com.ibm.websphere.userprofile.UserProfileManager;
import com.ibm.websphere.userprofile.UserProfileCreateException;
import com.ibm.websphere.userprofile.UserProfileFinderException;
import com.ibm.websphere.userprofile.UserProfileRemoveException;

//Creates a Userprofile using the new API

public class UPServlet_ReadWrite extends HttpServlet {

 public void doGet (HttpServletRequest req, HttpServletResponse res)
 throws ServletException, IOException {

 PrintWriter out;
 res.setContentType("text/html");
 out = res.getWriter();

 UserProfileManager manager = UserProfileManager.getUserProfileManager();
 UserProfile userprofile;

 try {

 //Try creating the UserProfile
 userprofile = manager.addUserProfile("bpink");

 } catch(UserProfileCreateException e1) {

 try {

 //Try finding the existing in readWrite mode.
 //Second argument indicates whether we want to get userprofile
 //in read only mode or read write mode.

 userprofile = manager.getUserProfile("bpink",true);

 } catch(UserProfileFinderException e) {
 e.printStackTrace();
 return;
 }

 }

 }

}
```

```

//Set the properties

userprofile.setAddress1("myaddress1");
userprofile.setAddress2("myaddress2");
userprofile.setFirstName("Pinkowski");
userprofile.setSurName("Ben");
userprofile.setDayPhone("555-6677");
userprofile.setNightPhone("556-6765");
userprofile.setCity("MYCITY");
userprofile.setNation("myCountry");
userprofile.setEmployer("MyEmployer");
userprofile.setFax("7823470");

userprofile.setLanguage("mylanguage");
userprofile.setEmail("MyEmail@email");
userprofile.setStateOrProvince("myState");
userprofile.setPostalCode("xxxxx");

//Freeing resources held by userprofile
manager.releaseResources(userprofile);
userprofile=null;

//Checking whether it updated the info

try {

 //Getting the existing userprofile in ReadOnly mode.

 userprofile = manager.getUserProfile("bpink",false);

} catch(UserProfileFinderException e1) {

 out.println("Error finding ");
 e1.printStackTrace();
 return;
}

//Displaying the properties of userprofile

out.println(userprofile.getAddress1()+"
");
out.println(userprofile.getAddress2()+"
");;
out.println(userprofile.getFirstName()+"
");;
out.println(userprofile.getSurName()+"
");;
out.println(userprofile.getDayPhone()+"
");;
out.println(userprofile.getNightPhone()+"
");;
out.println(userprofile.getCity()+"
");;
out.println(userprofile.getNation()+"
");;
out.println(userprofile.getEmployer()+"
");;
out.println(userprofile.getFax()+"
");;
out.println(userprofile.getLanguage()+"
");;
out.println(userprofile.getEmail()+"
");;
out.println(userprofile.getStateOrProvince()+"
");;
out.println(userprofile.getPostalCode()+"
");;

//Freeing resources held by userprofile
manager.releaseResources(userprofile);
}
}

```

## Example: UserProfileExtendedSample.java

```

/* -----
** Copyright 1997-99 IBM Corporation. All rights reserved.
**

```

```

** -----
*/
package com.ibm.servlet.personalization.userprofile;

import com.ibm.servlet.personalization.userprofile.UserProfile;
import com.ibm.websphere.userprofile.UserProfileExtender;

//Extensions of UserProfile to add new Columns should implement UserProfileExtender
public class UserProfileExtendedSample
 extends com.ibm.servlet.personalization.userprofile.UserProfile
 implements UserProfileExtender {

 //New column that is being added by this
 //derived class.
 public String cellPhone;

 //Manager Class will call this method to append new Column types.
 //If UserProfile class is extended to append new columns
 //TOTAL COLUMNS: Base Class columns + columns returned by this class

 public String[] getNewColumns() {
 //If variable name is "cellPhone," you need to
 //return "cellPhone" in array format. JDBC equivalent will be
 //generated automatically. You can add multiple columns.
 //For multiple columns: String newCol={"fieldName1","fieldName2",...};
 String[] newCol={"cellPhone"};
 return newCol;
 }

 public String getCellPhone() {
 // Need to call this method to
 // get the things from persistence store.
 return(String)getByType("cellPhone");
 }

 public void setCellPhone(String value) {
 cellPhone = value;
 //Call this method to store the
 //things in persistence store
 setByType("cellPhone", value);
 }
}

```

## Example: UPServletExampleExtended.java

```

import java.io.*;
import java.util.*;

import javax.servlet.*;
import javax.servlet.http.*;

import com.ibm.websphere.userprofile.UserProfile;
import com.ibm.websphere.userprofile.UserProfileManager;
import com.ibm.websphere.userprofile.UserProfileCreateException;
import com.ibm.websphere.userprofile.UserProfileFinderException;
import com.ibm.websphere.userprofile.UserProfileRemoveException;
import com.ibm.servlet.personalization.userprofile.UserProfileExtendedSample;

public class UPServletExtendedSample extends HttpServlet {

 public void doGet (HttpServletRequest req, HttpServletResponse res)
 throws ServletException, IOException
 {

```

```

UserProfileManager manager = UserProfileManager.getUserProfileManager();
UserProfile userprofile;

PrintWriter out;

res.setContentType("text/html");
out = res.getWriter();

try {
 //try Creating the UserProfile
 userprofile = manager.addUserProfile("bpink");
} catch(UserProfileCreateException e1) {
 try { //try finding the existing in readWrite mode
 userprofile = manager.getUserProfile("bpink",true);
 } catch(UserProfileFinderException e) {
 e.printStackTrace();
 return;
 }
}

userprofile.setAddress1("myaddress1");
userprofile.setAddress2("myaddress2");
userprofile.setFirstName("Pinkowski");
userprofile.setSurName("Ben");
userprofile.setDayPhone("555-6677");
userprofile.setNightPhone("556-6765");
userprofile.setCity("MYCITY");
userprofile.setNation("myCountry");
userprofile.setEmployer("MyEmployer");
userprofile.setFax("7823470");
userprofile.setLanguage("mylanguage");
userprofile.setEmail("MyEmail@email");
userprofile.setStateOrProvince("myState");
userprofile.setPostalCode("xxxxx");

//calling setCellPhone
((com.ibm.servlet.personalization.userprofile.UserProfileExtendedSample)
 userprofile).setCellPhone("346-4588");

//Freeing resources held by userprofile
manager.releaseResources(userprofile);
userprofile=null;

//Checking whether it updated the info
try {
 //Getting the existing userprofile
 userprofile = manager.getUserProfile("bpink",false);
} catch(UserProfileFinderException e1) {
 out.println("Error finding ");
 e1.printStackTrace();
 return;
}

```

```

 }

 out.println(userprofile.getAddress1()+"
");
 out.println(userprofile.getAddress2()+"
");;
 out.println(userprofile.getFirstName()+"
");;
 out.println(userprofile.getSurName()+"
");
 out.println(userprofile.getDayPhone()+"
");;
 out.println(userprofile.getNightPhone()+"
");;
 out.println(userprofile.getCity()+"
");
 out.println(userprofile.getNation()+"
");;
 out.println(userprofile.getEmployer()+"
");;
 out.println(userprofile.getFax()+"
");;
 out.println(userprofile.getLanguage()+"
");;
 out.println(userprofile.getEmail()+"
");;
 out.println(userprofile.getStateOrProvince()+"
");;
 out.println(userprofile.getPostalCode()+"
");

 //Calling getCellPhone
 out.println(((UserProfileExtendedSample)userprofile).getCellPhone()+"
");

 //Freeing resources held by userprofile
 manager.releaseResources(userprofile);
 userprofile=null;

 //For getting values by cellPhone
 out.println("

Retreiving by Cell Phone
");
 Enumeration enum = manager.findUserProfiles("cellPhone","346-4588");
 while(enum.hasMoreElements()) {

 com.ibm.websphere.userprofile.UserProfile up =
 (com.ibm.websphere.userprofile.UserProfile)enum.nextElement();
 out.println("first name :"+up.getFirstName()+"
");

 //Freeing resources held by userprofile
 manager.releaseResources(up);
 }
}
}
}

```

## Example: UserProfileExtended.java

```

package com.ibm.servlet.personalization.userprofile;
/* -----
** Copyright 1997-99 IBM Corporation. All rights reserved.
** -----
*/
import java.util.*;

import com.ibm.servlet.personalization.userprofile.UserProfile;

import com.ibm.websphere.userprofile.UserProfileExtender;
import com.ibm.websphere.userprofile.UserProfileProperties;

public class UserProfileExtended extends UserProfile implements UserProfileExtender,
 UserProfileProperties {
 //New column that is being added by this
 //derived class.
 public Hashtable properties;

 static String propCol ="properties";

 //Manager Class will call this method to append new Column types
 //to SQL Strings. If UserProfile class is extended to append new columns

```

```

//it should implement UserProfileExtender.
//COLUMNS: Base Class columns + columns returned by this class

public String[] getNewColumns() {
 //if variable name is properties, you need to
 //return "properties" . JDBC equivalent will be
 //generated automatically.
 String[] newCol={propCol};
 return newCol;
}

public Object getValue(String key) {
 // Need to call this method to
 // get the things from persistent store
 properties = (Hashtable) getByType(propCol);

 if(properties != null)
 return properties.get(key);

 else return null;
}

public void putValue(String key, Object value) {
 properties =(Hashtable) getByType(propCol);

 if(properties == null)
 properties = new Hashtable();

 properties.put(key,value);

 //store in persistent store
 setByType(propCol, properties);
}

public void removeValue(String key) {
 properties = (Hashtable) getByType(propCol);

 if(properties == null)
 return;

 properties.remove(key);

 //store in persistent store
 setByType(propCol, properties);
}
}

```

## Example: UPServletExtended.java

```

import java.io.*;
import java.util.*;

import javax.servlet.*;
import javax.servlet.http.*;

import com.ibm.websphere.userprofile.UserProfile;
import com.ibm.websphere.userprofile.UserProfileManager;
import com.ibm.websphere.userprofile.UserProfileCreateException;
import com.ibm.websphere.userprofile.UserProfileFinderException;
import com.ibm.websphere.userprofile.UserProfileRemoveException;
import com.ibm.websphere.userprofile.UserProfileProperties;

public class UPServletExtended extends HttpServlet {

```

```

public void doGet (HttpServletRequest req, HttpServletResponse res)
throws ServletException, IOException
{
 UserProfileManager manager = UserProfileManager.getUserProfileManager();
 UserProfile userprofile;

 PrintWriter out;

 res.setContentType("text/html");
 out = res.getWriter();

 try {

 //try Creating the UserProfile

 userprofile = manager.addUserProfile("bpink");

 } catch(UserProfileCreateException e1) {

 try { //try finding the existing in readWrite mode

 userprofile = manager.getUserProfile("bpink",true);
 } catch(UserProfileFinderException e) {
 e.printStackTrace();
 return;
 }

 }

 userprofile.setAddress1("myaddress1");
 userprofile.setAddress2("myaddress2");
 userprofile.setFirstName("Pinkowski");
 userprofile.setSurName("Ben");
 userprofile.setDayPhone("555-6677");
 userprofile.setNightPhone("556-6765");
 userprofile.setCity("MYCITY");
 userprofile.setNation("myCountry");
 userprofile.setEmployer("MyEmployer");
 userprofile.setFax("7823470");
 userprofile.setLanguage("mylanguage");
 userprofile.setEmail("MyEmail@email");
 userprofile.setStateOrProvince("myState");
 userprofile.setPostalCode("xxxxx");

 //calling putValue

 ((UserProfileProperties)userprofile).putValue("name","HHHHHHH");
 ((UserProfileProperties)userprofile).putValue("Date",new java.util.Date());

 //Freeing resources held by userprofile
 manager.releaseResources(userprofile);
 userprofile=null;

 //Checking whether it updated the info

 try {

 //Getting the existing userprofile

 userprofile = manager.getUserProfile("bpink",false);

 out.println(userprofile.getAddress1()+"
");
 out.println(userprofile.getAddress2()+"
");
 out.println(userprofile.getFirstName()+"
");
 out.println(userprofile.getSurName()+"
");
 out.println(userprofile.getDayPhone()+"
");
 }
}

```

```

 out.println(userprofile.getNightPhone()+"
");
 out.println(userprofile.getCity()+"
");
 out.println(userprofile.getNation()+"
");
 out.println(userprofile.getEmployer()+"
");
 out.println(userprofile.getFax()+"
");
 out.println(userprofile.getLanguage()+"
");
 out.println(userprofile.getEmail()+"
");
 out.println(userprofile.getStateOrProvince()+"
");
 out.println(userprofile.getPostalCode()+"
");

 //Getting the values

 out.println(((UserProfileProperties)userprofile).getValue("name")+"
");
 out.println(((UserProfileProperties)userprofile).getValue("Date")+"
");
 out.println("Removing Values ");
 ((UserProfileProperties)userprofile).removeValue("name");
 ((UserProfileProperties)userprofile).removeValue("Date");
 out.println(((UserProfileProperties)userprofile).getValue("name")+"
");
 out.println(((UserProfileProperties)userprofile).getValue("Date")+"
");

 //Freeing resources held by userprofile
 manager.releaseResources(userprofile);

 } catch(UserProfileFinderException e1) {

 out.println("Error finding ");
 e1.printStackTrace();
 return;
 }
}
}
}

```

---

## userprofile.xml

To *installation\_root/properties*, add a file named `userprofile.xml` in the following format. Specify enterprise bean class names; data wrapper class name; and JNDI names for the read-only bean, read/write bean, and data source (from step 2). You must also add user ID and password information for the JNDI data source

The following example file contains class names as provided in WebSphere Application Server. If data wrapper and enterprise bean class names are extended programmatically, change them accordingly.

```

<?xml version="1.0"?>

<userprofile>
 <userprofile-enabled>true</userprofile-enabled>
 <userprofile-wrapper-class>
 <classname>
 com.ibm.servlet.personalization.userprofile.UserProfile
 </classname>
 </userprofile-wrapper-class>
 <userprofile-manager-name>
 User Profile Manager
 </userprofile-manager-name>
 <userprofile-bean>
 <readonly-interface>
 com.ibm.servlet.personalization.userprofile.UP_ReadOnly
 </readonly-interface>
 <readwrite-interface>
 com.ibm.servlet.personalization.userprofile.UP_ReadWrite
 </readwrite-interface>
 <readonlyhome-interface>
 com.ibm.servlet.personalization.userprofile.UP_ReadOnlyHome
 </readonlyhome-interface>
 <readwritehome-interface>

```

```
 com.ibm.servlet.personalization.userprofile.UP_ReadWriteHome
 </readwritehome-interface>
 <readonly-JNDI-lookupName>UP_ReadOnlyHome</readonly-JNDI-lookupName>
<readwrite-JNDI-lookupName>UP_ReadWriteHome</readwrite-JNDI-lookupName>
 </userprofile-bean>

 <userprofile-store>
 <database-userid></database-userid>
 <database-password></database-password>
 <database-datasource></database-datasource>
 </userprofile-store>

</userprofile>
```

---

## Chapter 29. Assembling applications with the Assembly Toolkit

Assemble enterprise application modules (EAR files) from new or existing Java 2 Platform, Enterprise Edition (J2EE) Version 1.2 or 1.3 modules, including these archives: Web application archives (WAR), resource adapter archives (RAR), enterprise bean (EJB) JAR files, and application client archives (JAR). This packaging and configuration of code artifacts into application modules or stand-alone Web modules is necessary for deploying the applications onto the application server.

The Assembly Toolkit replaces the Application Assembly Tool (AAT). The Assembly Toolkit consists of the J2EE Perspective of the WebSphere Studio Application Developer product. With the Assembly Toolkit, you can create and modify J2EE applications and modules, edit deployment descriptors, and map databases.

The Assembly Toolkit is one of the tools provided by the Application Server Toolkit (ASTK). Follow instructions available with the ASTK to install the Assembly Toolkit.

Gather the code artifacts that you want to package into one or more assembled modules. Code artifacts include these items that you have created and unit tested in your favorite integrated development environment:

- Enterprise beans
- Servlets, JavaServer Pages (JSP) files and other Web components
- Resource adapter (*connector*) implementations
- Application clients
- Other supporting classes and files

The Assembly Toolkit provides extensive online documentation. The articles on Assembly Toolkit provided in the Information Center supplement that documentation.

1. Start the Assembly Toolkit.
2. Optional: Read the online documentation for the Assembly Toolkit.
  - Read the section **Assembly Tool** on the Welcome to the Application Server Toolkit page. To access this page, click **Help > Welcome > Application Server Toolkit**.
  - Click **Help > Help Contents > Assembly Toolkit information**. The displayed documentation provides extensive information about the Assembly Toolkit.
  - Press F1 to access information specific to an Assembly Toolkit view or window.
  - Visit the information center for IBM WebSphere Studio Application Developer at <http://publib.boulder.ibm.com/infocenter/wsphelp/index.jsp>. Click **WebSphere Studio Application Developer > J2EE development**. The documentation in the Information Center for WebSphere Studio is similar to that in the Assembly Toolkit online information.
  - See the article “Assembly Toolkit: Resources for learning” on page 1407” for additional sources.
3. Optional: Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
4. Optional: Open the J2EE Hierarchy view. Click **Window > Show View > J2EE Hierarchy**. Other helpful views include the Project Navigator view (**Window > Show View > Other > J2EE > Project Navigator**) and the Navigator view (**Window > Show View > Navigator**).
5. **5.1+** Optional: To use an application assembly service of WebSphere Business Integration (WBI) Server Foundation, select the **Integration Server** target server. Available WBI assembly services include ActivitySession, Application profiling, Extended access, Extended messaging, Internationalization, Last participant support, and Pushdown.
  - a. Click **Project > Properties > J2EE**.
  - b. For **Target server**, select **Integration Server**. For this release, **Integration Server v5.1**.
  - c. Click **OK**.

6. Migrate EAR, WAR, enterprise bean JAR files, application client JAR files, or resource adapter RAR files created with the Application Assembly Tool (AAT) or a different tool to the Assembly Toolkit. To migrate files, import the files to the Assembly Toolkit.
7. Optional: Migrate a project from J2EE 1.2 to J2EE 1.3 using the J2EE Migration wizard. As part of the migration, you can migrate CMP 1.x beans to CMP 2.x beans. The J2EE Migration wizard is similar to the earconvert batch utility or the **File > ConvertEar** option of the AAT.
  - a. In the J2EE Hierarchy view, right-click the enterprise application project (EAR file) you want to migrate.
  - b. Click **Migrate > J2EE Migration Wizard**.
  - c. Follow the instructions in the wizard.
8. Create an enterprise application project to which you can add archive files. You can create an enterprise application project separately or when you create archive files such as the following:
  - Create a Web project.
  - Create an application client.
  - Create an enterprise bean (EJB) project.
  - Create a resource adapter (connector) project.
9. Edit the deployment descriptors as needed. You can edit deployment descriptors for enterprise application, Web, application client, and enterprise bean (EJB) modules.
10. Optional: Generate enterprise bean (EJB) to relational database (RDB) mappings for EJB modules.
11. Verify the archive files.
12. Generate code for deployment for EJB modules or for enterprise applications that use EJB modules.
13. Generate code for deployment for Web services-enabled modules or for enterprise applications that use Web service modules.
14. Optional: Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard. Note that **Run on Server** works on the Windows, Linux/Intel, and AIX operating systems only; you cannot deploy remotely from the Assembly Toolkit to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

### Important

**Important:** Use **Run On Server** for unit testing only. Application Server Toolkit controls the WebSphere Application Server installation and, when an application is published remotely, the Toolkit overwrites the server configuration file for that server. Do not use on production servers.

For instructions on remote testing, see the article "Setting Up a Remote WebSphere Application Server in WebSphere Studio V5" at [http://www7b.boulder.ibm.com/wsdd/techjournal/0303\\_yuen/yuen.html](http://www7b.boulder.ibm.com/wsdd/techjournal/0303_yuen/yuen.html).

After assembling your applications, use a systems management tool to deploy the EAR or WAR files onto the application server. The systems management tool follows the security and deployment instructions defined in the deployment descriptor, and enables you to modify bindings specified within the Assembly Toolkit. The tool locates the required external resources that the application uses, such as enterprise beans and databases.

Select a tool to use:

- Administrative console installation pages (GUI)
- Java administrative programs (programming). See "Deploying and managing using programming" in the Information Center.
- wsadmin AdminApp install command (scripting). See "Deploying and managing using scripting" in the Information Center.

If you are uncertain of which systems management tool to use, try using the administrative console.

If your application has a large number of modules, it might not install successfully onto a server. Package your application so that the .ear file contains necessary modules only. Modules can include metadata for the modules such as information on deployment descriptors, bindings, and IBM extensions.

Use the administrative console at installation to complete the security instructions defined in the deployment descriptor and to locate required external resources, such as enterprise beans and databases. You can add configuration properties and redefine binding properties defined in the Assembly Toolkit.

---

## Application assembly and J2EE applications

Application assembly is the process of creating an enterprise archive (EAR) file containing all files related to an application, as well as an XML deployment descriptor for the application. This configuration and packaging prepares the application for deployment onto an application server.

EAR files are comprised of the following archives:

- Enterprise bean JAR files (known as EJB modules)
- Web archive (WAR) files (known as Web modules)
- Application client JAR files (known as client modules)
- Resource adapter archive (RAR) files (known as resource adapter modules)

Ensure that modules are contained in an EAR file so that they can be deployed onto the server. The exceptions are WAR modules, which you can deploy individually. Although WAR modules can contain regular JAR files, they cannot contain the other module types described previously.

The assembly process includes the following actions:

- Selecting all of the files to include in the module.
- Creating a deployment descriptor containing instructions for module deployment on the application server.

As you configure properties using the Assembly Toolkit, the tool generates the deployment descriptor for you. While the Assembly Toolkit graphical interface is recommended, you can also edit descriptors directly in your favorite XML editor.

- Packaging modules into a single EAR file, which contains one or more files in a compressed format.

---

## Archive support in Version 5

The following archives and Web components are supported in Version 5.0:

- Java 2 Platform, Enterprise Edition (J2EE) Version 1.2 and 1.3 enterprise archive (EAR) files
- Enterprise bean (EJB) 2.0 JAR files
- Servlet 2.3 Web archive (WAR) files
- Application client 1.2 and 1.3 JAR files
- Connector 1.0 resource adapter archive (RAR) files

These archive files and Web components are back-level and can be read but not created or changed:

- J2EE 1.2 EAR files
- EJB 1.1 JAR files
- Servlet 2.2 WAR files
- Application client 1.2 JAR files

---

## Starting the Assembly Toolkit

The Assembly Toolkit provides a graphical interface for packaging code artifacts into various archives (modules) and configuring related Java 2 Platform, Enterprise Edition (J2EE) Version 1.2 or 1.3 compliant deployment descriptors.

The Assembly Toolkit is a component of the Application Server Toolkit (ASTK). To install the Assembly Toolkit, follow the installation instructions for the ASTK and, when prompted by the ASTK installation program, select to install the application assembly toolkit.

If you have installed the Assembly Toolkit component of ASTK previously and you install the Assembly Toolkit again, you must delete the workspace of the previous installation of ASTK before starting the Assembly Toolkit. The default workspace directory is *my\_directory\IBM\astk\workspace*. If you do not delete the workspace for a previous installation of ASTK, you might encounter error messages such as the following when starting the Assembly Toolkit:

Problems during startup. Check the ".log" file in the ".metadata" directory of your workspace.

1. Run the `astk` executable.
2. In the Application Server Toolkit window, specify the workspace directory and click **OK** to launch the graphical interface.

The navigation tree displays a hierarchical structure used to build the contents of a new module, or to work with the contents of an existing module.

Consider whether you have any existing J2EE 1.2 application modules that you would like to migrate to J2EE 1.3.

You can import or create new modules of the following types, to assemble into an application module later:

- Assembling enterprise bean (EJB) modules
- Assembling Web modules
- Assembling application client modules
- Assembling resource adapter modules

Rather than import or create new modules to assemble an application, you can proceed directly to assembling a new application module. While assembling an application module, you can create any new modules that you need.

## astk command

The **astk** command starts the Application Server Toolkit. The command file is the `astk` executable file.

### Location of the command file

The `astk` executable file resides in the main installation directory for Application Server Toolkit (ASTK).

### Command syntax

- Issue the **astk** command:

```
ASTK_install_root/astk
```

Or, double-click the **ASTK** icon.

- The **astk** command has no options or command-line parameters.

### Usage notes

- Is the `astk` executable file read-only?  
Yes
- Is this file updated by a product component?  
No
- How and when are the contents of this file used?

The `astk` executable file provides the Assembly Toolkit component for the Application Server Toolkit. Run the `astk` executable file to start the Assembly Toolkit. There are no parameters or command-line options.

---

## Migrating code artifacts to the Assembly Toolkit

You can migrate enterprise archive (EAR), Web archive (WAR), enterprise bean JAR, application client JAR, resource adapter archive (RAR) files created with the Application Assembly Tool (AAT) or a different tool to the Assembly Toolkit. To migrate files, import the files to the Assembly Toolkit.

1. Start the Assembly Toolkit.
2. Import an enterprise application.
3. Import a WAR file.
4. Import an application client file.
5. Import an enterprise bean JAR file.
6. Import a resource adapter RAR file. RAR files are also known as *connectors*.
7. Verify the archive files.
8. Generate code for deployment.

## Importing enterprise applications

You can import an enterprise archive (EAR) file and define a new enterprise application project using the Assembly Toolkit.

1. Start the Assembly Toolkit.
2. Click **File > Import**. Alternatively, you can right-click **Enterprise Applications** in a view such as the J2EE Hierarchy view and click **Import**. Or, on Windows platforms, you can drag the EAR file and drop it on a view.
3. In the Import dialog, specify the EAR file to import and the project name:
  - a. Click **EAR file > Next**.
  - b. Specify the EAR file to import. Use **Browse** to locate the EAR file and specify its full path name.
  - c. Optional: Specify a new enterprise application project name. A project name is assigned automatically. The project name you specify must be unique within the directory.
  - d. Specify the project location. Use **Browse** to locate the directory for the project files.
  - e. **5.1+** Select a target server. To use the Application profiling or Last participant support application assembly services of WebSphere Business Integration (WBI) Server Foundation, select the **Integration Server** target server.
  - f. Click **Finish**.
4. Verify the contents of the new enterprise application project in either of the following ways:
  - In the **J2EE Hierarchy** view, expand **Enterprise Applications** and view the new project.
  - Click **Window > Show View > Navigator** to see the associated files for the enterprise application project in a Navigator view.

## Importing WAR files

You can import a Web application archive (WAR) file and define a new enterprise archive (EAR) project and Web module for the WAR file using the Assembly Toolkit.

1. Start the Assembly Toolkit.
2. Click **File > Import**. Alternatively, you can right-click **Web Modules** in a view such as the J2EE Hierarchy view and click **Import**. Or, on Windows platforms, you can drag the WAR file and drop it on a view.

3. In the Import dialog, specify a WAR file and a Web project name:
  - a. Click **WAR file > Next**.
  - b. Specify a WAR file. Use **Browse** to locate the WAR file and specify its full path name.
  - c. Specify a Web project name. For example, if you are importing the HelloWorld.war file, you might name the project HelloWorld. Click **New** and specify HelloWorld for the project name.
  - d. Optional: To add the WAR file and Web project to an enterprise application, enable **Configure advanced options** and click **Next**. On the J2EE Settings page, specify the EAR project, the context root (Web project), and the J2EE 1.2 or 1.3 specification to use for the Web module. The J2EE 1.3 specification (the default) includes the Servlet 2.3 specification and the JSP 1.2 specification; applications developed for the J2EE 1.3 specification typically target a WebSphere Application Server Version 5.x server. Then, click **Next**. On the Features page, specify a feature for the Web project. For example, enable **Default synchronization policy for CVS repository** to have a .cvsignore file generated for the WEB-INF/classes directory. Then, click **Next** or **Finish**.
  - e. Click **Finish**.
4. Verify the contents of the new Web module in either of the following ways:
  - In the J2EE Hierarchy view, expand **Web Modules** and view the new module.
  - Click **Window > Show View > Navigator** to see the associated files for the Web module in a Navigator view.

## Importing client applications

You can import an application client JAR file into a new or existing enterprise application using the Assembly Toolkit.

1. Start the Assembly Toolkit.
2. Click **File > Import**. Alternatively, you can right-click **Application Client Modules** in a view such as the J2EE Hierarchy view and click **Import**. Or, on Windows platforms, you can drag the application client JAR file and drop it on a view.
3. In the Import dialog, specify the application client file and project name:
  - a. Click **App Client JAR file > Next**.
  - b. Specify the application client JAR file to be imported. Use **Browse** to locate the JAR file and specify its full path name.
  - c. Specify an application client project name. For example, if you are importing the HelloWorld.jar file, you might name the project HelloWorld. Click **New** and specify HelloWorld for the project name.
  - d. **5.1+** Select a target server. To use the Application profiling or Last participant support application assembly services of WebSphere Business Integration (WBI) Server Foundation, select the **Integration Server** target server.
  - e. Specify the enterprise archive (EAR) file into which to import the application client project.
  - f. Click **Finish**.
4. Verify the contents of the new application client module in either of the following ways:
  - In the J2EE Hierarchy view, expand **Application Client Modules** and view the new module.
  - Click **Window > Show View > Navigator** to see the associated files for the application client module in a Navigator view.

## Importing EJB files

You can import an enterprise bean (EJB) JAR file and define a new enterprise archive (EAR) project and EJB module for the enterprise bean JAR file using the Assembly Toolkit.

1. Start the Assembly Toolkit.

2. Click **File > Import**. Alternatively, you can right-click **EJB Modules** in a view such as the J2EE Hierarchy view and click **Import**. Or, on Windows platforms, you can drag the enterprise bean JAR file and drop it on a view.
3. In the Import dialog, specify the EJB JAR file and project name:
  - a. Click **EJB JAR file > Next**.
  - b. Specify the enterprise bean JAR file to import. Use **Browse** to locate the JAR file and specify its full path name.
  - c. **5.1+** Select a target server. To use an application assembly service of WebSphere Business Integration (WBI) Server Foundation, select the **Integration Server** target server. Available WBI assembly services include ActivitySession, Application profiling, Extended access, Extended messaging, Internationalization, Last participant support, and Pushdown.
  - d. Specify an EJB project name. For example, if you are importing the HelloWorld.jar file, you might name the project HelloWorld. Click **New**, specify HelloWorld for the project name, specify whether you want to use the EJB 1.1 or 2.0 specification (EJB 2.0 is the default), and click **Next**.
  - e. Name the enterprise archive (EAR) file into which to import the enterprise bean JAR file. The name must be unique among EAR files in the directory.
  - f. Click **Finish**.
4. Verify the contents of the new EAR file and EJB module in either of the following ways:
  - In the J2EE Hierarchy view, expand **Enterprise Applications** or **EJB Modules** and view the new modules.
  - Click **Window > Show View > Navigator** to see the associated files for the EAR file and EJB module in a Navigator view.

## Importing RAR files or connectors

You can import a resource adapter archive (RAR) file, or connector, and define a new enterprise archive (EAR) project and connector module using the Assembly Toolkit.

1. Start the Assembly Toolkit.
2. Right-click **Connector Modules** in a view such as the J2EE Hierarchy view and click **Import > Import Connector Module**.
3. In the Import dialog, specify the connector file and project name:
  - a. Specify the name of the RAR file to import. Use **Browse** to locate the RAR file and specify its full path name.
  - b. Specify a connector project name. For example, if you are importing the HelloWorld.rar file, you might name the project HelloWorld. Click **New**, specify HelloWorld for the project name, and click **Next**.
  - c. **5.1+** Select a target server. To use the Application profiling or Last participant support application assembly services of WebSphere Business Integration (WBI) Server Foundation, select the **Integration Server** target server.
  - d. If you want the connector project not to be part of an enterprise application, specify **Standalone connector project**.
  - e. If the connector project is not to stand alone, name the enterprise archive (EAR) file into which to import the RAR file. The name must be unique among EAR files in the directory.
  - f. If you want the Assembly Toolkit to overwrite existing resource files without first warning you that the files are changing, specify **Overwrite existing resources without warning**. The default is not to overwrite files without warning.
  - g. Click **Finish**.
4. Verify the contents of the new connector module in either of the following ways:

- In the J2EE Hierarchy view, expand **Enterprise Applications** or **Connector Modules** and view the new modules.
- Click **Window > Show View > Navigator** to see the associated files for the connector module in a Navigator view.

---

## Creating enterprise applications

Before you can deploy your archive files onto an application server, you must assemble them in an enterprise application archive (EAR) file. This article describes how to create a Java 2 Platform, Enterprise Edition (J2EE) enterprise application project using the Assembly Toolkit. After you create an enterprise application project, you can add (import) archive files such as Web application archives (WAR), resource adapter archives (RAR), enterprise bean (EJB) JAR files, and application client archives (JAR) files.

1. Start the Assembly Toolkit.
2. Click **File > New > Project**. Or, if you are working in the J2EE perspective, click **File > New > Enterprise Application Project** and skip step 3a below.
3. In the New Project dialog, create an enterprise application project:
  - a. Click **J2EE > Enterprise Application Project > Next**.
  - b. Specify whether you want an EAR file that supports J2EE 1.2 or 1.3, and click **Next**.
  - c. On the Enterprise Application Project page:
    - 1) Specify an EAR file name and location.
    - 2) To change the default project location, click **Browse** and specify a new location.
    - 3) **5.1+** Select a target server.

To use an application assembly service of WebSphere Business Integration (WBI) Server Foundation, select the **Integration Server** target server. Available WBI assembly services include ActivitySession, Application profiling, Extended access, Extended messaging, Internationalization, Last participant support, and Pushdown.
    - 4) Click **Next**.
  - d. Optional: On the EAR Module Projects page, select the existing modules that you want to add to the new enterprise application project. To create new modules for this enterprise application, click **New Module**. On the New Module Project page, select **Create default module projects** to create modules for application client, enterprise bean (EJB), Web or connector projects. You can use the default project names for the modules or specify different project names. If you clear the **Create default module projects** check box, you can select a single module type and proceed with the proper wizard for that project type. Then, click **Finish** to create the project modules and add their names to the list of available modules on the EAR Module Projects page.
  - e. Click **Finish**.
  - f. Optional: Confirm that you want to view the J2EE Hierarchy view.
4. Verify the contents of the new enterprise application in either of the following ways:
  - In the **J2EE Hierarchy** view, expand **Enterprise Application** and view the new EAR file.
  - Click **Window > Show View > Navigator** to see the associated files for the enterprise application in a Navigator view.

---

## Creating Web applications

In the Assembly Toolkit, you create and maintain resources for Web applications in Web projects. There are two types of Web projects, dynamic and static. Dynamic web projects can contain dynamic J2EE resources such as servlets, JavaServer Pages (JSP) files, filters, and associated metadata, in addition to static resources such as images and HTML files. Static Web projects only contain static resources.

Dynamic Web projects are always imbedded in enterprise application projects. Creating a Web project in the Assembly Toolkit requires that an enterprise application (EAR) project exist, or the Assembly Toolkit

creates one for you. Creating a Web project updates the `application.xml` deployment descriptor of the specified enterprise application project to define the Web project as a module element. If you are importing a WAR file rather than creating a Web project new, the WAR Import wizard requires that you specify a Web project, which already requires an EAR project.

This article describes how to create a dynamic Web project using the Assembly Toolkit. For instructions on how to create a static Web project, see the Assembly Toolkit online help. In the Assembly Toolkit, click **Help > Help Contents > Assembly Toolkit information > Web development > Tasks > Working with Web projects > Creating new static Web projects**.

1. Start the Assembly Toolkit.
2. Optional: View an animation file that shows how to create a dynamic Web project using the Assembly Toolkit. In the Assembly Toolkit, click **Help > Help Contents > Assembly Toolkit information > Web development > Tasks > Working with Web projects > Creating new dynamic Web projects > Show Me**.
3. Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
4. Click **File > New > Dynamic Web Project**.
5. On the Dynamic Web Project page of the New Web Project dialog:
  - a. Specify a Web project (WAR file) name.
  - b. Specify a location for the WAR file. To change the default WAR files location, click **Browse** and specify a new location.
  - c. Decide whether you want to accept the defaults associated with a dynamic Web project or configure advanced options. If you want to accept the defaults, deselect **Configure advanced options**. Otherwise, select **Configure advanced options** and **Next**. Step 6 describes the defaults and advanced options for a dynamic Web project.
6. If you selected **Configure advanced options**, you can customize the Web project options:
  - a. Specify a new or existing enterprise application (EAR) project to be associated with your new Web project for purposes of deployment. If you want to add a Web project as a module to another enterprise application project in the future, open the `application.xml` editor for the enterprise application project and select **Add** on the General page.
  - b. Provide a **Context root** value. The context root is the Web application root, the top-level directory of your application when it is deployed to a Web server. The default value is the name of your Web project. You can change the context root after you create a project using the project Properties dialog, which you access from the project's context menu.
  - c. From the J2EE Level drop-down list, select the appropriate Sun Microsystems Servlet and JSP specification level for the dynamic elements you plan to include in your Web project. Any new servlets and JSP files that you expect to create should adhere to the latest specification level available; previous specification levels are offered to accommodate any legacy dynamic elements that you expect to import into the project.
  - d. Click **Next**.
  - e. Optional: On the Features Page, select one or more of the Web project features and click **Next**.
  - f. Optional: Select **Use a default Page Template for the Web Site** if you want your entire Web site to share a common page template. If you want to use one of the sample templates provided, select **Sample Template** and then choose one of the templates shown in the **Thumbnail** box. If you want to use a template of your own, select **User-defined Template** and then click **Browse** to select the template from the file system. The default is not to use a page template.
7. Click **Finish**. A new Web project is created, reflecting the J2EE folder structure that specifies the location of web content files, class files, class paths, the deployment descriptor, and supporting metadata.
8. Verify the contents of the new Web project in either of the following ways:

- In the **J2EE Hierarchy** view, expand **Enterprise Applications** and the enterprise application associated with your Web project to view the new WAR file.
- Click **Window > Show View > Navigator** to see the associated files for the Web project in a Navigator view.

You can now begin creating or importing content for your Web project using the New File wizards or the Import wizards available from the **File** menu.

---

## Creating application clients

Application client projects contain programs that run on networked client systems. An application client project is deployed as a JAR file.

In the Assembly Toolkit, you can create and add an application client project to a new or existing enterprise application project.

1. Start the Assembly Toolkit.
2. Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. Click **File > New > Application Client Project**.
4. In the Application Client project creation dialog:
  - a. Select the Java 2 Platform, Enterprise Edition (J2EE) specification version to which you want your project to adhere, and click **Next**.
  - b. Name the application client project and specify its location. To change the default project location, click **Browse** and specify a new location. If you specify a non-default project location that is already being used by another project, the project creation will fail.
  - c. **5.1+** Select a target server. To use application assembly services of WebSphere Business Integration (WBI) Server Foundation such as Application profiling, select the **Integration Server** target server.
  - d. Specify a new or existing enterprise application (EAR) project to be associated with your new application client project for purposes of deployment. Select an existing enterprise application project from the drop-down list or type a new project name. Or, click **New** and create a new enterprise application. Note that if you type a new EAR project name, the EAR project will be created in the default location with the lowest compatible J2EE version based on the version of the project being created. If you want to specify a different version or a different location for the enterprise application, you must click **New** and create a new enterprise application.
  - e. Optional: If you are creating a new enterprise application project or if you have no module dependencies to specify, skip this step. Otherwise, click **Next** to specify module and JAR file dependencies. On the Module Dependencies page, select dependent JAR files or modules within the associated enterprise application project. This updates the runtime class-path and Java project build path with the appropriate JAR files. Application client modules, EJB modules, and Web modules can all have dependencies on EJB modules or utility JAR files. Modules cannot depend on WAR or application client JAR files.
  - f. Click **Finish** to create the application client project.
5. Verify the contents of the new application client project in either of the following ways:
  - In the **J2EE Hierarchy** view, expand **Enterprise Applications** and the enterprise application associated with your application client project to view the new JAR file.
  - Click **Window > Show View > Navigator** to see the associated files for the application client project in a Navigator view.

After creating an application client project, you can edit the application client deployment descriptor if default properties are not sufficient. In the Client Deployment Descriptor editor, you can add enterprise bean, resource, or resource environment references as well as view and edit source code.

For detailed instructions on adding enterprise bean, resource, or resource environment references, see the Assembly Toolkit online help. In the Assembly Toolkit, click **Help > Help Contents > Assembly Toolkit information > J2EE application development > Tasks > Configuring application client modules with the client deployment descriptor editor**. Similar information is in the information center for IBM WebSphere Studio Application Developer at <http://publib.boulder.ibm.com/infocenter/wsphelp/index.jsp>. Click **WebSphere Studio Application Developer > J2EE development > Tasks > Configuring application client modules with the client deployment descriptor editor**.

---

## Creating EJB modules

In the Assembly Toolkit, you can create and test enterprise beans that conform to the distributed component architecture defined in the Sun Microsystems Enterprise JavaBeans (EJB) specification and that support extended functionality for WebSphere Application Server.

You can create enterprise beans (either with or without inheritance) such as session beans, container-managed persistence (CMP) entity beans, bean-managed persistence (BMP) entity beans, or message-driven beans. Using the EJB deployment descriptor editor of the Assembly Toolkit, you can set deployment descriptor and assembly properties for enterprise beans.

This article describes how to create an EJB project (or EJB module) using the Assembly Toolkit.

1. Start the Assembly Toolkit.
2. Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. Click **File > New > EJB Project**.
4. In the New EJB Project dialog:
  - a. Select the EJB specification version to which you want your EJB project to adhere, and click **Next**. If you plan on using EJB 2.0 enterprise beans, you must specify an EJB 2.0 project. You can add EJB 1.1 enterprise beans to an EJB 2.0 project. An EJB 2.0 project must exist in a J2EE 1.3 enterprise application project. Your available options can differ, depending on the J2EE preferences defined.
  - b. Name the EJB project and specify its location. To change the default project location, click **Browse** and specify a new location. If you specify a non-default project location that is already being used by another project, the project creation will fail.
  - c. **5.1+** Select a target server. To use an application assembly service of WebSphere Business Integration (WBI) Server Foundation, select the **Integration Server** target server. Available WBI assembly services include ActivitySession, Application profiling, Extended access, Extended messaging, Internationalization, Last participant support, and Pushdown.
  - d. Specify a new or existing enterprise application (EAR) project to be associated with your new EJB project for purposes of deployment. Select an existing enterprise application project from the drop-down list or type a new project name. Or, click **New** and create a new enterprise application. Note that if you type a new EAR project name, the EAR project will be created in the default location with the lowest compatible J2EE version based on the version of the project being created. If you want to specify a different version or a different location for the enterprise application, you must click **New** and create a new enterprise application.
  - e. Optional: If you are creating a new enterprise application project or if you have no module dependencies to specify, skip this step. Otherwise, click **Next** to specify module and JAR file

dependencies. On the Module Dependencies page, select dependent JAR files or modules within the associated enterprise application project. Note that this page is available only if you are using an existing enterprise application project.

- f. Click **Finish** to create the EJB project.
5. Verify the contents of the new EJB project in either of the following ways:
    - In the **J2EE Hierarchy** view, expand **Enterprise Applications** and the enterprise application associated with your EJB project to view the new JAR file.
    - Click **Window > Show View > Navigator** to see the associated files for the EJB project in a Navigator view.

After you have an EJB project to hold enterprise beans, you can do the following:

- Create or import enterprise beans to your EJB project.
- Add methods to the home and remote interfaces.
- Add custom finders.
- Add and define additional CMP fields.
- Add relationships.
- Edit the EJB deployment descriptor if default properties are not sufficient.
- Create EJB access beans and use them to create your client application.
- Map enterprise beans to RDB tables.

For detailed instructions on creating CMP fields or CMP finder methods for entity beans, relating CMP fields, adding methods to interfaces, or managing enterprise beans, see the Assembly Toolkit online help. In the Assembly Toolkit, click **Help > Help Contents > Assembly Toolkit information > Enterprise JavaBeans (EJB) development > Tasks**. Similar information is in the information center for IBM WebSphere Studio Application Developer at <http://publib.boulder.ibm.com/infocenter/wsphelp/index.jsp>. Click **WebSphere Studio Application Developer > J2EE development > Tasks > Developing EJB applications**.

---

## Creating connector modules

A *connector* is a J2EE component that provides access to Enterprise Information Systems (EIS), and must comply to the J2EE Connector architecture (JCA). An *Enterprise Information System (EIS)* is a set of related classes that lets an application access a resource such as data, or an application on a remote server, often called a resource adapter.

This article describes how to create a connector project using the Assembly Toolkit.

1. Start the Assembly Toolkit.
2. Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. Click **File > New > Connector Project**.
4. In the New Connector Project dialog:
  - a. If you want your connector project to be a stand-alone project, select **Standalone connector project**. Selecting that the connector project stand alone disables the enterprise archive (EAR) project option at the bottom of the page.
  - b. Name the connector project and specify its location. To change the default project location, click **Browse** and specify a new location.
  - c. **5.1+** Select a target server. To use the Application profiling or Last participant support application assembly services of WebSphere Business Integration (WBI) Server Foundation, select the **Integration Server** target server.
  - d. If you specified that the connector project stand alone, specify a new or existing enterprise application (EAR) project to be associated with your new connector project for purposes of deployment. Select an existing enterprise application project from the drop-down list or type a new

project name. Or, click **New** and create a new enterprise application. Note that if you type a new EAR project name, the EAR project will be created in the default location with the lowest compatible J2EE version based on the version of the project being created. If you want to specify a different version or a different location for the enterprise application, you must click **New** and create a new enterprise application.

- e. Optional: If you are creating a new enterprise application project or if you have no module dependencies to specify, skip this step. Otherwise, click **Next** to specify module and JAR file dependencies. On the Module Dependencies page, select dependent JAR files or modules within the associated enterprise application project.
  - f. Click **Finish** to create the connector project.
5. Verify the contents of the new connector project in either of the following ways:
- In the **J2EE Hierarchy** view, expand **Enterprise Applications** and the enterprise application associated with your connector project to view the new JAR file.
  - Click **Window > Show View > Navigator** to see the associated files for the connector project in a Navigator view.

---

## Editing deployment descriptors

A deployment descriptor is an extensible markup language (XML) file that describes how to deploy a module or application by specifying configuration and container options. When you create a module, the Assembly Toolkit creates deployment descriptor files for the module.

You can edit a deployment descriptor file manually. However, it is preferable to edit a deployment descriptor using an Assembly Toolkit deployment descriptor editor to ensure that the deployment descriptor has valid properties and that its references contain appropriate values.

Deployment descriptor editor	Resources modified in the editor
Application deployment descriptor editor	<ul style="list-style-type: none"> <li>• application.xml</li> <li>• ibm-application-bnd.xmi</li> <li>• ibm-application-ext.xmi</li> </ul>
Web deployment descriptor editor	<ul style="list-style-type: none"> <li>• WEB-INF/web.xml</li> <li>• Binding information</li> <li>• IBM binding and extensions information such as ibm-web-bnd.xmi and ibm-web-ext.xmi files</li> </ul>
Enterprise bean (EJB) deployment descriptor editor	<ul style="list-style-type: none"> <li>• ejb-jar.xml</li> <li>• ibm-ejb-jar-bnd.xml</li> <li>• ibm-ejb-jar-ext.xml</li> <li>• ibm-ejb-access-bean.xml</li> </ul>
Client deployment descriptor editor	<ul style="list-style-type: none"> <li>• application-client.xml</li> <li>• ibm-application-client-bnd.xmi</li> <li>• ibm-application-client-ext.xmi</li> </ul>
Web services editor	<ul style="list-style-type: none"> <li>• webservicex.xml</li> <li>• ibm-webservicex-bnd.xmi</li> <li>• ibm-webservicex-ext.xmi</li> </ul>
Web services client editor	<ul style="list-style-type: none"> <li>• webservicexclient.xml</li> <li>• ibm-webservicexclient-bnd.xmi</li> <li>• ibm-webservicexclient-ext.xmi</li> </ul>

1. Ensure that you are working in the J2EE Perspective. Click **Window > Open Perspective > J2EE**.
2. In a J2EE Hierarchy view (**Window > Show View > J2EE Hierarchy**), right-click the module with deployment descriptor values that you want to browse or edit, and click **Open With > Deployment Descriptor Editor**. A deployment descriptor editor for the module displays in a view. You can click tabs such as **Overview**, **Module**, **Security**, and **Source** at the bottom of the view to browse or edit specific

deployment descriptor values. Clicking **Source** displays editable source code; it is preferable to edit values in fields on or accessible from the other tabs rather than edit the source code manually.

**5.1+** If you selected the **Integration Server** target server for a module, tabs for application assembly services of WebSphere Business Integration (WBI) Server Foundation also display. Available WBI assembly services include ActivitySession, Application profiling, Extended access, Extended messaging, Internationalization, Last participant support, and Pushdown.

3. Edit the deployment descriptor values as desired. For information on fields in the deployment descriptor editor, press F1 and click a topic.
4. Save your changes to the deployment descriptor.
  - a. Close the deployment descriptor editor.
  - b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.

You also can save changes to deployment descriptors at any time by pressing Ctrl-S.

---

## Mapping enterprise beans to database tables

You can map enterprise bean JAR files (EJB modules) to relational database (RDB) tables using the EJB to RDB Mapping wizard of the Assembly Toolkit. The wizard creates EJB to RDB mappings for the following situations:

### Existing enterprise bean but no database schema

*Top Down* mapping generates a default database schema and a mapping from one or more existing enterprise beans.

### Existing database schema but no enterprise bean

*Bottom Up* mapping generates one or more enterprise beans and mappings from an existing database schema.

### Existing enterprise bean and database schema

*Meet In the Middle* mapping matches existing enterprise beans with existing database tables. You can match by name, by name and type, or by neither.

1. In the J2EE Hierarchy view, right-click the EJB module.
2. Click **Generate > EJB to RDB Mapping**.
3. After the wizard opens, press F1 and select a type of mapping. The online help provides detailed information on generating a mapping.
4. For EJB 2.0 projects, on the EJB to RGB Mapping page specify whether you want to create a new backend (*Top Down*) or use an existing backend (*Bottom Up* or *Meet In the Middle*) where the schema exists in the backend but without a mapping file. If you previously generated a mapping, you can create and map unmapped elements or open the mapping editor to manually make changes. In EJB 2.0, your mapping and schema files make up a *backend* for EJB 2.0 projects. You can have multiple backend folders for each project; for example, one DB2 and one Oracle backend. The wizard uses one database backend only as the default, but you can define as many as you need.
5. Follow the instructions in the wizard and in the online help.
6. Click **Finish** to generate the mapping.

## Mapping constraints for databases

Each of your Java 2 platform, Enterprise Edition (J2EE) applications (in an EAR file) can have more than one enterprise bean Container Managed Persistence (CMP) module in it. Each EJB CMP module (as a JAR file) can contain more than one CMP bean. You can configure each bean to connect to its own data source by using the different Java Naming and Directory Interface (JNDI) names of each data source.

However, there are some constraints:

- The deployment tool only enables you to map EJB CMP beans to different databases at the EJB JAR level. There are different backend ids for different database schema mapping. The product uses the attribute *backendId* to distinguish database specific code. For example, the code that accesses an

Oracle database is different from that accessing a DB2 database. Even for the same vendor, different versions of their products can result in different generated code.

- At run time, WebSphere Application Server uses the *CurrentBackendId* attribute to access the correct back end related code. You can only configure the *CurrentBackendId* at the EJB JAR level. This means that **all** of the EJB CMP beans within a specific EJB JAR file (which contains all the CMR beans) must connect to the same type of data source (that is, the same vendor, same version).
- Even though you can connect EJB CMP beans to different databases of the same type, the process fails if your connections result in a *table join* between tables from different databases. Various actions such as EJB Query , Inheritance support, *readAhead..*, and so on, can result in a table join situation.
- The datasource needs to be an XA datasource to support multiple databases' connection within a transaction.

---

## Verifying archive files

The Assembly Toolkit validates code when you request code validation manually, automatically during a resource change, and automatically during a build.

As part of validating the code, the validation checks for the following:

- Required deployment properties contain values.
  - Values specified for environment entries match their associated Java types.
  - In both enterprise archive (EAR) and Web archive (WAR) files:
    - The target enterprise bean of the link exists for enterprise bean (EJB) references.
    - The target role exists for security role references.
    - Security roles are unique.
  - Each module listed in the deployment descriptor exists in the archive for EAR files.
  - Files for icons, servlets, error and welcome pages listed in the deployment descriptor have corresponding files in the archive for WAR files.
  - For EJB modules:
    - All class files referenced in the deployment descriptor exist in the JAR file.
    - Method signatures for enterprise bean home, remote and implementation classes are compliant with the EJB 2.0 specification.
1. Optional: Specify whether you want automatic code validation during a resource change or during a build. The default is for automatic code validation.
    - a. In the J2EE Hierarchy view, right-click on a project.
    - b. Click **Properties > Validation**.
    - c. Ensure that the **Run validation** options for builds and for automatic validation are selected. Select **Override validation preferences** to disable automatic code validation.
    - d. If you changed the **Validation** settings, click **Apply** or **OK**.
  2. Optional: Specify validation options for a project. The default is to check all validators for a project during code validation. For an enterprise application project, the validators might be for DTD, EAR, Web services, XML, XML schema, or XSL files.
    - a. In the J2EE Hierarchy view, right-click the project containing the code that you want to validate.
    - b. Click **Properties > Validation**.
    - c. Select **Override validation preferences**.
    - d. Select the validators you want checked during code validation.
    - e. If you changed the **Validation** settings, click **Apply** or **OK**.
  3. Right-click the project containing the code that you want to validate and click **Run Validation** to manually validate the code.

The results of the code validation are shown in a Tasks view. For information on the results, select an entry in the Tasks view, press F1, and click **Tasks view**.

If your application module contains EJB modules, generate code for deployment. Otherwise, you are ready to deploy the application module (or stand-alone Web module) onto the application server.

---

## Generating code for EJB deployment

This task assumes you have already assembled an enterprise bean (EJB) module, added it to an application, saved the application, and verified the application.

Before installing your application in WebSphere Application Server, you must generate deployment code for the application. This step is required for EJB modules and for any enterprise application archive (EAR) files that contain EJB modules. During code generation, the Assembly Toolkit prepares entity bean (JAR) files for deployment in a run-time environment. If your EJB project contains container-managed persistence (CMP) beans that have not been mapped, generating deployment code creates a default top-down mapping.

1. If you have turned automatic validation off, manually validate your enterprise beans before generating deployment code for them. If validating your beans results in compilation errors or validation errors, fix the errors before generating deployment code. However, if validating your beans results in warning or information messages, you can generate deployment code.
2. If you have changed the class path of your EJB project, ensure that the source folder for your EJB project is at the beginning of the class path of the project. Generating deployment code imports both the JAR file and the source code of the JAR file, so entries on the class path must be in the correct order.
3. In the J2EE Hierarchy view of the Assembly Toolkit, right-click on the enterprise application (EAR file) or EJB module (enterprise bean JAR file) for which you want to generate code for deployment.
4. Click a **Generate Deployment Code** option.
  - For EAR files, click **Generate Deployment Code**.
  - For enterprise bean JAR files, click **Generate > Deployment and RMIC Code > EJB\_module > Finish**.

Alternatively, you can generate deployment code for enterprise bean JAR files using the deployment tool for Enterprise JavaBeans (ejbdeploy) from a command prompt. For a detailed list of available options in the EJBDeploy tool, enter `ejbdeploy` from a command prompt.

Code is generated into the folder where your enterprise beans are located. Problems with the generation of Java RMI stub compiler (RMIC) code result in a window that displays error messages.

Install the Java 2 Platform, Enterprise Edition (J2EE) application on your server machine. You can install the application onto a server using the administrative console. Before installing the application, you might need to set class paths.

---

## Generating code for Web service deployment

This task assumes you have already assembled a module enabled with Web services, added it to an application, saved the application, and verified the application.

Before installing your application in WebSphere Application Server, you must generate deployment code for the application. This step is required for Web services-enabled modules and for any enterprise application archive (EAR) files that contain Web services-enabled modules.

1. If you have turned automatic validation off, manually validate any modules that use Web services with the JSR109 Web services validator before generating deployment code for them. If validating your module results in compilation errors or validation errors, fix the errors before generating deployment code. However, if validating your module results in warning or information messages, you can generate deployment code.

2. In the J2EE Hierarchy view of the Assembly Toolkit, right-click on the Web services-enabled module (WAR, enterprise bean JAR, or application client JAR file) for which you want to generate code for deployment.
3. Click **Web Services > Deploy Web Service**. Alternatively, you can generate deployment code for Web services-enabled modules using the deployment tool for Web services (wsdeploy) from a command prompt.
4. If messages indicate that automatic file overwriting is not enabled, click **Yes to All** so the generated files are added to the module.
5. If errors such as *Unbound classpath variable: WAS\_50\_PLUGINDIR* appear in the Tasks list, change the Java build path libraries properties to define that variable to be the WebSphere Application Server installation directory.

Install the Java 2 Platform, Enterprise Edition (J2EE) application on your server machine. You can install the application onto a server using the administrative console. Before installing the application, you might need to set class paths.

---

## Assembly Toolkit: Resources for learning

Use the following links to find relevant supplemental information about the Assembly Toolkit. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

## Chapter 30. Deploying and managing applications

After you develop an enterprise application and configure an application server, you can use the administrative console to install application files on the server and manage the activity of deployed applications.

1. Install your application on your application server.
2. Start and stop applications.
3. Edit the administrative configuration for an application. Go to the settings page for an application, change the values for settings as needed, and click **OK**.
4. Export applications.
5. Export DDL files.
6. Update application binary files.
7. Uninstall applications.

After making changes to administrative configurations of your applications, ensure that you click **Save** on the administrative console taskbar to save the changes.

---

### Enterprise applications

Enterprise applications (or J2EE applications) are applications that conform to the Java 2 Platform, Enterprise Edition, specification.

Enterprise applications can consist of the following:

- Zero or more EJB modules
- Zero or more Web modules
- Zero or more connector modules (packaged in RAR files)
- Zero or more application client modules
- Additional JAR files containing dependent classes or other components required by the application
- Any combination of the above

A J2EE application is represented by, and packaged in, an enterprise archive (EAR) file.

---

### Installing a new application

To install an enterprise application to a WebSphere Application Server configuration, you can use the administrative console or the wsadmin tool. The steps below describe how to use the administrative console to install an application, EJB component, or Web module.

**Note:** Once you start performing the steps below, click **Cancel** to exit if you decide not to install the application. Do not simply move to another administrative console page without first clicking **Cancel** on an application installation page.

1. Click **Applications > Install New Application** in the console navigation tree. The first of two Preparing for application install pages is shown.
2. On the first Preparing for application install page:
  - a. Specify the full path name of the source application file (.ear file otherwise known as an EAR file). The EAR file that you are installing can be either on the client machine (the machine that runs the Web browser) or on the server machine (the machine to which the client is connected). If you specify an EAR file on the client machine, then the administrative console uploads the EAR file to the machine on which the console is running and proceeds with application installation. You can also specify a stand-alone WAR or JAR file for installation.
  - b. If you are installing a stand-alone WAR file, specify the context root.

- c. Click **Next**.
3. On the second Preparing for application install page:
  - a. Select whether to generate default bindings. Using the default bindings causes any incomplete bindings in the application to be filled in with default values. Existing bindings are not altered. You can customize default values used in generating default bindings. For example, you can specify JNDI prefix for all the EJB files in EJB modules, default data source and connection factory settings for EJB modules, virtual host for web modules, and so on. "Preparing for application installation settings" on page 1413" describes available customizations and provides sample bindings.
  - b. Click **Next**. The Install New Application pages are now shown. If you chose to generate default bindings, you can proceed to the Summary step (step 23 below). "Example: Installing an EAR file using the default bindings" on page 1417" provides sample steps.
4. On the **Step: Provide options to perform the installation** panel, provide values for the following settings specific to WebSphere Application Server. Default values are used if you do not specify a value.
  - a. For **Pre-compile JSP**, specify whether to precompile JSP files as a part of installation. The default is not to precompile JSP files.
  - b. For **Directory to Install Application**, specify the directory to which the application EAR file will be installed. The default value is the value of APP\_INSTALL\_ROOT/*cell\_name*, where the APP\_INSTALL\_ROOT variable is *install\_root/installedApps*; for example, C:\WebSphere\AppServer\installedApps\*cell\_name*.
 

**Note:** If an installation directory is not specified when an application is installed on a single-server (base) configuration, the application is installed in APP\_INSTALL\_ROOT/*base\_cell\_name*. When the base server is made a part of a Network Deployment configuration (using the addNode utility), the cell name of the new configuration becomes the cell name of the deployment manager node. If the -includeapps option is used for the addNode utility, then the applications that are installed prior to the addNode operation still use the installation directory APP\_INSTALL\_ROOT/*base\_cell\_name*. However, an application that is installed after the base server is added to the network configuration uses the default installation directory APP\_INSTALL\_ROOT/*network\_cell\_name*. To move the application to the APP\_INSTALL\_ROOT/*network\_cell\_name* location upon running the addNode operation, you should explicitly specify the installation directory as \${APP\_INSTALL\_ROOT}/\${CELL} during installation. In such a case, the application files can always be found under APP\_INSTALL\_ROOT/*current\_cell\_name*.
  - c. For **Distribute Application**, specify whether WebSphere Application Server expands or deletes application binaries in the installation destination. The default is to enable application distribution. As a result, when you save changes in the console, application binaries for newly installed applications are expanded to the directory specified. The binaries are also deleted when you uninstall and save changes to the configuration. If you disable this option, then you must ensure that the application binaries are expanded appropriately in the destination directories of all nodes where the application is expected to run.
  - d. For **Use Binary Configuration**, specify whether the application server uses the binding, extensions, and deployment descriptors located with the application deployment document, the deployment.xml file (default), or those located in the EAR file. The default is not to use the binary configuration.
  - e. For **Deploy EJBs**, specify whether the EJBDeploy tool runs during application installation. The tool generates code needed to run EJB files. The default is not to run the EJBDeploy tool. You must enable this setting if the EAR file was assembled using the Assembly Toolkit and the EJBDeploy tool was not run during assembly, if the EAR file was not assembled using the Assembly Toolkit tool, or if the EAR file was assembled using versions of the Application Assembly Tool (AAT) previous to Version 5. Note that enabling this setting might cause the installation program to run for several minutes.

- f. For **Application Name**, name the application. Application names must be unique within a cell and cannot contain characters that are not allowed in object names (see "Object names" in the Information Center).
  - g. For **Create MBeans for Resources**, specify whether to create MBeans for various resources (such as servlets or JSP files) within an application when the application is started. The default is to create MBean instances.
  - h. For **Enable class reloading**, specify whether to enable class reloading when application files are updated. The default is not to enable class reloading. For EJB modules or any non-Web modules, enabling class reloading sets `reloadEnabled` to `true` in the `deployment.xml` file for the application. If an application's class definition changes, the application server run time stops and starts the application to reload application classes.  
 For Web modules such as servlets and JavaServer page (JSP) files, a Web container reloads a Web module only when the IBM extension `reloadingEnabled` in the `ibm-web-ext.xmi` file is set to `true`. You can set `reloadingEnabled` to `true` when editing your Web module's extended deployment descriptors in an assembly tool.  
 To disable reloading of a Web module, set the IBM extension `reloadingEnabled` in the `ibm-web-ext.xmi` file to `false`. Or, if the Web module has the IBM extension `reloadingEnabled` in the `ibm-web-ext.xmi` file set to `true`, enable class loading, and set the **Reload Interval** property to zero (0).
  - i. For **Reload Interval**, specify the number of seconds to scan the application's file system for updated files. The default is the value of the reload interval attribute in the IBM extension (META-INF/ibm-application-ext.xmi) file of the EAR file. To enable reloading, specify a value greater than zero (for example, 1 to 2147483647). To disable reloading, specify zero (0).  
 The reload interval specified here overrides the value specified in the IBM extensions for each Web module in the EAR file (which in turn overrides the reload interval specified in the IBM extensions for the application in the EAR file). This setting takes effect only if class reloading is enabled.
  - j. For **Deploy WebServices**, specify whether the Web services deploy tool `wsdeploy` runs during application installation. The tool generates code needed to run applications using Web services. The default is not to run the `wsdeploy` tool. You must enable this setting if the EAR file contains modules using Web services and has not previously had the `wsdeploy` tool run on it, either from the **Web Services > Deploy Web Service** menu of the Assembly Toolkit or from a command line.
5. If your application uses EJB modules, on the **Step: Provide JNDI Names for Beans** panel, specify a JNDI name for each enterprise bean in every EJB module. You must specify a JNDI name for every enterprise bean defined in the application. For example, for the EJB module `MyBean.jar`, specify `MyBean`.
  6. If your application uses EJB modules that contain Container Managed Persistence (CMP) beans that are based on the EJB 1.x specification, for **Step: Provide default datasource mapping for modules containing 1.x entity beans**, specify a JNDI name for the default data source for the EJB modules. The default data source for the EJB modules is optional if data sources are specified for individual CMP beans.
  7. If your application has CMP beans that are based on the EJB 1.x specification, for **Step: Map datasources for all 1.x CMP**, specify a JNDI name for data sources to be used for each of the 1.x CMP beans. The data source attribute is optional for individual CMP beans if a default data source is specified for the EJB module that contains CMP beans. If neither a default data source for the EJB module nor a data source for individual CMP beans are specified, then a validation error displays after you click **Finish** (step 23) and the installation is cancelled.
  8. If your application defines EJB references, for **Step: Map EJB references to beans**, specify JNDI names for enterprise beans that represent the logical names specified in EJB references. Each EJB reference defined in the application must be bound to an EJB file before clicking **Finish** on the Summary panel.
  9. If your application defines resource references, for **Step: Map resource references to resources**, specify JNDI names for the resources that represent the logical names defined in resource

- references. Each resource reference defined in the application must be bound to a resource defined in your WebSphere Application Server configuration before clicking on **Finish** on the Summary panel.
10. If your application uses Web modules, for **Step: Map virtual hosts for web modules**, select a virtual host from the list that should map to a Web module defined in the application. The port number specified in the virtual host definition is used in the URL that is used to access artifacts such as servlets and JSP files in the Web module. Each Web module must have a virtual host to which it maps. Not specifying all needed virtual hosts will result in a validation error displaying after you click **Finish** on the Summary panel.
  11. On the **Step: Map modules to application servers** panel, for every module select a target server or a cluster from the **Clusters and Servers** list. Select the check box beside **Module** to select all of the application modules or select individual modules.
  12. If the application has security roles defined in its deployment descriptor then, for **Step: Map security roles to users/groups**, specify users and groups that are mapped to each of the security roles. Select the check box beside **Role** to select all of the roles or select individual roles. For each role, you can specify if predefined users such as **Everyone** or **All Authenticated users** are mapped to it. To select specific users or groups from the user registry:
    - a. Select a role and click **Lookup users** or **Lookup groups**.
    - b. On the Lookup users/groups panel shown, enter search criteria to extract a list of users or groups from the user registry.
    - c. Select individual users or groups from the results displayed.
    - d. Click **OK** to map the selected users or groups to the role selected on the **Step: Map security roles to users/groups** panel.
  13. If the application has Run As roles defined in its deployment descriptor, for **Step: Map RunAs roles to user**, specify the Run As user name and password for every Run As role. Run As roles are used by enterprise beans that must run as a particular role while interacting with another enterprise bean. Select the check box beside **Role** to select all of the roles or select individual roles. After selecting a role, enter values for the user name, password, and verify password and click **Apply**.
  14. If your application contains EJB 1.x CMP beans that do not have method permissions defined for some of the EJB methods, for **Step: Ensure all unprotected 1.x methods have the correct level of protection**, specify if you want to leave such methods unprotected or assign protection with deny all access.
  15. If your application contains message driven enterprise beans, for **Step: Provide Listener Ports for messaging beans**, provide a listener port name for every message driven bean. If a name is not specified for each bean, then a validation error displays after you click on **Finish** on the Summary panel.
  16. If your application uses EJB modules that contain CMP beans that are based on the EJB 2.0 specification, for **Step: Provide default datasource mapping for modules containing 2.0 entity beans**, specify a JNDI name for the default data source and the type of resource authorization to be used for the default data source for the EJB modules. The default data source for EJB modules is optional if data sources are specified for individual CMP beans.
  17. If your application has CMP beans that are based on the EJB 2.0 specification, on the **Step: Map datasources for all 2.0 CMP** panel, for each of the 2.0 CMP beans specify a JNDI name and the type of resource authorization for data sources to be used. The data source attribute is optional for individual CMP beans if a default data source is specified for the EJB module that contains CMP beans. If neither a default data source for the EJB module nor a data source for individual CMP beans are specified, then a validation error is shown after you click **Finish** and installation is cancelled.
  18. If your application contains EJB 2.0 CMP beans that do not have method permissions defined in the deployment descriptors for some of the EJB methods, on the **Step: Ensure all unprotected 2.0 methods have the correct level of protection** panel, specify whether you want to assign a specific role to the unprotected methods, add the methods to the exclude list, or mark them as unchecked. Methods added to the exclude list are marked as uncallable. For methods marked unchecked no authorization check is performed prior to their invocation.

19. If the **Deploy EJBs** setting is enabled on the **Provide options to perform the installation** panel, then you can specify options for the EJBDeploy tool on the **Step: Provide options to perform the EJB Deploy** panel. On this panel, you can specify extra class path, rmic options, database types, and database schema names to be used while running the EJBDeploy tool. The tool is run on the EAR file during installation after you click **Finish**.
20. If your application contains resource environment references, for **Step: Mapping Resource Environment References to Resources**, specify JNDI names of resources that map to the logical names defined in resource environment references. If each resource environment reference does not have a resource associated with it, a validation error is shown after you click **Finish**.
21. If your application defines **Run-As Identity** as *System Identity*, for **Step: Replacing RunAs System to RunAs Roles**, you can optionally change it to *Run-As role* and specify a user name and password for the Run As role specified. Selecting *System Identity* implies that the invocation is done using the WebSphere Application Server security server ID and should be used with caution as this ID has more privileges.
22. If your application has resource references that map to resources that have an Oracle database doing backend processing, for **Step: Specify the isolation level for Oracle type provider**, specify or correct the isolation level to be used for such resources when used by the application. Oracle databases support ReadCommitted and Serializable isolation levels only.
23. On the Summary panel, verify the cell, node, and server onto which the application modules will install. Beside the **Cell/Node/Server** option, click **Click here** and verify the settings. Then click **Finish**.  
**Note:** After clicking **Finish**, if you receive an OutOfMemory exception and the source application file does not install, your system might not have enough memory or your application might have too many modules in it to install successfully onto the server. If lack of system memory is not the cause of the exception, package your application again so the .ear file has fewer modules. If lack of system memory and the number of modules are not the cause of the exception, check the options you specified on the Java Virtual Machine page of the application server running the administrative console. Then, try installing the application file again.
24. Associate any shared libraries that the application needs to the application. (See "Managing shared libraries" in the Information Center.)
25. Click **Save** on the administrative console taskbar to save the changes to your configuration. The application is registered with the administrative configuration and application files are copied to the target directory, which is *install\_root/installedApps/cell\_name* by default or the directory that you designate. For the single-server (base) installation, application files are copied to the destination directory when you click **Save**; for the Network Deployment installation, files are copied to remote nodes when the configuration on the deployment manager synchronizes with the configuration on individual nodes.
26. Start the application.
27. Test the application. For example, point a Web browser at the URL for the deployed application and examine the performance of the application. If necessary, update the application.

## Preparing for application installation settings

Use this page to install an application (EAR file) or module (JAR or WAR file).

To view this administrative console page, click **Applications > Install New Application**.

Follow the steps on this page to install an application or module. You must complete, at minimum, the first step; you must complete some or all of the later steps, depending on whether you are installing an application, EJB module, or Web module.

### Path

Specifies the fully qualified path to the .ear, .jar, or .war file for the enterprise application.

Use **Local path** if the browser and application files are on the same machine (whether or not the server is on that machine, too).

Use **Server path** if the application file resides on any node in the current cell context. You can browse the entire file system of a node if the node agent or deployment manager is running on that selected node. Only .ear, .jar, or .war files are shown during the browsing.

During application installation, application files are typically uploaded from a client machine running the browser to the server machine running the administrative console, where they are deployed. In such cases, the Web browser running the administrative console is used to select EAR, WAR, or JAR modules to upload to the server machine.

In some cases, however, the application files reside on the file system of any of the nodes in a cell. To have the application server install these files, use the **Server path** option.

You can also use this option to specify an application file already residing on the machine running the application server. For example, the field value on Windows NT might be C:\WebSphere\AppServer\installableApps\test.ear. If you are installing a stand-alone WAR module, then you also must specify the context root.

### Context Root

Specifies the context root of the Web application (WAR).

This field is used only to install a stand-alone WAR file. The context root is combined with the defined servlet mapping (from the WAR file) to compose the full URL that users type to access the servlet. For example, if the context root is /gettingstarted and the servlet mapping is MySession, then the URL is http://host:port/gettingstarted/MySession.

### Generate Default Bindings

Specifies whether to generate default bindings. If you place a check mark in the check box, then any incomplete bindings in the application are filled in with default values. Existing bindings are not altered.

By choosing this option, you can directly jump to the Summary step and install the application if none of the steps have a red asterisk (\*) next to them. A red asterisk denotes that the step has incomplete data and requires a valid value. On the Summary panel, verify the cell, node and server on which the application is installed.

Bindings are generated as follows:

- EJB JNDI names are generated of the form *prefix/ejb-name*. The default prefix is *ejb*, but can be overridden. The *ejb-name* is as specified in the deployment descriptors `<ejb-name>` tag.
- EJB references are bound as follows: If an `<ejb-link>` is found, it is honored. Otherwise, if a unique enterprise bean is found with a matching home (or local home) interface as the referenced bean, the reference is resolved automatically.
- Resource reference bindings are derived from the `<res-ref-name>` tag. Note that this action assumes that the `java:comp/env` name is the same as the resource global JNDI name.
- Connection factory bindings (for EJB 2.0 JAR files) are generated based on the JNDI name and authorization information provided. This action results in default connection factory settings for each EJB 2.0 JAR file in the application being installed. No bean-level connection factory bindings are generated.
- Data source bindings (for EJB 1.1 JAR files) are generated based on the JNDI name, data source user name password options. This results in default data source settings for each EJB JAR file. No bean-level data source bindings are generated.
- Message-driven bean (MDB) listener ports are derived from the MDB `<ejb-name>` tag with the string `Port` appended.
- For .war files, the virtual host is set as `default_host` unless otherwise specified.

The default strategy suffices for most applications or at least for most bindings in most applications. However, it does not work if:

- You want to explicitly control the global JNDI names of one or more EJB files.
- You need tighter control of data source bindings for CMPs. That is, you have multiple data sources and need more than one global data source.
- You must map resource references to global resource JNDI names that are different from the `java:comp/env` name.

In such cases, you can alter the behavior with an XML document (a custom strategy). Use the **Specific bindings file** field to specify a custom strategy and see the field's help for examples.

## Prefixes

Specifies prefixes to use for generated JNDI names.

## Override

Specifies whether to override existing bindings.

If this check box is checked, the existing bindings are overridden by the generated ones.

## EJB 1.1 CMP bindings

Specifies the default data source JNDI name.

If the **Default Bindings for EJB 1.1 CMPs** radio button is selected, specify the JNDI name for the default data source to be used with the CMP 1.1 beans. Also specify the user ID and password for this default data source.

## Connection Factory Bindings

Specifies the default data source JNDI name.

If the **Default connection factory bindings** radio button is selected, specify the JNDI name for the default data source to be used with the bindings. Also specify the resource authorization.

## Virtual Host

Specifies the virtual host for WAR modules.

## Specific bindings file

Specifies a bindings file that overrides the default binding.

Alter the behavior of the default binding with an XML document (*aka* custom strategy). Custom strategies extend the default strategy so you only need to customize those areas where the default strategy is insufficient. That is, you only need to describe how you want to change the bindings generated by the default strategy; you do not have to define bindings for the entire application.

Brief examples of how to override various aspects of the default bindings generator follow:

### Controlling an EJB JNDI name

```
<?xml version="1.0"?>
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
 <module-bindings>
 <ejb-jar-binding>
 <jar-name>helloEjb.jar</jar-name>
<!-- this name must match the module name in the .ear file -->
 <ejb-bindings>
 <ejb-binding>
 <ejb-name>HelloEjb</ejb-name>
<!-- this must match the <ejb-name> entry in the EJB jar DD -->
 <jndi-name>com/acme/ejb/HelloHome</jndi-name>
```

```

 </ejb-binding>
 </ejb-bindings>
</ejb-jar-binding>
</module-bindings>
</dfldbndngs>

```

### Setting the connection factory binding for an EJB JAR file

```

<!DOCTYPE dfldbndngs SYSTEM "dfldbndngs.dtd">
<dfldbndngs>
 <module-bindings>
 <ejb-jar-binding>
 <jar-name>yourEjb20.jar</jar-name>
 <connection-factory>
 <jndi-name>eis/jdbc/YourData_CMP</jndi-name>
 <res-auth>Container</res-auth>
 </connection-factory>
 </ejb-jar-binding>
 </module-bindings>
</dfldbndngs>

```

### Setting the connection factory binding for an EJB file

```

<?xml version="1.0">
<!DOCTYPE dfldbndngs SYSTEM "dfldbndngs.dtd">
<dfldbndngs>
 <module-bindings>
 <ejb-jar-binding>
 <jar-name>yourEjb20.jar</jar-name>
 <ejb-bindings>
 <ejb-binding>
 <ejb-name>YourCmp20</ejb-name>
<!-- this matches the ejb-name tag in the DD -->
 <connection-factory>
 <jndi-name>eis/jdbc/YourData_CMP</jndi-name>
 <res-auth>PerConnFact</res-auth>
 </connection-factory>
 </ejb-binding>
 </ejb-bindings>
 </ejb-jar-binding>
 </module-bindings>
</dfldbndngs>

```

### Overriding a Resource Ref Binding from a WAR, EJB JAR file, or J2EE client JAR file

Example code for overriding a Resource Ref Binding from a WAR file follows. Use similar code to override a Resource Ref Binding from an enterprise bean (EJB) JAR file or a J2EE client JAR file.

```

<?xml version="1.0"?>
<!DOCTYPE dfldbndngs SYSTEM "dfldbndngs.dtd">
<dfldbndngs>
 <module-bindings>
 <war-binding>
 <jar-name>hello.war</jar-name>
 <resource-ref-bindings>
 <resource-ref-binding>
 <!-- the following must match the resource-ref in the DD -->
 <resource-ref-name>jdbc/MyDataSrc</resource-ref-name>
 <jndi-name>war/override/dataSource</jndi-name>
 </resource-ref-binding>
 </resource-ref-bindings>
 </war-binding>
 </module-bindings>
</dfldbndngs>

```

### Overriding MDB JMS listener ports

```

<?xml version="1.0"?>
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
 <module-bindings>
 <ejb-jar-binding>
 <jar-name>YourEjbJar.jar</jar-name>
 <ejb-bindings>
 <ejb-binding>
 <ejb-name>YourMDB</ejb-name>
 <listener-port>yourMdbListPort</listener-port>
 </ejb-binding>
 </ejb-bindings>
 </ejb-jar-binding>
 </module-bindings>
</dfltbndngs>

```

## Example: Installing an EAR file using the default bindings

An example of a simple .ear file installation using the default bindings follows:

1. Go to the Preparing for application install pages. Click **Applications > Install an Application** in the console navigation tree.
2. For **Path**, specify the full path name of the .ear file. For this example, the base file name is my\_appl.ear and the file resides on a server at C:\sample\_apps.
  - a. Select the **Server path** radio button and click **Browse**.
  - b. On the Browse Remote Filesystems page, click on the name of the node that holds the my\_appl.ear file, **C:\, sample\_apps, my\_appl.ear**, and then **OK**.
3. Now that a value is given for **Path**, on the first Preparing for application install page, click **Next**.
4. On the second Preparing for application install page, place a checkmark beside the **Generate Default Bindings** check box and click **Next**. Using the default bindings causes any incomplete bindings in the application to be filled in with default values. Existing bindings are not changed. By choosing this option, you can directly jump to the Summary step.
5. On the Install New Application page, click on **Summary**, the last step.
6. On the Summary panel, verify the cell, node, and server onto which the application files will install.
  - a. Beside the **Cell/Node/Server** option, click **Click here**.
  - b. On the **Map modules to application servers** panel, select the server onto which the application files will install from the **Clusters and Servers** list, place a checkmark in the check box beside **Module** to select all of the application modules, and click **Next**.

Because my\_appl.ear does not require any additional settings to complete an installation, the Summary panel displays again.
7. On the Summary panel, click **Finish**.

---

## Enterprise application collection

Use this page to view and manage enterprise applications.

To view this administrative console page, click **Applications > Enterprise Applications**.

### Name

Specifies the name of the installed (or deployed) application. Application names must be unique within a cell and cannot contain characters that are not allowed in object names.

### Status

Indicates whether the application deployed on the application server is started, stopped, or unavailable.

## Enterprise application settings

Use this page to configure an enterprise application.

To view this administrative console page, click **Applications > Enterprise Applications** > *application\_name*.

### Name

Specifies a logical name for the application. Application names must be unique within a cell and cannot contain characters that are not allowed in object names.

**Data type** String

### Starting Weight

Specifies the order in which applications are started when the server starts. The application with the lowest starting weight is started first.

**Data type** Integer  
**Default** 1  
**Range** 0 to 100

### Application Binaries

Specifies the directory to which the application EAR file will be installed. The default value is the value of `APP_INSTALL_ROOT/cell_name`, where the `APP_INSTALL_ROOT` variable is `install_root/installedApps`; for example, `C:\WebSphere\AppServer\installedApps\cell_name`.

You can specify an absolute path or use a pathmap variable such as `#{MY_APPS}`. You can use a pathmap variable in any installation though it is particularly needed when installing an application on a cluster with members on heterogeneous nodes because, in such cases, there might not be a single way to specify an absolute path. A WebSphere Application Server variable `#{CELL}` that denotes the current cell name can also be in the pathmap variable; for example, `#{MY_APP}/#{CELL}`.

You can define WebSphere Application Server variables on the WebSphere Variables page of the administrative console, accessed by clicking **Environment > Manage WebSphere Variables**.

**Data type** String  
**Units** Full path name

### Use Metadata From Binaries

Specifies whether the application server uses the binding, extensions, and deployment descriptors located with the application deployment document, the `deployment.xml` file (default), or those located in the enterprise application resource (EAR) file.

**Data type** Boolean  
**Default** false

### Enable Distribution

Specifies whether WebSphere Application Server expands or deletes application binaries in the installation destination. The default is to enable application distribution. Application binaries for installed applications are expanded to the directory specified. The binaries are also deleted when you uninstall and save changes to the configuration. If you disable this option, then you must ensure that the application binaries are expanded appropriately in the destination directories of all nodes where the application runs.

**Data type** Boolean  
**Default** true

## Classloader Mode

Specifies whether the class loader searches in the parent class loader or in the application class loader first to load a class. The standard for JDK class loaders and WebSphere Application Server class loaders is PARENT\_FIRST. By specifying PARENT\_LAST, your application can override classes contained in the parent class loader, but this action can potentially result in ClassCastException or LinkageErrors if you have mixed use of overridden classes and non-overridden classes.

The options are PARENT\_FIRST and PARENT\_LAST. The default is to search in the parent class loader before searching in the application class loader to load a class.

<b>Data type</b>	String
<b>Default</b>	PARENT_FIRST

## WAR Classloader Policy

Specifies whether to use a single class loader to load all WAR files of this application or to use a different class loader for each WAR file.

The options are APPLICATION and MODULE. The default is to use a separate class loader to load each WAR file.

<b>Data type</b>	String
<b>Default</b>	MODULE

## Create MBeans for Resources

Specifies whether to create MBean files for various resources (such as servlets or JSP files) within an application.

<b>Data type</b>	Boolean
<b>Default</b>	true

## Reload Enabled

Specifies whether to enable class reloading when application files are updated.

For EJB modules or any non-Web modules, setting **Reload Enabled** to true sets reloadEnabled to true in the deployment.xml file for the application. If an application's class definition changes, the application server run time stops and starts the application to reload application classes.

For Web modules such as servlets and JavaServer page (JSP) files, a Web container reloads a Web module only when the IBM extension reloadingEnabled in the ibm-web-ext.xmi file is set to true. You can set reloadingEnabled to true when editing your Web module's extended deployment descriptors in an assembly tool.

To enable reloading of a Web module, where you also want reloading of EJB and non-Web modules enabled:

1. Set the IBM extension reloadingEnabled in the ibm-web-ext.xmi file to true.
2. Set this **Reload Enabled** property to true.
3. Set the **Reload Interval** property to a value greater than zero (for example, 1 to 2147483647).

To enable reloading of a Web module only, and not enable reloading of EJB or non-Web modules:

1. Set the IBM extension reloadingEnabled in the ibm-web-ext.xmi file to true.
2. Set the IBM extension reload interval attribute in the ibm-web-ext.xmi file to a value greater than zero (for example, 1 to 2147483647).
3. Set this **Reload Enabled** property to false.

To disable reloading of a Web module, set the IBM extension reloadingEnabled in the `ibm-web-ext.xml` file to `false`. Or, if the Web module has the IBM extension reloadingEnabled in the `ibm-web-ext.xml` file set to `true`, to disable reloading using the administrative console:

1. Set this **Reload Enabled** property to `true`.
2. Set the **Reload Interval** property to zero (0).

<b>Data type</b>	Boolean
<b>Default</b>	false

## Reload Interval

Specifies the number of seconds to scan the application's file system for updated files. The default is the value of the reload interval attribute in the IBM extension (`META-INF/ibm-application-ext.xml`) file of the EAR file.

To enable reloading, specify a value greater than zero (for example, 1 to 2147483647). To disable reloading, specify zero (0).

The reload interval specified here overrides the value specified in the IBM extensions for each non-Web module in the EAR file (which in turn overrides the reload interval specified in the IBM extensions for the application in the EAR file). The reload interval attribute takes effect only if class reloading is enabled.

The range is from 0 to 2147483647.

<b>Data type</b>	Integer
<b>Units</b>	Seconds

## Target mapping collection

Use this page to manage mappings of deployed applications or modules to servers or clusters.

To view this administrative console page, click **Applications > Enterprise Applications > *application\_name* > Target Mappings**.

### **Target:**

States the name of the target server or cluster to which the application or module maps. You specify the target on the Map modules to application servers page accessed from the settings for an application.

### **Node:**

Specifies the node name if the target is a server.

### **Status:**

Indicates whether the status of the application running on the target server or cluster is started, stopped or unavailable.

### **Target mapping settings:**

Use this page to map a deployed application or module to a server or cluster.

To view this administrative console page, click **Applications > Enterprise Applications > *application\_name* > Target Mappings > *target\_name***.

### **Target:**

States the name of the target server or cluster to which the application or module maps. You specify the target on the Map modules to application servers page accessed from the settings for an application.

**Data type** String

*Enabled:*

Indicates whether the application modules installed on the target server are started (or enabled) when the server starts. This sets the initial state of application modules. A true value indicates that the corresponding modules are enabled and thus are accessible when the server starts. A false value indicates that the corresponding modules are not enabled and thus are not accessible when the server starts.

**Data type** Boolean  
**Default** true

---

## Starting and stopping applications

You can start an application that is not running (has a status of *Stopped*) or stop an application that is running (has a status of *Started*).

1. Go to the Enterprise Applications page. Click **Applications > Enterprise Applications** in the console navigation tree.
2. Check the check box for the application you want started or stopped.
3. Click a button:

Option	Description
<b>Start</b>	Runs the application and changes the state of the application from <i>Stopped</i> to <i>Started</i> .
<b>Stop</b>	Stops the processing of the application and changes the state of the application from <i>Started</i> to <i>Stopped</i> .

To restart a running application, place a check mark in the check box for the application you want to restart, click **Stop** and then click **Start**.

The status of the application changes and a message stating that the application started or stopped displays at the top the page.

---

## Exporting applications

You can export an enterprise application to a location of your choice. Exporting applications enables you to back up your applications and preserve binding information for the applications. You might export your applications before updating installed applications or migrating to a later version of the WebSphere Application Server product.

1. Click **Applications > Enterprise Applications** in the administrative console navigation tree to access the Enterprise Applications page.
2. Place a check mark in the check box beside the application and click **Export**.
3. On the Export Application EAR Files page, click on the link to download the exported EAR file.
4. Use the browser dialogue to specify a location at which to save the exported EAR file and click **OK**.

The file containing binding information is exported to the specified node and directory, and has the name *enterprise\_application\_name.ear*.

---

## Exporting DDL files

You can export the DDL files (Table.ddl) in the EJB modules of the application to a location of your choice.

1. Click **Applications > Enterprise Applications** in the administrative console navigation tree to access the Enterprise Applications page.
2. Place a checkmark in the check box beside the application and click **Export DDL**. If the application has no DDL files in any of its EJB modules, then the message *No DDL files were found* displays at the top of the page. If the application has DDL files in its EJB modules, then a page displays listing DDL files in the format `appName.ear/_module.jar_Table.ddl`.
3. Click on a file in the list to download the file to your machine.

---

## Updating applications

You can update an application deployed on a server. The steps below describe how to update a deployed application using the administrative console.

**Note:** You can also update applications using the wsadmin tool, which provides updating capabilities identical to those available using the administrative console. Further, in some situations, you can update applications without needing to restart the application server.

1. Update the contents of the application and reassemble it, using the Assembly Toolkit. Typical tasks include adding or editing assembly properties, adding or importing modules into an application, and adding enterprise beans, Web components, and files.
2. Go to the Applications page of the administrative console. Click **Applications > Enterprise Applications** in the console navigation tree.
3. Back up the application. Place a checkmark in the check box beside the application you want uninstalled and click **Export** to export the application to an EAR file and preserve the binding information.
4. With a checkmark beside the application, click **Update**. The binding information of the updated (new) version of the application merges with the binding information from the installed (old) version. Then, the older version uninstalls from the configuration and the new version installs.
5. Complete the steps in the Preparing for application update page and the pages that follow it. See information on installing applications and on the settings page for application installation for guidance. Note that the installation steps have the merged binding information from the new version and the old version. If the new version has bindings for application artifacts such as EJB JNDI names, EJB references or resource references, then those bindings will be part of the merged binding information. If new bindings are not present, then bindings are taken from the installed (old) version. If bindings are not present in the old version and if the default binding generation option is enabled, then the default bindings will be part of the merged binding information. You can select whether to ignore bindings in the old version or ones in the new version.
6. Map the installed application or module to servers or clusters. Use the Map modules to application servers page of the Install New Application pages displayed during updating the application. Or, after updating the application, use the Map modules to application servers page accessed from the Enterprise Applications page.
  - a. Go to the Map modules to application servers page. Click **Applications > Enterprise Applications** in the console navigation tree, click the application name, and then click **Map modules to application servers**.
  - b. Specify the application server where you want to install modules contained in your application and click **OK**.
7. Click **Save** on the administrative console taskbar to save the changes to your configuration. In the single server (base) product, after you click **Save** the old version of the application is uninstalled and the new version is installed into the configuration. The application binaries for the old version are deleted from the destination directory and the new binaries are copied to the directory. In the Network

Deployment product, the old application files are deleted and new files are copied when the configuration on the deployment manager synchronizes with the configuration on the node where the application is installed. If the application is running when you update it, the application stops running before its files are copied to the destination directory of the node and restarts after the copy operation completes. Thus, the application is unavailable on the node during the time the node is synchronizing its configuration with the deployment manager.

8. Examine the values specified for **Reload Enabled** and **Reload Interval** on the settings page for your enterprise application. If reloading of application files is enabled and the reload interval is greater than zero (0), the application's files are reloaded after the application is updated. For Web modules such as servlets and JavaServer page (JSP) files, a Web container reloads a Web module only when the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file is also set to `true`. You can set reloadingEnabled to `true` when editing your Web module's extended deployment descriptors in an assembly tool.
9. Restart the application so the changes take effect. If the application is updated while it is running, WebSphere Application Server stops the application, updates the application logic and restarts the application.
  - a. Click **Applications > Enterprise Applications** in the console navigation tree to go to the Enterprise Applications page.
  - b. Check the check box for the updated application.
  - c. Click **Start**.
10. Optional: If the application you are updating is deployed on a server that has its application class loader policy set to SINGLE on the Application Server settings page of the administrative console, restart the server.

## Hot deployment and dynamic reloading

You can make various changes to applications and their contents without having to stop the server and start it again. Making these types of changes is known as *hot deployment and dynamic reloading*.

Hot deployment is the process of adding new components (such as WAR files, EJB Jar files, enterprise Java beans, servlets, and JSP files) to a running server without having to stop the application server process and start it again.

Dynamic reloading is the ability to change an existing component without needing to restart the server in order for the change to take effect. Dynamic reloading involves:

- Changes to the implementation of a component of an application, such as changing the implementation of a servlet
- Changes to the settings of the application, such as changing the deployment descriptor for a Web module

If the application you are updating is deployed on a server that has its application class loader policy set to SINGLE on the application server settings page of the administrative console, you might not be able to dynamically reload your application. At minimum, you must restart the server after updating your application.

1. Locate your expanded application files. The application files are in the directory you specified when installing the application or, if you did not specify a custom target directory, are in the default target directory, `install_root/installedApps/cell_name`. Your EAR file, `${APP_INSTALL_ROOT}/cell_name/application_name.ear`, points to the target directory. The `variables.xml` file for the node defines `${APP_INSTALL_ROOT}`.

It is important to locate the expanded application files because, as part of installing applications, a WebSphere application server unjars portions of the EAR file onto the file system of the computer that will run the application. These expanded files are what the server looks at when running your application.

If you cannot locate the expanded application files, look at the `binariesURL` attribute in the `deployment.xml` file for your application. The attribute designates the location the run time uses to find the application files.

For the remainder of this information on hot deployment and dynamic reloading, `application_root` represents the root directory of the expanded application files.

2. Locate application metadata files. The metadata files include the deployment descriptors (`web.xml`, `application.xml`, `ejb-jar.xml`, and the like), the bindings files (`ibm-web-bnd.xmi`, `ibm-app-bnd.xmi`, and the like), and the extensions files (`ibm-web-ext.xmi`, `ibm-app-ext.xmi`, and the like).

Metadata XML files for an application can be loaded from one of two locations. The metadata files can be loaded from the same location as the application binary files (such as `application_root/META-INF`) or they can be loaded from the WebSphere configuration tree,

`${CONFIG_ROOT}/cells/cell_name/applications`

`/application_EAR_name/deployments/application_name/`. The value of the `useMetadataFromBinary` flag specified during application installation controls which location is used. If specified, the metadata files are loaded from the same location as the application binary files. If not specified, the metadata files are loaded from the application deployment folder in the configuration tree.

For the remainder of this information, `metadata_root` represents the location of the metadata files for the specified application or module.

3. CAUTION: If you are running WebSphere Application Server on a group of machines using Network Deployment and you are changing an application on a particular node, disable automatic synchronization.
  - a. Click **System Administration > Node Agents** in the administrative console navigation tree, click on a node agent name, and then click **File Synchronization Service**.
  - b. On the File Synchronization Service page, remove the checkmark from the check box for **Automatic Synchronization** and click **OK**.

When you run WebSphere Application Server on a group of machines using Network Deployment and you change a file on the disk in the expanded application directory for a particular node, you can lose those changes the next time node synchronization occurs. In the Network Deployment environment, the configuration stored by the deployment manager is the master copy and any changes detected between that master copy and the copy on a particular machine trigger the master copy to be downloaded to the node.

4. Optional: Examine the values specified for **Reload Enabled** and **Reload Interval** on the settings page for your enterprise application. If reloading of application files is enabled and the reload interval is greater than zero (0), the application's files are reloaded after the application is updated. For Web modules such as servlets and JavaServer page (JSP) files, a Web container reloads a Web module only when the IBM extension `reloadingEnabled` in the `ibm-web-ext.xmi` file is also set to `true`. You can set `reloadingEnabled` to `true` when editing your Web module's extended deployment descriptors in an assembly tool.
5. Change or add the following components or modules as needed:
  - Application files
  - WAR files
  - EJB Jar files
  - HTTP plug-in configuration files
6. For changes to take effect, you might need to start, stop, or restart an application. "Starting and stopping applications" on page 1421 provides information on using the administrative console to start, stop, or restart an application. "Example: Starting an application using wsadmin" and "Example: Stopping running applications on a server using wsadmin" in the Information Center provide information on using the wsadmin scripting tool.
7. If you disabled automatic synchronization in step 3, return to the File Synchronization Service page, enable **Automatic Synchronization**, and click **OK**.

## Changing or adding application files

You can change or add application files on application servers without having to stop the server and start it again. This file describes--

- Updating an existing application on a running server (providing a new EAR file)
- Adding a new application to a running server
- Removing an existing application from a running server
- Changing or adding files to existing EJB or Web modules
- Changing the `application.xml` file for an application
- Changing the `ibm-app-ext.xmi` file for an application
- Changing the `ibm-app-bnd.xmi` file for an application
- Changing a non-module Jar file contained in the EAR file

### Updating an existing application on a running server (providing a new EAR file)

Reinstall an updated application using the administrative console or the `wsadmin $AdminApp install` command with the `-update` option.

Both reinstallation methods enable you to update an existing application using any of the other steps listed in this file, including changing classes, adding modules, removing modules, changing modules, or changing metadata files. The application reinstallation methods detect the changes in your application and prompt you for additional binding data that might be needed to install the application. The reinstallation process automatically stops and restarts your application on the appropriate servers.

<b>Hot deployment</b>	Yes
<b>Dynamic reloading</b>	Yes

### Adding a new application to a running server

Install an application using the administrative console or the `wsadmin install` command.

<b>Hot deployment</b>	Yes
<b>Dynamic reloading</b>	No

### Removing an existing application from a running server

Stop the application and then uninstall it from the server. Use the administrative console to stop the application and then uninstall it. Or run the `wasadmin stopApplication` command and then the `uninstall` command.

<b>Hot deployment</b>	Yes
<b>Dynamic reloading</b>	No

### Changing or adding files to existing EJB or Web modules

1. Update the application files in the `application_root` location.
2. Restart the application. Use the administrative console to restart the application. Or run the `wasadmin stopApplication` and `startApplication` commands.

<b>Hot deployment</b>	Yes
<b>Dynamic reloading</b>	No

### Changing the `application.xml` file for an application

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the wasadmin stopApplication and startApplication commands.

<b>Hot deployment</b>	Not applicable
<b>Dynamic reloading</b>	Yes

### Changing the ibm-app-ext.xmi file for an application

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the wasadmin stopApplication and startApplication commands.

<b>Hot deployment</b>	Not applicable
<b>Dynamic reloading</b>	Yes

### Changing the ibm-app-bnd.xmi file for an application

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the wasadmin stopApplication and startApplication commands.

<b>Hot deployment</b>	Not applicable
<b>Dynamic reloading</b>	Yes

### Changing a non-module Jar file contained in the EAR file

1. Update the non-module Jar file in the *application\_root* location.
2. If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the wasadmin stopApplication and startApplication commands.  
If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

<b>Hot deployment</b>	Yes
<b>Dynamic reloading</b>	Yes

### Changing or adding WAR files

You can change WAR files on application servers without having to stop the server and start it again. This file describes--

- Changing an existing JSP file
- Adding a new JSP file to an existing application
- Changing an existing servlet class (editing and recompiling)
- Changing a dependent class of an existing servlet class
- Adding a new servlet using the Invoker (Serve Servlets by class name) facility or adding a dependent class to an existing application
- Adding a new servlet, including a new definition of the servlet in the web.xml deployment descriptor for the application
- Changing the web.xml file of a WAR file
- Changing the ibm-web-ext.xmi file of a WAR file
- Changing the ibm-web-bnd.xmi file of a WAR file

### Changing an existing JSP file

Place the changed JSP file directly in the *application\_root/module\_name* directory or the appropriate subdirectory. The change will be automatically detected and the JSP will be recompiled and reloaded.

<b>Hot deployment</b>	Not applicable
-----------------------	----------------

**Dynamic reloading** Yes

### Adding a new JSP file to an existing application

Place the new JSP file directly in the *application\_root/module\_name* directory or the appropriate subdirectory. The new file will be automatically detected and compiled on the first request to the page.

**Hot deployment** Yes

**Dynamic reloading** Yes

### Changing an existing servlet class (editing and recompiling)

1. Place the new version of the servlet `.class` file directly in the *application\_root/module\_name/WEB-INF/classes* directory. If the `.class` file is part of a Jar file, you can place the new version of the Jar file directly in *application\_root/module\_name/WEB-INF/lib*. In either case, the change will be detected, the Web application will be shut down and reinitialized, picking up the new class.
2. If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the `wasadmin stopApplication` and `startApplication` commands.

If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

**Hot deployment** Not applicable

**Dynamic reloading** Yes

### Changing a dependent class of an existing servlet class

1. Place the new version of the dependent `.class` file directly in the *application\_root/module\_name/WEB-INF/classes* directory. If the `.class` file is part of a Jar file, you can place the new version of the Jar file directly in *application\_root/module\_name/WEB-INF/lib*. In either case, the change will be detected, the Web application will be shut down and reinitialized, picking up the new class.
2. If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the `wasadmin stopApplication` and `startApplication` commands.

If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

**Hot deployment** Not applicable

**Dynamic reloading** Yes

### Adding a new servlet using the Invoker (Serve Servlets by class name) facility or adding a dependent class to an existing application

1. Place the new `.class` file directly in the *application\_root/module\_name/WEB-INF/classes* directory. If the `.class` file is part of a Jar file, you can place the new version of the Jar file directly in *application\_root/module\_name/WEB-INF/lib*. In either case, the change will be detected, the Web application will be shut down and reinitialized, picking up the new class.

This case is treated the same as changing an existing class. The difference is that adding the servlet or class does not immediately cause the Web application to reload because the class has never been loaded before. The class simply becomes available for execution.

2. If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the `wasadmin stopApplication` and `startApplication` commands.

If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

**Hot deployment** Yes

**Dynamic reloading** Not applicable

### **Adding a new servlet, including a new definition of the servlet in the web.xml deployment descriptor for the application**

1. Place the new .class file directly in the *application\_root/module\_name/WEB-INF/classes* directory. If the “.class” file is part of a Jar file, you can place the new version of the Jar file directly in *application\_root/module\_name/WEB-INF/lib*.

You can edit the web.xml file in place or copy it into the *application\_root/module\_name/WEB-INF/classes* directory. The new .class file will not trigger a reloading of the application.

2. Restart the application. Use the administrative console to restart the application. Or run the wasadmin stopApplication and startApplication commands. After the application restarts, the new servlet is available for service.

<b>Hot deployment</b>	Yes
<b>Dynamic reloading</b>	Not applicable

### **Changing the web.xml file of a WAR file**

1. Edit the web.xml file in place or copy it into the *metadata\_root/module\_name/WEB-INF* directory.
2. Restart the application. Use the administrative console to restart the application. Or run the wasadmin stopApplication and startApplication commands.

<b>Hot deployment</b>	Yes
<b>Dynamic reloading</b>	Yes

### **Changing the ibm-web-ext.xmi file of a WAR file**

Edit the extension settings as needed. You can change all of the extension settings. The only warning is if you set the reloadInterval property to zero (0) or the reloadEnabled property to false, the application will no longer automatically detect changes to class files. Both of these changes disable the automatic reloading function. The only way to re-enable automatic reloading is to change the appropriate property and restart the application. See other task descriptions in this file for information on restarting an application.

<b>Hot deployment</b>	Not applicable
<b>Dynamic reloading</b>	Yes

### **Changing the ibm-web-bnd.xmi file of a WAR file**

1. Edit the bindings as needed. You can change all of the values but ensure that the entities you are binding to are present in the configuration of the server.
2. Restart the application. Use the administrative console to restart the application. Or run the wasadmin stopApplication and startApplication commands.

<b>Hot deployment</b>	Not applicable
<b>Dynamic reloading</b>	Yes

### **Changing or adding EJB Jar files**

You can change EJB Jar files on application servers without having to stop the server and start it again. This file describes--

- Changing the ejb-jar.xml file of an EJB Jar file
- Changing the ibm-ejb-jar-ext.xmi or ibm-ejb-jar-bnd.xmi file of an EJB Jar file
- Changing the Table.ddl file for an EJB Jar file
- Changing the Map.mapxmi or Schema.dbxmi file for an EJB Jar file
- Updating the implementation class for an EJB file or a dependent class of the implementation class for an EJB file
- Updating the Home/Remote interface class for an EJB file
- Adding a new EJB file to an existing EJB Jar file

### Changing the `ejb-jar.xml` file of an EJB Jar file

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the `wasadmin stopApplication` and `startApplication` commands.

<b>Hot deployment</b>	Not applicable
<b>Dynamic reloading</b>	Yes

### Change the `ibm-ejb-jar-ext.xml` or `ibm-ejb-jar-bnd.xml` file of an EJB Jar file

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the `wasadmin stopApplication` and `startApplication` commands.

<b>Hot deployment</b>	Not applicable
<b>Dynamic reloading</b>	Yes

### Changing the `Table.ddl` file for an EJB Jar file

Rerun the DDL file on the user database server. Changing the `Table.ddl` file has no effect on the application server and is a change to the database table schema for the EJB files.

<b>Hot deployment</b>	Not applicable
<b>Dynamic reloading</b>	Not applicable

### Changing the `Map.mapxml` or `Schema.dbxml` file for an EJB Jar file

1. Change the `Map.mapxml` or `Schema.dbxml` file for an EJB Jar file.
2. Regenerate the deployed code artifacts for the EJB file.
3. Apply the new EJB Jar file to the server.
4. Restart the application. Use the administrative console to restart the application. Or run the `wasadmin stopApplication` and `startApplication` commands.

<b>Hot deployment</b>	Not applicable
<b>Dynamic reloading</b>	Yes

### Updating the implementation class for an EJB file or a dependent class of the implementation class for an EJB file

1. Update the class file in the `application_root/module_name.jar` file.
2. If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

If automatic reloading is not enabled, restart the application of which the EJB file is a member. If the updated module is used by other modules in other applications, restart those applications as well. Use the administrative console to restart the application. Or run the `wasadmin stopApplication` and `startApplication` commands.

<b>Hot deployment</b>	Not applicable
<b>Dynamic reloading</b>	Yes

### Updating the Home/Remote interface class for an EJB file

1. Update the interface class of the EJB file.
2. Regenerate the deployed code artifacts for the EJB file.
3. Apply the new EJB Jar file to the server.
4. If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

If automatic reloading is not enabled, restart the application of which the EJB file is a member. Use the administrative console to restart the application. Or run the wasadmin stopApplication and startApplication commands.

<b>Hot deployment</b>	Not applicable
<b>Dynamic reloading</b>	Yes

### Adding a new EJB file to an existing EJB Jar file

1. Apply the new or updated Jar file to the *application\_root* location.
2. If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the wasadmin stopApplication and startApplication commands.

<b>Hot deployment</b>	Yes
<b>Dynamic reloading</b>	Yes

## Changing the HTTP plug-in configuration

You can change the HTTP plug-in configuration without having to stop the server and start it again. This file describes--

- Changing the application.xml file to change the context root of a WAR file
- Changing the web.xml file to add, remove, or modify a servlet mapping
- Changing the server.xml file to add, remove, or modify an HTTP transport or changing the virtualhost.xml file to add or remove a virtual host or to add, remove, or modify a virtual host alias

### Changing the application.xml file to change the context root of a WAR file

1. Change the application.xml file.
2. Regenerate the plug-in configuration file using the administrative console or by running the GenPluginCfg.bat/sh script.

<b>Hot deployment</b>	Yes
<b>Dynamic reloading</b>	No

### Changing the web.xml file to add, remove, or modify a servlet mapping

1. Change the web.xml file.
2. Regenerate the plug-in configuration file using the administrative console or by running the GenPluginCfg.bat/sh script.

If the Web application has file serving enabled or has a servlet mapping of /, you do not have to regenerate the plug-in configuration. In all other cases the regeneration is required.

<b>Hot deployment</b>	Yes
<b>Dynamic reloading</b>	Yes

### Changing the server.xml file to add, remove, or modify an HTTP transport or changing the virtualhost.xml file to add or remove a virtual host or to add, remove, or modify a virtual host alias

1. Change the server.xml file to add, remove, or modify an HTTP transport or change the virtualhost.xml file to add or remove a virtual host or to add, remove, or modify a virtual host alias.
2. Regenerate the plug-in configuration file using the administrative console, by running the GenPluginCfg.bat/sh script, or by running a wsadmin command.

<b>Hot deployment</b>	Yes
<b>Dynamic reloading</b>	Yes

---

## Uninstalling applications

After an application no longer is needed, you can uninstall it. Uninstalling an application deletes the application from the WebSphere Application Server configuration repository and it deletes the application binaries from the file system of all nodes where the application modules are installed.

1. Click **Applications > Enterprise Applications** in the administrative console navigation tree to access the Enterprise Applications page.
2. Stop the application. Select the application you want uninstalled and click **Stop**.
3. Back up the application. Select the application you want uninstalled and click **Export** to export the application to an EAR file and preserve the binding information.
4. Select the application you want uninstalled and click **Uninstall**.
5. Click **Save** on the console taskbar to save changes made to the administrative configuration.

In the single-server (base) product, application binaries are deleted after you click **Save**. In the Network Deployment product, application binaries are deleted when configuration changes on the deployment manager synchronize with configurations for individual nodes.

## Deploying and managing applications: Resources for learning

Use the following links to find relevant supplemental information about deploying and managing applications using the administrative console. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.
