Contents

Administration

The Administration topic provides the key information for DB2 UDB^(TM) for iSeries^(TM). Follow these links to find a specific topic in one of the DB2^(R) Universal Database^(TM) for iSeries Information Center resources.

You can also explore other database information using the main navigation bar or the **Database finder**.

Print this topic
View and print this topic in PDF format.

Commitment control
Learn how to use commitment control to ensure data integrity. Commitment control allows you to define and process a group of changes to resources, such as database files or tables, as a transaction.

Database backup and recovery
Backing up your data regularly is an important practice in the event that data recovery is necessary. See this topic for methods of database backup and recovery.

Database administration
See several topics that will help you to manage your database.

Distributed database administration
Learn how to set up and maintain databases distributed across several systems.

Queries and reports
Create and run queries using various methods, including SQL, the OPNQRYF command, the OS/400^(R) Create Query API (QQQQRY), ODBC, and Query for iSeries.

Security
Authorizing users to data at the system and data levels allows you to control access to your database. These links describe various security methods for controlling your database.

Note: Read the "Code example disclaimer" on page 14 for important legal information.

Print this topic

To view or download the PDF version of this document, select Administration (about 217 KB).

Saving PDF files

To save a PDF on your workstation for viewing or printing:
1. Right-click the PDF in your browser (right-click the link above).
2. 》 Click **Save Target As...** if you are using Internet Explorer. Click **Save Link As...** if you are using Netscape Communicator. 《
3. Navigate to the directory in which you would like to save the PDF.
4. Click **Save**.

Downloading Adobe Acrobat Reader

≫ You need Adobe Acrobat Reader to view or print these PDFs. You can download a copy from the Adobe Web site (www.adobe.com/products/acrobat/readstep.html) . ≪

Database administration

Database administration contains the following topics:

"Alter and manage database objects"
The iSeries server provides both SQL and system methods for altering and managing the database objects you create. These links show you how to work with library, table, view, journal, alias, and index objects.

Create database objects
The first step in developing your database is to create the objects that will hold your data. This category covers both SQL and file-based methods for creating tables, views, and indexes (with SQL) as well as physical and logical files (with file-based methods).

Ensure data integrity
iSeries provides several different integrity measures, including constraints, trigger programs, and commitment control.

Import and export data between systems
This topic describes how to load and unload data between systems.

Manage journals
You can use journal management to audit database and other activities on your server, as well as recover changes.

Work with multiple databases
Set up multiple independent user databases on your iSeries. This topic describes how to use independent disk pools to configure multiple databases.

"Work with triggers and constraints" on page 4
Triggers and constraints can be used to manipulate and manage data in your database tables. These links describe different methods for adding and using triggers and constraints.

"Write DB2 programs" on page 5
This topic describes the various ways to write applications to access DB2 UDB for iSeries.

Alter and manage database objects

There are several methods available for working with database objects. You can use the iSeries Navigator interface, SQL methods, or the traditional file interface. The table below shows the available optionsfor each task. Click the appropriate "X" for more information about performing the task.

The iSeries Navigator tasks are documented in the Online help. For more information about accessing iSeries Navigator objects and using Online help, see iSeries Navigator database tasks.

Task	iSeries Navigator	SQL	Traditional file interface
Display table (file) attributes (catalog)	X	X	X
Drop database objects	X	X	X
Change schema (library) list	X		X
Add a column to a table	X	X	X

Task	iSeries Navigator	SQL	Traditional file interface
Add or alter an identity column	X	X	
Change a table (file) definition	X	X	X
Copy a table (file)	X		X
Copy column definitions	X		
Display contents of tables (files) and views	X	X	X
Display locked rows (records)	X		X
Edit table (file) data	X	X	X
Move a table (file)	X		X
Reorganize a table (file)	X		X
Altering a sequence	X	X	

Create database objects

The first step in developing any DB2 Universal Database database is to create the database objects that will hold the actual data. For SQL-based databases, you create tables, views, and indexes; for system file databases, you create physical or logical files.

Once these basic objects exist you can "Alter and manage database objects" on page 2 them, as needed.

You can create objects using iSeries Navigator, SQL, or the traditional file interface. The table below shows the available options for each task. Click the appropriate "X" for more information about performing the task.

The iSeries Navigator tasks are documented in the Online help. For more information about accessing iSeries Navigator objects and using Online help, see iSeries Navigator database tasks.

Task	iSeries Navigator	SQL	Traditional file interface
Create a map of database object relationships	X		
Create a package	X	X	X
Create a schema (library)	X	X	
Create a stored procedure	X	X	
Create a table (file)	X	X	X
Create a user-defined function	X	X	
Create a user-defined type	X	X	
Create a view or logical file	X	X	X
Create an alias	X	X	X
Create an index or access path	X	X	X
Create an object using Run SQL Scripts	X		
Generate SQL for database objects	X		

Task	iSeries Navigator	SQL	Traditional file interface
Create a sequence	X	X	

Ensure data integrity

Protecting your database against inadvertent insertions, deletions, and updates is accomplished using commitment control, constraints, and triggers. Constraints basically govern how data values can change, while triggers are automatic actions that start, or *trigger*, an event, such as an update of a specific table.

Select one of the following topics:
- Ensure data integrity with commitment control
- "Work with triggers and constraints"

Import and export data between systems

Importing data is the process of retrieving data from external sources, while exporting data is the process of extracting data from DB2 Universal Database for iSeries and copying the data to another server.

Importing data into DB2 Universal Database for iSeries can be a one-time event or it can be an ongoing task, like weekly updates for business reporting purposes. These types of data moves are typically accomplished through import, export, or load functions.

Select one of the following topics:
- File management: Copying database files
- Copying a table
- Moving a table
- Copy source file data
- Loading and unloading data from non-iSeries systems

The Query Management Programming manual also contains information about importing and exporting data between servers.

Work with mulitple databases

With iSeries servers, you can work with multiple databases. The iSeries server provides a system database (often referred to as SYSBAS) and the ability to work with one or more user databases. User databases are implemented on the iSeries server through the use of independent disk pools, which are set up in the Disk Management function of iSeries Navigator. Once an independent disk pool is set up, it appears as another database under the Databases function of iSeries Navigator.

When you expand an iSeries server in iSeries Navigator and then expand Databases, a list of databases appears that you can work with. To establish a connection to a database, expand the database that you want to work with.

For more information about working with multiple databases, see the Disk Management topic.

Work with triggers and constraints

A trigger is a type of stored procedure program that is automatically called whenever a specified action is performed on a specific table. Triggers are useful for keeping audit trails, for detecting exceptional conditions, for maintaining relationships in the database, and for running applications and operations that coincide with the change operation.

Constraints are restrictions or limitations that you place on your database. Constraints are implemented at the table level. You can use constraints to create referential integrity in your database.

You can work with triggers and constraints using iSeries Navigator, SQL, or the traditional file interface. The table below shows the available options for each task. Click the appropriate "X" for more information about performing the task.

The iSeries Navigator tasks are also documented in the Online help. For more information about accessing iSeries Navigator objects and using Online help, see iSeries Navigator database tasks.

Task	iSeries Navigator	SQL	Traditional file interface
Write an external trigger program	X		X
Add an external trigger	X		X
Add an SQL trigger	X	X	
Write an SQL trigger program	X	X	
Enable and disable a trigger	X		X
Remove a trigger	X	X	X
Create a key constraint	X	X	X
Remove a key constraint	X	X	X
Create a referential constraint	X	X	X
Enable and disable a referential constraint	X		X
Remove a referential constraint	X	X	X
Create a check constraint	X	X	X
Remove a check constraint	X	X	X
Manage check pending constraints	X		

Write DB2 programs

DB2 Universal Database for iSeries provides many methods for programmatically accessing or updating iSeries data.

Select one of the following topics:
- Write a program that uses embedded SQL
- Write an external function program
- Write an external procedure program
- Write an external trigger
- Write an SQL CLI application
- Write applications that use SQL

Database backup and recovery

Saving your data can be time-consuming and requires discipline. However, it is crucial that you back up your data because you never know when you may need to do a server recovery. Use the topics listed here to properly back up your data and recover it if necessary.

Backup and recovery
Learn how to plan a backup and recovery strategy, back up your server, manage tape libraries, set up disk protection for your data. This topic also includes information about the Backup, Recovery and Media Services plug-in to iSeries(TM) Navigator, information about recovering your server, and answers to some frequently asked questions about backup and recovery.

Recovering and restoring your database
See this article in the Database Programming topic for the tasks necessary to recover data.

Journal management
Use journal management to provide a means by which you can record the activity of objects on your system. This topic provides information how to set up, manage, and troubleshoot system-managed access-path protection (SMAPP), local journals, and remote journals on an iSeries server.

Distributed database administration

Distributed database administration contains the following topics:

Plan and design
Design a distributed relational database that will best meet your needs.

Set up a distributed relational database
Prepare you application requesters and application servers to send and receive work.

Administration and operations tasks
Learn the common tasks that a distributed database administrator performs.

Communications
Configure distributed relational database communications.

Security
Guard your distributed relational database against security problems.

Data availability and protection
Protect and ensure access to your distributed relational database.

Performance
Improve the performance of your distributed relational database.

Handle problems
Resolve problems in your distributed database.

Write applications
Write high-level language programs that use SQL statements for distributed applications.

Queries and reports

One of the most common tasks that you perform with your database is to retrieve information. iSeries servers provide several methods to create and run queries and reports.

You can use an SQL statement to retrieve information. This SQL statement is called a query. The query searches the tables stored in your database to find the answer to the question that you posed with your SQL statement. The answer is expressed as a set of rows, which is referred to as the result set. Once a query has been run, you can also create a report to display the data provided in your result set. For detailed information about creating SQL statements, see the SQL programming topic.

In addition to using SQL, you can use other functions and products to create and run queries and reports. See the following manuals for detailed information.

- Query for iSeries
- Query Management Programming
- iSeries Query Manager

In addition, the iSeries Navigator interface provides SQL Assist, which can be used to create SQL statements. SQL Assist helps you to build SQL Select, Insert, Update, and Delete statements. See Building SQL statements with SQL Assist for more information.

Changes to Query for iSeries

In V5R3, the Query for iSeries manual was not updated, but numerous functional updates were made to the product. These updates are summarized below:

- Support for BINARY, VARBINARY, BLOB, CLOB, DBCLOB, and ROWID data types.
- Support for larger numeric and decimal numbers, plus support for large numeric literals.
- The BINARY, VARBINARY, HEX, and LENGTH built-in functions were added. They are described below.
- The VARCHAR function now supports conversion from CLOB to VARCHAR.
- The VARGRAPHIC function now supports conversion from CLOB to DBCS graphic, CLOB to UCS2 graphic, DBCLOB to DBCS graphic, and DBCLOB to UCS2 graphic.

A binary constant is used for comparing a literal with a binary field (BINARY, VARBINARY, or BLOB). Binary constants are represented with an X followed by a sequence of characters that starts and ends with a string delimiter. The characters between the string delimiters must be an even number of hexadecimal digits. A hexadecimal digit is a digit or any of the letters A through F (uppercase and lowercase), as shown in the following example:

```
Field      Test  Value
binarycol eq    X'12AF'
```

BINARY built-in function for Query (added):

The BINARY function returns a BINARY representation of a string of any type. The form is:

```
>>-BINARY--(--string-expression--+-----------+--)--------------><
                                 '-, integer-'
```

The result of the function is a fixed-length binary string. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

The first argument must be a string-expression whose value must be a built-in character string, graphic string, binary string, or row ID data type.

The second argument specifies the length attribute for the resulting binary string. The value must be between 1 and 32766. If the second argument is not specified, the following rules apply:

- If the string-expression is the empty string constant, the length attribute of the result is 1.
- Otherwise, the length attribute of the result is the same as the length attribute of the first argument, unless the argument is a graphic string. In this case, the length attribute of the result is twice the length attribute of the argument.

The actual length is the same as the length attribute of the result. If the length of the string-expression is less than the length of the result, the result is padded with hexadecimal zeros up to the length of the result. If the length of the string-expression is greater than the length attribute of the result, truncation is performed.

VARBINARY built-in function for Query (added):

The VARBINARY function returns a VARBINARY representation of a string of any type. The form is:

```
>>-VARBINARY--(--string-expression--+----------+--)----------><
                                     '-, integer-'
```

The result of the function is VARBINARY. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

The first argument is a string-expression whose value can be a character string, graphic string, binary string, or row ID.

The second argument specifies the length attribute for the resulting binary string. The value must be between 1 and 32740 (32739 if nullable). If the second argument is not specified, the following rules apply:
- If the string-expression is the empty string constant, the length attribute of the result is 1.
- Otherwise, the length attribute of the result is the same as the length attribute of the first argument, unless the argument is a graphic string. In this case, the length attribute of the result is twice the length attribute of the argument.

  The actual length is the same as the length attribute of the result. If the length of the string-expression is less than the length of the result, the result is padded with hexadecimal zeroes up to the length of the result. If the length of the string-expression is greater than the length attribute of the result, truncation is performed.

HEX built-in function for Query (added):

The HEX function returns a hexadecimal representation of a value. The form is:

```
>>-HEX--(--expression--)--------------------------------------><
```

The argument can be of any built-in data type. The result of the function is a character string. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result is a string of hexadecimal digits. The first two digits represent the first byte of the argument, the next two digits represent the second byte of the argument, and so forth. If the argument is a datetime value, the result is the hexadecimal representation of the internal form of the argument.

The length attribute of the result is twice the storage length attribute of the argument. The length attribute of the result cannot be greater than 32766 for fixed-length results or greater than 32740 for varying-length results. If the argument is a varying-length string, the result is a varying-length string. Otherwise, the result is a fixed-length string.

The CCSID of the string is the default SBCS CCSID at the current server.

LENGTH built-in function for Query (added):

The LENGTH function returns the length of a value. The form is:

```
>>-LENGTH--(--expression--)-----------------------------------><
```

The argument must be an expression that returns a value of any built-in data type. The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result is the length of the argument. The length of strings includes blanks. The length of a varying-length string is the actual length, not the length attribute. The length of a graphic string is the number of double-byte characters (the number of bytes divided by 2). The length of all other values is the number of bytes used to represent the value:

- 2 for small integer
- 4 for large integer
- 8 for big integer
- The integral part of (p/2)+1 for packed decimal numbers with precision p
- p for zoned decimal numbers with precision p
- 4 for single-precision float
- 8 for double-precision float
- The length of the string for strings
- 3 for time
- 4 for date
- 10 for timestamp
- 26 for row ID

«

Security

Securing your database requires you to establish ownership and public authority to objects and specific authority to your applications.

For detailed information about iSeries security, see the Security Reference topic.

Select one of the following topics:
- Control DDM and DRDA[(R)] access
- Grant file and data authority
- Limit access to specific fields of a database file
- Specify public authority
- Use database file capabilities to control I/O operations
- Use logical files to secure data

Appendix. Notices

This information was developed for products and services offered in the U.S.A.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not give you any license to these patents. You can send license inquiries, in writing, to:
